Abstract

Background: Mobile health (mHealth) offers significant benefits for patients with stroke, facilitating remote monitoring and personalized health care solutions beyond traditional settings. However, there is a dearth of comprehensive data, particularly qualitative insights, on the barriers to mHealth access. Understanding these barriers is crucial for devising strategies to enhance mHealth use among patients with stroke.

Objective: This study aims to examine the recent literature focusing on barriers to mHealth access among patients with stroke.

Methods: A systematic search of PubMed, MEDLINE, Web of Science, and CINAHL Plus Full Text was conducted for literature published between 2017 and 2023. Abstracts and full texts were independently screened based on predetermined inclusion and exclusion criteria. Data synthesis was performed using the convergent integrated analysis framework recommended by the Joanna Briggs Institute.

Results: A total of 12 studies met the inclusion criteria. The majority were qualitative studies (about 42%), followed by mixed methods (25%), pilot studies (about 17%), nonrandomized controlled trials (about 8%), and observational studies (about 8%). Participants included patients with stroke, caregivers, and various health care professionals. The most common mHealth practices were home-based telerehabilitation (30%) and poststroke mHealth and telecare services (20%). Identified barriers were categorized into two primary themes: (1) at the patient level and (2) at the health provider-patient-device interaction level. The first theme includes 2 subthemes: health-related issues and patient acceptability. The second theme encompassed 3 subthemes: infrastructure challenges (including software, networking, and hardware), support system deficiencies, and time constraints.

Conclusions: This systematic review underscores significant barriers to mHealth adoption among patients with stroke. Addressing these barriers in future research is imperative to ensure that mHealth solutions effectively meet patients' needs.

Introduction

Background

Stroke, a leading cause of disability and mortality worldwide, necessitates immediate and ongoing interventions for optimal recovery [1]. While mobile health (mHealth) technologies offer promising solutions for chronic disease management, understanding and addressing the unique barriers faced by patients with stroke is crucial for ensuring their equitable access and optimal use [2,3]. While previous research has explored mHealth adoption in various populations, the cognitive impairments [4], rehabilitation needs [5], and potential technology literacy limitations of patients with stroke [6] require distinct consideration. mHealth, encompassing the use of mobile devices, applications, and wireless communication devices, offers promising avenues to deliver personalized health care solutions to patients with stroke beyond the confines of traditional health care settings [3,7].

The health care landscape has evolved with the proliferation of mobile devices and the availability of high-speed internet connectivity. Consequently, mHealth platforms have emerged as tools that can potentially bridge the gap between health care providers and patients, enabling continuous monitoring, real-time communication, and targeted interventions [8,9]. In the context of stroke, where timely interventions and ongoing support are crucial, mHealth can revolutionize poststroke care by providing patients with access to rehabilitation exercises, medication reminders, educational resources, and even telemedicine consultations [3,6,10]. Despite the promise of mHealth, realizing its benefits for patients with stroke is contingent upon understanding and mitigating the barriers that hinder its widespread adoption and use. Previous research has underscored the importance of identifying these barriers to ensure equitable access and optimal use of mHealth services among patients with stroke [11]. While existing literature has explored mHealth adoption in various populations, the unique challenges faced by patients with stroke deserve particular attention due to the nature of their condition, potential cognitive impairments, and the necessity of tailored interventions. The period between 2017 and 2023 has witnessed substantial advancements in mHealth technologies, health care policies, and the prevalence of mobile device usage among diverse demographic groups. Consequently, there is a need to assess the current status of mHealth access among patients recovering from stroke within this evolving landscape. By systematically reviewing the literature and synthesizing recent findings, this study aims to delineate the barriers that impede access to mHealth services among patients with stroke, analyze their impact, and propose actionable recommendations for stakeholders in the health care ecosystem.

In light of the growing importance of digital health and its potential benefits for patients with stroke, investigating the barriers to mHealth access is a critical step toward ensuring that these advancements are inclusive and patient centered. By identifying these barriers and proposing strategies to overcome them, this study seeks to contribute to the advancement of stroke care in the digital health era.

Objective

This study seeks to evaluate recent literature, focusing on the notable barriers to accessing mHealth services within the population of patients with stroke. Through this assessment, the study aims to offer recommendations aimed at effectively addressing these barriers and propelling progress in this critical domain of health care.

Methods

Identify Relevant Studies

We adhered to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [12] while conducting this systematic review. This approach guided the presentation of the flow diagram depicting the identification, screening, exclusion, and inclusion of literature. To identify studies published between 2017 and 2023 that reported barriers to mHealth access among the patients with stroke, we systematically searched 4 electronic databases: PubMed, MEDLINE, Web of Science, and CINAHL Plus Full Text, on September 1, 2023. Our search involved the combination of terms: *(Stroke* or Cerebrovascular Accident* or CVA* or Cerebrovascular Apoplexy or Brain Vascular Accident* or Cerebrovascular Stroke* or Apoplexy or Cerebral Stroke* or Acute Stroke* or Acute Cerebrovascular Accident* or Brain Infarction* or Brain Infarct* or Anterior Circulation Brain Infarction or Brain Venous Infarction* or Venous Brain Infarction* or Anterior Cerebral Circulation Infarction or Posterior Circulation Brain Infarction or Cerebral Infarction* or Cerebral Infarct* or Left Hemisphere, Infarction, Cerebral or Subcortical Infarction* or Posterior Choroidal Artery Infarction or Anterior Choroidal Artery Infarction or Hemorrhagic Stroke* or Subarachnoid Hemorrhagic Stroke* or Intracerebral Hemorrhagic Stroke* or Ischemic Stroke* or Ischaemic Strok* or Cryptogenic Ischemic Stroke* or Cryptogenic Stroke* or Cryptogenic Embolism Stroke* or Wake-up Stroke* or Acute Ischemic Stroke* or Embolic Stroke* or Cardioembolic Stroke* or Cardio-embolic Stroke* or Thrombotic Stroke* or Acute Thrombotic Stroke*) AND (Tele-Referral* or Virtual Medicine or Tele Intensive Care or Tele ICU or Mobile Health or mHealth or Telehealth or eHealth or Remote Consultation or Teleconsultation* or Telenursing or Telepathology or Teleradiology or Telerehabilitation* or Remote Rehabilitation* or Virtual Rehabilitation*) AND (Barrier*)* using Boolean operators. Additionally, we manually searched the reference lists of the included studies to ensure inclusivity. All identified references were cataloged using EndNote.

Study Selection

We conducted a 3-step selection process. First, we screened titles and abstracts to identify eligible studies. Then, we assessed the full text to determine relevance. Finally, inclusion criteria were applied to ensure that only studies aligned with our objectives were included. Conversely, exclusion criteria were used to eliminate literature not pertinent to the review (see Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- The study included patients with stroke aged 18 years or older. The study may also encompass other populations, such as caregivers and health care teams, but patients with stroke must be included
- Original studies using quantitative, qualitative, or mixed methods approaches
- Studies that identified barriers to accessing mobile health (mHealth) services among patients with stroke (all types of strokes are eligible)
- In this study, mHealth is identified as the practice of medicine and public health supported by mobile devices. It encompasses the use of mobile devices, such as smartphones, tablet computers, personal digital assistants, and others, for health services, information, and data collection [13]
- Studies conducted in various settings, including inpatient, outpatient, or home environments
- Studies published in the English language
- Studies published between January 2017 and December 2023

Exclusion criteria:

- Studies that did not involve patients were excluded.
- Exclusion of conference proceedings, abstracts, review articles, theoretical papers, protocols, dissertations, letters to the editor, opinion (viewpoint) pieces, statement papers, government documents, or working papers

Data Extraction

For this review, we used a standardized data extraction chart that included the following data points for each study: Reference, country, year, study design, total sample size, target population, participant age (years), main study aim, main findings, presence of mHealth in included studies, key barriers to accessing mHealth, and further research implications.

Data Synthesis

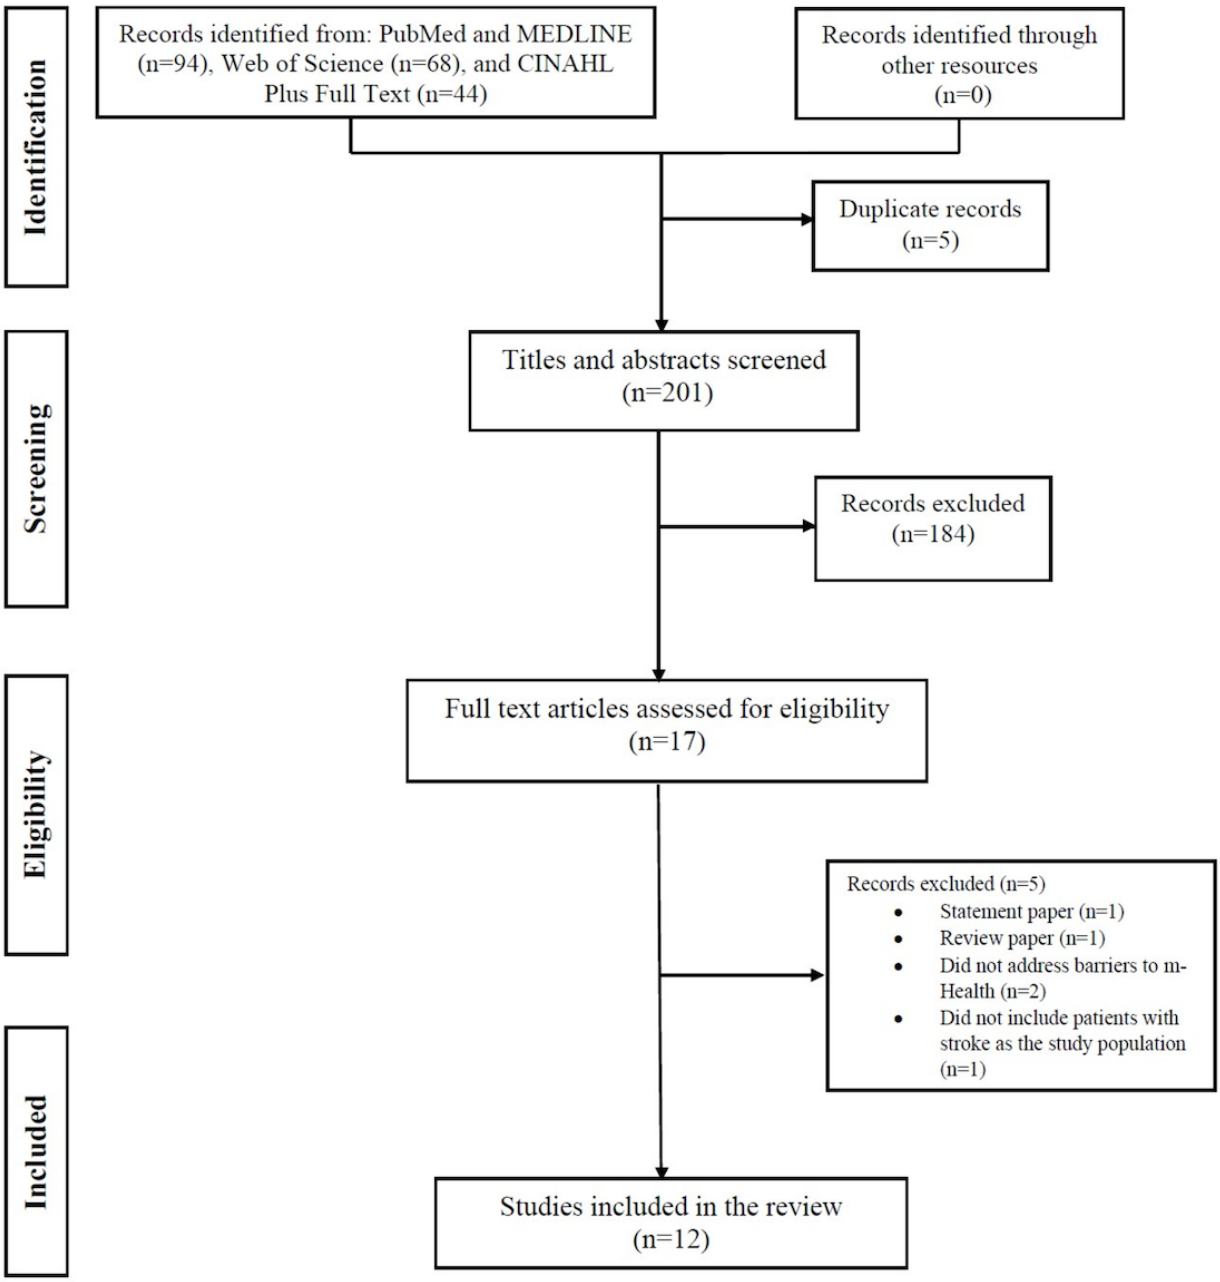
For the data synthesis of the included studies in this review, we used the convergent integrated analysis framework recommended by the Joanna Briggs Institute (JBI) for systematic reviews. In this process, themes will be derived from the key findings of the included studies by analyzing both commonalities and distinctions among the primary findings related to key barriers in accessing mHealth. Furthermore, subthemes will be extracted as necessary, aligning with the specific focus of the corresponding findings, akin to the methodology used by qualitative researchers [14].

Results

Search Results

Following the PRISMA guidelines [12], we initially identified a total of 206 articles. Out of these, 94 were obtained from PubMed and Medline, 68 from Web of Science, and 44 from CINAHL Plus Full Text. No additional articles were found from other sources. After a thorough review, we identified and removed 5 duplicate articles. Subsequently, the remaining articles underwent screening based on their titles and abstracts, following the inclusion and exclusion criteria (Textbox 1). At this stage, 184 articles did not meet the inclusion criteria and were excluded, leaving us with 17 articles eligible for full-text screening. During the full-text screening phase, 5 articles were excluded. Of these, 1 was identified as a statement paper, 1 was a review paper, 2 did not address barriers to mHealth, and 1 did not include patients with stroke as the study population. Consequently, 12 studies were included in the review (Figure 1).

Figure 1. Flowchart diagram displaying the selection method of qualified studies.



Data Summary

Multimedia Appendix 1 [15-26] provides a summary of each included study, including reference, country, year, study design, total sample size, target population, participant age (years), main study aim, main findings, presence of mHealth in included studies (optional), key barriers to accessing mHealth, and implications for further research.

Description of Included Studies

Table 1 shows that all included studies were published between 2017 and 2023, with the most publications in 2023 (n=5, 42%) and 2022 (n=3, 25%). Among these, one publication was found each in 2017, 2018, 2020, and 2021. Most of the included studies were conducted in the United States (n = 4, 33%). Other countries include the United Kingdom (n=2, 17%), Hong Kong (China) (n=2, 17%), Brazil (n=1, 8%), and the Netherlands (n=1, 8%). In terms of study design, qualitative studies were the most popular (n=5, 42%), followed by mixed methods (n=3, 25%), pilot studies (n=2, 17%), nonrandomized control trials (n=1, 8%), and observational studies (n=1, 8%). Among the patients with stroke included in the study, there was no specific stroke type identified (n=9, 64%), ischemic stroke (n=2, 14%), hemorrhagic stroke (n=2, 14%), and chronic hemiplegic stroke (n=1, 7%).

[b]mHealth: mobile health.

[c]VR: virtual reality.

[d]CCT: computerized cognitive.

[e]MST: metacognitive strategy.

Additionally, caregivers (n=3, 43%), clinicians (n=1, 14%), rehabilitation therapists (n=1, 14%), occupational therapists (n=1, 14%), and nurses (n=1, 14%) were included in the study. Sample sizes ranged from 1 to 50 (n=9, 75%), over 50 to 100, over 100 to 200, and over 200 (all n=1, 8%). The most common mHealth practices in the included studies were home-based telerehabilitation (n=3, 30%) and poststroke mHealth and telecare service (n=2, 20%). The rest of mHealth consisted of remote physical exercise, a home-based web-based clinic, self-administered virtual reality (VR) telerehabilitation, and home care arm rehabilitation, as well as remote cognitive (CCT) and metacognitive strategy training (MST; all n=1, 10%).

Description of Barriers to mHealth Access in Patients With Stroke

Multimedia Appendix 1 [15-26] provides a summary of the barriers to mHealth accessibility experienced by patients with stroke. Having used the convergent integrated analysis framework recommended by JBI for systematic reviews [14], we can discern two primary themes: (1) at the patient-level and (2) at the health provider-patient-device interaction level. The first theme included 2 subthemes: health-related barriers and patient acceptability. The second theme encompassed 3 subthemes: infrastructure (inclusive of software, networking, and hardware), deficiencies in support systems, and constraints on available time (Table 2).

Table 2. Barriers to mobile health (mHealth) access.

Study	Barriers to mHealth Themes						
	The patient-level		The health provider-patient-device interaction level				
	Health-related barriers	Patient acceptability	Infrastructure			Deficiencies in support systems	Constraints on available time

The Patient Level

Health-Related Barriers

Our results indicate that health-related issues are among the barriers to mHealth access for patients with stroke. A study evaluating a home-based telerehabilitation system in patients with chronic hemiparetic stroke found that fatigue due to illness prevented patients from using the Home-Based Telerehabilitation Program [15]. Similarly, a clinical trial study from Brazil aimed at determining adherence and barriers to attending a remote physical exercise program for individuals after stroke shows that health-related factors such as a lack of motor skills, physical fitness, exercise-related pain, and other constraints are significant barriers preventing them from using the remote physical exercise program [20]. For instance, in a qualitative study conducted with survivors of stroke experiencing partial visual loss, caregivers and occupational therapists revealed that patients believed their lack of confidence and fear of using technology prevented them from learning new things, and their readiness to embrace technology was a barrier to telerehabilitation [25].

Patient Acceptability

Five studies in our review have highlighted patient acceptability as the primary barrier to mHealth [17,22-25]. For example, a mixed-method study identified facilitators and barriers to using self-administered VR telerehabilitation, suggesting that a lack of experience or confidence with technology hindered access to self-administered VR telerehabilitation [22]. Moreover, a pilot study found that patients with stroke, especially older adults with stroke, may have limited digital literacy skills, making it challenging to use mHealth tools effectively. Additionally, a study points out that participants' attitudes and acceptance of mHealth interventions may vary; some individuals may be hesitant or skeptical about using technology for health care purposes [24].

The Health Provider-Patient-Device Interaction Level

Infrastructure

Software

The complexity of mHealth software can pose challenges for patients in its usage [16,18,19,26]. For instance, a qualitative study conducted in Singapore explored the perceived barriers and facilitators of telerehabilitation by patients with stroke, caregivers, and rehabilitation therapists. The study noted that teletherapists encountered difficulties conducting comprehensive patient assessments remotely [26]. Similarly, patients perceived limitations in the variety and scope of rehabilitation exercises available through telerehabilitation, attributing this to issues related to the interface and design of the remote platform [26]. In line with this, another study aimed to explore potential mHealth apps to aid survivors of stroke with poststroke care and determine how demographic variables affect app preferences. This study found that the complexity of app usage acted as a barrier, preventing some users from using these apps effectively [18]. Considering apps on outdated smartphones or operating systems can result in challenges for patients when running and installing complex apps. In addition, there is a noticeable mismatch between the technical complexity of the apps and the users' capacities, as they lack the knowledge to address issues like nonfunctionality, showdowns, freezing, and crashes in the apps [27,28].

Network

In our review, 4 included studies highlighted the significance of network issues as a critical barrier to mHealth access [21,22,24,26]. Of these, 2 studies emphasized the importance of reliable internet access for effective remote interventions. Poor internet connectivity or limited access to high-speed internet in certain areas can impede the successful implementation of mHealth interventions [24,26]. Furthermore, the high cost and limited availability of internet access to support the equipment in survivors of stroke's homes can prevent them from accessing mHealth services [21,22]. Patients and health care professionals mainly rely on an internet-based system where health care providers must promptly update patient information. On the other hand, patients can use the apps to receive health updates and discuss their symptoms with health care providers effectively [29,30]. Thus, the absence of a digital option can restrict internet access and cause challenges, both at the patient's house and within the health care facility. However, adopting an offline mode can make it difficult to transfer data, which typically relies on web-based connectivity.

Hardware

Hardware malfunctions, such as those in mobile phones or computers, are considered significant factors affecting the delivery of mHealth services [15,18,22,24,26]. For instance, in a pilot study aiming to implement a home-based Telerehabilitation Program that included arm motor therapy games, therapeutic arm exercises, remote stroke education, and videoconferencing, hardware malfunctions limited patients' access to the intervention [15]. Moreover, a qualitative study highlighted equipment setup–related difficulties as a barrier to mHealth access, with patients with stroke encountering challenges in setting up and using the required equipment [26]. For example, getting ready for video-recorded exercise can be a challenge among patients with stroke when setting up the iPad, sensors, and monitoring equipment for heart and blood pressure [31]. In addition, specific details, such as the correct connection of the limb sensor node to assess the patient's range of motion and troubleshoot unexpected hardware problems, may not be straightforward, even though general instructions are provided. Another study focusing on remote interventions, which often rely on technology, noted that one potential barrier could be the accessibility of the necessary technology (eg, smartphones, computers, etc) for individuals with chronic stroke, especially those who may not be familiar with or have easy access to such devices [24].

Deficiencies in Support Systems

Lack of support systems is a significant barrier to mHealth access, as indicated by 6 included studies in our review [16,19,20,22-24]. For instance, a qualitative research study investigated the experiences of 13 survivors of stroke and health care providers regarding the use of a poststroke telecare service [19]. The study found that the lack of general guidelines for operating a telecare service, technical issues, and limited human

resources presented challenges to patients in using the service (eg, difficulties in joining Zoom meetings and troubleshooting) [19]. Another study also emphasized the importance of adequate training and support for participants using mHealth tools. This study recommended initial in-person sessions to familiarize participants with the technology, indicating that additional support might be necessary for some individuals [24]. In a mixed methods study aimed at identifying facilitators and barriers to the use of self-administered VR telerehabilitation, it was mentioned that a lack of an exercise companion and a safe environment for exercising prevented some individuals from using self-administered VR telerehabilitation [20].

Constraints on Available Time

In our study, we have found that constraints on available time are considered a barrier to mHealth, as mentioned in 4 published studies [15,16,20,25]. For example, 1 included study stated that conflicts with other medical appointments prevent patients with stroke from completing a home-based telerehabilitation program [15]. Additionally, work commitments are also a factor preventing patients with from using mHealth at home [20]. This issue is not limited to patients alone; it also affects health care providers. Qualitative research revealed that time-related issues are prevalent among providers, such as occupational therapists who reported having limited time to spend with survivors of stroke when providing mHealth interventions [25]. Additionally, a prior study highlighted the importance of the design and development stages of mHealth in reducing disruptions to health care providers' established workflows [32]. The study emphasized the transformation of functionalities into practical health tools, aiming to facilitate the integration of mHealth into their existing structured workflows, ultimately influencing increased engagement in the adoption of mHealth.

Discussion

The study aimed to explore recent literature to uncover possible barriers to mHealth access among patients with stroke. Although mHealth offers an important option for accessing needed health services, and people with stroke are currently using it for various purposes, this study identified several barriers inhibiting its use. One such barrier is health-related issues. Prior studies have shown that 25%-85% of survivors of stroke report experiencing fatigue, regardless of the severity of their condition [33,34]. As fatigue develops over time, it can result in the inability to perform basic activities, such as dressing and eating, and eventually limit more complex activities like shopping and preparing meals [35]. Considering that the study included complex telerehabilitation activities (eg, games, therapeutic programs, education, and videoconferencing), access to the program among patients with stroke could be limited due to fatigue. It is also important to consider a patient's age when examining fatigue, whether they are young or old [36-38]; this finding aligns with our study, which included patients aged 40 and older who had experienced strokes.

Despite the rise of mHealth to connect patients to health services outside of a clinical setting, our study found that patients' readiness and acceptance were barriers to accessing mHealth. Similar to previous studies, patients with stroke reported that visual and physical impairments hindered their access to mHealth, as they lacked the confidence to communicate electronically and were concerned about making mistakes during remote interactions [25,39]. These impairments, affecting sight and physical activity, may contribute to reduced readiness for mHealth. Additionally, digital health literacy should be considered, as patients with stroke, particularly those in the older population, may have difficulty obtaining, interpreting, and evaluating health information through digital sources [40]. A similar finding was observed in another study, where older patients with stroke had less access to phone or video telephone visits due to a lack of digital literacy and access, as well as a lack of experience using such technology [41]. In terms of acceptability, patients with stroke who perceived m-Health as useless (e.g., only making phone calls) restricted their access to mHealth applications, such as mobile home-based exercise programs [42].

One of the main obstacles for mHealth is the availability of adequate infrastructure to provide effective and comprehensive care to patients with stroke. The review identified the limitations of the current software in conducting patient assessments and delivering a wide range of rehabilitation exercises. Since the main goal of rehabilitation is to improve the patient's physical impairments, a health care provider needs to perform physical exams to determine and evaluate the intervention. Without such contact through mHealth, the health care provider's assessment ability is compromised, and the assessment accuracy might be reduced. However, previous studies have proposed remote methods to assess patients with stroke, such as internet-based telerobotic devices, videoconferencing, camera-based artificial intelligence (AI) models with wearable sensors, and remote Fugl-Meyer Assessment protocols [43-46]. The validity of the proposed methods was still low, and additional equipment and advanced software are required to capture the more accurate physical examination details.

The studies in the review also highlighted the narrow range of exercises the patients could perform through mHealth. A systematic review of home-based technologies for stroke rehabilitation revealed technology that increases the variety of exercise, such as games, telerehabilitation, robotic devices, VR devices, and tablets. This review also pointed out the limitations of each technology, which is consistent with our findings that the equipment requires proper guidance in setting up and using to achieve the therapeutic goals [47].

Besides having the proper software and hardware for mHealth services for patients with stroke, the studies also highlighted poor or limited internet connectivity as a major barrier to implementing mHealth. Many mHealth interventions require timely monitoring, access to the database, or health care. Some studies have explored alternative solutions to enhance mHealth delivery in areas with limited or nonexistent internet access. For example, some studies have used Firebase, a local offline database, or caching the user interface and assets to help patients stay connected to the information if the patients lose an internet connection [48-50]. Others have integrated communities or schools as a link between larger hospitals and patients who cannot access the internet [51,52]. Nevertheless, internet connectivity remains a critical obstacle for mHealth, as it was

considered a super social determinant of health that affects other aspects of health equity [53]. Therefore, promoting affordable and reliable internet access would be beneficial, especially for those who face disadvantages in accessing health care.

Our review reported deficiencies in support systems in using mHealth, including the need for general guidelines in using the services, technical issues, additional support, the lack of an exercise companion, and a safe environment. The lack of general guidelines or instructions in using a relative innovation can influence patients' or caregivers' decision to use and continue use. Our findings are congruent with previous longitudinal studies of the continued use of mHealth apps, indicating that users will not be motivated to continue service if they do not understand how the system works based on their initial interactions [54]. Along with a limited support system, most of the participants in our studies are notably older adults, and a prior study revealed that older adults, in general, have a lower rate of adopting mHealth [55]. The adoption of mHealth is not a simple process and requires not only technical assistance but also human support to enhance their experience and interaction with mHealth [56,57]; thus, concise and clear guidelines are essential in facilitating and engaging their usage. Another study also points out that mobile health for older adult patients used an aging barrier framework to explore usability problems and reported that participants have difficulties understanding the navigation structure of the apps and overseeing important text, buttons, and icon elements [58]. Therefore, clear guidelines and instructions should be considered when developing mHealth for survivors of stroke.

Regarding technical issues, it can be solved or reduced by additional support. Our findings align with a study evaluating patients' experience with the usability of a diabetes mHealth system. Technical issues related to functionality or operation can impact the overall usability of apps, such as challenges in deleting or inputting glucose values, resulting in difficulties in accurately interpreting value ranges (51). Furthermore, participants who encounter technical issues may struggle to navigate through different functions; for instance, participants have reported experiencing navigation difficulties while reporting glucose diary values. Prior studies have also highlighted the significance of app navigation for patients with stroke who face challenges in managing their medication [28,59]. Thus, navigation within apps is crucial as if it is difficult and user-unfriendly, it can impact patients' ability to carry out their tasks effectively [28,59].

For safety concerns, an mHealth system used to guide exercise for patients with cardiac disease developed safe algorithms to detect and warn of risky situations during exercise [60]. However, the lack of an exercise companion was not mentioned in previous studies. This can be considered for mHealth, especially exercise programs that may create live animations to exercise with patients.

In this study, researchers identified the constraint of available time as a major obstacle to accessing mHealth services among patients with stroke. This encompassed challenges such as patients' struggles with time management, inefficient use of available time, and the timely availability of caregivers [16,25,61,62]. These findings are consistent with prior studies investigating the barriers and incentives related to mHealth access among this demographic [63,64]. The effective management of time is a crucial element in the success of any mHealth intervention designed for patients with stroke [62].

The qualitative studies revealed that successful use of mHealth necessitates ongoing engagement with a caregiver, which is particularly crucial for older patients, those with more pronounced physical impairments, or those with lower digital health literacy levels. However, the effectiveness of mHealth was hampered by the limited availability of caregivers, posing challenges to sustaining quality rehabilitation approaches in home-based programs [16]. Effective time management can prove advantageous for both patients with stroke and caregivers when using telerehabilitation systems. Conversely, time constraints have been linked to decreased productivity and diminished quality within mHealth systems. Ultimately, the efficiency and efficacy of telerehabilitation hinge on the optimal use of scarce resources, notably time [65,66].

According to our findings, mHealth plays an essential role in managing and rehabilitating patients with stroke, improving and advancing the quality of care and patient outcomes, and increasing accessibility to health care resources. However, using mHealth in stroke care raises substantial concerns regarding data privacy and security. Survivors of stroke often rely on mobile applications, assisted devices for telerehabilitation, and remote monitoring tools to track their progress, communicate with health care providers, and access educational materials [24]. The data generated and transmitted through these platforms may sometimes include sensitive medical information, such as personal health records and mobility metrics. As a result, discussing mHealth in the context of stroke care must address these patient privacy and security concerns. Data transmission and storage are the most important aspects of patient privacy and security. As mobile health heavily relies on technology, cloud infrastructure, and apps, many potential risks and vulnerabilities emerge. Surprisingly, Müthing et al [67] uncovered a concerning reality within the mHealth app landscape. Their study revealed that many mHealth apps currently available lack adequate privacy and security safeguards. Even among apps certified by trusted organizations or widely adopted by the health care community, 89% were observed to transmit information digitally; alarmingly, 66% of this data was not encrypted. Moreover, there is a notable concern regarding the potential for data to be misplaced, stolen, or lost, primarily stemming from the mobile nature of the devices used in mHealth. The common habit of multiple family members sharing mobile devices like smartphones and tablets can exacerbate these concerns [68]. These risk concerns underscore the imperative requirement for solid security measures within the mHealth environment. In addition, many stakeholders have rights and responsibilities concerning an individual's medical records and the information they contain. To effectively minimize potential security risks for users in the future, it is crucial to systematically identify all parties involved and those who might be considered data "custodians" [68,69]. Informed consent, privacy policy, and access control are critical areas of concern when using mHealth. Informed consent serves as the

gateway to data sharing, granting individuals or their legal representatives the authority to specify when and with whom their personal information can be shared. However, consumers often find themselves unaware of the extensive data collection and analysis methods used by mHealth services and the extent of data sharing with third parties. This issue is exacerbated by the fact that only (183/600, 30.5%) of widely used mobile health apps have privacy policies and that most apps could negatively affect users due to privacy and security violations [69]. Moreover, many mHealth industry privacy policies often resemble lengthy academic articles with language at a university level, making them daunting for the average user to navigate [68]. Therefore, to address these concerns effectively, a set of proactive steps is required, particularly when considering the needs of older adults, the majority of patients with stroke. The future focus should be on simplifying and updating existing privacy policies to make them user-friendly, age-friendly, and compliant with regulations. Collaborating and providing active support for developing a robust regulatory framework for mHealth apps are essential. This framework should empower all users, including older adults, to control their technology and decide who can access information on their mobile devices. Significantly enhancing user privacy, with specific attention to the unique requirements of older adults, is paramount. Furthermore, promoting public technology literacy and creating awareness about responsible and cautious mobile device usage through educational initiatives is vital for empowering users and ensuring the secure adoption of mHealth solutions.

Certain limitations regarding the systematic review need to be considered. First, the ages of participants in the included studies are all over 40, with most having a median age of 55 years or older. Given the paper's focus on improving outcomes for survivors of stroke through mHealth, the older age range—whether due to sampling bias or the characteristics of patients with stroke—might negatively impact the user experience compared to younger generations. This could be attributed to varying levels of exposure to technology. Another potential limitation is the number of participants included in some of the studies. Most (7 out of 12) of the studies included fewer than 20 participants, and 10 out of 12 included fewer than 100 participants. Given the accessibility of current technology, smaller sample sizes could lead to a greater possibility of outliers, which might not adequately represent the general population of survivors of stroke, thus, introducing unintended bias. Another limiting factor is the criterion of including only English-language papers. Because stroke does not discriminate by language, including only papers written in English could omit potentially useful research regarding mHealth and survivors of stroke. Finally, this study focused solely on barriers to mHealth access in patients with stroke with a limited number of 12 included studies. To increase generalizability, future research should explore a broader range of contributing factors.

Steps Toward the Digital Health Era

The Digital Health Era is transforming the health care paradigm through various key initiatives. One of the most significant breakthroughs in the acceptance of mHealth, telemedicine, and remote patient monitoring, which greatly improve health care accessibility by enabling remote consultations and timely interventions, particularly in remote regions, is the widespread adoption of mobile devices and advanced communication technologies [70,71]. Our study has extensively explored this aspect. The integration of wearable technology and health apps also plays a crucial role in empowering individuals to actively manage their health [72-74]. These tools monitor vital signs and activity levels and provide real-time feedback, promoting a proactive approach to wellness [75-77]. Additionally, big data analytics and AI have transformed diagnostics, treatment strategies, and predictive health care [78-80]. AI algorithms analyze vast amounts of patient data, identifying patterns, and offering valuable insights to aid health care providers in making informed decisions [78-80]. The Digital Health Era emphasizes a focus on preventive care and personalized medicine, where health care providers leverage data-driven insights to create tailored treatment plans based on an individual's genetics, lifestyle, and specific health requirements [81,82]. Overall, the evolution toward the Digital Health Era is reshaping health care through initiatives such as telemedicine, wearable technology, big data analytics, and a focus on preventive care, personalized medicine, and user-centered design. These interventions must take into account the realities and constraints of the intended users. The advancements in different domains lay the foundation for an interlinked, data-driven health care system centered on patient requirements. Technology is vital in this evolution, enhancing patient outcomes, boosting productivity, and revolutionizing the health care experience. This ongoing amalgamation has the potential to establish a future where technology and health care converge effortlessly, leading to a more comprehensive and convenient health care environment for all.

Conclusions

This review has highlighted significant barriers to mHealth access among patients with stroke, emphasizing the gap between mHealth's potential and practical use. Key challenges include health-related issues, patient acceptance, infrastructure challenges, support system deficiencies, and time constraints. These findings point to the urgent need for user-friendly mHealth solutions and robust support mechanisms. Addressing these issues is critical to ensure that mHealth technologies are not only available but are also effectively adopted by survivors of stroke. Future research should focus on overcoming these barriers to enable mHealth to fully support poststroke rehabilitation and care. The goal must be to transform these obstacles into opportunities for innovation, ensuring mHealth's role as a cornerstone of patient-centered health care.

Abstract

Background: Wearable activity trackers, including fitness bands and smartwatches, offer the potential for disease detection by monitoring physiological parameters. However, their accuracy as specific disease diagnostic tools remains uncertain.

Objective: This systematic review and meta-analysis aims to evaluate whether wearable activity trackers can be used to detect disease and medical events.

Methods: Ten electronic databases were searched for studies published from inception to April 1, 2023. Studies were eligible if they used a wearable activity tracker to diagnose or detect a medical condition or event (eg, falls) in free-living conditions in adults. Meta-analyses were performed to assess the overall area under the curve (%), accuracy (%), sensitivity (%), specificity (%), and positive predictive value (%). Subgroup analyses were performed to assess device type (Fitbit, Oura ring, and mixed). The risk of bias was assessed using the Joanna Briggs Institute Critical Appraisal Checklist for Diagnostic Test Accuracy Studies.

Results: A total of 28 studies were included, involving a total of 1,226,801 participants (age range 28.6-78.3). In total, 16 (57%) studies used wearables for diagnosis of COVID-19, 5 (18%) studies for atrial fibrillation, 3 (11%) studies for arrhythmia or abnormal pulse, 3 (11%) studies for falls, and 1 (4%) study for viral symptoms. The devices used were Fitbit (n=6), Apple watch (n=6), Oura ring (n=3), a combination of devices (n=7), Empatica E4 (n=1), Dynaport MoveMonitor (n=2), Samsung Galaxy Watch (n=1), and other or not specified (n=2). For COVID-19 detection, meta-analyses showed a pooled area under the curve of 80.2% (95% CI 71.0%-89.3%), an accuracy of 87.5% (95% CI 81.6%-93.5%), a sensitivity of 79.5% (95% CI 67.7%-91.3%), and specificity of 76.8% (95% CI 69.4%-84.1%). For atrial fibrillation detection, pooled positive predictive value was 87.4% (95% CI 75.7%-99.1%), sensitivity was 94.2% (95% CI 88.7%-99.7%), and specificity was 95.3% (95% CI 91.8%-98.8%). For fall detection, pooled sensitivity was 81.9% (95% CI 75.1%-88.1%) and specificity was 62.5% (95% CI 14.4%-100%).

Conclusions: Wearable activity trackers show promise in disease detection, with notable accuracy in identifying atrial fibrillation and COVID-19. While these findings are encouraging, further research and improvements are required to enhance their diagnostic precision and applicability.

Introduction

As health care budgets around the world continue to soar, the need for cost-effective interventions that both reduce health care costs and improve patient outcomes has never been more urgent [1]. Early detection of medical conditions offers a pathway to achieve these goals, enabling prompt intervention during acute medical events or even pre-emptive action before such events occur [2]. Wearable activity monitors are emerging as a potential tool in this evolving landscape.

In recent years, wearable activity trackers have become ubiquitous tools, widely adopted for tracking and enhancing physical activity and other lifestyle behaviors, helping to mitigate the risk of chronic diseases [3]. These devices measure a plethora of activity metrics such as steps taken, distance covered, energy expenditure, physical activity intensities, and sleep patterns [4]. The scientific literature has witnessed a surge in original studies and systematic reviews and meta-analyses, focused on determining the reliability and validity of activity trackers for measuring activity levels [5,6] and their effectiveness in intervening in daily activity patterns and downstream health outcomes [7-12]. These studies have shown that interventions using consumer-based wearable activity trackers can increase physical activity participation and lead to significant improvements in health outcomes, across a range of populations [7-12]. As wearable technology has progressed, wearable activity trackers offer increasing potential to move beyond activity metrics and aid in the early identification of diseases and other medical events.

Rapid technological advancements have significantly extended the capabilities of contemporary consumer-grade wearable activity trackers such as Fitbits and Apple Watches [13]. Modern wearables incorporate sophisticated sensors capable of monitoring a wide array of physiological parameters beyond just movement including heart rate, blood oxygen levels, sleep quality, and stress markers [14]. While this expanded functionality holds promise for disease detection and monitoring, the evidence supporting the use of consumer wearables for such applications remains limited. For example, the systematic review by Alban-Cadena et al [15] evaluated wearable sensors for monitoring Parkinson disease–related gait impairments and symptoms such as tremors, bradykinesia, and dyskinesia. However, most included studies were very small (10-20 participants) and were conducted in controlled laboratory environments using specialized setups such as multi-sensor accelerometer arrays worn on the ankles and spine. While offering the potential for home-based rehabilitation, the generalizability of these findings to widely adopted, consumer-oriented wearable trackers designed for real-world, free-living conditions is unclear.

Other recent systematic reviews have evaluated the accuracy of wearable tracking devices for detecting specific health conditions such as arrhythmias [16], cardiovascular disease [17,18], and COVID-19 [19]. However, these reviews have notable limitations. Most included studies were conducted in controlled laboratory settings, limiting the generalizability of their findings to real-world, free-living conditions [16,17,19]. Additionally, these reviews focused narrowly on individual clinical outcomes, preventing comparisons of wearables' detection accuracy across different medical conditions and events. For example, the narrative syntheses highlighted wearables' potential as complementary tools for detecting cardiovascular conditions such as arrhythmias, atrial fibrillation, myocardial infarction, and heart failure [16,17]. The meta-analysis of Lee et al [18] of 26 studies found wearable devices had a pooled sensitivity of 94.80% and specificity of 96.96% for atrial fibrillation detection. In contrast, Cheong et al [19] reported lower diagnostic accuracy for COVID-19 detection, with area under the curve (AUC) values ranging from 75% to 94.4% and sensitivity and specificity ranging from 36.5% to 100% and 73% to 95.3%, respectively. Notably, all but one review [18] used narrative synthesis approaches [16,17,19], limiting their ability to quantify detection accuracy, and preventing readers from comparing detection accuracy across conditions reported in the respective reviews.

As wearable technology rapidly evolves, with frequent introductions of new and more advanced devices, the scientific evidence base for disease detection is growing, encompassing a wider range of medical conditions and events. Consequently, there is now sufficient data to warrant a comprehensive systematic review with meta-analyses, allowing quantitative comparisons of wearables' detection accuracy across various conditions in real-world settings.

Our systematic review and meta-analysis aim to fill this crucial gap by comprehensively assessing the reliability and accuracy of consumer-grade wearable activity trackers for detecting and monitoring a wide range of medical conditions and events in free-living, real-world settings. Unlike previous reviews that relied on narrative synthesis approaches, our quantitative meta-analyses will allow for robust comparisons of wearables' diagnostic performance across diverse conditions and events. By rigorously evaluating evidence from studies conducted in real-world contexts, our review will provide evidence to guide the responsible and effective implementation of wearable technology for early detection and continuous health monitoring by researchers, health care providers, policy makers, technology companies, and other stakeholders. As consumer adoption of wearables continues to rise rapidly worldwide, our comprehensive synthesis will assist in harnessing their potential while mitigating risks and ensuring appropriate use.

Methods

Protocol and Registration

The protocol for this systematic review was prospectively registered on PROSPERO (ID CRD42023407867) and this paper is reported according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [20] guidelines.

Selection Criteria and Search Strategy

The inclusion criteria are summarized in Table S1 in Multimedia Appendix 1. The inclusion criteria were developed using the population, exposure, outcomes, and study type criteria as follows: adult population (aged 18 years or older) in free-living

conditions, that have not been recruited based on a specific health condition or diagnosis; use of a wearable activity tracker (eg, Fitbit, Apple Watch, or a research-grade accelerometer) for the detection of any disease or medical event (eg, atrial fibrillation, the onset of infectious disease, and falls). To be eligible, the wearable activity tracker had to be able to detect movement behavior (ie, include an accelerometer), but could also include other types of sensors (eg, light sensor and temperature sensor). The wearable activity tracker had to consist of a single device worn on a single body location (eg, on the wrist or chest, not across both); studies needed to assess the actual diagnosis of a medical condition or occurrence of events that had clinical relevance (eg, falls). Eligible studies are needed to report an outcome related to diagnostic accuracy, such as specificity or sensitivity of the device for early detection of disease or medical events. Examples could include but were not limited to, providing effect estimates of overall diagnostic accuracy (%), sensitivity (%), and specificity (%) with 95% CIs; and validation studies conducted under free-living conditions that were reported in a peer-reviewed journal study were included. This included secondary analyses conducted within the context of observational studies, experimental studies, or quasi-experimental studies. Both consumer-initiated studies, where existing consumers who had purchased their own wearables were invited to join a study, and researcher-initiated studies, where researchers recruited participants and provided them with wearables, were included, as they represent 2 complementary real-world contexts in which wearable devices are often implemented for disease detection and monitoring. Studies were included only if they evaluated wearable devices provided by health care providers or researchers as part of a formal monitoring program, and the detection of a specific clinical event or disease was a prespecified outcome measure of the study. Studies examining consumer-driven self-tracking with personal wearables outside of a health care context were excluded. The following were also excluded: studies involving children or adolescents, studies examining symptoms within people known to have a specific disease, wearable devices that cannot track activity levels (eg, continuous glucose monitors), studies evaluating an array of wearable sensors worn at multiple body locations (eg, watch plus skin patch) or pedometers, studies measuring the association between an exposure and an outcome (eg, using odds ratios, relative risk, and hazard ratios), lab- or hospital-based studies, and conference abstracts or dissertations.

Ten databases were searched (CINAHL, Cochrane Library, Embase via OVID, MEDLINE via OVID, Emcare via OVID, JMIR Publications, ProQuest Central, ProQuest Nursing and Allied Health Source, PsycINFO, and Scopus) using subject heading, keyword, and MeSH (Medical Subject Headings) term searches for terms related to “wearable device” and “detection” (see Table S2 in Multimedia Appendix 1 for the full search strategy). We intentionally used broad search terms to ensure a comprehensive capture of the evidence base, including all types of medical conditions and events, without restricting our search to predefined diagnostic or event outcomes. Database searches were limited to peer-reviewed journal studies published in English from inception to April 1, 2023.

Data Management and Extraction

Search results were imported into ASReview (version 2.0; ASReview Community), an open-source software artificial intelligence tool designed for screening studies for systematic reviews. Title or abstract screening was conducted in ASReview by paired independent reviewers (BS and DD, RC, TF, JB, IW, KS, CS, AM, or EE). The software uses an active learning algorithm that iteratively selects the most relevant studies for inclusion based on the initial judgments made by the research team. The screening was stopped when 100 consecutive nonrelevant studies were screened. Following title or abstract screening, results were then imported to EndNote X9 (Clarivate) where duplicates were removed and then exported into Covidence (Veritas Health Innovation) for full-text screening, data extraction, and risk of bias scoring which was completed in duplicate by paired independent reviewers (BS and DD, RC, TF, JB, IW, KS, CS, AM, or EE), with disagreements resolved by discussion.

Data were extracted in duplicate by paired independent reviewers (BS and DD, RC, TF, JB, IW, KS, CS, AM, or EE) using a standardized extraction form in Covidence. The risk of bias in the included reviews was assessed by 2 independent reviewers in duplicate using the Joanna Briggs Institute (JBI) Critical Appraisal Checklist for Diagnostic Test Accuracy Studies. Studies were rated out of nine for the following items: (1) enrollment of consecutive or random sample, (2) the avoidance of a case-control design, (3) inappropriate exclusions, (4) the interpretation of index test results, (5) the prespecification of thresholds, (6) reference standard classification, (7) the interpretation of reference standard, (8) timing of tests, and (9) analysis.

Data Synthesis and Analysis

For each meta-analysis, data were combined at the study level. Separate meta-analyses were performed for (1) COVID-19 detection, (2) atrial fibrillation or arrhythmia detection, and (3) fall detection. Outcomes of interest were analyzed and data were pooled using sensitivity (%), specificity (%), AUC (%), accuracy (%), and positive predictive value (PPV), with 95% CIs as the effects measures. Sensitivity (%) denotes the percentage of individuals with the disease or condition correctly identified by the test, while specificity (%) represents the percentage of those without the disease or condition correctly identified as negative. The AUC (%) quantifies the test’s overall diagnostic accuracy, ranging from 0% to 100%, with higher values indicating better performance. Accuracy (%) reflects the proportion of all tests accurately classified, and PPV (%) indicates the likelihood that a positive test result correlates with the disease or condition being tested for. If 95% CIs were not reported in a study, they were calculated based on available data, using recommended formulas [21]. Publication bias was evaluated using funnel plots of effect sizes and standard errors and evaluating for asymmetries or missing sections within the plot, for meta-analyses that involved more than 10 studies. The Cochran Q test was used to assess statistical heterogeneity and the I^2 statistic was used to quantify the proportion of the overall outcome attributed to variability. The following cut-off values for the I^2 statistic were used: 0% to 29%=no heterogeneity; 30%

to 49%=moderate heterogeneity; 50% to 74%=substantial heterogeneity; and 75% to 100%=considerable heterogeneity [22]. Subgroup analyses were undertaken to evaluate device type (Fitbit, Apple watch, Oura ring, and others) for outcomes that had at least 2 studies in each subgroup. Sensitivity analyses for the meta-analysis were performed by removing the study with the lowest sensitivity, specificity, AUC, accuracy, or PPV. All meta-analyses were performed using Stata/MP (version 16; StataCorp).

The overall level of evidence was graded using the Oxford Centre for Evidence-Based Medicine 2011 Levels of Evidence, as follows: grade A: consistent level 1 studies (ie, individual randomized controlled trials); B: consistent level 2 (ie, individual cohort studies) or 3 studies (ie, individual case-control studies) or extrapolations from level 1 studies; C: level 4 studies (ie, case series) or extrapolations from level 2 or 3 studies; or D: level 5 (ie, expert opinion without explicit critical appraisal) evidence or inconsistent or inconclusive studies of any level [23]. Each outcome of interest was assigned a "Grade of Recommendation" based on meeting these criteria.

Deviations From the Registered Protocol

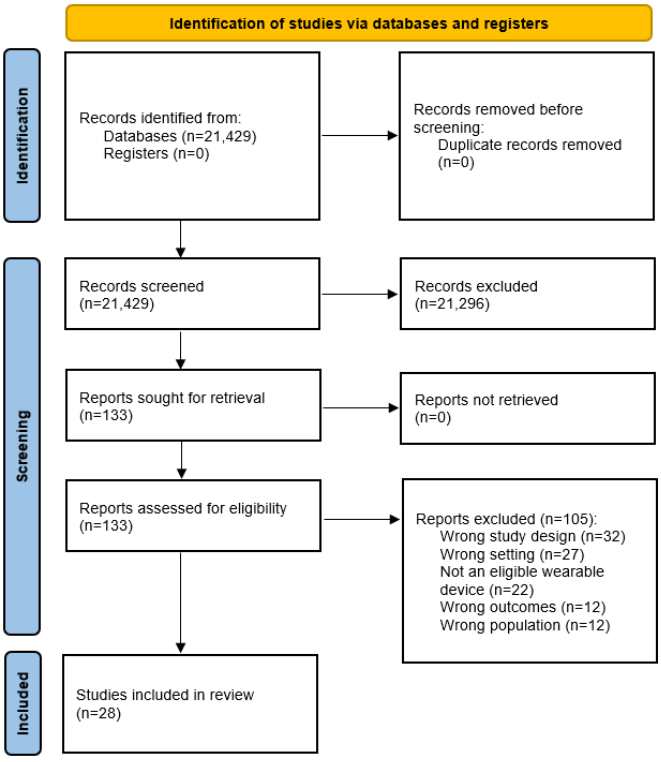
We planned to use the Effective Public Health Practice Project Quality Assessment Tool to assess study quality and risk of bias. However, during data extraction and quality assessment, we opted to use the JBI Critical Appraisal Checklist for Diagnostic Test for Accuracy Studies, as this instrument was more relevant to the included studies. Further, we were unable to conduct subgroup analyses for the type of wearable for atrial fibrillation and fall detection, due to an insufficient number of studies.

Results

Overview

Of the 21,429 records identified following the database search, 28 were eligible (see Figure 1 for PRISMA flowchart including reasons for exclusions; see Table S3 in Multimedia Appendix 1 for a complete list of full texts that were excluded during the final stage of screening, with reasons). An overview of all included study's characteristics is shown in Table S4 in Multimedia Appendix 1. There was a total of 1,226,801 participants (median sample size 264, IQR 96-8338; range 29-455,699). Median participant age was 47.3 (IQR 36.6-66), between 28.6 and 78.3, years and 21 (75%) studies involved female and male participants (gender was not reported in 7 (25%) studies). A total of 16 (57%) studies evaluated COVID-19, 5 (18%) studies evaluated atrial fibrillation, 3 (11%) studies assessed a broad range of cardiac arrhythmias, 3 (11%) studies assessed falls, and 1 (3.6%) study assessed viral symptoms. The devices used in the studies were Fitbit (n=6), Apple Watch (n=6), Oura ring (n=3), a combination of various devices (ie, studies that used a combination of the Apple Watch, Fitbit, Garmin, and other devices; n=7), Empatica E4 (n=1), Dynaport MoveMonitor (n=2), Samsung Galaxy Watch (n=1), and other or not specified (n=2). The median score for the JBI Critical Appraisal Checklist for Diagnostic Test Accuracy Studies was 6 (IQR 5-7; range 1-9) out of 9 (Table S5 in Multimedia Appendix 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



There was sufficient data in the included studies to conduct meta-analyses for the following clinimetrics: (1) COVID-19 detection (accuracy, %; sensitivity, %; AUC, %; and specificity, %), (2) atrial fibrillation detection (PPV, %; sensitivity, %; and specificity, %), and (3) falls detection (sensitivity, %; and specificity, %).

Meta-Analysis Results

COVID-19 Detection

Meta-analysis results of AUC, accuracy, sensitivity, and specificity for COVID-19 detection are shown in Figure 2. Meta-analyses of 9 studies showed a pooled AUC of 80.15% (95% CI 71.03%-89.27%) and 5 studies had a pooled accuracy of 87.54% (95% CI 81.57%-93.51%). Pooled sensitivity from 8 studies was 79.53% (95% CI 67.73%-91.33%), and 7 studies showed a pooled specificity of 76.79% (95% CI 69.44%-84.13%).

Subgroup analysis for device type for sensitivity and specificity are shown in Figures S6 and S7 in Multimedia Appendix 1, respectively. A summary of sensitivity and specificity for the different devices is shown in Figure 3. Overall, the Fitbit had a sensitivity and specificity of 75.39% and 90.60%, respectively, the Oura ring had a sensitivity and specificity of 80.47% and 72.60%, respectively, and combined devices had a sensitivity and specificity of 82.69% and 74.62%, respectively.

The results of sensitivity analyses are shown in Figure S3 in Multimedia Appendix 1. Following the removal of the worst-performing study, AUC was 84.10%, accuracy was 88.65%, sensitivity was 85.62%, and specificity was 78.57%.

Grade of recommendation: (B) consistent level 2 studies supporting the use of wearable activity trackers for the detection of COVID-19.

Figure 2. Meta-analysis of accuracy, sensitivity, AUC, and specificity of wearable activity trackers for detection of COVID-19. AUC: area under the curve.

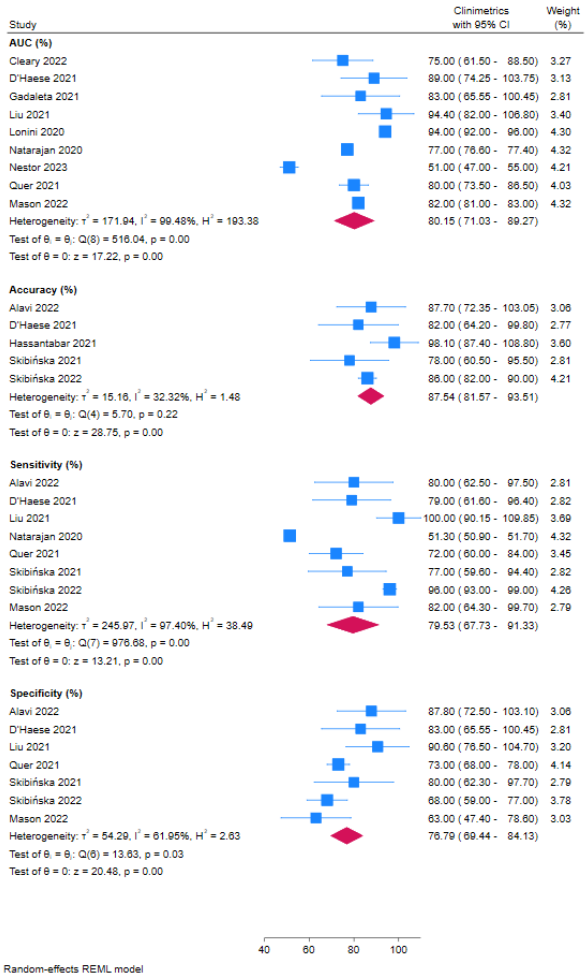


Figure 3. Overview of sensitivity and specificity for the different devices for COVID-19 detection.

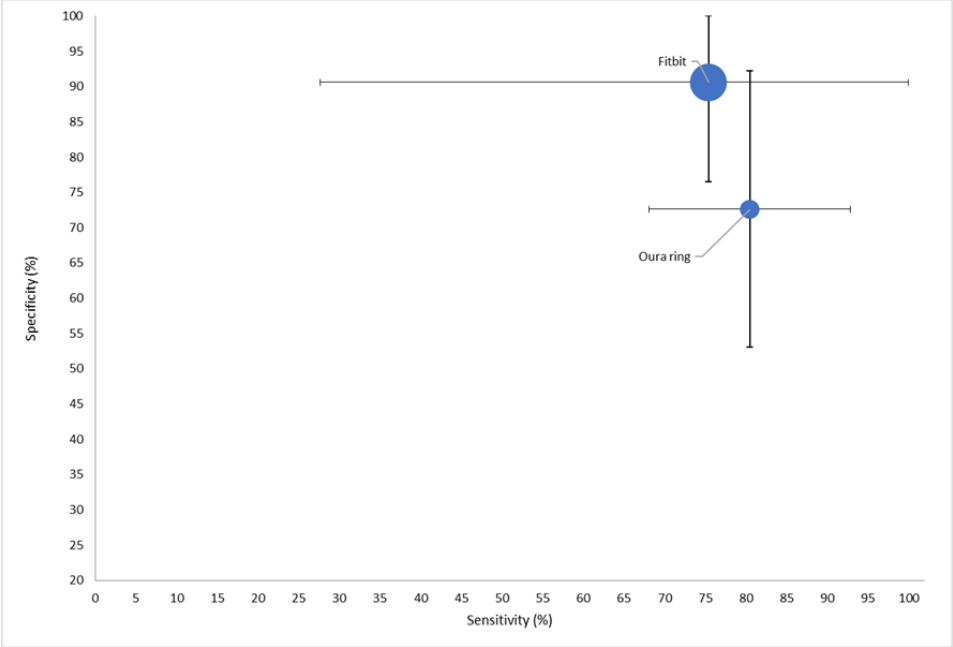


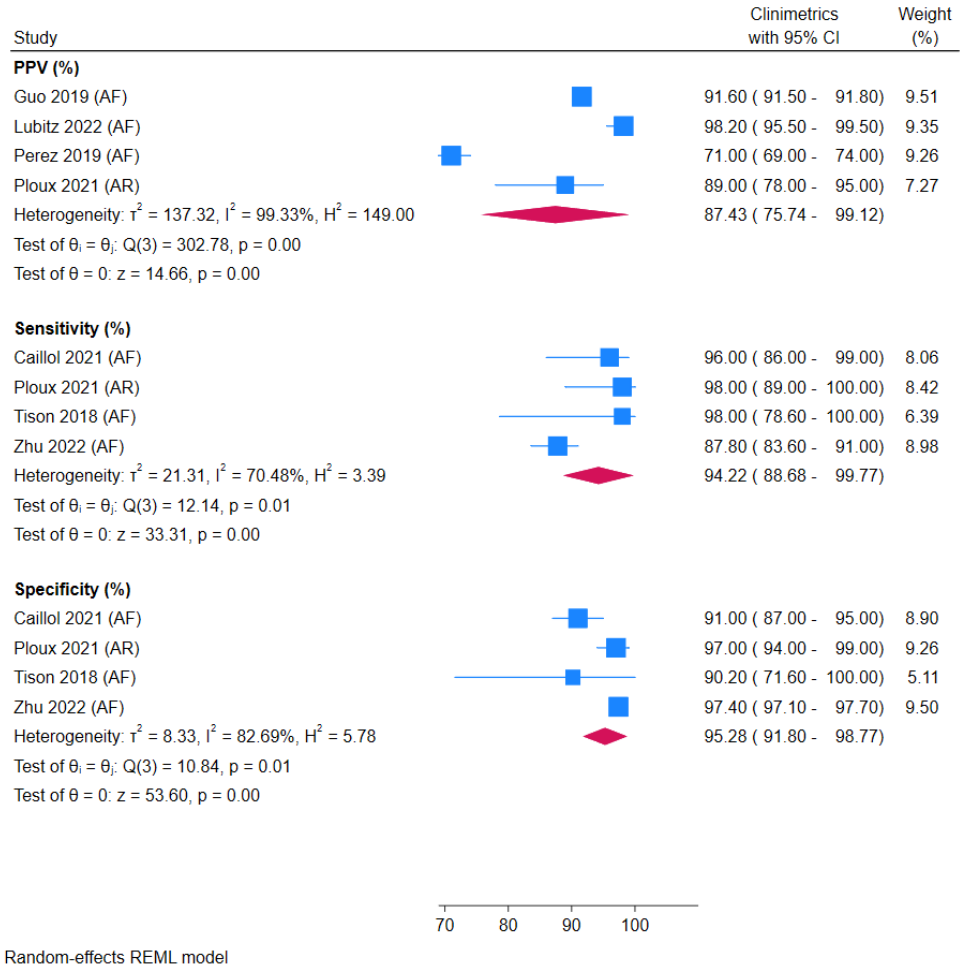
Atrial Fibrillation Detection

Pooled analyses of PPV, sensitivity, and specificity for atrial fibrillation detection are shown in Figure 4. Meta-analysis of 4 studies showed a combined PPV of 87.43% (95% CI 75.74%-99.12%). Pooled sensitivity was 94.22% (95% CI 88.68%-99.77%; 4 studies) and pooled specificity was 95.28% (95% CI 91.80%-98.77%; 4 studies).

The results of sensitivity analyses are shown in Figure S4 in Multimedia Appendix 1. Following the removal of the worst-performing study, PPV was 93.64%, sensitivity was 97.28%, and specificity was 95.55%.

Grade of recommendation: (B) consistent level 2 studies supporting the use of wearable activity trackers for the detection of atrial fibrillation.

Figure 4. Meta-analysis of PPV, sensitivity, and specificity of wearable activity trackers for detection of AF and AR. AF: atrial fibrillation; AR: arrhythmia; PPV: positive predictive value.

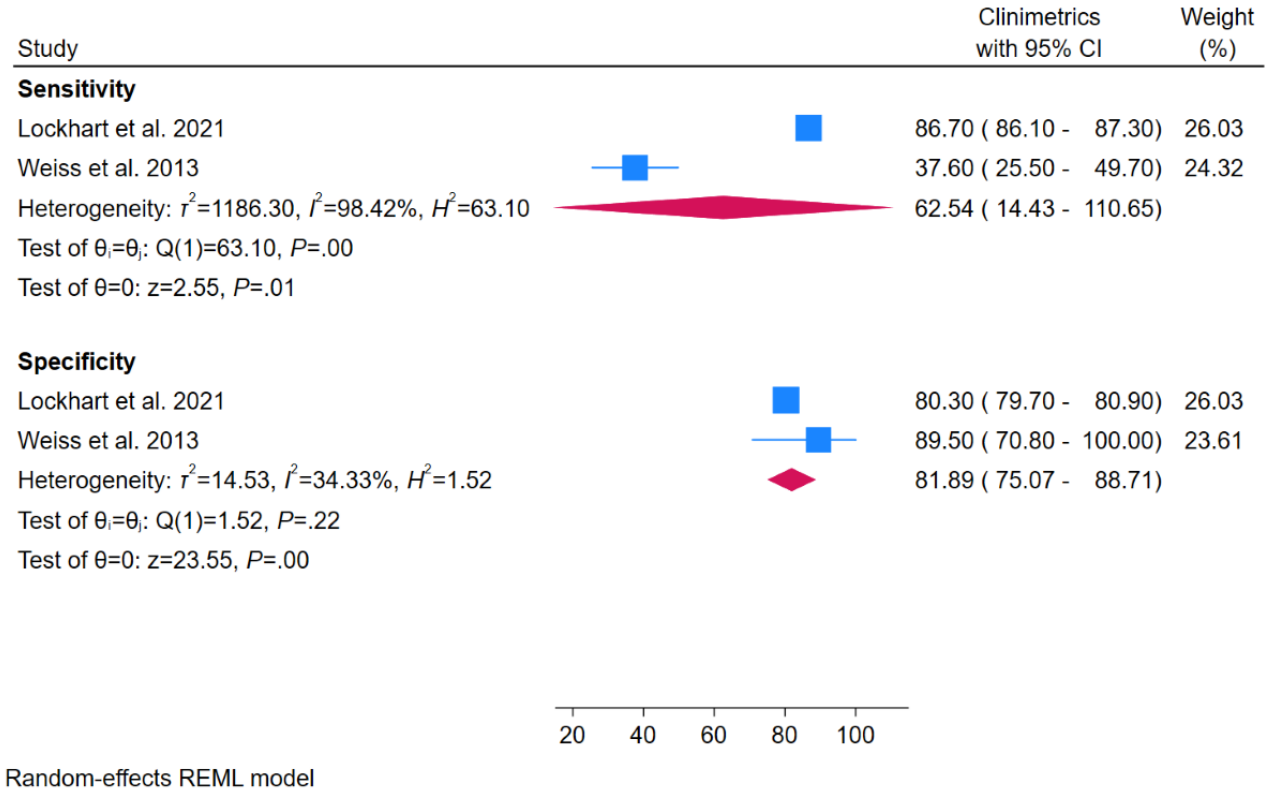


Falls Detection

Meta-analysis results of sensitivity and specificity for fall detection are shown in Figure 5. Meta-analyses of 2 studies showed a specificity of 62.54% (95% CI 14.43%-100%) and a sensitivity of 81.89% (95% CI 75.07%-88.17%). There was an insufficient number of studies for subgroup analyses of device type and sensitivity analyses for fall detection.

Grade of recommendation: (D) inconsistent or inconclusive studies of any level for the use of wearable activity trackers to predict falls.

Figure 5. Meta-analyses of sensitivity and specificity of wearable activity trackers for detection for fall detection.



Discussion

Principal Findings

In this study, we set out to systematically review and meta-analyze the current evidence regarding wearable activity trackers' ability to detect medical conditions and events under free-living conditions. To date, the majority of studies have focused on the detection of COVID-19, with a smaller number of studies focused on cardiac conditions and falls. For COVID-19 detection, the devices generally demonstrated good sensitivity and specificity. The most promising results were found for the detection of atrial fibrillation, for which the wearables showed high sensitivity and specificity. Whereas, for fall detection, the present findings devices showed moderate sensitivity but lower specificity. These findings indicate that while these devices are becoming more dependable for monitoring specific health conditions, their performance varies depending on the condition being detected.

The current body of evidence on the diagnostic potential of wearable activity trackers is notably skewed toward COVID-19 detection, a focus that is understandable given the pandemic's global impact and the consequent urgent need for monitoring solutions. Researching the feasibility of detecting COVID-19 through wearables holds appeal due to the availability of widely used reference standards. Rapid and polymerase chain reaction tests, widely used, allow for easy self-reporting of COVID-19 diagnoses by many individuals. In contrast, accessing a reliable gold standard for other health outcomes poses significant challenges. However, what was surprising to note is the limited number of studies exploring these trackers for other health conditions, especially given that numerous wearables advertise features such as sleep apnea detection—a topic noticeably absent in our findings. Our extensive database search identified only a handful of studies each related to cardiac issues and falls. This gap in the literature is striking considering the wide array of health conditions that could theoretically be monitored using wearable technology, given their ability to capture data related to heart rate, movement, skin temperature, and more. Such capabilities would suggest that a broad spectrum of medical conditions could be measured, spanning cardiovascular and respiratory conditions to neurological and psychological disorders. It is important to note that we intentionally focused on the accuracy of data collected in free-living conditions (with a view to understanding current-day diagnostic capabilities). We note numerous laboratory-based studies that were excluded (eg, [24] and [25]) suggesting that a wider range of diagnostic outcomes may become available in the future. Furthermore, many studies were excluded because they focused on monitoring symptoms in people with a known diagnosis (eg, seizures in people with epilepsy [26], and freezing gait in Parkinson disease [27]) which was outside the scope of this study, but highlights wearable activity trackers' potential for medical condition monitoring.

This study revealed that wearable activity trackers demonstrate moderate to high sensitivity and specificity for COVID-19 detection. It is interesting to compare our results with those for other COVID-19 screening tests. A systematic review by Mistry et al [28] on lateral flow devices (LFD) tests (also known as rapid antigen tests) evaluated 24 papers across 8 different LFD brands, covering over 26,000 test results. Their findings indicated that sensitivity ranged from 37.7% to 99.2% and specificity ranged from 92.4% to 100% [28]. Comparatively,

this study's pooled sensitivity for wearable-detected COVID-19 was 79.5% (range 51.3%-100%), which is in line with the LFD results. However, our specificity of 76.8% (range 63%-90.6%) was slightly lower. According to UK government guidelines, the benchmarks for COVID-19 workplace screening are ≥68% for sensitivity and ≥97% for specificity [29]. This suggests that while wearable activity monitor detection meets the sensitivity criterion, it falls short on specificity.

The most promising results were observed for the detection of atrial fibrillation, with figures that compare favorably to other clinical tests. For example, the sensitivity and specificity of a 12-lead electrocardiogram for detecting atrial fibrillation have previously been shown to range between 93% and 97% [30,31], which appears similar to our sensitivity and specificity of 94.2% and 95.3%, respectively. Over the course of 2022-2023, major brands, such as Fitbit [32], Apple Watch [33], Garmin [34], and Samsung [35], received approval from the US Food and Drug Administration for their atrial fibrillation detection features. The relatively higher accuracy in identifying cardiac arrhythmias as compared to COVID-19 is perhaps expected, given that cardiac functions can be deduced from wearables' optical heart-rate sensors. In contrast, COVID-19 detection usually requires intricate algorithms that amalgamate multiple data points [36,37].

While wearable activity trackers demonstrated effectiveness in detecting cardiac arrhythmia and COVID-19, our meta-analysis revealed that their accuracy in detecting falls was only moderate. The devices were generally effective in identifying actual falls, with a sensitivity of 81.9%. However, they also generated a significant number of false positives, as evidenced by a lower specificity of 62.5%. This aligns with existing literature on the subject [38,39]. It is crucial to note that our review specifically focused on the performance of these devices in real-world conditions among the general population. Most existing studies on fall detection with wearables have been conducted in controlled laboratory settings using simulated falls, where accuracy has generally been higher [38,39]. The false positives in fall detection are likely due to the devices relying on accelerometry data, which can misinterpret other rapid downward movements as falls. Further research is needed to refine the algorithms used in these devices to improve their performance in fall detection. Future studies might incorporate additional metrics, such as rapid changes in heart rate or galvanic skin response, which may accompany a fall, to enhance accuracy.

This study offers several significant strengths, including being the first systematic review and meta-analysis focused on the real-world accuracy of wearable activity trackers in detecting medical conditions and events. The review analyzed a robust data set from 28 studies, involving over 1 million participants, enabling a comprehensive meta-analysis of various outcomes. Instead of limiting our focus to specific diagnostic outcomes, we examined a broad range of medical conditions. Our search strategy was exceptionally thorough, encompassing 10 databases and reviewing over 21,000 studies to capture a wide array of diagnostic outcomes. Methodologically, we adhered to the PRISMA 2020 guidelines, which included conducting sensitivity and subgroup analyses, as well as evaluating the certainty of the evidence.

Study limitations must be acknowledged. There was considerable heterogeneity in the designs of included studies, such as their reference standards, diagnostic tests, and sample characteristics. Given the size of the current evidence, there were too few studies to conduct separate subgroup analyses based on specific device models or software versions. Our review included both researcher-initiated and consumer-initiated studies to provide a comprehensive assessment of wearable activity trackers in real-world settings. Researcher-initiated studies typically involved smaller sample sizes and controlled participant recruitment, while consumer-initiated studies often had larger sample sizes and reflected more naturalistic use patterns. While this combination enhances the generalizability of our findings, it also introduces heterogeneity. We acknowledge this as a limitation and suggest that future research should consider these differences when interpreting results. Additionally, our review only identified studies in the domains of COVID-19, cardiovascular conditions, and falls as eligible. While laboratory-based studies are being conducted for event detection in other health domains (such as stress and respiratory conditions), our focus was intentionally on studies conducted in free-living conditions. This approach offers insights into the wearables' event detection capabilities in real-world settings, as opposed to artificial (eg, laboratory) conditions.

Clinical Implications

The use of wearable activity trackers for detecting medical events is an emerging field with both significant promise and challenges. Wearable activity trackers demonstrate comparable ability to detect COVID-19 and atrial fibrillation compared with other clinical tests such as lateral flow tests and electrocardiograms. However, wearables offer the additional advantage of continuous, real-time monitoring for conditions requiring constant surveillance. As such, they may empower patients to take a more proactive role in their health care by giving them immediate feedback and data about their condition. They may also contribute to improved surveillance and resource planning for health care systems, which could be particularly useful in times of epidemics or pandemics.

Certain wearable device features excel at detecting specific medical events. For COVID-19, devices combining heart rate monitors, skin temperature sensors, and accelerometers proved effective by detecting deviations from an individual's baseline across multiple physiological parameters. In contrast, for atrial fibrillation detection, Food and Drug Administration-approved devices relied on optical heart rate sensors providing photoplethysmography data, capable of identifying irregular heart rhythms characteristic of arrhythmias. Fall detection primarily uses accelerometer data, with wrist-worn placement crucial for sensing sudden deceleration and impact forces. However, false positives persist due to nonfall rapid movements. Looking ahead, integrating multiple sensors can enhance accuracy across various medical conditions. Yet, fundamental sensor limitations may remain. Aligning device capabilities with specific use cases and recognizing sensor shortcomings

will inform future research and benchmarking efforts amid evolving technology.

As consumer wearables gradually morph from being lifestyle tools to over-the-counter medical instruments, they present a range of challenges, including concerns about data privacy and security, which will require stringent protective measures. Furthermore, as wearable devices become increasingly sophisticated in detecting medical conditions, such as atrial fibrillation, they offer both benefits and pitfalls. On the positive side, these devices have the potential to identify asymptomatic atrial fibrillation episodes. This is enormously beneficial, since currently, stroke is the first manifestation in at least 25% of atrial fibrillation-related stroke cases [40]. Early detection could therefore lead to timely intervention and stroke prevention. However, health care professionals have reported an uptick in patient consultations triggered by atrial fibrillation alerts from wearables, resulting in a surge of medical tests, such as electrocardiograms, to confirm diagnoses [41]. While some clinicians see this as an advancement in patient-initiated health care, others question the necessity of such screening, particularly in patient subgroups where atrial fibrillation may have a relatively benign prognosis [42]. Moreover, the use of wearables can generate both false positives and negatives, potentially causing unnecessary anxiety, diagnostic tests, and treatments, or giving users a false sense of security.

Future Research

Our review reveals that the current peer-reviewed evidence base concerning the event detection capabilities of consumer wearable activity trackers in free-living conditions is limited to COVID-19, cardiac function, and falls. This was somewhat surprising, given the potential of these devices to diagnose numerous other conditions. Our findings indicate a significant gap in the current literature, which was not apparent in previous reviews that typically focused on specific conditions and did not highlight the lack of studies across a broader range of conditions. Considering the diverse array of sensors incorporated in modern wearable activity trackers, these devices offer considerable potential for detecting and monitoring medical events across an extensive spectrum of health conditions into the future. This may include respiratory conditions, neurological disorders, mental health, stress and fatigue, and even environmental and allergic reactions. This will require research across the product design continuum, from algorithm training to laboratory testing and free-living testing. This will be made all the more challenging by the rapid pace at which new devices and models are released into the market. In the future, our meta-analysis could be updated to provide insight into the accuracy of such diagnostics by condition, device, and population.

Conclusions

This study provides a comprehensive overview of the current state of evidence regarding the diagnostic capabilities of consumer wearable activity trackers in real-world settings. While the devices show promise in detecting conditions, such as COVID-19 and atrial fibrillation, with moderate to high sensitivity and specificity, their performance in detecting falls is moderate, highlighting the need for further refinement of detection algorithms. The existing literature is notably skewed toward COVID-19, leaving a significant gap in our understanding of how these devices can be used for a broader range of health issues. This gap, which was not apparent in previous reviews, underscores the necessity for future research to expand the scope of conditions studied. As wearable technology continues to evolve, it is crucial to address the challenges posed by false positives and negatives, data privacy, and security concerns. This will ensure that the rapid advancements in this field can be matched by robust scientific validation, enabling these devices to realize their full potential as tools for health care monitoring and intervention.

Data Availability

All data generated or analyzed during this study are included in this published article and Multimedia Appendix 1.

Authors' Contributions

All authors contributed to the review protocol. BS, SC, AM, RC, DD, JB, TF, KS, CS, EE, IW, and CM designed the search strategy and selected studies. BS, AM, RC, DD, JB, TF, KS, CS, EE, and IW extracted the data. BS analyzed the data. BS, SC, and CM drafted the manuscript. All authors contributed to the drafting of the review. All authors revised the manuscript critically for important intellectual content. All authors approved the final version of the article. All authors had access to all the data in the study and could take responsibility for the integrity of the data and the accuracy of the data analysis. The corresponding author attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Conflicts of Interest

None declared.

Abstract

Background: The rates of substance use among adolescents are alarmingly high, and current treatment options lack integration of parent-focused interventions, despite evidence that effective parenting practices can mediate treatment outcomes for adolescents involved in substance use. Accessibility and other barriers to parental interventions may be mitigated through mobile health (mHealth); however, few mHealth platforms target substance use behaviors for adolescents through the implementation of behavioral parent training strategies.

Objective: This study seeks to review current mHealth platforms within empirical literature that are designed to increase effective parenting through behavioral parent training techniques. Because of the paucity of mHealth modalities that use parenting strategies to target substance use in adolescents, the objective was expanded to include mHealth platforms addressing behavior problems among youth, given that parent-targeted treatments for these clinical presentations overlap with those for adolescent substance use. Overall, the systematic review was conducted to inform the development of mHealth apps for parents of youth involved in substance use, improve accessibility, and better align with parental needs.

Methods: This systematic review was conducted using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) method to select relevant articles across several databases. Each study was assessed for relevance and inclusion. Each study was reviewed for demographics, delivery medium, intervention status as stand-alone treatment or as an enhancement to treatment, mobile device used, mental health condition targeted, intervention type, underlying intervention theory, behavior change theory applied in design, behavior change techniques, parent training techniques, youth outcomes, parent outcomes, visual design, content, and features.

Results: Overall, 11 studies were included. Nearly all studies (9/11, 82%) predominantly sampled female caregivers. Most of the studies (6/11, 55%) integrated social learning theory. Only a few of the studies (2/11, 18%) discussed the embedded behavior change theories, whereas all the studies (11/11, 100%) used at least one behavior change technique to encourage change in parental behaviors. Many of the studies (7/11, 64%) tailored design features to the end user. Of the various behavioral parent training techniques, nearly all studies (10/11, 91%) included the skill of strengthening the parent-child relationship. A preliminary evaluation of treatment outcomes suggests a positive impact of parent-targeted mHealth interventions. When reported, the effect sizes for treatment ranged from Cohen *d*=0.38 to Cohen *d*=1.58 for youth and from Cohen *d*=0.13 to Cohen *d*=2.59 for parents.

Conclusions: Although features and techniques were referenced, only a few of the studies provided specific information related to behavior change theory (2/11, 18%), visual design (2/11, 18%), and the translation of parent-targeted interventions to mHealth platforms. Such information would be useful for the development of mHealth apps. Preliminary outcomes for youth and parents are encouraging, but future studies should consider conducting a meta-analysis as the body of studies grows to determine aggregate statistical findings.

Introduction

Background

Adolescent substance use occurs at alarming rates in the United States, with approximately 4.3 million youths using illicit substances in 2019 [1]. Despite evidence indicating that 1.1 million of these youths needed substance use treatment, <1% obtained treatment [1]. For the few youth who receive substance use treatment, parent-focused interventions, shown to improve parenting practices that mediate adolescent outcomes, are often a missing component [2-4]. This is concerning because there are limited resources and pathways of access for parents of adolescents involved in substance use to receive parenting resources or support [5-7].

This inability to access parent-focused interventions may be related to both a lack of availability of these interventions [8,9] and logistical, personal, or systemic barriers to treatment engagement [10-15]. Nonetheless, less frequently acknowledged is that the currently available treatment options for parents of adolescents involved in substance use may not embody the type of treatment that these parents desire. Recent research showed that, among parents of youth in treatment for substance use, the majority (72%) perceived a need for parent-focused services related to parenting their adolescent child after substance use treatment; when aftercare was offered via mobile phone, this figure increased to 91% [16]. One interpretation of these findings is that parents are not currently receiving support through their preferred medium.

Taken together, these findings highlight the need for greater access to strategies for engaging in effective parenting of children with a history of substance use, and leveraging mobile health (mHealth) may help address this service gap. Unfortunately, while the development of mHealth apps is moving at a rapid pace in most fields of health care, it lags in the area of adolescent substance use [17]. There is only 1 published study of an mHealth app for parents of youth involved with substances [18]. However, this app focuses on delivering mindfulness interventions and excludes a focus on behavioral parent training. Given the demonstrated benefits of behavioral parenting approaches in curtailing adolescent substance use [4,19] and the potential advantages that mHealth apps offer in broadening access and reach, it is surprising that more attention has not been paid to developing an mHealth intervention specifically for parents of youth involved in substance use.

This systematic review seeks to evaluate mHealth apps in empirical literature designed to increase effective parenting through behavioral parent training techniques for behavior problems in their child. Given the overlap in behavioral parent training interventions for behavior problems and substance use [20-23], the results of this review could inform the development of future parent-focused mHealth apps for parents of youth involved in substance use, improving accessibility and matching parental desires for treatment mediums [24,25].

Behavioral Parenting Practices and Adolescent Substance Use

Parenting practices shape the development and outcome of a child [26]. The literature is replete with results showing that ineffective parenting practices such as poor monitoring and supervision, inconsistent discipline, poor limit setting, and low positive parenting are associated with a range of behavior problems [27], including substance use disorders [28,29]. On the basis of the plethora of research demonstrating the importance of effective parenting practices, evidence-based treatments designed to treat behavior problems among adolescents, including substance use, are heavily steeped in addressing ineffective parenting using behavioral parent training [20,22]. Broadly, behavioral parent training is an evidence-based approach to helping parents apply behavioral strategies to improve their child's behavior and increase positive family interactions; it is also referred to as parent management training and parenting training [30].

mHealth Apps for Behavioral Parent Training

After conducting a literature review, Jones et al [31] concluded that behavioral parent training is a strong fit for transfer to technological mediums such as smartphone apps. We concur and argue that behavioral parent training is compatible for translation to mHealth because key parenting strategies in the behavioral parent training protocols can be aided with smartphone apps that include design features tapping into general principles of behavior change to promote parenting behaviors. Specifically, app features such as routine prompts and timely notifications with tips may promote consistent implementation of rules, facilitate limit setting, and support the use of consistent discipline. In fact, prompting through push notifications aligns with behavior change theories in mHealth that emphasize the use of reminders to enact skills and the integration of motivational support [32,33] to foster the consistent use of learned, effective parenting practices; for example, the use of encouragement may include periodic messages that remind parents of a learned parenting skill and encourage them to continue using the skill.

Objectives

The original aim of this study was to systematically review available noncommercial mHealth apps for parents of youth involved in substance use. However, the limited literature on mHealth apps providing parental intervention to target adolescent substance use made this aim challenging. In an effort to continue to explore and review this subject despite the scarcity of research, the objective of this study expanded. In particular, the focus shifted slightly to a systematic review of mHealth apps that provide behavioral parent training or components of behavioral parent training to enhance the use of effective parenting for behavior problems in youth. This shift broadened the search for current mHealth apps in the literature, while also maintaining relevance and applicability to parent-targeted mHealth interventions for adolescent substance use. More

specifically, the behavioral parenting interventions that have been implemented to target youth behavior problems significantly overlap with those used to intervene on adolescent substance use. The large overlap in treatment content may be related to the notion that adolescent substance use is often conceptualized through a broader lens of behavioral problems in youth [20-23]. Therefore, the results of this review could generalize to the development of future parent-focused mHealth apps for parents of youth involved in substance use [24,25].

This study sought to answer four main research questions:

1. What are the general characteristics of behavioral parent training apps under development?
2. What is the empirical evidence underlying behavioral parent training apps under development?
3. What are the main parenting strategies covered in behavioral parent training apps under development?
4. What implications do the characteristics, empirical evidence, and parenting strategies evidenced in current behavioral parent training apps have on the development of an mHealth app for parents of youth with behavior problems involved in substance use?

To answer these questions, we summarized the major design elements, features, content, and theoretical foundations of the evaluated apps and paralleled these with the components of substance use treatment to provide recommendations for the design of mHealth apps for parents of adolescents who use substances. In contrast to existing studies, these objectives enhance knowledge about apps tailored specifically for parents of adolescents who use substances.

While prior studies have reviewed mHealth apps based on behavior change theory and techniques, they included a narrow focus on these factors [33-35] and did not review behavioral parenting practices. Some studies have reviewed commercial parenting apps [17,36], apps for specific groups of parents (eg, fathers with low-income status and new parents [36-38]), or apps for parents with adult children [39]. However, these studies did not review apps designed to teach behavioral parenting skills to address behavior problems exhibited by their child. Indeed, several reviews provide information about the effectiveness of technology-based interventions for behavior change and for parents of children with emotional or behavioral issues [40-42]. However, these reviews included a mix of dated mediums alongside mHealth apps, including websites, software, videoconferencing services, and SMS text messaging.

Methods

Literature Search

The search was conducted electronically in English between June and September 2019, again in March 2021, and once more in October 2022. No restrictions on the date or year of article publication were imposed in the original 2019 search, and the 2021 and 2022 searches were limited to materials published in the time since the prior searches. The following databases were used: PsycINFO, MEDLINE (PubMed), Google Scholar, Scopus, Web of Science, and WorldCat. References from selected articles and past literature review articles were also examined to identify potential sources that may have met our criteria for this review [39,40,43,44].

The following mobile technology search terms were used: *mobile phone*, *mHealth*, *eHealth*, *SMS*, *text messaging*, *mobile application*, *tablet*, *smartphone*, and *cell phone*. The following parent treatment search terms were used: *parent training*, *intervention*, *treatment*, *parent management training*, *parent-child interaction*, and *behavioral training*. The following mental health search terms were used: *behavior*, *attention-deficit/hyperactivity disorder*, *autism spectrum disorder*, *posttraumatic stress disorder*, *trauma*, *psychological*, and *disorders*. These terms were entered into databases using various search combinations, including *(mobile phone OR cell phone OR smartphone OR tablet) AND (parent train* OR treat* OR parent management train*) AND (behav* OR trauma OR disorder OR attent* OR psycholog* OR autism) AND (SMS* OR text messag* OR application OR mHealth OR eHealth)*.

The search conducted in October 2022 to update the results used the original search terms with date restricted to the years since the search conducted in March 2021 (ie, 2021-2022). In the search update, searches in 3 databases were modified to limit the number of results for relevance. Specifically, in MEDLINE (PubMed), the search was limited to clinical trials and randomized controlled trials; in Scopus, it was limited to articles; and in Web of Science, additional search criteria—*adol* OR child* OR parent* OR caregiver OR mother OR father OR youth*—were applied to filter out irrelevant results.

Study Selection and Eligibility Criteria

Due to the paucity of studies in this field, the titles and abstracts identified from the search process included both peer-reviewed feasibility or acceptability articles and conference proceedings. Articles were screened against predefined inclusion criteria (Textbox 1) by 3 reviewers (SRR-P, KIM, and KL), who independently conducted the search and met afterward to integrate the search results and make joint decisions about inclusion and exclusion for each record.

Textbox 1. Criteria for eligibility.

Inclusion criteria

- The study investigated parent-targeted interventions to influence child mental health conditions (defined as the presence of adverse behavioral and emotional symptoms that may be contributing to psychological difficulties). These conditions may include disruptive behaviors and conduct disorder symptoms, substance use, attention-deficit/hyperactivity disorder symptoms, trauma symptoms, and autism spectrum disorder symptoms; however, developmental, language, speech, and motor delays were excluded because these may not always be directly related to psychological symptoms.
- The study provided data on the efficacy or effectiveness of the intervention.
- The study provided data on either parent or child outcomes.
- The interventions only used mobile or tablet devices (studies were excluded if they involved the use of websites or computers in any capacity).
- The intervention content, such as specific parenting skills, was delivered via SMS text messaging or mobile apps (as opposed to professionals delivering interventions via mobile devices).
- Either stand-alone treatments or enhancements to existing treatments were included if the intervention involved more than simple reminders to attend regular treatment, based on the rationale that even enhanced treatment components may serve as stand-alone interventions with further research development.
- Studies involving biological parents, nonbiological parents, and foster caregivers were included.
- Studies that involved interventions targeting parents of children ranging in age from 2 to 18 years were included, based on the rationale that regardless of differences in implementations depending on the age of the child the basic principles of certain effective parenting practices (eg, parental monitoring) remain consistent.
- The articles or conference papers were in English.

Identification and Description of Study Characteristics

Study Characteristics Assessed

Each article selected for the review was assessed for various characteristics, including demographics, delivery medium, intervention status as stand-alone treatment or as an enhancement to treatment, mobile device used, mental health condition targeted, intervention type, underlying intervention theory, behavior change theory applied in design, behavior change techniques, parent training techniques, youth outcomes, parent outcomes, visual design, content, and features. Each of these characteristics was operationalized according to this review's context (Textbox 2).

Textbox 2. Operationalization of the characteristics and features reviewed.

Characteristics and operationalization

- Delivery medium: the method used to deliver the intervention on the mobile device, which included the use of a mobile app, electronic monitoring wristbands, and the use of smartphone or tablet features such as SMS texting, video calls, and video recordings
- Stand-alone treatment: the intervention is administered solely via the mobile device without being administered alongside, or in conjunction with, in-person treatment
- Enhancement to treatment: the intervention is administered in person, and the mobile device is used as a supplemental feature of treatment
- Mobile device used: the type of mobile device used to deliver the intervention
- Mental health condition targeted: the adverse behavioral or emotional symptoms exhibited by the children of the population of parents studied
- Type of intervention used, incorporated, or adapted: the parent-targeted intervention used in the research study that can be fully used, shortened, selectively used, or adapted, with the primary skills being implemented
- Underlying intervention theory: the theoretical foundation of the parent-targeted intervention
- Behavior change theory applied in design: a method for understanding how variations in treatments or interventions can lead to changes in behavior (Hekler et al [45])
- Behavior change techniques: a range of 26 methods used in the design of the mobile intervention to change an individual's behavior [46]; the definitions of these 26 techniques can be found in the taxonomy developed by Abraham and Michie [46]
- Youth outcomes: changes in youth symptoms or behaviors after parent-targeted intervention is administered
- Parent outcomes: changes in parent behaviors after parent-targeted intervention is administered
- Visual design: assessment of the visual quality and look and feel of the program, including aesthetics, layout, and size [43]
- Content: assessment of the material provided and learned in the program, including the use of evidence-based content, quality of information provision, completeness and conciseness, and clarity about the program's purpose [43]
- Features: assessment of different aspects used in the design of the mobile intervention

These characteristics were first assessed through careful reading of each article by the lead author (KIM). If the relevant elements could not be identified through reading the article, the references of the article were reviewed to determine whether they were included in the preliminary work. The authors of 2 (18%) of the 11 studies were contacted to inquire whether further research surrounding the initial study had been conducted. One author responded to the inquiry. To identify behavior change techniques, visual design qualities, content, and theoretical foundations, the methodologies outlined in the following subsections were used.

Identification of Behavior Change Techniques

Interventions were evaluated for the types and number of behavior change techniques using the taxonomy of behavior change techniques developed by Abraham and Michie [46].

Assessment of Visual Design and Content

Visual design and content were evaluated using Enlight (MindTools.io), a 5-point rating system ranging from 1=*very poor* to 5=*very good*, developed for the assessment of eHealth interventions [43].

Identification and Assessment of Theoretical Foundations

Theoretical foundations of the treatments and mobile apps were assessed through the implementation of a theory coding scheme [47]. This coding scheme outlines various steps for classifying the presence of the use of theory in interventions [47]. In this review, theoretical foundations were coded as present based on their mention in the article or its references (ie, item 1 [47]). When referenced or mentioned by the study, the presence of a theoretical foundation was coded. When assessing behavior change theory in the design of the mobile interventions, it was noted when a theory was not specifically mentioned but only alluded to in the study. Specifically, when a study mentioned the use of theory without specifying the name of the theory or its characteristics, it was marked accordingly.

Results

Demographic Information and Designs of Reviewed Studies

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) method was used to conduct the systematic search [48,49] (Figure 1), which included the PRISMA checklist that can be found in Multimedia Appendix 1 [50]. Through this process, a total of 11 studies were included in this review, and each was assessed for demographic information (Table 1). The earliest studies reviewed were published in 2014 [51,52]. Of the 11 studies, 7 (64%) were randomized controlled trials. The sample sizes ranged from 10 to 371 participants. Most of the parents included were mothers (ranging from 77% to 100%); however, in the study by May et al [50], the intervention was delivered to fathers. The parental ages ranged from 18 to ≥50 years. The target children's ages ranged from 2 to 18 years. Each study recruited participants from a range of settings, including primary care clinics (1/11, 9%), community health agencies (4/11, 36%), social services (2/11, 18%), juvenile justice centers (1/11, 9%), early education agencies (1/11, 9%), community parenting support groups (2/11, 18%), autism organizations and intervention centers (1/11, 9%), child psychiatrist (1/11, 9%), schools (1/11, 9%), and social media platforms (3/11, 27%). Families were included if the child had "externalizing behavior problems," "disruptive behaviors," "symptoms of conduct disorder," "autism spectrum disorder," or "attention-deficit/hyperactivity disorder."

Schaeffer et al [58], 2022	Female (100)	Male (55.9)	Mean 39.4 y (NR)	Mean 14.6 y (NR)	Social media and juvenile justice centers	White (76.5); Hispanic or Latinx (14.7)	10,001-20,000 (17.6); 20,001-30,000 (14.7); 50,001-60,000 (14.7); ≥60,000 (26.5)	Sole adult household (44.1); 2-parent household (29.4)	12 wk
Sonne et al [59], 2016	NR	Male (69.2)	NR	Mean 9.3 y (NR)	Community health agencies and child psychiatrist	NR	NR	NR	4 wk
Sullivan et al [60], 2019	Mother (95)	Male (55)	Mean 50 y (NR)	Mean 8.9 y (NR)	Social service agencies	White (95)	NR	Married (50); single (25)	10 wk

[a]Caregiver identification aligns with the report in the respective articles; identification as a mother or father should not assume gender.

[b]NR: not reported.

[c]Jones et al [51] define low income as the "adjusted gross income did not exceed 150% of the federal poverty limit, which takes into account both income and number of residents in the home."

[d]Mason et al [57] did not provide specific financial ranges; however, the sample was described as "low income."

[e]Pina et al [52] did not provide the ages of the children but specified that they were in grades K-12.

Of the 11 studies, 4 (36%) did not report the race or ethnicity of the sample. Among studies that reported race or ethnicity, the majority of the participants (ranging from 79% to 95%) were either from ethnic minority families (3/11, 27%) [51,53,56] or White (4/11, 36%) [54,57,58,60]. Information pertaining to socioeconomic status followed a similar pattern. Of the 11 studies, 5 (45%) included families who were identified as coming from a lower socioeconomic background [51,53,56-58],

2 (18%) included participants experiencing financial stress [50,54], and 4 (36%) either did not report income [52,55,59] or did not provide any socioeconomic information [60].

Of the 8 studies that reported the marital or partnership status of the parents, caregivers, or legal guardians, 5 (62%) reported that the majority (ranging from 50% to 90.6%) of the participants came from a 2-parent household (married couple or cohabiting couple).

Treatments were implemented for time periods ranging from 2 to approximately 16 weeks. Of the 11 interventions, 4 (36%) served as an enhancement to treatment, and 7 (64%) served as stand-alone treatments. Most of the studies (7/11, 64%) used a mobile app as a delivery medium.

Theoretical Frameworks

Transferring treatment to a digital platform requires consideration of both the intervention's theoretical framework and the theoretical frameworks that promote behavior change within a mobile platform.

Theoretical Framework of the Interventions

All studies (11/11, 100%) identified for this review drew from empirically based or evidence-based parent management training curricula, including the Chicago Parent Program, Behavioral Parent Training, Multisystemic Therapy, Behavioral Model Training, Helping the Noncompliant Child, and The Incredible Years Program. It is understood that the most prominent theoretical frameworks for these treatments include behaviorism (operant principles), the ecological systems framework developed by Bronfenbrenner [61], social learning theory, and the coercion model.

Of the 11 studies, 6 (55%) [51,53,56,57,59,60] explicitly discussed social learning theory, 2 (18%) [51,53] discussed the coercion model, 1 (9%) [58] discussed the social ecological framework developed by Bronfenbrenner [61], and 1 (9%) [55] discussed the transactional model of stress as the main theoretical framework for the parenting interventions included in the apps. Of the 11 studies, 4 (36%) did not expressly mention the coercion model as a theoretical framework, but this model was implied through information related to app content [52,57-59]; for example, these studies described implementing skills such as parental communication, effective parent-child interaction, monitoring, and limit setting to improve parental responses to child behaviors considered problematic, which is a tenet central to the coercion model [62]. Of the 11 studies, 2 (18%) did not expressly mention the guiding theoretical framework, and nor did they provide enough information to make inferences about the theoretical framework [50,54]. However, these studies did reference several behavioral parent training skills that are drawn from multiple interventions (eg, parent-child interaction therapy and parent management training).

Across all studies, when provided, there was a general mention of the theoretical framework for the interventions. While all studies (11/11, 100%) named the parenting skills used, only a few (4/11, 36%) provided comprehensive and specific information about specific parenting strategies (eg, examples of the language used or a description of the applications of skills to in vivo situations) [51,52,57,58]. These studies discuss examples of the applications of individual parenting skills to daily life situations [51,58] or specific language used to deliver the skill [52,57].

Theoretical Frameworks Promoting Behavior Change Within a Mobile Platform

Only 2 (18%) of the 11 studies described the use of behavior change theories in the design of the mobile intervention for parents [51,53], which included social cognitive theory [53] and self-determination theory [51]. Details about these frameworks were found by reviewing preliminary, formative research [31,51,53]. No other study provided information about behavior change theories having guided the mobile intervention design. Of note, Schaeffer et al [58] have a manuscript in preparation that aims to describe the development of the mobile app. As such, this manuscript under preparation may allude to the behavior change theories that underlie the mobile app development. Nonetheless, the lack of behavior change theory implementation in mobile interventions is consistent with findings from past reviews [33,34,63], suggesting that designing mobile phone–based interventions without a theoretical foundation for behavior change within design is a common practice across different niches in the mobile intervention literature.

However, an evaluation of the studies using the taxonomy of behavior change techniques [46] revealed that these techniques were frequently used. The number of behavior change techniques included in the interventions ranged from 2 [49] to 9 [51]. The most used behavior change techniques within the apps included providing instruction (9/11, 82%), prompting practice (9/11, 82%), and prompting self-monitoring of a behavior (8/11, 73%). Taken together, the studies seem to have implemented some behavior change techniques widely, but the techniques were not guided by a stated behavior change theory in most of the studies (9/11, 82%; Table 2).

Table 2. Characteristics and features of reviewed studies.

Study, year	Sample, n; design	Delivery medium	Standalone treatment or an enhancement to treatment	Mobile device used	Mental health condition targeted	Type of intervention used, incorporated, or adapted	Underlying intervention theory	Behavior change theory applied in design	Behavior change techniques	Parent training skills used in intervention	Youth outcomes	Parent outcomes
Breitenstein et al [53], 2016	79; RCT[a]	MA[b]	Standalone treatment	Tablet	Behavior problems	Chicago Parent Program	CM[c], SLT[d], and SCT[e]	SCT (theory was specified in a referenced article or preliminary work that was referenced)	CR[f], GE[g], M or D[h], OSC[i], PF[j], PI[k], PP[l], and SM[m]	Parent-child relationship; clear expectations and rules; rewards and incentives; setting behavior goals; and effective requests	No significant change in child behavior problems	Improvement in parental warmth (Cohen *d*=0.31); improvement in parental self-efficacy (Cohen *d*=0.13), and improvement in parental follow-through on skills (Cohen *d*=0.18)
Feil et al [54], 2018	42; RCT	MA	Standalone treatment	Smartphone	Conduct and antisocial behaviors	Behavioral parent training skills	—[n]	—	FU[o], GE, PP, RG[p], SGS[q], and SM	Clear expectations and rules; rewards and incentives; setting behavior goals	—	No significant change in parenting behaviors

[ai]CDT: child development theory.

[aj]RT: resilience theory.

Design Elements

Features

Assessment of all the studies suggested the presence of 5 features: tailoring intervention content, push notifications, tracking of behaviors, modeling skills through video demonstration, and reward systems. The reviewed studies varied in their implementation of these features. First, many of the studies (7/11, 64%) included options for the end user to tailor mobile app intervention content or features. Options to tailor intervention content included defining individualized behavioral goals such as completing household chores, following a bedtime routine, returning home by curfew, and completing homework (4/7, 57%) [53,54,58,59]; creating a schedule for when to use the parenting skills provided in the app (eg, choosing when to engage in particular modules, creating a routine for parents, and allowing ongoing access to psychoeducation; 3/7, 43%) [53,59,60]; delivering just-in-time interventions according to individual stress level (2/7, 29%) [52,58]; selecting rewards or contingencies that they think their child would value (4/7, 57%) [53,54,58,59]; and receiving psychoeducation tailored to individual circumstances (eg, how to intervene when the child is in a risky situation and using time-outs with children who have experienced trauma; 4/7, 57%) [51,53,58,60]. Several studies also offered opportunities to tailor features of the app (6/11, 54%). Options to tailor app features included choosing icons, avatars, and profile photos that embody the user (2/11, 18%%) [54,60]; filming oneself practicing skills with the youth (1/11, 9%) [51]; and integration of the user's name in the delivery medium (4/11, 36%) [54,57-59]. Notably, only a few of the studies (2/11, 18%) provided comprehensive visual examples or a description of the treatment content and mobile platform. As a result, other design features may be embedded in the apps but have not been identified in this review.

Second, most of the mobile interventions (8/11, 73%) included push notifications and SMS text messages to prompt practice of strategies or provide reinforcement and encouragement [50-52,55-59].

Third, some of the studies (3/11, 27%) included a mechanism for tracking youth behaviors [54,58,59], such as completing steps in a routine, monitoring the youth's location, and assessing the completion of positive behaviors. Behaviors were tracked either by parents [60] or by both parents and children [54,58,59], and they were logged by adding events to a log sheet [54,58] or by moving through a checklist in situ [59]. Behavioral tracking (ie, assessing and following the behaviors of the youth concerned) was implemented through the mobile intervention in each of these studies.

Fourth, some of the studies (4/11, 36%) included videos modeling parent-child interactions and other parenting skills [51,53,58,60].

Finally, nearly half of the studies (5/11, 45%) featured a reward system for either the parent or the child [53,54,58-60] that was implemented through the mobile intervention. For children, rewards included points [54,58] and stickers [59], while parents earned completion badges and certificates [53] or accessories for an avatar family [60].

Content

Broadly, the mobile intervention content related to behavioral parent training skills included strengthening the parent-child relationship (10/11, 91%; the exception was the study by Feil et al [54]), setting clear expectations and rules (8/11, 73%; the exceptions were the studies by May et al [50], Mason et al [57], and Hemdi and Daley [55]), the establishment of rewards and incentives (6/11, 55%) [51,53,54,56,58,59], setting behavioral goals for the youth (5/11, 45%) [52-54,58,59], the use of effective communication and requests (5/11, 45%) [51-53,57,58], praising desired behaviors (4/11, 36%) [51,52,56,60], modeling effective behaviors (4/11, 36%) [51,52,56,58], planned and active ignoring (4/11, 36%) [51,52,56,60], and the implementation of monitoring and supervision (3/11, 27%) [57-59]. Although an indication of behavioral parent training skills can be gleaned from the description of the intervention, it is challenging to determine the exact number of these skills. This difficulty stems from a lack of detailed information in the articles regarding the specific skills provided in the mobile intervention. Of note, some of the studies (2/11, 18%) [51,56] involved enhancements to in-person treatment delivery, suggesting that additional skills were likely provided and discussed through the technology, although they were not explicitly mentioned in the manuscripts.

Ideally, a review of app content includes an assessment across 4 domains: evidence-based content, quality of information provision, completeness and conciseness, and clarity about the program's purpose [43]. To fully implement this evaluation, studies must provide comprehensive information, including examples of content across the intervention (eg, specific messages designed for the end user, video dialogue, and prompts used to encourage practice). Unfortunately, most of the studies (10/11, 90%) included in this review did not include enough information for a thorough review of app content across these 4 dimensions. In fact, only 1 (9%) of the 11 studies [52] allowed for a partial evaluation of content according to the Enlight domains.

For 8 (73%) of the 11 studies, specific, direct content was not described [50,51,53-56,58,60]. Consequently, the content could not be evaluated against the Enlight domains.

Of the 11 studies, 3 (27%) provided specific examples of content [52,57,59]. However, the information was not comprehensive in that it consisted of brief sample treatment statements and lacked psychoeducation related to the skills being implemented. For 2 (67%) [57,59] of these 3 studies, none of the Enlight domains could be evaluated. With regard to the third study [52], some Enlight domains were assessed (ie, clear and concise goals, quality information necessary to obtain these goals, and clarity regarding the purpose and target population of the program). The evaluation showed that the content fulfilled these domains at *good* levels.

Visual Design

Ideally, a review of visual design includes the evaluation of aesthetics, layout, and size [43]. As with content evaluation, studies must provide a comprehensive collection of visualization of the mobile app. Because this assessment examines font consistency, the harmony of colors used throughout, and the size of the layout on the mobile device [43], a comprehensive set of visualizations would include examples of various pages in the app design and include examples of color, font, images, and treatment content. Most of the studies (6/11, 54%) included in this review provided few visualization examples, which created difficulty in conducting a full assessment of the visual design used throughout the app.

Of the 11 studies, 4 (36%) were not evaluated for visual design because either the interventions were SMS text message based [50,56,57] or no visual information was provided in the article [55]. Among the remaining 7 studies, 6 (86%) included examples of the mobile intervention with snapshots of select screens, rather than a visual design sample of the app in its entirety [52-54,58-60]. Of note, 1 (17%) of these 6 studies included visualizations of the mobile app through a website, rather than within the published study article [58]. Because of the scarcity of visual examples among the studies included in this review, evaluation based on the Enlight criteria was completed for the components of the intervention the researchers selected to present, rather than the app in totality. The results showed that the aesthetics classifications included *not attractive* (1/6, 17%), *fair* (1/6, 17%), *attractive* (2/6, 33%), and *very attractive* (2/6, 33%). The layout classifications ranged from *fair* (1/6, 17%) and *good* (4/6, 67%) to *very good* (1/6, 17%). The size qualities ranged from *fair* (1/6, 17%) and *good* (2/6, 33%) to *very good* (3/6, 50%).

Most of the studies (4/11, 36%) implemented muted colors on certain screens or activities for parent-directed content [52,53,59,60]. For parent- and child-directed or child-only–directed content, colors were brighter than those seen on parent-directed content screens [54,59]. Using brighter colors with children aligns with the robust literature on the preference of younger children for brighter, more saturated colors over more muted colors [64-66]. The depiction of families was an overwhelmingly common visual design element; for example, the studies included photos of families on home pages who resembled the families using the app [53], actual photos of the families themselves [54], or the integration of the names of the children [58].

Treatment Outcomes

Youth Outcomes

Of the 11 studies, 8 (73%) provided youth outcomes. Of these 8 studies, 7 (88%) indicated substantial improvement in the youth. Of these 7 studies, 6 (86%) were randomized controlled trials and indicated that the youth showed greater improvement in the technology-enhanced group when compared to the control group [51,53,55-58]. Overall, the youth in these randomized trials exhibited a decrease in behavioral and mood-related problems [51,55,56,58]; for example, Lefever et al [56] reported that youth with parents in the intervention condition demonstrated a significant improvement in cooperative behavior with a small to medium effect size (Cohen d=0.38); Hemdi and Daley [55] reported significant improvement in hyperactivity for youth in the intervention condition with a large effect size (Cohen d=−1.54); Jones et al [51] reported significant improvements in the intensity (Cohen d=0.99) and presence of disruptive behaviors (Cohen d=0.54) with medium to large effect sizes for youth in the intervention condition; Mason et al [57] reported significant small to medium effect sizes, demonstrating a decrease in depressive (Cohen d=−0.63) and anxiety (Cohen d=−0.57) symptoms; and Schaeffer et al [58] reported significant decreases in substance use, delinquency, and status offenses for youth in the intervention condition with medium to large effect sizes (ranging from Cohen d=0.54 to Cohen d=0.84).

Of the 8 studies, 2 (25%) were pilot studies [59,60]. Although these studies did not use a randomized group as a comparison, both reported similar improvements in youth behavior problems; for example, Sonne et al [59] reported a significant reduction in inattention at a medium effect size (Cohen d=0.73), improvement in conduct-related behaviors at a large effect size (Cohen d=1.02), and improvement in youth sleep at a medium effect size (Cohen d=0.67). Sullivan et al [60] reported an increase in youth prosocial behavior at a small effect size (Cohen d=0.40).

Parent Outcomes

Most of the studies (10/11, 91%) reported parent outcomes. Many of the studies (9/11, 81%) reported parental improvements when using mobile technology. Among the 7 studies using a randomized controlled trial design, all (7/7, 100%) reported parental improvements in the technology intervention groups compared to their respective control groups. Specifically, Breitenstein et al [53] reported an improvement with small to medium effect sizes in parental warmth (Cohen d=0.31), parental self-efficacy (Cohen d=0.13), and parental follow-through on skills (Cohen d=0.18). Hemdi and Daley [55] reported large effect sizes for reduction in parental stress (Cohen d=−0.98) and parental depression (Cohen d=−2.05) among parents in the mobile intervention group. Lefever et al [56] reported a medium effect size in the observation of parenting skills use (Cohen d=0.68), a small to medium effect size in the improvement in responsive parenting skills (Cohen d=0.35), and a small effect size in the growth of use of parenting skills (Cohen d=0.28). Jones et al [51] reported a greater improvement in parental engagement and the generalization of parenting skills for the parents using a mobile intervention with weekly attendance (Cohen d=0.88), participating in midweek check-ins (Cohen d=2.59), and the completion of home practice (Cohen d=0.63), reflecting medium to large effect sizes. Schaeffer et al [58] reported small to medium effects in the improvement of discipline consistency (Cohen d=0.44) and rule clarity and structure (Cohen d=0.32). Mason et al [57] reported small to medium effect sizes in the improvements of parent relations (Cohen d=0.41) and parenting skills (Cohen d=0.51), reflecting medium effect sizes. Finally, and of note, while Feil et al [54] reported a small to medium effect size in the reduction of negative parenting behaviors, the researchers note that this

finding is insignificant and did not report this coefficient. Therefore, this reported finding is not included in Table 2.

Of the 10 studies, 3 (30%) were pilot studies that incorporated parent outcomes. Although these studies did not use a randomized group as a comparison, they described a small effect size in the improvement of parental self-efficacy (Cohen *d*=0.41) [60], significant improvements in parental frustration [60], and improvements in parent-child relationship [50] among the participants engaging in the mobile intervention.

Discussion

Overview

This study systematically reviewed noncommercial mHealth apps that provide behavioral parent training or components of behavioral parent training for parents of children with behavior problems. This study had the specific goals of summarizing (1) general characteristics, (2) theoretical frameworks and empirical evidence, and (3) parenting strategies. The broad aim for this review was to use the results to inform the development of an app for parents of teens who are involved in substance use behaviors.

Use of Theory

This review found that all studies (11/11, 100%) included in this review used parent training interventions that are theoretically grounded. However, there was a paucity of clear information outlining the theoretical framework for the components designed within the mobile apps. While many of the apps were based on face-to-face parent management training interventions that have well-established theoretical frameworks (eg, Helping the Noncompliant Child, Parent-Child Interaction Therapy, and Parent Management Training), the studies often only referenced the interventions [56,57,59,60] or reported specific parenting skills without specifying the originating intervention [50,54,55]. Determining relevant theoretical frameworks required deductive reasoning based on a knowledge of the named intervention or parenting skill. Using this expertise, we found that many of the apps (6/11, 55%) used social learning theory [67], while only a few (4/11, 36%) [51-53,59] indicated the use of the coercion model [62], either by mentioning this model by name [51,53] or by describing the benefits of the parenting skills that were selected for inclusion in the apps [52,59].

Given that parent training interventions can draw from different theoretical frameworks beyond social learning theory and the coercion model [68] and that the full in-person treatment programs were not transferred to the mobile apps in the reviewed studies, implicit communication of the theoretical framework through only naming the originating intervention or specific skills is not sufficient. It is important to clearly state the relevant theoretical framework for the content transferred to mobile devices because the inclusion of a particular intervention does not guarantee that its principles are embodied in the mobile platform. A deeper analysis of whether specific interventions are consistent with the theory in terms of mobile app features could not be performed due to a lack of information.

Behavior Change

Although behavior change theory is a vital component of mobile interventions [33,34,62,69], the results of this review reveal that most of the studies (9/11, 81%) did not explicitly refer to behavior change theory. The absence of behavior change theory as a framework for app design in many of the reviewed studies (9/11, 81%) may be due to at least 3 reasons. First, many of the studies (8/11, 72%) failed to provide sufficient information about the content and development of the mobile intervention, making it challenging to understand the detailed study characteristics. Second, the studies may have relied on behavior change theories for the originating curriculum due to the well-established programs on which the interventions are based. However, this overlooks the challenges of transferring the interventions to mobile devices. Many parent management training curricula incorporate behavior change theories that consider factors such as personal motivation, social support, and perceived barriers and benefits of behavior change. While similar theories may be used in mHealth interventions, there are additional considerations, such as the need to focus more on technology-specific behavior change theories; for example, the technology acceptance model [70] focuses on how individuals perceive and adopt novel technologies, and it may be a suitable theory to embed in mHealth development. The lack of prior designs centered on the individual's perspective remains a gap. Third, there may have been a general oversight in including a coherent behavior change theory in the intervention's design. Given the impact of behavior change theory on the effectiveness of interventions [33,34,69,71], its inclusion is crucial for the development of effective parent-targeted mobile interventions.

Although behavior change theories were not commonly cited in the reviewed studies, behavior change techniques were used. The most used techniques were providing instruction, prompting practice, and self-monitoring [46]. The findings of this study are consistent with prior reviews showing that self-monitoring was the most frequently used behavior change technique in mobile interventions across different populations [33,35]. In this review, self-monitoring described tracking both the implementation of parental skills and behaviors and the presence of desired behaviors in children. The limitations of the studies in terms of behavior change theory and techniques will be discussed further while summarizing the design elements (refer to the next subsection).

Mobile Intervention Design

In this review, we evaluated the design of mobile interventions used in the included studies based on their content, visual design, and features. While all studies incorporated particular parenting skills (11/11, 100%), comprehensive information regarding the implementation of specific skills was not included in many of the studies (4/11, 36%). When information was provided, there was limited detail on the selection and integration of the skills into the mobile platform. This lack of information made it challenging to critically assess these interventions and consider them in their entirety for use with different populations, such as parents of adolescents recovering from substance use.

The visual design and features of the mobile interventions in the included studies were designed to be personalized. Each mobile intervention had its own way of promoting personalization through visual design and features; for example, users could customize the visual design by selecting icons, fonts, and colors that were personally appealing [53,54,59]. This practice of personalizing the layout and design has also been noted in previous literature reviews [72], suggesting consistent focus across populations and areas of study. The features of these mobile interventions also facilitated individuality, including avatar families [60], tailored messages [56], and the option to choose specific skills to practice based on individual needs [53].

In addition, the use of badges, rewards, logs, and tokens as a feature in the reviewed mobile interventions was a common pattern This feature was also noted in previous reviews as prevalent [72]. The use of rewards aimed at positively reinforcing desired behaviors in both parents and adolescents and encouraged individualization. Positive reinforcement, in which a stimulus increases the frequency of a particular behavior, is a well-established behavior change technique [73]. When implemented within a structured framework, positive reinforcement can be effective in promoting desired behaviors [73].

Treatment Outcomes

The preliminary findings of the reviewed studies indicate potential for positive parent and child outcomes after the use of a behavioral parent training app [50,51,55-60], but further research is necessary to support these findings. Most of the studies that reported on youth and parent outcomes (8/11, 72%) used interventions that were grounded in well-established theoretical frameworks [51,53,55-60], suggesting that theory-driven interventions may play a critical role in outcomes after behavioral parent training delivered through mobile devices.

To optimize the effectiveness of behavioral parenting apps, future studies should incorporate behavior change theories in the design and development process. The limited information available in previous studies on the content and development of parent-targeted interventions within mobile platforms makes it challenging to identify the behavior change theory applied, if any (the exceptions were the studies by Jones et al [31], Jones et al [74], May et al [75], Breitenstein et al [53], Schaeffer et al [58], Jones et al [51], and May et al [50]). Thus, further empirical research is necessary to determine the influence of behavior change theory on the outcomes of behavioral parent training delivered through mHealth apps.

Implications for mHealth Parenting Apps to Address Teen Substance Use

The development of behavioral parent training apps for parents of children with mental health difficulties is still in the preliminary stages, with available apps developed primarily for parents of younger children. However, there is a need for apps for parents of adolescents with conduct problems, including substance use. These apps are crucial because effective parenting strategies are related to decreased levels of substance use [2,3], and engagement in mobile platforms may be helpful for parents with difficulty accessing treatment in the community. Studies have revealed that it is challenging for parents to both access and engage in evidence-based treatments with behavioral parenting strategies in community settings [76,77].

While mHealth platforms provide accessibility, customization is key to fostering engagement. Thankfully, most of the apps (7/11, 63%) in this review of mHealth apps for delivering behavioral parent training included features such as customization and personalization, which are considered good practice [78,79]. However, the reviewed apps lacked integration within the app and between the app and smartphones. This limitation is due to the predominant focus on parents of younger children. However, as parents spend less time with their children, and key parenting strategies broaden to include monitoring and supervision during adolescence [80], the integration of features is likely to become increasingly important for behavioral parent training apps. To address this gap, it is recommended that a more comprehensive integration of app design and mobile phone features occur for apps targeting parents of adolescents; for example, location-based reminders could be used to track a teen's location and send reminders or prompts relevant to their current location to the parent because parents often either rely on youth reports of their location or do not check in on potential location changes. Specifically, if the teen is at a location where they are likely to use substances, the app could send a reminder for the parent to have a preplanned conversation with their teen or to check up on their whereabouts. In addition, geofencing could be used to set up web-based boundaries around specific locations, sending an alert or reminder when the teen enters an *off-limits* location and offering suggestions for which parenting strategies to use to address the infraction. Alternatively, an alert with scripted language that is consistent with effective praise [21] could be sent to the parent if the teen's movements suggest that an off-limits area was avoided so that the parent can engage in providing praise in the moment because offering immediate praise and feedback is key for changing behavior [73]. Notably, Schaeffer et al [58] used similar location-based strategies to encourage the monitoring and supervision of adolescents.

In addition, an app could be designed to use GPS data to generate reports that summarize the adolescent's whereabouts over time. These reports could serve as personalized feedback with recommendations to the parents. This sort of analysis could help parents discern patterns and areas that require the use of certain parenting strategies. Moreover, push notifications could be integrated to remind parents to use a specific parenting strategy at a designated time or in response to a trigger that was defined by the personalized feedback report. Rich integration of features may bring social learning theory and the coercion model to the forefront, resulting in the potential integration of behavior change theories and techniques. If so, this integration could address limitations in most current noncommercial apps.

Limitations and Strengths

It is important to consider the results of this review within the context of a few limitations. First, this review only looked at a specific area of mHealth research: mobile phone–based

interventions that were designed to provide behavioral parenting practices to parents of children with mental health difficulties. Studies on mobile interventions targeting parenting for parents of children with medical issues were not included in this review. Given the overlap in issues related to ineffective parenting between parents of children with behavior problems and parents of children with chronic medical conditions such as asthma and obesity [81], future studies may benefit from reviewing parenting apps designed for both groups for a broader view. Second, this review was based on a new field of research. As such, there was a paucity of studies available for review. As a result, we included studies involving children of different ages, spanning different developmental windows and parenting needs. Notably, 2 (18%) of the 11 studies provided insight into current behavioral parenting apps for parents of teens [57,58]. Third and last, because of the small pool of studies, synthesis of data to obtain overall effect sizes was not possible. Therefore, as the field grows, the effectiveness of parent-targeted mobile interventions for parents of youth with mental health issues should be empirically assessed using statistical analyses to develop a meta-analysis. The garnering of data will provide more robust evidence of the effectiveness of these interventions in a population of youth with mental health difficulties.

Despite these limitations, this review has some strengths that make it valuable for understanding current noncommercial parenting apps for informing the development of similar apps for related problems in childhood and adolescence. By focusing on behavioral parenting apps for parents of children and adolescents with mental health difficulties, this review provides targeted and relevant information for developers who are interested in designing an app using parenting practices that are well established for other behavior problems occurring in youth, including substance use [2-4,7,82]. Finally, the results of this review provide clear information about current practices and patterns so that future research can more closely align the development of apps with design features that may increase treatment engagement [72,83] and, hopefully, buttress outcomes.

Abstract

Background: Limited information exists on the impact of mobile health (mHealth) use by community health workers (CHWs) on improving the use of maternal health services in sub-Saharan Africa (SSA).

Objective: This systematic review addresses 2 objectives: evaluating the impact of mHealth use by CHWs on antenatal care (ANC) use, facility-based births, and postnatal care (PNC) use in SSA; and identifying facilitators and barriers to mHealth use by CHWs in programs designed to increase ANC use, facility-based births, and PNC use in SSA using a sociotechnical system approach.

Methods: We searched for articles in 6 databases (MEDLINE, CINAHL, Web of Science, Embase, Scopus, and Africa Index Medicus) from inception up to September 2022, with additional articles identified from Google Scholar. After article selection, 2 independent reviewers performed title and abstract screening, full-text screening, and data extraction using Covidence software (Veritas Health Innovation Ltd). In addition, we manually screened the references lists of the included articles. Finally, we performed a narrative synthesis of the outcomes.

Results: Among the 2594 records retrieved, 10 (0.39%) studies (n=22, 0.85% articles) met the inclusion criteria and underwent data extraction. The studies were published between 2012 and 2022 in 6 countries. Of the studies reporting on ANC outcomes, 43% (3/7) reported that mHealth use by CHWs increased ANC use. Similarly, of the studies reporting on facility-based births, 89% (8/9) demonstrated an increase due to mHealth use by CHWs. In addition, in the PNC studies, 75% (3/4) showed increased PNC use associated with mHealth use by CHWs. Many of the studies reported on the importance of addressing factors related to the social environment of mHealth-enabled CHWs, including the perception of CHWs by the community, trust, relationships, digital literacy, training, mentorship and supervision, skills, CHW program ownership, and the provision of incentives. Very few studies reported on how program goals and culture influenced mHealth use by CHWs. Providing free equipment, accessories,

and internet connectivity while addressing ongoing challenges with connectivity, power, the ease of using mHealth software, and equipment maintenance support allowed mHealth-enabled CHW programs to thrive.

Conclusions: mHealth use by CHWs was associated with an increase in ANC use, facility-based births, and PNC use in SSA. Identifying and addressing social and technical barriers to the use of mHealth is essential to ensure the success of mHealth programs.

Introduction

Background

Sub-Saharan Africa (SSA) continues to have the highest maternal morbidity and mortality globally [1,2]. The region contributes only 15% of the world's population [3] while accounting for 70% of all maternal deaths [4]. In 2020, SSA had a maternal mortality ratio (MMR) of 545 maternal deaths per 100,000 live births and a 1 in 40 lifetime risk of maternal death [5]. These estimates are significantly higher than in any other region of the world [5].

Between 2000 and 2015, the MMR decreased in many regions, including SSA [6]. Unfortunately, recent trends in the MMR have not been promising; it has either increased or remained the same between 2016 and 2020 [7,8]. There are projections that the MMR may stay the same or increase by 2030 [9]. As such, there is a need for innovative approaches to reduce the MMR.

One way to accelerate the reduction in the MMR is to improve the coverage of maternal health services [7]. This includes improving the use of maternal health services within the continuum of care, that is, ≥4 antenatal care (ANC) contacts, facility-based births attended by skilled attendants, and early postnatal care (PNC) [7]. Providing high-quality care along the maternal health continuum has been shown to reduce maternal mortality [10-14]. However, the use of available services remains a significant challenge in SSA; for example, the use of ANC and PNC among women of reproductive ages between 15 to 24 years in 28 SSA countries was only 55% and 40%, respectively [15]. Studies in SSA showed lower rates of facility-based births, with women in rural areas having lower rates of facility-based births than those in urban areas [16,17]. Using data from the most recent surveys in SSA countries, Wan et al [18] and Straneo et al [19] found that only 7 out of 10 pregnant women give birth in health facilities in the region.

The impact of community health workers (CHWs) on increasing the use of maternal health services has been established [20]. Working collaboratively with communities, health facilities, national ministries of health (MOHs), and international health agencies, CHWs advocate for improved care and reduce cultural and other barriers preventing women from accessing maternal health services [21]. In addition, CHWs provide education, identify and refer women seeking maternal health services to health facilities, and may offer case management for selected health conditions [22]. Therefore, CHWs are an essential component in reducing maternal deaths, increasing the use of maternal health services, and eventually achieving the United Nations' Sustainable Development Goal 3.

To improve the efficiency of the tasks and responsibilities carried out by CHWs and help support improvements in clinical outcomes, mobile health (mHealth) technologies are increasingly being introduced to CHW programs [23]. mHealth is the use of mobile and wireless technologies in health care [24]. In general, evidence has shown that mHealth can improve outcomes in patients with chronic diseases, tuberculosis, and HIV infection [25]. In maternal health, mHealth has been shown to improve the coverage of ANC, facility-based births, and PNC [26,27]. However, previous reviews have not specifically examined the impact of mHealth tools when used by CHWs as the primary implementers. Specifically for CHWs, mHealth has been used to train them, improve their performance and retention, support data collection, support patient adherence to medication, and provide clinical decision support [28-32]. There is no review on mHealth use by CHWs to improve the maternal health continuum of care in SSA.

Objectives

Although some of the results in the aforementioned studies hold promise regarding the use of mHealth by CHWs in general, there is a lack of robust evidence on the impact of mHealth use by CHWs to improve the use of services along the maternal health continuum of care in SSA, especially when compared with CHWs who do not use mHealth. This review aims to provide evidence synthesis on the impact of mHealth use by CHWs in SSA to improve the coverage of maternal health services in comparison with CHWs not using mHealth. In addition, it examines the factors that support or hinder the successful implementation of mHealth for the improved use of maternal health services. These aims are captured in 2 objectives. First, we assessed the impact of mHealth use by CHWs on ANC use, facility-based births, and PNC use in SSA, comparing the outcomes with those achieved by CHWs not using mHealth. Second, we reviewed the facilitators and barriers to mHealth use by CHWs in programs designed to increase ANC use, facility-based births, and PNC use.

Methods

Overview

This systematic review adheres to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist (Multimedia Appendix 1) and guidelines [33]. As this is a mixed methods systematic review, we synthesized and integrated findings from both quantitative and qualitative studies to provide a more comprehensive understanding of the research question. We registered the review with PROSPERO (CRD42022346364), and the protocol was published previously [34].

Eligibility Criteria

The review included studies involving eligible women of reproductive age (15-49 y) using care across the maternal health continuum: pregnant women using ANC at any gestational age, pregnant women accessing intrapartum care at health care facilities, and women accessing PNC up to 42 days after giving birth regardless of the mode of giving birth. We included all studies that reported the use of mHealth by CHWs to improve the use of these 3 services. CHWs were included if they met the definition set by the World Health Organization (WHO): "health workers based in communities...who are either paid or volunteer, who are not professionals, and who have fewer than 2 years training but at least some training" [35]. For intervention studies included in the review, the comparator was CHW programs that were not using mHealth. We included ANC visits, facility-based births, and PNC visits as outcomes. We also collected qualitative data about facilitators and barriers to mHealth use by CHWs as described in the included studies. Further details and review criteria are outlined in the published protocol [34].

Search Strategy and Data Sources

We searched 6 databases (Scopus, MEDLINE, CINAHL, Web of Science, Embase, and Africa Index Medicus) from inception up to September 2022. To develop the concepts for search terms, we combined the following concepts: "women accessing maternal health services (pregnancy OR childbirth OR postnatal care) AND mHealth AND community health workers AND SSA countries." We included all known synonyms and related terms identified from the literature. We adapted the search terms to each database. Due to challenges in reproducibility, we used Google Scholar as part of reference checking [34]. For Google Scholar, we developed search terms mirroring these major concepts and searched the first 1000 results for any new articles that met the inclusion criteria but were not captured by the other databases. The search strategy, including search terms for Google Scholar, is presented in Multimedia Appendix 2. We included randomized controlled trials (RCTs), quasi-experimental studies, nonexperimental quantitative studies, qualitative studies, and mixed methods studies that met the inclusion criteria. We excluded reviews and other summary-type articles, policy documents, commentaries, abstracts and conference proceedings, case reports, and protocols. Manual searches were conducted by reviewing the references lists of systematic reviews and all included articles. The included articles were limited to the SSA region as defined by the World Bank [36]. To reduce language bias, ensure the identification of all relevant studies regardless of publication time, and allow the generalization of findings to SSA, we did not limit the search by language or year of publication.

Data Extraction

JCFK retrieved all studies from the electronic databases. CK and HRZ independently screened the titles and abstracts of the extracted articles, independently assessed full-text articles for inclusion, and conducted manual searches. An audit log was kept throughout the process, including documentation of reasons for exclusion. CK and HRZ performed the data extraction. TvdA resolved all discrepancies. Covidence software (Veritas Health Innovation Ltd) was used for the screening and data extraction [37].

We extracted information on the authors; publication year; study designs; country and geographic scope; the type and scope of work performed by CHWs; and mHealth characteristics, including platforms used, devices used, delivery methods, and the functions of mHealth. We also extracted the study results based on the outcomes as well as the facilitators and barriers to mHealth use.

Risk-of-Bias Assessment, Analysis, and Synthesis

All included studies underwent a risk-of-bias assessment conducted by CK and HRZ using the Mixed Methods Assessment Tool [38]. Regardless of the results of the risk-of-bias assessment, we included all studies in data extraction, analysis, and synthesis. Due to the heterogeneity of the studies, we conducted a narrative synthesis using the 3 steps proposed by Popay et al [39]. Narrative synthesis involves synthesizing data using words and text, rather than statistical methods that are often used for qualitative studies or when meta-analysis is not possible due to heterogeneity in the study designs or outcomes.

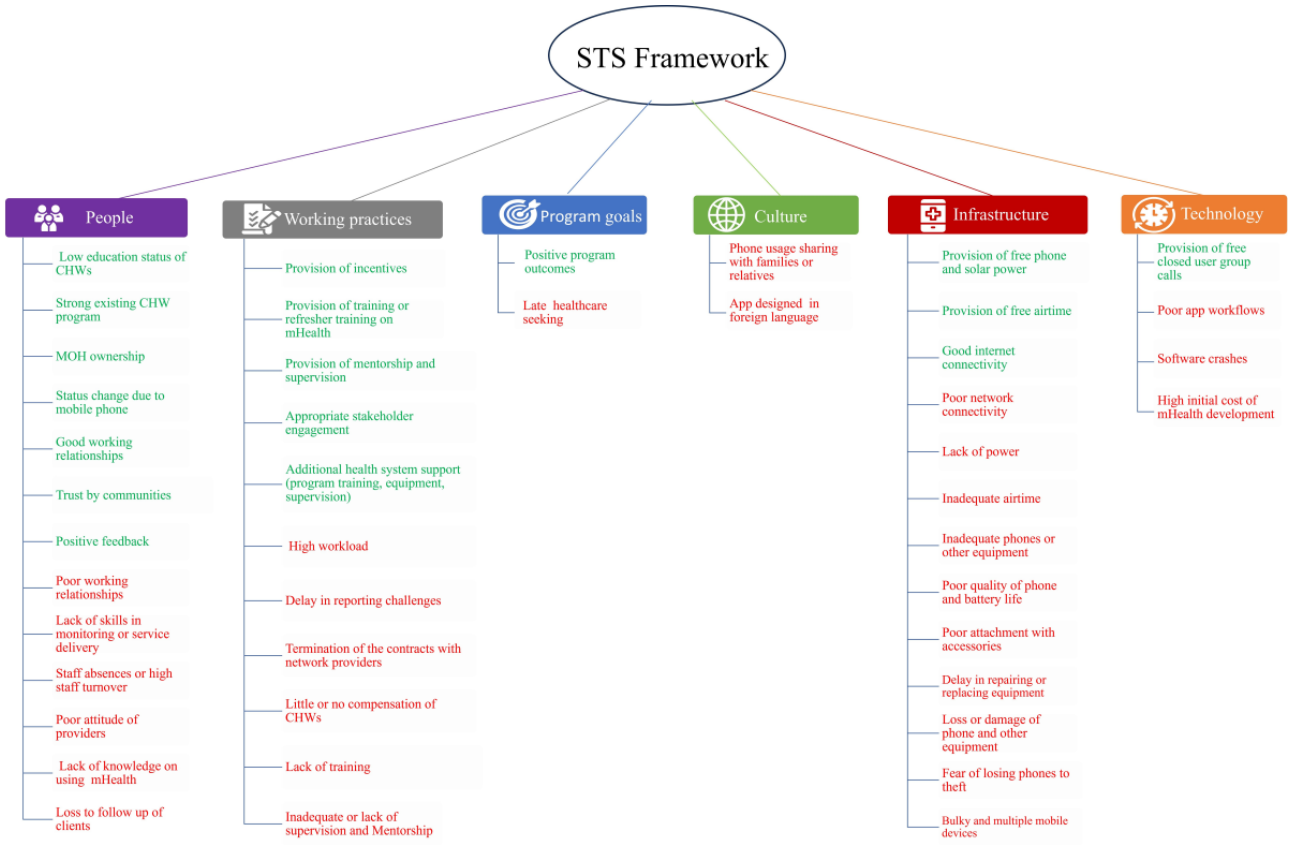
First, a preliminary synthesis based on the review objectives was performed. For the impact of mHealth use by CHWs on the use of maternal health services, we described the direction and size of the impact on ANC attendance, facility-based births, and PNC attendance, with the results tabulated. For facilitators and barriers to mHealth use, we inductively conducted a thematic analysis to identify barriers and facilitators to mHealth use by CHWs [40]. After thematic analysis, we synthesized and reflected on the results using the sociotechnical system (STS) framework developed by Davis et al [41]. The STS framework is not specific to CHWs or mHealth; however, it provides a useful lens for understanding how various dimensions—such as (1) people, (2) working practices, (3) program goals, (4) culture, (5) infrastructure, and (6) technology—influence the implementation and use of new technologies. The first 4 cover the social dimension of mHealth, while the last 2 cover the technology dimension of mHealth [42]. Applying the STS framework allowed a comprehensive and up-to-date analysis of the barriers and facilitators of both the technical and social systems of mHealth, rather than focusing on technology alone as has been done in other digital health studies [43,44]. Further discussion on the dimensions of the STS is presented in the

Results section, while Figure 1 outlines details of the 6 dimensions of the STS framework.

Second, we explored within- and between-study relationships to describe the variability in the results before integrating and synthesizing the findings.

Finally, we assessed the robustness of the synthesis by reflecting on the methodology and the results in the Discussion section.

Figure 1. Facilitators and barriers mapped according to the sociotechnical system (STS) framework. mHealth: mobile health.

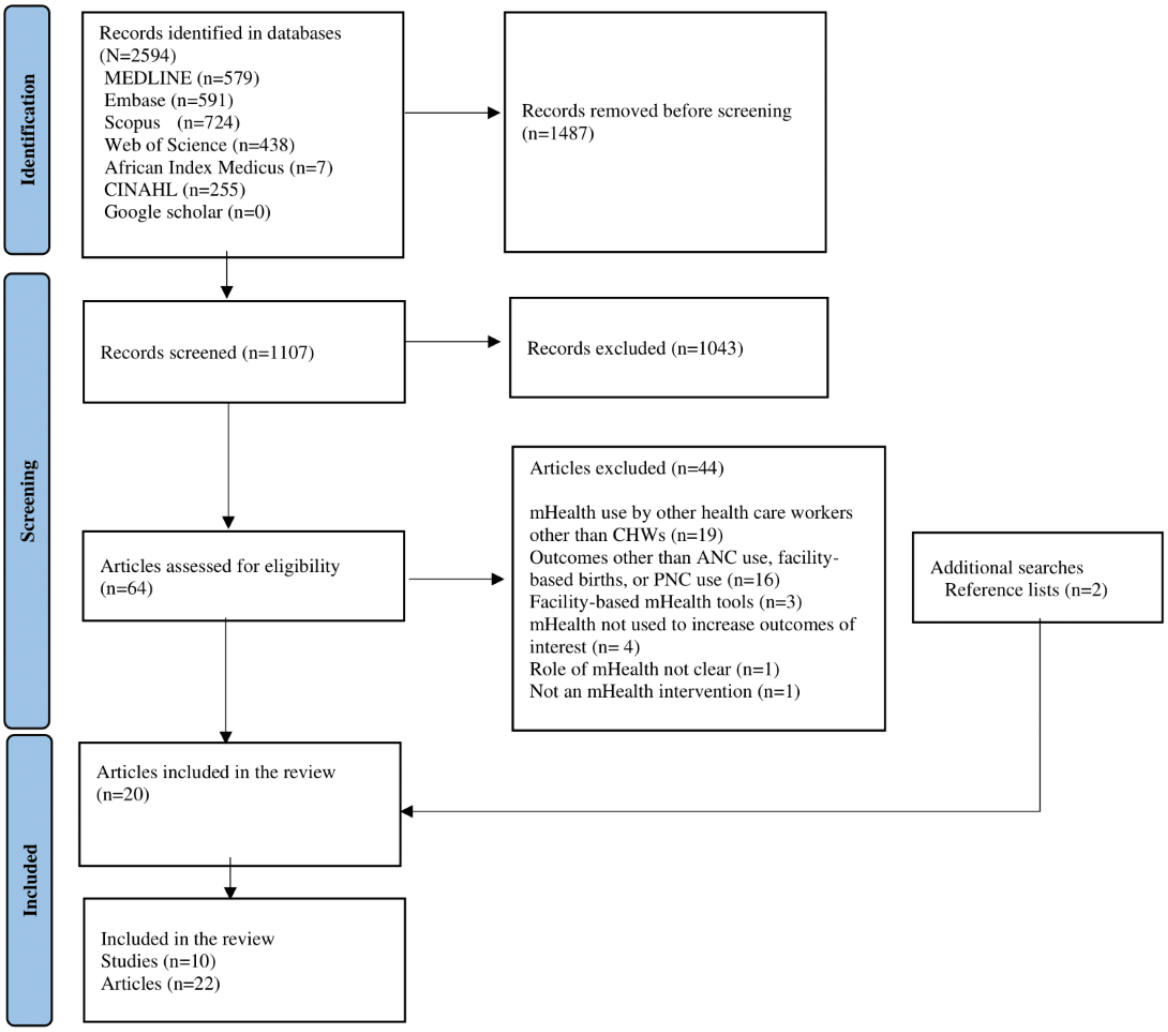


Results

Summary of the Studies

We retrieved 2594 records from all databases (refer to Figure 2 for the PRISMA flow diagram). After removing 1487 (57.32%) duplicates from the 2594 records, 1107 (42.68%) articles underwent title and abstract screening. Of these 1107 articles, 1043 (94.22%) were excluded, leaving 64 (5.78%) articles. After full-text screening, 20 (31%) of the 64 articles were included. We found 2 additional articles from reference searching, resulting in a final number of 10 studies comprising 22 articles. The reasons for exclusion of 44 articles after full-text screening included mHealth use by health care workers other than CHWs (n=19, 43%); outcomes other than ANC use, facility-based births, or PNC use (n=16, 36%); facility-based mHealth tools (n=3, 7%); mHealth not used to improve the outcomes of interest (n=4, 9%); unclear role of mHealth (n=1, 2%); and not an mHealth intervention (n=1, 2%; Multimedia Appendix 3).

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. ANC: antenatal care; CHW: community health worker; mHealth: mobile health; PNC: postnatal care.



Characteristics of the Studies

The 10 studies were published between 2012 and 2022 (refer to the Risk-of-Bias Assessment subsection for the study designs used). Of the 10 studies, 3 (30%) were published in Tanzania [45-47]; 2 (20%) each in Ethiopia [48,49] and Uganda [50,51]; and 1 (10%) each in Rwanda [52], Mozambique [53], and Kenya [54]. The mHealth program for Rwanda was implemented nationally, while the other mHealth programs were implemented either as a pilot or at a subnational level. Half of the mHealth platforms used were mobile apps (5/10, 50%) [45-47,49,53], followed by SMS text messaging–based platforms (4/10, 40%) [48,50,52,54] and voice calls (1/10, 10%) [51].

Risk-of-Bias Assessment

All 22 included articles were assessed for risk of bias using the Mixed Methods Assessment Tool (Multimedia Appendix 4 [55-58]). Of the 4 qualitative articles, 3 (75%) were assessed as low risk of bias [55,56,59], and 1 (25%) had an unclear risk of bias [57]. Of the 4 RCTs, 1 (25%) had an unclear risk of bias [53], while 3 (75%) had a high risk of bias [45,48,51]. Of the 7 quantitative nonrandomized articles, 3 (43%) had a low risk of bias [46,52,60], while 4 (57%) had a high risk of bias [50,58,61,62]. Of the 2 descriptive articles, 1 (50%) had a low risk of bias [47], and 1 (50%) had a high risk of bias [63]. Finally, of the 5 mixed methods articles, 1 (20%) had a low risk of bias [54], while 4 (80%) had a high risk of bias [49,64-66].

Impact of mHealth Use by CHWs on the Use of Maternal Health Services

Overview

The 10 included studies (13/22, 59% articles) reported at least 1 outcome of interest (Table 1). We present the findings based on the outcome of interest.

Table 1. Quantitative studies reporting on the impact of mobile health (mHealth) use by community health workers (CHWs).

Study, year; outcomes of interest	Study design	Country (context)	Intervention description	mHealth description	Main findings
Sevene et al [53], 2020; ANC[a] and facility-based births	Cluster randomized controlled trial	Mozambique (subnational, rural, and urban districts)	• Intervention: CHWs made home visits to pregnant women to provide education, danger signs identification, referrals, birth preparedness, and PNCb; CHWs also measured blood pressure and administered drugs for severe hypertensive disease; other interventions included transport support and health talks at health facilities • Control: there were 6 control clusters where CHWs conducted home visits without using mHealth; no other interventions were provided	• Type: Mobile app (PIERS[c] On the Move) • Use: the app was used for clinical decision support during the CHW home visit; CHWs used the app to identify pregnant women with danger signs (using pictograms), and if danger signs were present, they would refer the client to health facilities; if no danger signs were present, CHWs measured blood pressure, and if women met predefined criteria for referral, they would be referred immediately to an appropriate health facility	• ANC: no difference. In comparison to control clusters, no difference in ≥4 ANC visits (48.6% vs 42.5%, aOR[d] 1.57, 99% CI 0.97-2.52) • Facility-based births: no difference. No differences in facility-based births (67.3% vs 74.2%, aOR 0.80, 99% CI 0.28-2.61; *P*=.71) or births at comprehensive emergency obstetric and neonatal care facilities (11.3% vs 13%, aOR 0.85, 99% CI 0.27-2.62; *P*=.70)
Hackett et al [45], 2018; facility-based births	Cluster randomized controlled trial	Tanzania (pilot and rural district)	• Intervention: in 16 clusters, CHWs were trained in integrated maternal, neonatal, and child health; CHWs also conducted household visits to educate and refer clients to care during pregnancy and the postpartum period; mHealth app was used during the home visits • Control: CHWs trained in integrated maternal, neonatal, and child health but used paper-based tools in 16 control clusters	• Type: mobile app (developed using CommCare, an open-source platform designed specifically for use by frontline health workers) • Use: CHWs used the app to register pregnant women, counsel pregnant women, identify danger signs, flag women who needed referrals, and create reminders for CHWs to follow up with the women they referred	• Facility-based births: increase in use. A majority of pregnant women (74%) gave birth in transit or at the facility in the intervention villages compared with those in the control villages (62%); the odds of facility delivery were 2 times the odds between the intervention and control group (OR[e] 1.96, CI 1.21-3.19; *P*=.01)
Atnafu et al [48], 2017; ANC and facility-based births	Cluster randomized controlled trial	Ethiopia (subnational, rural, and urban districts)	• Intervention: the intervention targeted pregnant women in 2 clusters. Partial: higher cadre CHWs (ie, HEWs[f]) in 1 cluster were provided mHealth, while lower cadre volunteer CHWs were responsible for community mobilization, education, and referrals but were not provided mobile phones. Full: in 1 cluster, HEWs were provided mHealth, and volunteer CHWs were provided regular mobile phones for voice calls • Control: no mHealth use by CHWs; CHWs performed home visits and community mobilization	• Type: SMS text messaging based (FrontlineSMS) and regular mobile phone for voice calls • Use: mHealth was used for SMS text messaging reminders to CHWs to follow up with pregnant women at 14, 24, 30, and 36 weeks of pregnancy to encourage them to attend all ANC visits and give birth at health facilities; in addition, voice calls were used to arrange referrals and communication between HEWs and volunteer CHWs; other functions included data collection and reporting as well as supply chain management	• ANC: increase in the use of ANC. High ANC attendance at baseline at both intervention and control sites; significant increase in ≥4 ANC visits at intervention sites in comparison with control sites (partial intervention: 45.3%-59.8%; *P*<.001; full intervention: 15.8%-31.5%; *P*<.001; control sites: 24.5%-23.3%) • Facility-based births: decrease in home births. Home births decreased at all intervention sites (partial intervention: 61.6%-33.7%; full intervention: 50.7%-35.8%; control sites: 72.8%-58.5%)

Study, year; outcomes of interest	Study design	Country (context)	Intervention description	mHealth description	Main findings
Ayiasi et al [51], 2016; ANC and facility-based births	Cluster randomized controlled trial	Uganda (pilot, 2 rural districts)	• Intervention: existing CHWs (called village health teams) conducted 2 ANC home visits and 1 PNC home visit to provide standardized educational messages for maternal and newborn care in 8 clusters; in addition, each village health team had unlimited calls with health care workers for clinical consultation • Control: village health teams in 8 health clusters provided usual community mobilization	• Type: voice calls • Use: mobile phones were used for clinical consultation between CHWs and providers and to arrange for referrals from the communities to health facilities	• ANC: no significant differences in the rates of ANC visits. A majority of the women (85%) in the intervention clusters made ≥3 ANC visits compared with those in the control clusters (71%); aOR 1.82, 95% CI 0.65-5.09; *P*=.26) • Facility-based births: higher at intervention sites than at control sites. Three times higher (90%) at the intervention sites than at the control sites (28%); the intervention increased the odds of facility-based births by 18-fold (OR 17.94, 95% CI 6.3-51.4; *P*<.001)
Webber et al [46], 2022; Webber et al [64], 2019; ANC, facility-based births, and PNC	Interrupted time series	Tanzania (subnational, rural)	• Intervention: CHWs were trained to educate pregnant women on the importance of ANC, giving birth at facilities, and identifying danger signs using an mHealth app; other interventions implemented included birth kit distribution at 34 to 36 weeks' gestation and transport support • Control: CHWs who were not using mHealth	• Type: mobile app (based on community health toolkit) • Use: the mobile health app supported CHWs in providing education on the importance of attending ANC visits, giving birth at facilities, and identifying danger signs	• Early results for facility-based births: suggested an increase in facility-based births. Rates of facility-based births increased (Bunda town from 87% to 93%, Bunda rural from 70% to 84%, and Tarime from 48% to 67%) between 2015 and 2016 • Final evaluation for ANC: no difference. No difference in ≥4 ANC visits after introducing mHealth (immediate change: OR 1.19, 95% CI 0.93-1.51; *P*=.17; gradual effect: OR 1.02, 95% CI 0.99-1.05; *P*=.24) • Final evaluation for facility-based births: increase in use. There was an increase in facility-based births from 71.8% at baseline to 85.1% after the intervention, with an immediate increase in the odds of facility-based births (OR 1.51, 95% CI 1.14-2.01; *P*=.004) and a small gradual effect (OR 1.03, 95% CI 1.00-1.07; *P*=.06). • Final evaluation for PNC: no difference. No significant immediate change and a decline in the trend of PNC use after introducing mHealth (immediate change: OR 1.07, 95% CI 0.61-1.89; *P*=.81; gradual effect: OR 0.92, 95% CI 0.86-0.98; *P*=.01)
Hategeka et al [52], 2019; ANC, facility-based births, and PNC	Interrupted time series	Rwanda (national program, rural and urban districts)			

Study, year; outcomes of interest	Study design	Country (context)	Intervention description	mHealth description	Main findings
			• Intervention: CHWs with mHealth supported pregnant women with education, follow-up, and linkage to care across the maternal health continuum. The intervention was stratified: Facilities in 20 districts received the usual support. Facilities in 10 districts received health system strengthening by 2 NGOs[g] (including ongoing training for CHWs and equipment provision to health facilities) • Control: CHWs not using mHealth	• Type: SMS text messaging based • Use: the open-source RapidSMS platform was used to facilitate communication between the health system and CHWs, facilitate clinical appointments by using reminders, support clinical decisions by providing information on what CHWs should do during an emergency, and facilitate referrals in emergencies by linking CHWs with the ambulance drivers; other functions of the RapidSMS system included registries or vital events tracking, data collection and reporting, and use an electronic health record system	• Rwanda Demographic and Health Survey (2014-2015) data in 29 of the 30 districts: For ANC, no difference. No change in any ANC visits (immediate change: −1.00, 95% CI −2.30 to 0.29 and gradual effect: −0.04, 95% CI −0.14 to 0.06). No change in ≥4 ANC visits (immediate change: −1.69, 95% CI −9.94 to 6.55 and gradual effect: −0.40, 95% CI −1.09 to 0.27). No change in first trimester ANC visits (immediate change: −3.80, 95% CI −13.66 to 6.05 and gradual effect: −0.62, 95% CI −1.43 to 0.19). For facility-based births, no difference. No change in facility-based births; (immediate change: −1.79, 95% CI −6.16 to 2.58 and gradual effect: −0.13, 95% CI −0.49 to 0.22) • Routine health facility data in all 30 districts: For ANC, no difference. No change in all 30 districts (*P*=.51 and *P*=.70 for supported districts and *P*=.38 and *P*=.50 for nonsupported districts). Facility-based births: a gradual increase in facility-based births. At the supported sites, there was no immediate change in facility-based births, but there was a change in gradual effect (estimate: 0.015 facility-based births per 1000 population, 95% CI 0.007-0.023; *P*<.001); no change in nonsupported sites. For PNC, an immediate increase in PNC visits. Change in supported facilities (immediate increase of 0.11 PNC visits per 1000 population, 95% CI 0.033-0.179; *P*=.007) and no change in trend; no change in the rate of PNC visits in nonsupported districts (*P*=.13)
Asiki et al [50], 2018; facility-based births	Nested cohort study	Uganda (pilot, rural)	• Intervention: in 13 clusters, CHWs registered pregnancies and made monthly visits to pregnant women to relay SMS text messages and track outcomes • Control: in 13 villages, CHWs followed pregnancies monthly using paper-based forms	• Type: SMS text messaging based • Use: mHealth supported CHWs to register pregnancies. In addition, each month, SMS text messaging reminders were sent to CHWs regarding which pregnant women they should visit to relay targeted messages on timely and safe ANC and facility-based births	• Facility-based births: decreases in-home births. Intervention home delivery was 9.2%, and control home delivery was 22.4%; after controlling for confounders, the intervention arm had lower odds of home births (aOR 0.38, 95% CI 0.15-0.97)
Mushamiri et al [54], 2015; ANC		Kenya (subnational, rural)			

Study, year; outcomes of interest	Study design	Country (context)	Intervention description	mHealth description	Main findings
	Mixed methods; the quantitative component used a nonrandomized control group study design		• Intervention: CHWs provided a community-based package of care and followed up with pregnant women using mHealth • Control: CHWs provided a community-based package of care and did not use mHealth	• Type: SMS text messaging–based platform • Use: SMS text messaging reminders were sent to CHWs to remind pregnant women 3 days before the ANC visit once they were registered in the mHealth program; reminders were sent twice if the women failed to attend the ANC visit; reminders were sent up to 18 months after giving birth	• ANC: mHealth increased the use of ANC. In comparison to the women not followed by CHWs using mHealth, the women in the intervention group had 3 times the odds of making more ANC visits, even after adjusting for HIV infection (aOR 2.58, 95% CI 1.10-6.01)
Nigussie et al [49], 2021; ANC, facility-based births, and PNC	Mixed methods	Ethiopia (rural and urban, subnational)	• Intervention: CHWs registered, referred, followed up, and tracked pregnant women along the maternal health continuum of care; CHWs and their supervisors used mHealth to support their tasks	• Type: mobile app • Use: once clients were registered in the app, the system sent notifications and reminders to CHWs via the app to visit pregnant women and remind them to visit a health facility for ANC and PNC; these reminders were also sent through SMS text messaging to CHWs and clients; in addition, the program supported with free caller user group, facilitating referrals from the community to the facility	• ANC: suggests increase in use. Pregnancy registration in the first and second trimesters increased between the third quarter of 2017 and the second quarter of 2018 (eg, first trimester registration increased from approximately 0% to approximately 10%), with a corresponding decline in registration in the third and fourth trimesters • Facility-based births: suggests increase in use. Facility-based births increased from approximately 100 per quarter to >900 in the second quarter of 2018 • PNC: suggests increase in use. PNC visits increased from approximately 100 per quarter to >700 in the second quarter of 2018
Fulcher et al [47], 2021 [65]; facility-based births, and PNC	Descriptive process evaluation	Tanzania (rural and urban, subnational)	• Intervention: CHWs registered and enrolled pregnant women, as well as conducted 3 ANC home visits and 3 PNC visits using mHealth; other supporting interventions included community savings, transport support, and stakeholder engagement	• Type: Mobile app (Mangologic app) • Use: the app helped CHWs to know when to conduct home visits, identify pregnant women with danger signs and refer them to care, follow up with the women within 3 days of referral, and coordinate referrals with health facilities; the app was also used for data collection	• Early findings for facility-based births: suggests increase in use. Among 13,231 births, 75% gave birth at hospitals in comparison with a baseline of 35%. Early findings for PNC: suggests increase in use. PNC attendance at intervention sites was 88% in comparison with a baseline of 36% from the demographic health survey • Final evaluation for facility-based births: suggests increase in use. Health facility births increased from 60%, 70%, 80%, and 80% between years 1 and 4. Final evaluation for PNC: suggests increase in use. The number of women who attended PNC visits increased 60%, 60%, 70%, and 80% in years 1, 2, 3, and 4, respectively

[a]ANC: antenatal care.

[b]PNC: postnatal care.

[c]PIERS: preeclampsia integrated estimate of risk.

[d]aOR: adjusted odds ratio.

[e]OR: odds ratio.

[f]HEW: health extension worker.

[g]NGO: nongovernmental organization.

ANC Outcomes

Of the 10 studies, 7 (70%; 8/22, 36% articles) [46,48,49,51-54,60] reported at least 1 ANC outcome. On the basis of outcomes, only 2 (29%) of the 7 studies reported on ANC visits in the first trimester [49,52]. None of the studies reported on ≥8 ANC contacts. Of the 7 studies, 3 (43%) [48,49,54] showed an association between mHealth use by CHWs and increased ANC use. On the basis of platforms used, the studies that showed an association used SMS text messaging–based platforms (2/7, 29%) [48,54] and a mobile app (1/7, 14%) [49].

The observational study conducted in Ethiopia by Nigussie et al [49], which had a high risk of bias, suggested increased ANC use after mHealth use by CHWs. Using a mobile app, the study showed an increase in ANC contacts in the first trimester by approximately 10%.

A total of 3 RCTs (n=1, 33% with an unclear risk of bias [53]; n=2, 67% with a high risk of bias [48,51]) reported on ANC outcomes. Atnafu et al [48] used an SMS text messaging–based platform to remind CHWs to follow up pregnant women at 14, 24, 30, and 36 weeks of pregnancy in Ethiopia. The study found a significant increase in the proportion of women with ≥4 ANC visits at the intervention sites in comparison with the control sites (cluster with higher cadre CHWs using an SMS text messaging–based platform vs lower cadre CHWs who were not provided mobile phones: 45.3% to 59.8%; *P*<.001; cluster with higher cadre CHWs using an SMS text messaging–based platform vs lower cadre CHWs using mHealth for voice calls: 15.8% to 31.5%, *P*<.001; control sites [no mHealth]: 24.5% to 23.3%). The RCT conducted by Sevene et al [53] in Mozambique involved a clinical decision support mHealth app primarily used to support CHWs to screen for hypertension and make referrals to health facilities for care when they enrolled pregnant women during initial home visits or scheduled community follow-ups of pregnant women. As a secondary outcome, the proportion of women with ≥4 ANC visits was not statistically different between the intervention and control sites. Finally, the study conducted by Ayiasi et al [51] in Uganda, where CHWs used voice calls for consultations with health care workers during home visits, showed no significant difference in the number of women who attended ≥3 ANC visits between the intervention and control sites.

Three quasi-experimental studies (four articles) reported on ANC outcomes. Using an SMS text messaging–based mHealth platform in Kenya, Mushamiri et al [54] reported positive findings when comparing pregnant women receiving appointment reminders from CHWs using mHealth and pregnant women receiving CHW care without mHealth. In the study, women receiving care from CHWs using mHealth and starting ANC in the second trimester had 3 times the odds of attending ANC visits (adjusted odds ratio [OR] 2.58, 95% CI 1.10-6.01) than women receiving care from CHWs not using mHealth [54].

An SMS text messaging–based study (reported by 2 articles, 50% of the four articles that used quasi-experimental study designs) [52,60] used an interrupted time series design to evaluate a nationally implemented RapidSMS platform in Rwanda that enabled 2-way communication between CHWs and health care workers, facilitating clinical appointments of pregnant women by using reminders, supporting the clinical decisions by providing information on what CHWs should do during an emergency, and facilitating referrals during emergencies. After scaling the RapidSMS platform countrywide, 10 districts received health system–strengthening support from 2 nongovernmental organizations (NGOs; ongoing training provided to CHWs and equipment provided to health facilities). By contrast, the rest of the districts received the usual support from the Rwanda MOH. Using Rwanda Demographic and Health Survey (2014-2015) data in 29 of the 30 districts of Rwanda, Hategeka et al [52] found no change in any ANC visits, ANC visits in the first trimester, or ≥4 ANC visits. Using routinely collected health facility data in 461 health facilities, Ruton et al [60] found no change in ANC visits in all 30 districts of Rwanda. Finally, a quasi-experimental study with a time series design by Webber et al [46] used an mHealth app in Tanzania to educate women on the importance of attending maternal health services. The findings showed no significant differences in ≥4 ANC visits after introducing mHealth.

Facility-Based Births

Of the 10 studies, 9 (90%; 12/22, 55% articles) reported on facility-based births. Of these 9 studies, 8 (89%) found an association between mHealth use by CHWs and an increase in facility-based births or a reduction in home births. Of these 8 studies, 3 (38%) [48,49,54] used an SMS text messaging–based platform, 4 (50%) [45-47,49] used a mobile app, and 1 (12%) used voice calls [51].

A process evaluation study with a low risk of bias implemented in Tanzania by Fulcher et al [47], in which CHWs used a mobile app to increase demand for facility services by pregnant women, showed an increase in facility-based births from year 1 to year 4 of implementation (from 60% to 90%). Nigussie et al [49] also found an increase in facility-based births after the implementation of mHealth by CHWs.

In an RCT with a high risk of bias conducted in Tanzania, Hackett et al [45] compared the impact of the mHealth app in intervention clusters where CHWs were using the app and control clusters where CHWs were not using mHealth. The odds of facility-based births in the intervention clusters were double those in the control clusters (OR 1.96, 95% CI 1.21-3.19). The RCTs conducted by Atnafu et al [48] and Ayiasi et al [51] also reported a reduction in home births (home births decreased at all intervention sites [cluster with higher cadre CHWs using an SMS text messaging–based platform vs lower cadre CHWs not provided with mHealth: 61.6% to 33.7%; cluster with higher cadre CHWs using an SMS text messaging–based platform vs

lower cadre CHWs using mHealth for voice calls: 50.7% to 35.8%; control sites: 72.8% to 58.5%]) and an increase in facility-based births (the intervention increased the odds of facility-based births by 18-fold [OR 17.94, 95% CI 6.3-51.4; *P*<.001]), respectively. However, Sevene et al [53] found no change in facility-based births between the intervention and control clusters.

Two quasi-experimental studies in which CHWs used mobile apps found a positive impact of mHealth on improving facility-based birth rates and reducing home birth rates. The study conducted in Tanzania by Webber et al [46], which had a low risk of bias, found that mHealth increased the odds of facility births (immediate increase: OR 1.51, 95% CI 1.14-2.01; *P*=.004; gradual effect: OR 1.03, 95% CI 1.00-1.07; *P*=.06). Asiki et al [50], who conducted a study in Uganda that had a high risk of bias, compared the impact of an SMS text messaging–based platform on CHWs using SMS text messaging reminders to follow up on pregnancy outcomes and CHWs not using mHealth. After controlling for confounders, mHealth reduced the odds of home births (adjusted OR 0.38, 95% CI 0.15-0.97). Two quasi-experimental articles based on the RapidSMS study in Rwanda showed mixed results. Hategeka et al [52] found no change in facility-based births. Ruton et al [60] found no change in the 20 districts that were not supported by the 2 NGOs, while there was a change in the 10 supported districts (gradual effect at the 10 supported sites: 0.015 facility-based births per 1000 population per month, 95% CI 0.007-0.023; *P*<.001), signifying the extra role played by embedding mHealth into broader health system–strengthening initiatives.

PNC Outcomes

Of the 10 studies, 2 (20%) observational studies [47,49] and 2 (20%) quasi-experimental studies reported on the impact of mHealth use by CHWs on PNC visits [46,60]. Of these 4 studies, 3 (75%) showed a positive association (n=2, 67% used a mobile app [47,49], and n=1, 33% used SMS text messaging [60]).

Fulcher et al [47] found that the mHealth app used by CHWs increased any PNC visits from 60% to 80% within 4 years of implementing the program. Nigussie et al [49] also showed an increase in any PNC visits after mHealth use by CHWs. In Rwanda, Ruton et al [60] reported an increase of 100% in PNC visits within a year of starting mHealth in the 10 districts that received extra NGO support (immediate increase of 0.11 PNC visits per 1000 population, 95% CI 0.033-0.179). However, the rate of PNC visits remained the same in the 20 districts not receiving health system strengthening. Finally, the study conducted in Tanzania by Webber et al [46] showed no impact of the mHealth app on PNC visits.

Facilitators and Barriers to mHealth Use

Overview

Of the 10 studies, 8 (80%; 14/22, 64% articles) reported on facilitators and barriers to mHealth uptake (Table 2; Figure 1). We will discuss facilitators and barriers simultaneously and in alignment with the 6 dimensions of the STS framework developed by Davis et al [41]: program goals, people, culture, working practices, infrastructure, and technology. The definitions of the dimensions are provided in each subsection that follows.

Table 2. Studies reporting on the barriers and facilitators to mobile health (mHealth) use by community health worker (CHWs).

Study, year	Article, year	Study design	mHealth description	Study aims and findings
Sevene et al [53], 2020	Boene et al [66], 2021	Mixed methods	Mobile app	• Facilitators: training on mHealth, refresher training, mentorship and supervision, improved status as health care workers through smartphone use, trust of communities, and good working relationships with clients • Barriers: poor battery life, difficulty in securely attaching accessories, lack of power to charge mobile phones, and poor network connectivity
Atnafu et al [48], 2017	Atnafu [61], 2015; Atnafu and Bisrat [62], 2015	Cross-sectional	SMS text messaging based	• Facilitators: good working relations with supervisors, as well as availability of free mobile phone and free airtime • Barriers: poor network connectivity, lack of power to charge mobile phones, an inadequate number of mobile phones or other equipment, loss or damage of mobile phone and other equipment, and inadequate airtime
Ayiasi et al [51], 2016	Ayiasi et al [55], 2015	Qualitative	Voice calls	• Facilitators: smartphones improved their status as health care workers, trust of communities, good working relations with supervisors, and positive supervisor feedback • Barriers: staff absences, lack of power to charge mobile phones, poor network connectivity, poor attitude of health care workers, and poor relationships with clients
Webber et al [46], 2022	Webber et al [64], 2019; Webber et al [57], 2020	Mixed methods; qualitative	Mobile app	• Facilitators: free mobile phone, airtime, and solar chargers • Barriers: poor network connectivity, lack of power to charge mobile phones, inadequate airtime, poor app navigation. and poor app workflows
Hategeka et al [52], 2019	Ngabo et al [63], 2012; Musabyimana et al [56], 2018; Mwendwa [59], 2016; Mwendwa [58], 2018	Descriptive, qualitative; qualitative; cross-sectional	SMS text messaging based	• Facilitators: MOHa ownership, incentives, strong existing CHW program, additional health system–strengthening activities, appropriate stakeholder engagement, high education level of CHWs, training, positive feedback, positive program outcomes, trust of communities, good working relations with supervisors, and good network connectivity • Barriers: high initial cost of development, illiteracy, poor network connectivity, lack of power to charge mobile phones, inadequate airtime, high workload due to both paper- and smartphone-based data entry, poor organization of training, app in a foreign language, inadequate supervision, an inadequate number of mobile phones or other equipment, poor relationships with clients, loss or damage of mobile phone and other equipment, and no stipend or salary for CHWs
Nigussie et al [49], 2021	Nigussie et al [49], 2021	Mixed methods	Mobile app	• Facilitators: appropriate stakeholder engagement and MOH ownership, as well as additional health system–strengthening activities • Barriers: high workload due to both paper- and smartphone-based data entry, mobile phone–sharing culture, a fear of losing mobile phones to theft, delay in reporting the challenges of mHealth, a lack of skills in monitoring service delivery, loss or damage of mobile phone and other equipment, poor network connectivity, inadequate airtime, delay in repairing or replacing equipment, and burden of carrying multiple mobile devices

Study, year	Article, year	Study design	mHealth description	Study aims and findings
Fulcher et al [47], 2021	Fulcher et al [47], 2021	Descriptive process evaluation	Mobile app	• Barriers: poor network connectivity, high loss to follow-up of clients, high attrition of CHWs, and software crashes
Mushamiri et al [54], 2015	Mushamiri et al [54], 2015	Mixed methods	SMS text messaging based	• Facilitator: free closed user group calls and good network connectivity • Barriers: contract termination with a network provider and late health-seeking behavior

[a]MOH: Ministry of Health.

People

The STS identifies this dimension as encompassing the users and stakeholders of a system and their characteristics. The included articles explored facilitators and barriers affecting CHWs, who are the main stakeholders, as well as their surrounding environment (eg, communities and supervisors), and their characteristics (eg, attitudes, behavior, and skills).

An unintended benefit yet powerful facilitator of mHealth use was the effect of the mHealth devices on the status of CHWs. mHealth improved the social status of CHWs because they were perceived as being recognized by the formal health system [55,66]. Perceived higher social status improved community trust, another facilitator identified in multiple studies [55,59,66]. Other facilitators identified included higher education level of CHWs [58,59], strong existing CHW program [63], MOH ownership of CHW programs [49,63], and positive feedback from supervisors [55,58,59].

The social dynamics within and outside the CHW program also positively or negatively impacted mHealth use. Good working relationships and positive feedback between CHWs, their supervisors, health care workers, and communities facilitated mHealth use [55,59,62,66]. By contrast, poor relationships among CHWs and communities and health care workers were singled out as barriers to mHealth use [49,55,56]. Other barriers identified in the studies included a lack of skills in monitoring service delivery by CHW supervisors [49], high staff absences and turnover [47,55], CHW illiteracy [59], poor attitude by facility-based staff [55], and high loss to follow-up of clients [47].

Working Practices

Processes refer to how practices and procedures are organized to support the system's uptake. The included articles described the influence of systems, practices, and procedures designed to support CHWs in effectively using mHealth. Additional existing health system–strengthening activities facilitated positive outcomes in some mHealth-enabled CHW programs [49]; for example, additional training, provision of extra equipment and supplies, and supervision in Rwanda's RapidSMS program facilitated mHealth use by CHWs [60]. In addition, engaging multiple and appropriate stakeholders, including telecommunication companies, facilitated the use of mHealth [49,63]. In a study in Kenya, suspending a contract with a mobile communication provider for a few weeks was one of the most significant barriers to SMS text messaging–based mHealth rollout [54].

Several other processes were reported in the studies. Adequate training and refresher training on mHealth [58,66], strong mentorship and supervision of CHWs [66], and enhancing the education levels of CHWs facilitated mHealth use [59]. By contrast, a high CHW workload [49], poor reporting systems [49,59], a lack of training or poor training organization [59], and inadequate supervision [59] were reported as barriers to mHealth use. The provision of incentives or salaries to CHWs was also mentioned, with regular incentives or salaries as a facilitator [63] and a lack of incentives or salaries or low incentives or salaries as a barrier to mHealth use [56].

Program Goals

This dimension explores how program performance and outcomes influence the uptake of a system. Very few studies reported on the impact of program goals on mHealth uptake by CHWs, and only 1 facilitator and 1 barrier were identified. Positive program outcomes (eg, he role played by CHWs in reducing mortality rates) in the RapidSMS program in Rwanda reinforced the use of mHealth [56,58,59]. The study conducted in Kenya reported late presentation to ANC as a barrier [54]. This factor had a detrimental impact on the mHealth-driven goals of ANC visits within the scope of this study.

Culture

In the STS framework, this dimension examines the influence of users' and stakeholders' beliefs, norms, and values within a system. Among the included studies, there was a lack of literature addressing how culture affected the use of mHealth. None of the studies reported on cultural factors that might facilitate mHealth adoption. The studies conducted in Ethiopia [49,62] identified the sharing of an mHealth-enabled mobile phone with other family members, a common norm, as a barrier to mHealth use because the mobile phone was often unavailable to CHWs when needed. In the study by Atnafu and Bisrat [62], more than a third of the CHWs reported sharing the mobile phone with other family members. In addition, the studies based on the RapidSMS platform in Rwanda cited the use of a foreign language (ie, English) in the app as a cultural barrier [58,59].

Infrastructure

This dimension encompasses the assets of a system. Among the included studies, mHealth equipment and internet connectivity were frequently noted as influential factors in the uptake of mHealth. Free mobile phones [57,62] as well as free airtime or reimbursement of airtime costs [57,62] were facilitators of mHealth use. The provision of solar power for charging devices was also reported as a facilitator [57]. Finally, reliable internet

connectivity was mentioned as a facilitator of mHealth use [54,63].

Most of the studies focused on barriers associated with mHealth devices and related equipment. The most commonly reported challenges included loss or damage of mobile phones and other equipment [49,62,63], delays in repairing or replacing equipment [49], the burden of carrying multiple mobile devices [49], a fear of losing mobile phones to theft [49], an inadequate number of mobile phones or other equipment [56,62], poor quality of mobile phones and battery life [66], and difficulty in securely attaching mobile phone accessories [66]. In many settings, especially rural settings, the lack of electricity was commonly reported as a barrier [55,57,59,61-64,66]. Finally, poor mobile network connectivity [47,49,55,57,59,61,62,64,66] and inadequate airtime [49,59,61,64] were also mentioned as barriers to mHealth use.

Technology

This dimension focuses on how mHealth software influences the uptake of mHealth use. Free closed user group calls facilitated the use of a voice-based mHealth platform; no other facilitators were identified [54]. However, several technology-related barriers were reported, including poor app workflows [57,64] and frequent app software crashes [47]. The study by Ngabo et al [63] reported the high cost of mHealth technology as a barrier.

Discussion

Principal Findings

This review is the first to synthesize evidence on the use of mHealth by CHWs to improve the use of maternal health services in SSA. While the results of most of the studies (8/9, 89%) supported that mHealth use by CHWs increase facility-based births, they are mixed for ANC and PNC use. For ANC and PNC, only approximately half (3/7, 43%) and three quarters of the studies (3/4, 75%) showed that mHealth use by CHWs increased the use of these services, respectively. On the basis of the intervention descriptions, mHealth use by CHWs may have increased use by creating demand for these services. As shown previously, the demand created by mHealth use is possible through multiple pathways. mHealth use by CHWs may have increased the knowledge of good maternal health practices, leading to behavior change toward health facility use for care [47]. This is particularly important for studies that use mHealth apps. In addition, primarily through SMS text messaging–based platforms, reminders may have encouraged pregnant women's attendance at health services [67]. It is also possible that mHealth may have increased demand by increasing satisfaction and trust in CHWs and the health system and may also have improved adherence to the practices used by CHWs to increase demand for health services [68].

This review adds evidence on the impact of mHealth use on the use of maternal health services. Previous reviews have focused on the impact of mHealth use on maternal health outcomes but did not distinguish the primary users of mHealth. A previous systematic review conducted by Gayesa et al [26] in low- and lower–middle-income countries found that mHealth use increased the odds of facility-based births and PNC use [26]. Similarly, Wagnew et al [69] reported that SMS text messaging–based mHealth increased the use of ≥4 ANC visits as well as facility-based births in low- and middle-income countries. Rahman et al [70] and Sondaal et al [27] also report positive effects of mHealth use on ANC coverage and facility-based births in low- and middle-income countries. However, our study is unique because it presents the effect of mHealth use specifically by CHWs, a target group not explored in the other studies. In addition, this is the first review to focus on SSA specifically.

We found mixed results on the impact of mHealth use by CHWs on ANC visits. Of the 7 studies that reported on ANC attendance, 3 (43%) showed that mHealth use by CHWs may increase ANC use. While the SMS text messaging–based mHealth studies in Kenya and Ethiopia [48,54] and the mobile app study in Ethiopia [49] found increases in the overall number of ANC visits or ≥4 ANC visits, all other studies (4/7, 57%) found no effect. We also observed that many studies reported ≥4 ANC visits as an outcome. Reporting on ≥4 ANC visits may be attributed to the previous WHO recommendation, according to which 4 ANC visits were deemed adequate [71,72]. Only 2 (29%) of the 7 studies reported on ANC visits in the first trimester, and none of the studies reported on ≥8 ANC contacts as recommended by recent WHO guidelines [73]. As observed in many settings, especially in SSA, women start ANC attendance late [74,75], which may affect the number of ANC visits; therefore, we suggest designing mHealth programs to specifically focus on encouraging early ANC attendance (Textbox 1). Designing mHealth to support women to start ANC attendance earlier may have 2 advantages. First, mHealth may help identify pregnancies early through decision support and referrals to health facilities. Second, mHealth may support the provision of high-quality, community-based ANC by CHWs [76]. This approach would ensure that mHealth supports the recommended ANC contacts as well as the quality and outcomes of these community contacts.

Textbox 1. A summary of recommendations for mobile health (mHealth) implementation in sub-Saharan Africa (SSA).

Maternal health continuum of care outcomes

- Antenatal care (ANC): design mHealth programs measuring the impact of mHealth on ANC attendance in the first trimester and ≥8 ANC contacts.
- Postnatal care: design more studies to measure the impact of mHealth on postnatal care.

Coverage of mHealth

- National scale-up of mHealth programs is required in settings where mHealth has been shown to work but is being implemented as a pilot or at the subnational level.
- Where national scale-up of mHealth is desired, consider adding health system–strengthening activities in addition to mHealth intervention.
- Scale up mHealth platforms that have been shown to work in other settings and countries in SSA.

Choice of mHealth platform

- Consider SMS text messaging–based platforms and mobile apps.

Sociotechnical system dimension requiring further data

- Design studies to measure the influence of culture and program goals on mHealth use.

We found very few studies (4/10, 40%) reporting on PNC outcomes compared with the studies reporting on ANC (7/10, 70%) and facility-based birth (9/10, 90%) outcomes. Of the 4 studies, 1 (25%) SMS text messaging–based study [60] and 2 (50%) mobile app studies [47,49] found increases in PNC visits after implementing mHealth programs. We suggest more studies designed to specifically show the effect of mHealth on PNC visits because providing care during the postnatal period reduces maternal and neonatal deaths as well as complications [7] (Textbox 1).

The findings from this review also have implications for the scale-up of mHealth programs and mHealth platforms of choice in SSA. Of the 10 included studies, only 1 (10%), which was conducted in Rwanda, was implemented nationally [52], while the rest (n=9, 90%) were implemented as pilots or at the subnational level. In addition, the majority of the studies (9/10, 90%) used either SMS text messaging or an mHealth app. As the results of this review show the benefits of mHealth use by CHWs on maternal health outcomes, we suggest a national scale-up in pilot or subnational programs; alternatively, new programs may consider the scale-up of mHealth from the beginning. As a choice of platform, this review has shown that SMS text messaging–based platforms or mHealth apps may be used as the platforms of choice (Textbox 1).

This review has also identified facilitators and barriers to mHealth use by CHWs across the 6 dimensions of the STS framework. Most of the studies reported facilitators and barriers with regard to people, working practices, infrastructure, and technology among the 6 dimensions. One of the common findings concerned the perceived improvement in CHWs' status when they started using mHealth, as well as improved trust. This finding is echoed across other studies in the literature [77,78] and may be an essential reason for introducing mHealth in limited-resource settings. A recent review on the use of mHealth by CHWs, specifically smart devices, also found that mHealth improves CHW status [79]. As echoed by Perry et al [31], improving the status of CHWs and increasing their recognition by the formal health system is a crucial enabler for successful CHW programs, and mHealth may provide the pathway to achieve this. In addition, paying attention to the social environment of CHWs, including relationships, plays a vital role in the success of mHealth programs [80].

The findings from the processes, infrastructure, and technology dimensions reinforce the importance of strengthening CHW programs and health service infrastructure before the introduction of mHealth or as part of its implementation. Critical components such as MOH ownership and stakeholder engagement, as well as standardized and robust systems such as training and the provision of incentives or salaries to CHWs need to be considered to ensure the success of mHealth in many settings. Other studies in the literature have also emphasized the need to build systems and appropriate governance to address barriers related to mHealth equipment and evolving mHealth technologies [81,82]. Therefore, we recommend that the design and implementation of mHealth programs in SSA should include health system–strengthening activities to maximize the impact of mHealth tools (Textbox 1).

We need further studies across the culture and goals dimensions of the STS framework. First, very few of the included studies reported on the influence of culture on mHealth use by CHWs in SSA. Incorporating various aspects of culture, such as the local language, into mHealth improves its acceptability, usability, and effectiveness [83,84]. Unfortunately, even in the literature, there are limited studies reporting on the impact of culture on mHealth use [84,85], and the results were similar in this review [58,59,62]. More studies should be designed to explore the impact of culture on mHealth use. Second, further research is needed on the impact of clearly defined goals as enablers and barriers to mHealth (Textbox 1).

Limitations

This review has some limitations that should be considered when interpreting the findings. First, it focused on mHealth interventions by CHWs for women of reproductive age using ANC, giving birth at health facilities, and using PNC within 42 days in SSA. While this limits generalizability to other

populations, settings, and maternal health outcomes, it allowed for a targeted examination of mHealth impact on key services across the continuum of care in a region with high maternal mortality.

Second, the review included studies that implemented mHealth alongside other health system–strengthening activities, making it difficult to isolate the effect of mHealth alone. However, this reflects the real-world implementation of mHealth as a tool to enhance CHW service delivery within broader health systems, rather than as a stand-alone solution.

Third, the review may have missed some relevant studies by excluding gray literature. In addition, not assessing publication bias could mean that the included studies are skewed toward positive findings. However, a comprehensive search of 6 databases and reference checking was conducted, and all studies meeting inclusion criteria from these sources were included.

Finally, studies were excluded if they lacked sufficient information on the mHealth intervention, which could introduce selection bias. However, this was necessary to ensure that the review could meaningfully synthesize and interpret how mHealth was used to impact outcomes.

Recommendations

This study has implications for program implementation, policy, and research. Although our recommendations focus on mHealth implementation in SSA, we hope some lessons can be applied to other settings. We present a summary of recommendations in Textbox 1.

Conclusions

The study found evidence that mHealth use by CHWs results in an increase in facility-based births. Although the results are mixed, approximately half of the studies (3/7, 43%) that reported on ANC and 75% (3/4) of studies that reported PNC attendance showed that mHealth use by CHWs increased the use of these services. We found limited studies (2/7, 29%) measuring the impact of mHealth on increasing ANC visits in the first trimester and no study reported on ≥8 ANC visits. On the basis of the STS framework, most of the studies explored barriers and facilitators across the people, processes and procedures, building and infrastructure, and technology dimensions. More studies are needed on the culture and goals dimensions of the STS to better understand the impact and uptake of mHealth for improving maternal health outcomes.

Authors' Contributions

CK, THD, TvdA, and IOOA were responsible for conceptualization and study design. CK, HRZ, JCFK, IOOA, and AVK were responsible for data collection. CK wrote the first draft. CK, THD, JCFK, AVK, JSM, DP, IOOA, and TvdA were responsible for the critical review and final approval of the manuscript.

Conflicts of Interest

DP also works for Brigham and Women's Hospital and Harvard Medical School and has done short-term contract work with Vanna Health, the World Health Organization, PIVOT, and Last Mile Health. All other authors declare no conflicts of interest.

Abstract

Background: Wearable sensors are increasingly being explored in health care, including in cancer care, for their potential in continuously monitoring patients. Despite their growing adoption, significant challenges remain in the quality and consistency of data collected from wearable sensors. Moreover, preprocessing pipelines to clean, transform, normalize, and standardize raw data have not yet been fully optimized.

Objective: This study aims to conduct a scoping review of preprocessing techniques used on raw wearable sensor data in cancer care, specifically focusing on methods implemented to ensure their readiness for artificial intelligence and machine learning (AI/ML) applications. We sought to understand the current landscape of approaches for handling issues, such as noise, missing values, normalization or standardization, and transformation, as well as techniques for extracting meaningful features from raw sensor outputs and converting them into usable formats for subsequent AI/ML analysis.

Methods: We systematically searched IEEE Xplore, PubMed, Embase, and Scopus to identify potentially relevant studies for this review. The eligibility criteria included (1) mobile health and wearable sensor studies in cancer, (2) written and published in English, (3) published between January 2018 and December 2023, (4) full text available rather than abstracts, and (5) original studies published in peer-reviewed journals or conferences.

Results: The initial search yielded 2147 articles, of which 20 (0.93%) met the inclusion criteria. Three major categories of preprocessing techniques were identified: data transformation (used in 12/20, 60% of selected studies), data normalization and standardization (used in 8/20, 40% of the selected studies), and data cleaning (used in 8/20, 40% of the selected studies). Transformation methods aimed to convert raw data into more informative formats for analysis, such as by segmenting sensor streams or extracting statistical features. Normalization and standardization techniques usually normalize the range of features to improve comparability and model convergence. Cleaning methods focused on enhancing data reliability by handling artifacts like missing values, outliers, and inconsistencies.

Conclusions: While wearable sensors are gaining traction in cancer care, realizing their full potential hinges on the ability to reliably translate raw outputs into high-quality data suitable for AI/ML applications. This review found that researchers are using various preprocessing techniques to address this challenge, but there remains a lack of standardized best practices. Our findings suggest a pressing need to develop and adopt uniform data quality and preprocessing workflows of wearable sensor data that can support the breadth of cancer research and varied patient populations. Given the diverse preprocessing techniques identified in the literature, there is an urgency for a framework that can guide researchers and clinicians in preparing wearable sensor data for AI/ML applications. For the scoping review as well as our research, we propose a general framework for preprocessing wearable sensor data, designed to be adaptable across different disease settings, moving beyond cancer care.

Introduction

Background

According to the US Food and Drug Administration, digital health is categorized as *mobile health* (mHealth), health information technology, wearable devices, telehealth, personalized medicine, and telemedicine [1]. Digital health has revolutionized health care by offering the potential for continuous and noninvasive monitoring of human physiological parameters, such as heart rate, sleep, and activity levels, to facilitate the early detection and prevention of life-threatening diseases [2]. Digital health consists of collecting, analyzing, storing, and sharing health care data by harnessing the power of technology, including smartphone apps, wearable sensors, telemedicine, the Internet of Medical Things, etc [3]. Due to the widespread use of mHealth technologies and routine use of wearable sensors (eg, smartwatches), the person-generated health data have become promising data sources for biomedical research [4].

Indeed, the integration of wearable sensors into cancer care has opened new pathways for remote monitoring, enabling health care providers to gather a wealth of real-time data from patients [5-7]. These wearables capture an array of physiological parameters, including skin temperature [8], offering insights into the patient's response to cancer treatment, quality of life, and overall well-being [9]. These continuous streams of data have the potential to transform cancer care by providing an improved understanding of patient conditions outside of the hospital setting, potentially improving clinical outcomes. Nevertheless, transforming raw data into meaningful analysis and insights presents numerous challenges, making standardized workflows for data preprocessing essential.

Data preprocessing involves a series of steps designed to clean and refine data to ensure its reliability and suitability for analysis using artificial intelligence and machine learning (AI/ML) techniques. The preprocessing steps help transform raw sensor data, which can be noisy and inconsistent, into a clean, structured format suitable for AI/ML models to process [10-12]. Without standardization in these procedures, there is a risk that subsequent data analysis might be based on flawed information, leading to uninterpretable data, a lack of generalizability, and erroneous conclusions. Typical preprocessing steps to make sensor data AI/ML ready include data cleaning (eg, noise reduction, outlier detection, and handling missing data) [13,14], data integration (eg, combining data sources and aligning time stamps), data transformation (eg, windowing and normalization) [15], dimensionality reduction (eg, feature selection), and data labeling (eg, annotating).

AI/ML's scope has become an amazing supportive tool for digital health [16,17] since its potential evolution to exploit meaningful relationships in biomedical data sets that can be used for diagnosis, prediction, and treatments [18-21]. AI/ML techniques have become popular in biometrics extraction mobile apps smart systems, such as eye disease detection [22-24], atrial fibrillation [25], heart rate monitoring [26], etc. In addition, a summary of the actual cancer statistics and its future directions is provided in the study by Moher et al [27].

Within the integration of electronic health record technology [26] in digital medicine, wearable monitoring devices have earned an important and crucial role for all people in the biomedical area (eg, patients, medical staff, and biomedical researchers). Oncology divisions have ultimately contemplated the importance of incorporating mHealth monitoring while conducting clinical cancer trials [1]. Moreover, multiple types of cancer disease detection using AI/ML techniques are a crucial factor considering its alarming impact rates on the population [27]. The mHealth integration on cancer applications for the development of AI/ML solutions has become popular in recent years [28]. However, the importance of data quality has not been highlighted while considering the design and development of prediction models. Building high-quality data is a critical step while applying AI/ML algorithms in mHealth and wearable studies; however, the emphasis on enriching the data quality is very limited in these studies, especially in oncology. Misclassifications, misdiagnoses, and wrong predictions can be avoided, and the whole mHealth system feasibility can be improved by enriching the data quality.

Goals of Our Review

This study aims to explore the use of wearable sensors for continuous monitoring of key physiological parameters in cancer care. We systematically reviewed the literature by identifying and assessing preprocessing workflows that are essential for transforming raw, noisy, and often inconsistent wearable sensor data into reliable and structured formats suitable for subsequent AI/ML modeling. By examining the current landscape of these practices, our research aims to improve wearable sensor data quality, specifically for cancer care, ensuring that downstream

data analyses and interpretations are rigorous and reproducible. Given the diverse preprocessing techniques identified in the literature, there is an urgency for a framework that can guide researchers and clinicians in preparing wearable sensor data for AI/ML applications. This paper proposes a framework designed to be adaptable across different continuous monitoring applications.

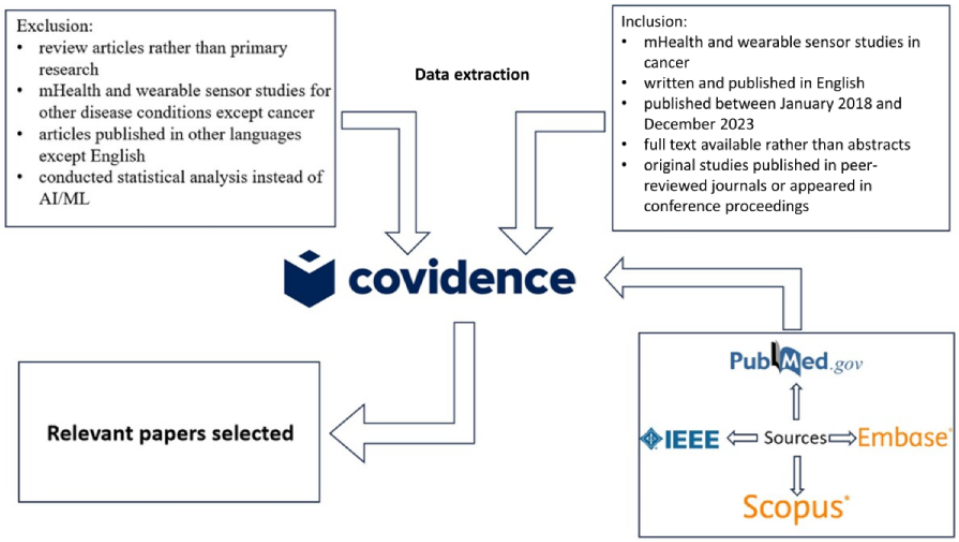
Methods

Search Strategy

We conducted a scoping review of articles written in English using the following literature databases: IEEE Xplore, PubMed, Embase, and Scopus, while following the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) guidelines [29]. We have used Covidence (Veritas Health Innovation Ltd) [30] for identification and screening stages. The search was performed on December 31, 2023, using the search queries shown in Multimedia Appendix 1. We selected full peer-reviewed publications from the last 5 years (from January 2018 to December 2023), focusing on preprocessing techniques used on wearable sensor data to ensure their readiness for AI/ML applications for different cancer populations. Searches were developed using 3 key concepts: wearable devices, AI/ML, and cancer. Controlled vocabulary and keywords were selected for the specific databases.

Figure 1 shows an illustration of the study selection process for this paper. The identified studies meeting the inclusion criteria were subsequently organized based on the major themes identified.

Figure 1. Illustration of the study selection process. AI/ML: artificial intelligence and machine learning; mHealth: mobile health.



Inclusion Criteria

Our results with the search query presented in Multimedia Appendix 1 were first imported into Covidence for screening. The title and abstracts of the resulting studies were screened to identify the studies related to preprocessing techniques for wearable sensor data in cancer. After identifying the eligible studies, additional inclusion exclusion criteria were applied to retrieve the primary studies of our review (Figure 2 in the *Results* section). Studies were eligible if they fulfilled the following inclusion criteria in our review: (1) mHealth and wearable sensor studies in cancer, (2) written and published in English, (3) published between January 2018 and December 2023, (4) full text available rather than abstracts, and (5) original studies published in peer-reviewed journals or appeared in conference proceedings. PRISMA-ScR checklist is provided in Multimedia Appendix 2.

Exclusion Criteria

Studies were not eligible if they fulfilled the following exclusion criteria in our review: (1) review articles rather than primary research, (2) mHealth and wearable sensor studies for other disease conditions except cancer, (3) articles published in other languages except English, and (4) conducted statistical analysis instead of AI/ML.

Data Extraction and Evaluation

The data were extracted from all studies meeting our inclusion criteria for the review and organized into tables containing each study's information (eg, authors' name, title, and year of publication), wearable sensor data collected in cancer studies (eg, activity data, physiological parameters, including steps, sleep, heart rate, blood oxygen saturation, and temperature), preprocessing techniques (eg, time segmentation, data filtering, data transformation, and imputation), wearable devices (eg, Fitbit [Google LLC], Empatica [Empatica Inc, and Actigraphy), type of AI/ML methods applied (eg, neural networks, decision trees, K-Nearest Neighbors, Supporting Vector Machine, and regressors), sample size (eg, number of participants; Table 1). The data for all selected studies were extracted independently by 3 authors (BLO, VG, and SWC) by mutual agreement, and discrepancies were resolved by discussion with other coauthors (RK, AJ, XC, and CZ). The outcomes from the data extraction part were finally evaluated independently by each author.

Table 1. Summary of eligible studies.

Reference	Cancer type	Sample size, N	Wearable sensor	Physiological parameter	Preprocessing procedure	Preprocessing category	AI/ML[a] techniques
Liu et al [30], 2023	Terminal cancer	40	Garmin VivoSmart 4	Steps, HR[b], sleep status, and blood oxygen saturation (measured during sleep time)	Missing data imputation	Data cleaning	LR[c], SVM[d], DT[e], RF[f], KNN[g], AdaBoost[h], and XGBoost[i]

Results

Overview

We identified 2147 studies in the initial extraction phase (n=248, 11.55% from PubMed; n=428, 19.93% from Scopus; n=996, 46.39% from IEEE Xplore; and n=475, 22.12% for Embase, including Embase, Embase Classic, MEDLINE, and PubMed-not-MEDLINE). A total of 173 (8.06%) duplicate articles were removed to produce 1974 (91.94%) for title and abstract screening. We conducted a thorough screening of titles and abstracts, which resulted in the exclusion of 1820 (92.2%) articles that did not meet the inclusion criteria. Following this

screening, we identified 154 (7.8%) articles for which we performed a full-text review to assess their eligibility for inclusion in our study in more detail. In the final screening, 20 (13%) of these 154 articles met our inclusion criteria and were considered for this scoping review, as shown in Figure 2. The workflow diagram for the systematic identification of scientific literature is shown in Figure 2. The geographical distribution of these studies is mapped in Figure 3, highlighting most research from the United States. These constituted 35% (7/20) of the selected publications. Terminal cancer research was reported from Taiwan.

In terms of publication years, our analysis revealed an uptick in the frequency of papers related to mHealth and wearables in cancer. Our review coincides with the emergence of the COVID-19 pandemic, during which there was a surge in research interest within the biomedical sciences, particularly related to the use of wearable technology in remote monitoring of patients with cancer. The distribution of publications during this period suggested that in the years 2020 to 2022 combined, approximately one-quarter of the selected studies were published, accounting for 25% (5/20) of our data set. The majority were distributed between the years 2021 to 2023, which collectively contributed to 75% (15/20) of the data quality improvement strategies for wearable data preprocessing in cancer care settings. In fact, 40% (8/20) of all selected studies were published in 2023 alone, marking a substantial rise and interest in this research domain.

Our findings reported the use of wearable technology across a diverse range of cancer types. Predominantly, the category encompassing “multiple types of cancer” accounted for 40% (8/20) of the studies in this area. The remainder of the research was distributed among specific types of cancer, with each category’s contribution detailed as follows: breast cancer (3/20, 15%), terminal cancer (3/20, 15%), pancreatic cancer (2/20, 10%), blood cancer (1/20, 5%), colorectal cancer (1/20, 5%), prostate cancer (1/20, 5%), and gynecologic cancer (1/20, 5%). In addition, the recent literature indicated a trend toward increased adoption of wearable technology for cancer surveillance, signifying a growing recognition of the potential benefits that wearables may offer in continuous patient monitoring across heterogeneous cancer types.

The initial database search yielded 2147 studies, of which 20 (0.93%) met the inclusion criteria after screening and full-text review (Figure 2). The included studies applied preprocessing techniques to wearable sensor data from a range of cancer populations, including breast, colorectal, gynecologic, and blood cancers, as well as multiple other types of cancer. The most commonly used wearable devices were actigraphy sensors and consumer-grade fitness trackers, which provided data on physical activity, sleep, heart rate, and other physiological parameters.

Various preprocessing approaches are used in each of the identified themes. The most common data transformation approaches included fast Fourier transform [31], time-series segmentation [33,34,39], and statistical feature calculation [30,35,45]. However, for the data normalization techniques, *z* score standardization and min-max normalization were the most frequently reported scaling methods [32,37,43,46,49] and for the data cleaning, imputation [30,37,40], outlier removal [36,46], and artifact filtering [32,41] approaches were used. Notably, 25% (5/20) of the studies combined multiple preprocessing techniques from different categories, suggesting that a comprehensive approach to data preparation may be beneficial [32,36,38,45,46]. However, there was significant heterogeneity in the specific techniques used and their implementations across studies, highlighting a lack of standardized preprocessing pipelines for wearable sensor data in cancer care.

The preprocessing techniques were applied to support a range of AI/ML applications, including treatment response prediction [35,42], symptom monitoring [44,47], and survival analysis [33,34]. The most common ML algorithms were random forests, support vector machines, and deep learning models, such as long short-term memory networks. However, few studies directly compared the impact of different preprocessing approaches on model performance, making it difficult to draw conclusions about optimal techniques.

Figure 2. PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) diagram for a scoping review of biomedical scientific literature. ML: machine learning.

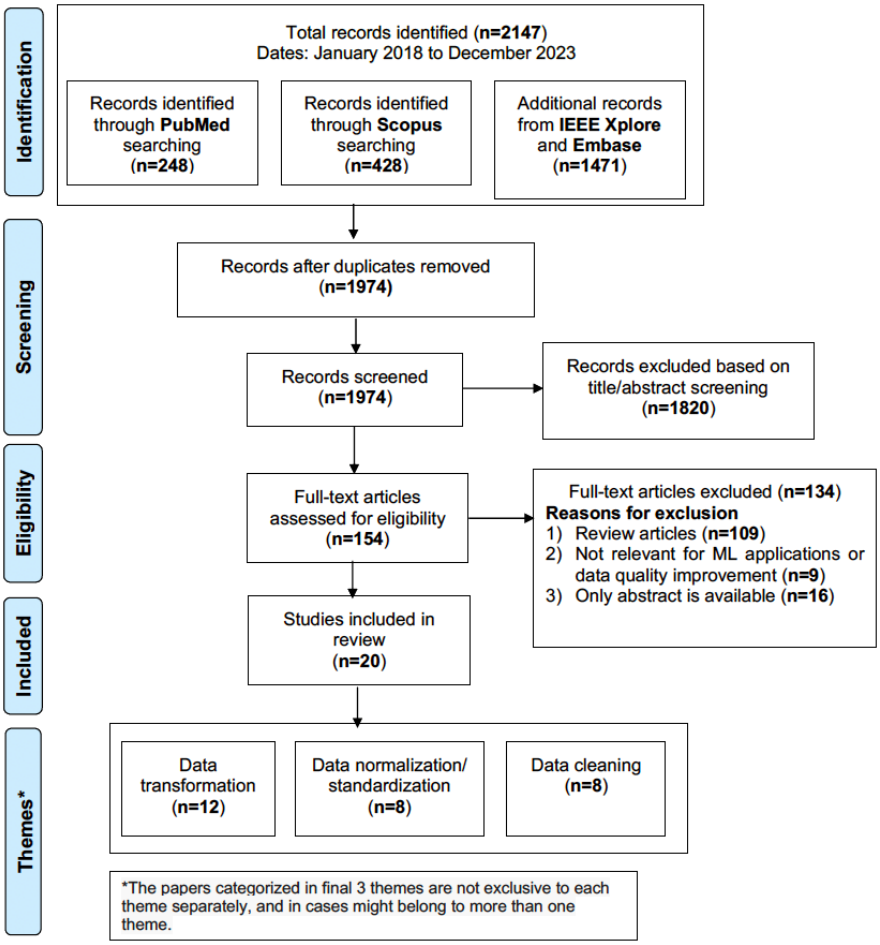

Figure 3. Relevant references by geographical location.

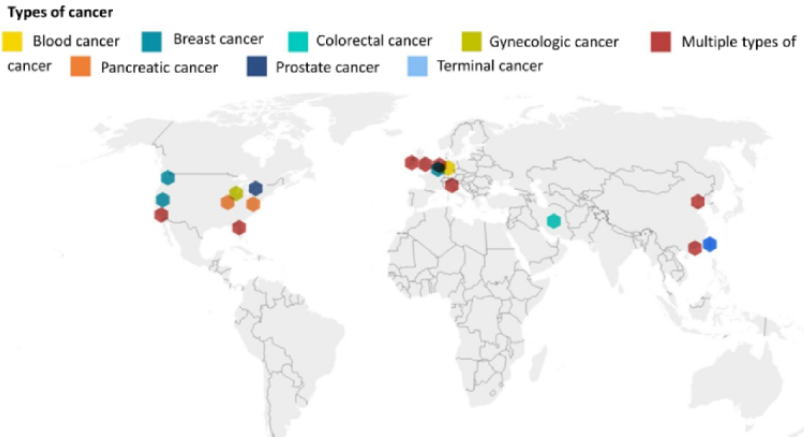


Major Themes Identified

Three major themes were identified, as outlined in Table 1: (1) data normalization and standardization (8/20, 40% of papers), (2) data transformation (12/20, 60% of papers), and (3) data cleaning (8/20, 40% of papers). These were subcategorized based on the preprocessing techniques. Data transformation comprises studies related to dimensionality reduction, data feature calculation, variable transformation, or domain transformation. Data normalization and standardization included data standardization or data normalization. The data cleaning category included data filtering, outliers' removal, imputation techniques, missing data, and duplicate removal. Multiple selected work categories were required to combine preprocessing tasks encompassing the previous 3 mentioned categories while addressing data quality issues [30-49], which are presented in Tables 1 and 2.

Table 2. A summary of relevant preprocessing elements on selected published works.

Reference	Time resolution	Exclusion criteria	Missing data imputation technique	Features extracted	Outcomes
Liu et al [30], 2023	Each day was a data point	Days with no wearable device data uploaded	Linear interpolation	A combination of basic demographic data, clinical assessment data, and wearable device data	Death event prediction
Zhao et al [31], 2022	Data were sent at a rate of 4 times per s	Determine whether an exercise is completed correctly or incorrectly	Not applicable	Statistical gyroscopic-based features obtained from all 3 axes (x, y, and z)	Rehabilitation
Moscato et al [32], 2022	A 2-min time window before the beginning of each session was created	Feature pairing was tested by Pearson correlation coefficient >0.9	Linear interpolation	12 features from the HRV[a] analysis, 5 features from the photoplethysmography morphological analysis, 17 features from the electrodermal activity, 3 features from the temperature, and 2 features from the activity index	Pain assessment
Yang et al [33], 2021	An average value of 20 timesteps within total time shortened to <500 timesteps	Time series >500 timesteps	Zero paddings until the maximum length of the time series was reached	Physical activity, angle, and spin	Survival prediction
Huang et al [34], 2023	A mean of 20 timesteps was chosen as the average value for 3 time frames (12, 24, and 48 h)	Properly designed patients' admission criteria	Zero padding was used to reach the maximum length of the time series	Physical activity, angle, and spin and the clinical data from patients were also considered	Survival prediction
Cos et al [35], 2021	Biobehavioral rhythmic features were computed for the entire tested period, and statistical and semantic features were generated daily	Biobehavioral rhythmic features were excluded due to the dimensions	Data-level and feature-level	First- and second-order statistical features from the daily step count, HR[b], and sleep time–series data	Pancreatectomy treatment outcomes from patients activity
Davoudi et al [36], 2021	Extracted relevant features from a 16-s window; data were eventually smoothed with a 30-s running average window	Data length <4 min	Not applicable	Time and frequency domain features	Physical activity recognition and energy expenditure estimation
Liu et al [37], 2020	Disaggregating the 15-min step count data and simulating the 1-min step count time series	Nonwear days were identified and removed before the analysis	Thresholding	Statistics from HR metrics and activity levels	Algorithm validation
Tedesco et al [38], 2021	Not provided	Wear time per day was <600 min	Feature mean	Statistical features from (1) demographics, (2) self-report health and lifestyle, (3) wearable data, and (4) laboratory tests	Cancer- specific mortality prediction
Dong et al [39], 2021	1-min epoch to aggregate and synchronize the raw actigraphy data	9.5 h window size for accelerometer data to fit models	Not applicable	Time and frequency domain features from actigraphy and laboratory tests	Salivary cortisol levels on in patients with pancreatic cancer
Patel et al [40], 2023	Numerical continuous variables involving sleep-wake times were entered in the 24 h format	Data were excluded from the 1-h period before and after going to bed	Average values	Sleep-based features and sleep-wake transitional-related features	Exploratory machine learning study
Asghari [41], 2021	Not provided	Data inconsistencies removal	Not applicable	Demographics, clinical features, and wearable data	Diagnostic prediction on CRC[c] older adults

Reference	Time resolution	Exclusion criteria	Missing data imputation technique	Features extracted	Outcomes
Rossi et al [42], 2021	Three distinct types of temporal segments for weekly observations	Periods before admission	Majority class	Activity or steps related features and clinical data	Postsurgery complications
Vets et al [43], 2023	Acceleration data's sampling rate was 30 Hz	Unknown data were discarded from further analysis	Spline interpolation	Statistical parameters from accelerometer readings	Rehabilitation study
Feng et al [44], 2023	A window of 48 h following step count decline	A decline of 1000 steps or more as a binary predictor among participants	Thresholding	Step counts calculated on different time windows	Physical activity monitoring on active treatment
van den Eijnden et al [45], 2023	The data were stored at 1-s intervals	Early stopping algorithm	Not applicable	For health dot sensor: RR[d], activity level (actlevel); for Elan wristband: statistical parameters from HR, and frequency domain features	Recovery scores
S et al [46], 2020	Temperature profiles had values from 16 sensors gathered for 1 d at every 5-min interval	Out-of-range temperature data discrimination	Not applicable	Linear and nonlinear features from the time-series temperature data	Introductory paper
Barber et al [47], 2022	Each day was considered an observation	Discrimination of days was applied to unscheduled contacts	Not applicable	Fatigue, physical function, anxiety, mean daily HR, daily steps, sleep, and time-related features	Feasibility and events prediction
Jacobsen et al [48], 2023	Raw signals were acquired with a frequency of >30 Hz; calculated parameters were stored with a rate of 1 Hz	Data points reduction due to interruptions	Not applicable	Noninvasive monitoring of vital signs and physical activity; SCC[e] events	Clinical complications during treatment
Li et al [49], 2023	Sampling frequency was 200 Hz for IMU[f]; the HR was stored at a sampling frequency was 1 Hz	Feature selection for redundancy removal	Majority class	HR metrics, physical activity parameters, Blood Mass Index, and blood oxygen statistical values	Physical fitness assessment

[a]HRV: heart rate variability.

[b]HR: heart rate.

[c]CRC: colorectal cancer.

[d]RR: respiratory rate.

[e]SCC: serious clinical complications.

[f]IMU: inertial measurement unit.

Data Transformation

Zhao et al [31] reported a proof-of-concept for postoperative rehabilitation in a small cohort of 4 patients with breast cancer, using a prototype that used peak detection and Fourier transform by switching time domain points of the 3D axis to a predetermined frequency. Yang et al [33] hypothesized that wristband actigraphy monitoring devices could predict in-hospital death of end-stage multiple types of patients with cancer during the hospitalization period admissions. To avoid variations in each patient's data length, zero padding was used until the maximum length of the time series was reached [33]. Scoring systems, such as the Palliative Prognostic Index and Palliative Performance Scale, were considered for fitting machine learning models (MLMs) [33]. Huang et al [34] reported a comparison study between the results of wearable-based activity monitoring with traditional prognostic tools for patients with end-stage cancer. In total 3 different time frames were segmented for preprocessing [34]. A mean of 20 timesteps was selected as the average value for each of the 3 different time frames (48, 24, and 12 h) [34]. Zero padding was used in the study by Huang et al [34], making it applicable to data transformation. Cos et al [35] used a wearable device to predict treatment outcomes in patients with pancreatic cancer, standardizing data before using ML methods.

Dong et al [39] proposed a general predictive modeling process that used actigraphy data to predict underlying salivary cortisol levels using graph representation learning. The raw sensor data were preprocessed using time window segmentation to reduce noise in the data [39]. Rossi et al [42] focused on predicting postdischarge oncologic surgical complications and their impact

on patient outcomes. There were 3 distinct types of temporal segments for each patient. They considered observations up to the second week after discharge, treating each week as a distinct observation [42].

Feng et al [44] evaluated the feasibility of daily step count monitoring and the association between step counts and treatment-emergent symptoms in patients with prostate cancer. As shown in Table 1, the preprocessing technique could be summarized as follows: (1) a decline of 1000 steps or more as a binary predictor and (2) time window segmentation [44]. Jacobsen et al [48] impacted medical literature by proposing self-supervised contrastive learning methods for hematological malignancy treatments. Noninvasive monitoring of vital signs and physical activity was recorded within serious clinical complications in the input data set [48]. Data downsampling was the selected preprocessing technique to eliminate physical interruptions [48]. These studies collectively illustrated diverse data transform methods, such as feature selection, time segmentation, domain transformation, and time windowing, to enhance wearable device data quality, making them more suitable for AI/ML modeling aimed at predicting patient outcomes in cancer care. In addition, these findings have leveraged a range of wearable technologies and AI/ML methods to advance cancer care. Techniques, such as peak detection and Fourier transform have been used for data preprocessing, supporting applications that include postoperative rehabilitation, physical activity classification, prediction of treatment outcomes, and assessment of cancer-specific mortality. These studies highlight the potential of integrating high-dimensional wearable data with clinical information to enhance patient monitoring and prognosis.

Data Normalization and Standardization

Barber et al [47] assessed the feasibility of postoperative intervention for patients with gynecologic cancer in a manner similar to Zhao et al [31], incorporating patient-reported outcomes and wearable activity data and also opting for standardization and normalization of preprocessing methods. Finally, Li et al [49] proposed a method using multimodel decision fusion based on multisource data for physical fitness assessment for patients with cancer. They enriched the raw data by using Baseline, Synthetic Minority Over-sampling Technique, random oversampling, adaptive synthetic oversampling, and Mahalanobis Distance and Boundary Constraints. The interval scaling method and *z* score standardization after segmentation are the common methods in the study by Li et al [49]. These additional investigations used tailored data preprocessing approaches to further refine the quality of wearable device data for subsequent analysis (eg, data partitioning for training and testing).

Moscato et al [32] proposed an automatic pain assessment for patients with cancer (21 in total) by using the Empatica wristband. Because all physiological signals were recorded at different sampling rates, different-order Butterworth filtering with different cutoff frequencies was the data enrichment selected method [32]. Each pulse was normalized with the *z* score procedure and processed with an automated algorithm that detects pulses suitable for heart rate variability analysis and derived metrics [32]. Liu et al [37] aimed to develop an unsupervised personalized sleep-wake identification algorithm using multistage data to explore the benefits of incorporating heart rate metrics and actigraphy data in these types of algorithms for the general population. After nonwear exclusion, there were 14 participants whose data qualified for analysis; 5 (36%) had high cholesterol, 6 (43%) participants had hypertension, 3 (21%) had cancer, 2 (14%) had diabetes mellitus, and 1 (7%) have had a stroke. They preprocessed the step count data, and 2 schematic ML-based models were designed by following the Markov model's fundamentals. To facilitate the fusion of step count and heart rate data in the models, downscaling was used to deal with the multigranularity data [37]. In addition, imputation techniques were implemented. Tedesco et al [38] explored the prediction of cancer-specific mortality over a 2- to 7-year period using a data set from a longitudinal study of 2291 70-year-old Swedish patients, integrating wearable and electronic health record data. They applied standardization and normalization preprocessing techniques within imputation.

Vets et al [43] aimed to determine the accuracy of a pretrained laboratory-based MLM to distinguish functional from nonfunctional arm motions through home interventions of survivors from breast cancer populations. From the accelerometer data, functional activity was defined using two separate methods: (1) the counts threshold method, and (2) a pretrained MLM [43]. Activity counts were calculated from the raw acceleration data [43]. The outcome "total minutes active" was calculated as the sum of the 1-second epochs where the count threshold exceeded 1 [43]. Data normalization was the final step before fitting AI/ML models. van den Eijnden et al [45] created a model that predicted continuous recovery scores (regressors) in perioperative care in the hospital and at home for objective oncology-based decision-making. They preprocessed data by obtaining a balanced split in which they equally divided the demographic predictors and surgery type into 2 groups by splitting the patients 10,000 times [45]. Finally, authors standardized features by scaling the data to a normal distribution with a mean of 0 and a unit variance [45]. S et al [46] introduced a noninvasive wearable device developed as an adjunct to current modalities to assist in the detection of breast tissue abnormalities in any type of breast tissue. In the study, data normalization and outliers' removal were the data transformation methods to enrich the quality of the collected temperature data.

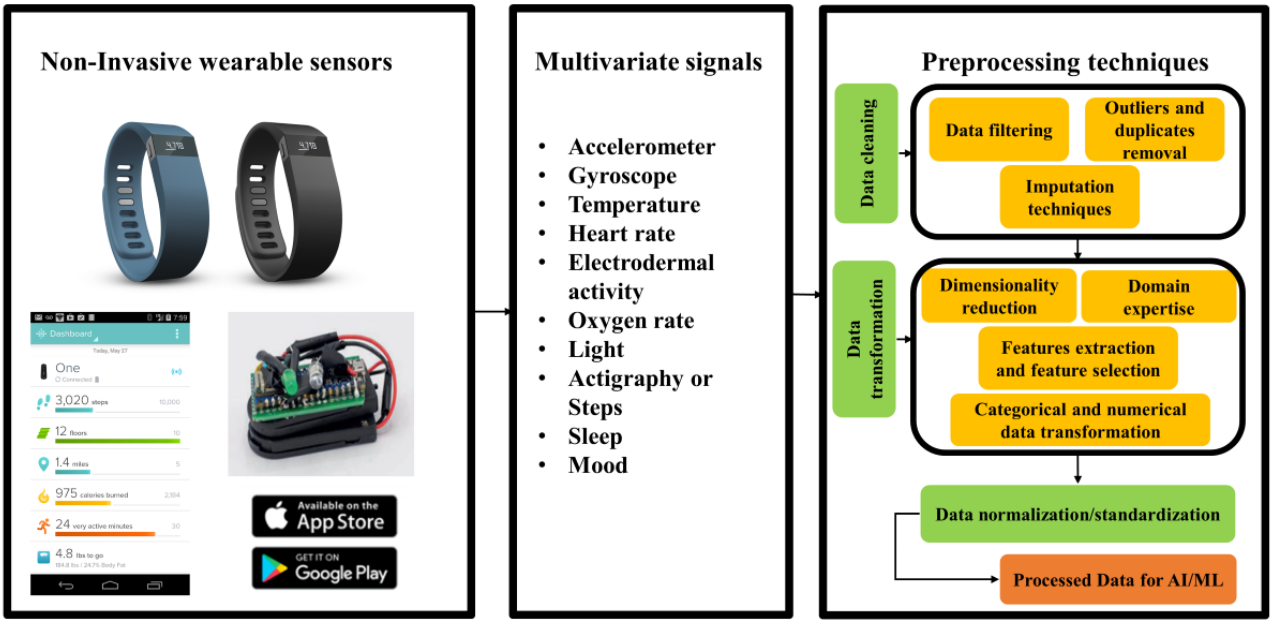
Data Cleaning

Liu et al [30] aimed to investigate the potential of using wearable devices and AI/ML to predict death events among patients with terminal cancer. To improve the model training, the authors used imputation techniques [30]. The data set was a combination of demographic, clinical, and wearable device data [30]. Davoudi et al [36] conducted a study comparing various accelerometer placements in classifying physical activity and associated energy expenditure among older adults. Of the 93 participants who completed the study, 27 (29%) were identified with a range of cancer diagnoses. Raw data were cleaned using bias reduction and eventually transformed by activity location and vector magnitude calculation [36]. Similarly, Patel et al

[40] sought to enhance prognostic tools by combining ML analysis of actigraphy, sleep data, and routine clinical data with a missing data imputation technique within averaging. Asghari [41] proposed an internet of things–based predicting model to predict colorectal cancer in older adults. The data preprocessing phase was required to clean the sensed medical internet of things data from the inconsistencies and the noises for the data mining phase [41]. Outliers' removal was the initial step selected for preprocessing.

Accordingly, we proposed a generalized preprocessing framework that comprises all 3 major data preprocessing themes (Figure 4), reflecting the core elements that were consistently reported across studies.

Figure 4. A general framework for data preprocessing techniques used to make noninvasive data collected from mobile health and wearable sensor artificial intelligence and machine learning (AI/ML) ready in cancer monitoring applications.



Discussion

Principal Findings

In this paper, we conducted a scoping review of the preprocessing techniques applied to wearable sensor data in cancer care. Our findings revealed a significant rise in the use of wearable sensors for patient monitoring, along with an increase in preprocessing methods for data analysis over the past 5 years. This likely stemmed from recent advancements in sensor technology, greater emphasis on personalized and remote patient care, the rising prevalence of big data analytics in health care, and increasing recognition of real-time health data for precision oncology.

Data transformation emerged as the most reported preprocessing technique, representing approximately 60% (12/20) of the literature findings. Most studies relied on data from commercially available products, except a study by Zhao et al [31], which assessed a prototype's efficiency in a small cohort. While published studies describing preprocessing methods for wearable devices are growing, the diagnoses being studied remain sparse and generally limited to single disease types or settings.

The physiological data captured from wearables are typically noisy, contain missing values, have outliers, redundant features, and erroneous measurements [50,51]. On the basis of the literature review in this paper, we found that various data cleaning procedures are used to clean the wearable sensor data, including data smoothing techniques (ie, moving average and exponential moving average) to reduce short-term signal artifacts and remove noise, removing duplicate entries, detection and removal of erroneous measurements due to sensor malfunctioning or losing contact of the sensor with skin or wearing the watch on incorrect body location, and outlier removal. The outlier removal for wearable data [52] in the reviewed studies consists of the range inspection of physiological parameter values with the clinically relevant range or developing a threshold using statistical techniques to detect outliers. Finally, missing data imputation is a critical component of data cleaning due to their ability to handle complex missing patterns as demonstrated in wearable-based data [53-57].

Our review suggests that the data cleaning procedures should be carefully inspected and applied based on the data captured from the wearables, as the captured data will produce false conclusions and predictions without proper data cleaning procedures, which is not acceptable in clinical research. In addition, the outliers' removal should be based on data behavior and domain knowledge, as a region of anomaly is often within the boundaries of normal patterns of physiological data; for example, for the heart rate data, the normal behavior might evolve, which can be considered anomalous behavior, and the removal of data points leads to the loss of critical data. A

generalized, automated, and adaptive data cleaning procedure is required for the wearable data to address the issues that arise due to improper data cleaning.

Time-series segmentation is the most used data transformation technique in wearable research identified in the review, necessitated by the multivariate nature of the data and varying sampling rates. Segmentation can be based on study outcomes, such as daily, hourly, or minute-by-minute intervals. Our review indicates that the optimal time window size for segmentation must be determined through experimentation to achieve the best performance results. This window size varies across different cancer cohorts and should be tailored to the specific data set rather than relying solely on literature. The granularity of time segmentation also affects feature extraction. For instance, summary statistics like mean, median, SD, and minimum, and maximum differ when calculated for daily versus hourly or minute-by-minute windows. The reviewed literature [58-60] also explores additional feature types, including frequency domain features and linear and nonlinear features.

Data compliance is another major challenge in wearable studies and has a profound impact on the study outcomes. Physiological data captured from wearables are highly variable [61] and have high noncompliance rates by the participants. The participants' compliance determines the validity of the data collected from the wearables and their utility. Different thresholds are established for various parameters, such as daily wear time or step counts to filter or preprocess the data [62-64]. This scoping review suggests that we should strive to develop algorithms for standardizing the physiological metrics collected, which includes establishing thresholds for data inclusion based on compliance, filtering data based on adequate wearable wear time in study participants undergoing cancer per day and per week, percentage of days on which wearable was worn by the participants, inclusion and exclusion of data due to participant wearable synchronization issues, etc. ML techniques can be exploited to automate the data compliance assessments for different data extracted in different types of cancer.

Finally, data normalization is critical to developing AI/ML-ready data for the wearable studies. The data scaling helps not only in building efficient and accurate MLMs but also removes the effect of different scales and ranges in the model prediction. Our review suggests that researchers should identify the appropriate normalization technique for their study and understand the data distribution and model results before and after applying these techniques.

In summary, this scoping review identified 3 main categories of preprocessing techniques: data transformation, data normalization and standardization, and data cleaning, that have been applied to wearable sensor data in cancer care. While these techniques are commonly used to prepare data for AI/ML analysis, there is a lack of standardization in their implementation and limited evidence of their comparative effectiveness. Moreover, wearable sensor data are highly unstructured, complex, and messy because it is generated continuously and with high frequency (thousands of observations per second), leading to rich streams of time-series data. Thus, there is an urgent need to develop novel preprocessing procedures and frameworks, enhancing data quality and data readiness for AI/ML applications in cancer research. Future work should focus on developing validated preprocessing pipelines and benchmarking their impact on AI/ML model performance across diverse cancer populations and wearable devices. By providing a generalizable framework, we aim to accelerate the development of AI/ML models in not only cancer care but also potentially other areas of health care that leverage wearable sensor data. Researchers and clinicians can adapt this framework to their specific needs, promoting standardization while allowing for necessary customization.

Preprocessing Techniques for General mHealth Applications

Preprocessing techniques have been a considerable topic of interest in the research community within its integration with the mHealth concept [65-67]. For example, cardiovascular diseases and diabetes are 2 conditions that have benefited from mHealth tools. In a study by Qaisar et al [68], an efficient method for the diagnosis of arrhythmia based on electrocardiogram inputs was proposed. The method combined multivariate processing, wavelet decomposition, frequency content-based subband coefficient selection, and ML techniques for preprocessing. In a study by Efat et al [69], a smart health monitoring tool for patients with diabetes was introduced. The objective of the authors was to use continuous sensor monitoring and processing with neural networks to provide a continuous evaluation of the patient's health risk status by considering the patients' noninvasive biometric data [69]. To improve data quality, the authors used data transformation. Photoplethysmography has been used for blood pressure monitoring by incorporating the mHealth concept [70]. The authors collected photoplethysmography signal data from smartphones and passed them through a high-pass filter with a cutoff frequency of 0.5 Hz. To filter out unwanted peaks and create a smooth signal, a moving average filter with a span of 5 data points was applied to the signals before peak detection was performed [70]. Peak detections were implemented by finding the local maximum values in the signals [70]. The incorporation of mHealth technology has brought several efficient alternatives for health care engineering. In addition, it becomes a challenging factor while addressing data quality issues. The general health care sector has experienced irregularities in converting raw data to suitable formats, there is not an exceptional case in cancer monitoring.

Proposed Preprocessing Framework

To address the challenges and limitations identified in the reviewed literature, we propose a general preprocessing framework to develop AI/ML-ready data for mHealth cancer monitoring applications. Figure 4 summarizes this framework for noninvasive physiological monitoring data analysis. While our framework is conceptually applied within the setting of general oncology monitoring to fit AI/ML models, it could also be applied in other disease settings by following the key elements and steps of data preprocessing techniques.

Our proposed framework (Figure 4) synthesizes the best practices identified in this review, offering a standardized approach to preprocessing wearable sensor data. The

framework's strength lies in its flexibility and broad applicability. While the framework was developed based on cancer care applications, its fundamental components, data cleaning, data transformation, and data normalization and standardization, are relevant to a wide range of chronic diseases that can benefit from continuous monitoring via wearable sensors. By extracting raw wearable-based data from a real-world scenario, as shown in this paper using the cancer care setting, researchers should be able to reproduce available preprocessing solutions to other settings that leverage wearable sensor data. For instance, the data cleaning techniques identified in cancer studies, such as handling missing data and removing artifacts, are equally crucial in preprocessing data for heart disease or diabetes monitoring. Similarly, the data transformation methods, including feature extraction and dimensionality reduction, can be adapted to extract relevant biomarkers for various conditions. The framework's emphasis on data normalization and standardization ensures that regardless of the specific disease context, the preprocessed data will be suitable for AI/ML applications.

Data captured from wearable sensors (eg, sleep parameters, heart rate, and steps) are unique in that they are collected passively, nonobtrusively, and continuously in real-world settings [71]. For cancer applications, the identification of noninvasive biomarkers is an attractive tool for possibly predicting clinical outcomes [72]. However, current challenges of applying AI/ML techniques in the cancer research setting include data quality issues, data dimensionality, diverse data types, dynamic evolution of disease states, lack of labeled data, frequent and irregular data sparsity, and data integration issues [73]. Noninvasive wearables, such as fitness trackers, smartwatches, and many medical monitoring devices, are built using standardized design and manufacturing processes. These standard processes pertain to aspects like how data are sampled (sampling rate), how the wearables are constructed (structural aspects), and how complex the devices are. Because of these standardized methods, wearable devices can operate in a manner that captures and provides data frequently, often in real time. This continuous stream of data means that wearables are consistently generating much information. Wearable technologies are still in their infancy in cancer research because they have not been widely implemented on patients diagnosed with oncology diseases. In addition, they still face challenges in being effectively used for cancer research because of difficulties in data collection, limited types of data captured, and the scattered nature of the data storage.

Strengths and Limitations of the Review and Preprocessing Techniques

Our review provides a valuable synthesis of current preprocessing practices for wearable sensor data in cancer applications and highlights key opportunities for standardization and future research. By transparently reporting our methods and potential biases, we aim to support the interpretability and trustworthiness of our findings. Prior research has primarily focused on ML methods rather than emphasizing on standardized preprocessing techniques to make the data AI/ML ready. Key strengths and limitations are summarized in Multimedia Appendix 3. In addition, we point out potential factors that may influence the validity of our scoping review.

First, despite our comprehensive search strategy across multiple databases, it is possible that some relevant studies were not captured, particularly if they were published in nonindexed journals or as gray literature. However, we believe the risk of missing significant preprocessing methodologies is low given the breadth of our search and focus on peer-reviewed articles.

Second, categorizing preprocessing techniques required some subjective interpretation, as nomenclature was not always consistent across studies. We mitigated this by having multiple authors independently classify techniques and resolve discrepancies through discussion. Nonetheless, some overlap between categories may remain. The framework we proposed offers a generalizable taxonomy but should be further validated and refined as the field evolves.

Third, our analysis was limited to assessing the reported preprocessing workflows in each study. Without access to the underlying data sets and code, we could not directly compare the effectiveness or reproducibility of different techniques. Quantitative benchmarking of preprocessing methods on standardized wearable data sets would be a valuable direction for future work to provide more objective guidance for researchers.

Conclusions

Herein, we conducted a scoping review of preprocessing techniques by focusing exclusively on enhancing raw data from wearables before fitting AI/ML models. Recently, there has been a worldwide interest in the data quality improvement elements in the biomedical area. Our review identified 3 different preprocessing categories applicable to cancer care. Data preprocessing plays a fundamental role in the knowledge discovery from analyzing cancer-related data, especially when data are captured from wearables. A general framework within conventional preprocessing tasks, including data cleaning, data transformation, and data normalization and standardization, has been proposed with a detailed preprocessing pipeline well described. However, due to the diversity of oncology diseases, we validated the availability of significant challenges in preprocessing technique implementation for AI/ML readiness. These methods can bring significant research outcomes across the enhancement of wearable data while addressing data quality issues through different data sets with diverse specifications. The general preprocessing framework proposed in this study represents a significant step toward standardizing the preparation of wearable sensor data for AI/ML applications. While developed in the context of cancer care, its principles are broadly applicable and adaptable to other chronic diseases requiring continuous monitoring. Future research should focus on validating and refining this framework across diverse health care contexts, potentially leading to more efficient and effective use of wearable sensor data in precision medicine.

Acknowledgments

The authors would like to thank Mrs Kate Saylor for her productive collaboration throughout the methodology development of this work. VG is supported by a National Heart, Lung, and Blood Institute (NHLBI) grant (K24HL156896). SWC is supported by the National Cancer Institute and NHLBI grants (R01CA249211 and K24HL156896). BLO is supported by an NHLBI training grant (T32HL007622).

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Authors' Contributions

Data extraction was performed by 3 authors (BLO, VG, and SWC) by mutual agreement, and discrepancies were resolved by discussion with other coauthors (RK, XC, AS, AJ, and CZ). The outcomes from the themes' categorization part were finally evaluated independently by each author. All listed authors have reviewed and contributed to the manuscript.

Abstract

Background: Usability has been touted as one determiner of success of mobile health (mHealth) interventions. Multiple systematic reviews of usability assessment approaches for different mHealth solutions for physical rehabilitation are available. However, there is a lack of synthesis in this portion of the literature, which results in clinicians and developers devoting a significant amount of time and effort in analyzing and summarizing a large body of systematic reviews.

Objective: This study aims to summarize systematic reviews examining usability assessment instruments, or measurements tools, in mHealth interventions including physical rehabilitation.

Methods: An umbrella review was conducted according to a published registered protocol. A topic-based search of PubMed, Cochrane, IEEE Xplore, Epistemonikos, Web of Science, and CINAHL Complete was conducted from January 2015 to April 2023 for systematic reviews investigating usability assessment instruments in mHealth interventions including physical exercise rehabilitation. Eligibility screening included date, language, participant, and article type. Data extraction and assessment of the methodological quality (AMSTAR 2 [A Measurement Tool to Assess Systematic Reviews 2]) was completed and tabulated for synthesis.

Results: A total of 12 systematic reviews were included, of which 3 (25%) did not refer to any theoretical usability framework and the remaining (n=9, 75%) most commonly referenced the ISO framework. The sample referenced a total of 32 usability assessment instruments and 66 custom-made, as well as hybrid, instruments. Information on psychometric properties was included for 9 (28%) instruments with satisfactory internal consistency and structural validity. A lack of reliability, responsiveness, and cross-cultural validity data was found. The methodological quality of the systematic reviews was limited, with 8 (67%) studies displaying 2 or more critical weaknesses.

Conclusions: There is significant diversity in the usability assessment of mHealth for rehabilitation, and a link to theoretical models is often lacking. There is widespread use of custom-made instruments, and preexisting instruments often do not display sufficient psychometric strength. As a result, existing mHealth usability evaluations are difficult to compare. It is proposed that multimethod usability assessment is used and that, in the selection of usability assessment instruments, there is a focus on explicit reference to their theoretical underpinning and acceptable psychometric properties. This could be facilitated by a closer collaboration between researchers, developers, and clinicians throughout the phases of mHealth tool development.

usability; quality evaluation; mobile health; physical exercise; rehabilitation; overview; umbrella review; psychometrics

Introduction

The development of mobile health (mHealth) [1,2] solutions has seen exponential growth in recent times, driven particularly by the global pandemic [3,4]. mHealth has been heralded as a tool to provide access to quality rehabilitation input for patients outside of the time they are able to spend with clinicians [5] and for patients in geographically remote areas [6]. Furthermore, similar to the observed trend of increased health information seeking on the internet [7], the democratization of access to rehabilitation could be achieved by individuals actively seeking stand-alone mHealth solutions.

However, there is also increasing awareness that mHealth solutions available to clinicians and their patients often lack quality evaluations [8,9]. Many mHealth solutions only have short-term (<30 days) data from small sample sizes to support their effectiveness [10]. Moreover, only limited standardized outcome measures are typically used [11,12].

Usability is one key aspect commonly included in the evaluation of mHealth solutions [5,9,11]. It has been touted as a determiner of the success of mHealth interventions [13]. Usability is often delineated from two related concepts: (1) the concept of utility that captures a system's ability to meet user needs [14] and (2) user experience is commonly understood as a broader concept of the experience of using an mHealth solution and may include measures of user beliefs [15]. However, usability may or may not be part of how user experience is captured, and many different definitions of usability appear in the literature [15-17].

The diversity in definitions of usability is mirrored by the diversity in usability models or frameworks. The 5 most commonly cited models of usability are that of ISO9241-11 [18] and its revision [19]; ISO/IEC25010 [20]; Nielsen's usability model [21]; and, in the context of health in particular, the People At the Centre of Mobile Application Development (PACMAD) model [14,22]. These models identify factors such as efficiency, or the resources expended to achieve a task; effectiveness, the level of accuracy and completeness of a task achieved using a mobile solution; and satisfaction or positive user interaction while operating the mobile solution as components of usability. The key difference between the PACMAD and the aforementioned frameworks is that these and other factors such as errors are seen as arising from 3 different sources: the user themselves, the task, and the context. This could be argued to be of particular importance for mHealth, where users may experience limitations such as perceptual or cognitive (aging) barriers [23]. These additionally impact on task demands and therefore represent an important consideration in the design of mHealth tools.

Usability assessment has been included in several good practice guidelines for the development of mHealth solutions [24-28], as well as in many evaluation frameworks [29,30], and can be regarded as a crucial step for evaluation at different stages of the typical mHealth development cycles. To date, however, no accepted standard for the assessment of usability of mHealth solutions exists. This means that researchers and developers of mHealth are faced with difficult decisions when designing mHealth evaluation procedures that strike the balance between responsiveness, reliability, and validity and are unable to compare existing solutions for the purpose of innovating. Further, clinicians are unable to be guided in their prescription of mHealth solutions, and there are significant barriers for consumers to engage with existing solutions.

Numerous systematic reviews have explored usability assessment approaches for various mHealth solutions in the context of physical rehabilitation. However, there is a lack of synthesis in this area of the literature. This may contribute to clinicians and developers needing to devote a significant amount of time and effort in analyzing and summarizing a large body of systematic reviews. An umbrella review can act as "a means for a rapid review of the evidence to address a broad and high-quality evidence base" [31]. Specifically, an umbrella review allows for a broader scope than individual systematic reviews that may focus on individual treatment options or individual conditions [32-34]. Hence, the aim of this umbrella review was to provide a "user-friendly" summary of the use of usability assessment instruments, or measurement tools, for researchers, clinicians, and consumers of mHealth irrespective of the specific area of application (eg, diabetes, tuberculosis, and sleep). Specifically, the objective was to summarize systematic reviews that investigated usability assessment instruments in mHealth interventions including those related to physical exercise rehabilitation. It is envisaged that such a summary will first aid researchers, developers, and clinicians to gain an overview of usability assessment instruments without needing to explore primary literature. Second, the presented summary may aide the development of mHealth usability assessment standards.

Methods

Overview

The umbrella review protocol was developed based on the *Cochrane Handbook for Systematic Reviews of Interventions* [33] and other relevant methodology sources [34] and was registered with PROSPERO (CRD42022338785). StArt (State of the Art through Systematic Review) software [35] was used for the first- and second-level screening of result datasets and extracting relevant information.

Inclusion Criteria

Based on the objectives of the study, the following inclusion criteria were formulated: (1) articles published between January 1, 2015, and April 27, 2023 (the date range reflected the launch of Apple ResearchKit in 2015, which accelerated mHealth development and research [36]); (2) containing data on human participants; (3) with the "unit of searching" [33] being "systematic reviews" [37,38] in order to reduce the effect of cumulative bias that may arise when including nonsystematic reviews; (4) examining usability assessment instruments of

mobile apps for health professionals and for health care consumers; and (5) published in the English language to enable all contributing authors to perform screening, extraction, and synthesis of the search results. No post hoc modifications were made to the inclusion criteria. Systematic reviews of usability assessment instruments of other (mobile) solutions such as wearables, sensors, virtual reality, blockchain, Internet of Things, simulated data, or solutions for health care professionals only were excluded.

Search Methods and Search Terms

The following databases were searched with a combination of the search terms mobile application*, mobile app, usab*, usab* criteria, usab* evaluat*, systematic review, mhealth, mobile health, and physical exercise: PubMed, Cochrane, IEEE Xplore, Epistemonikos, Web of Science, and CINAHL Complete, combined using Boolean operators OR and AND and customized for each database in accordance with their filtering specifications. The result sets were imported into StArt [35]. The full search syntax for each database are presented in Table S1 in Multimedia Appendix 1.

Data Collection and Analysis

A preliminary search of existing systematic reviews was conducted before finalizing the search terms in order to scope the extent and type of existing evidence [33]. The subsequent final search terms produced a result set that was more refined in focus and feasible in terms of the size of the expected result set. Following the removal of duplicates, 2-level screening was performed: title and abstract screening was performed by the primary author (SH), and a randomly selected subset of articles (118/1479, approximately 8%) was screened by a second author (VS; κ=0.87). Second-level, full-text screening was performed by the primary author (SH) using StArt for data extraction from the final result set. A data extraction form including basic reference details, as well as information such as population of interest and interventions studied, was discussed and agreed on by 3 authors (SH, GA, NS) before data extraction (see review protocol PROSPERO CRD42022338785 for more detail).

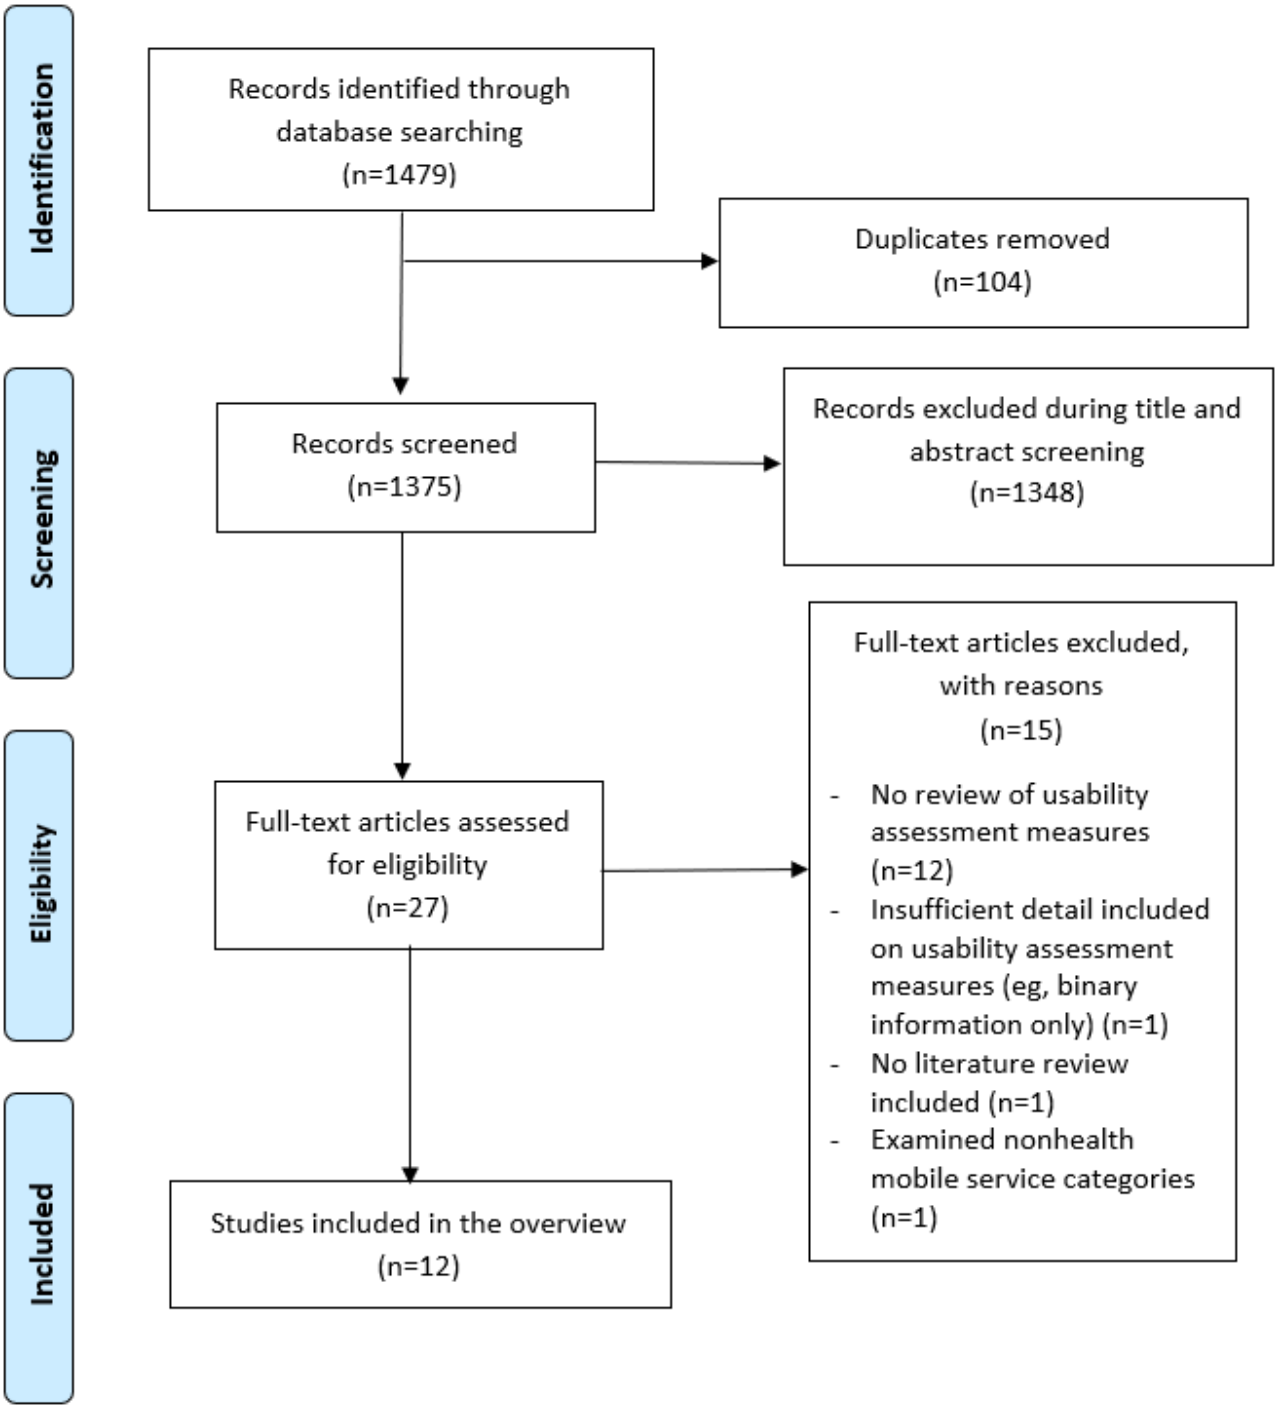
Quality assessment was completed using AMSTAR 2 (A Measurement Tool to Assess Systematic Reviews 2; Institute for Clinical Evaluative Sciences) [39] by the primary author (SH) and a second author (VS) separately (κ=0.823). Any disagreement was discussed and resolved via consensus. In line with recommendations by Shea et al [39], a discussion to determine AMSTAR 2 critical domains for this umbrella review occurred among 2 authors (SH, NS). Criteria 2, 4, and 7 were retained on the premise of constituting critical criteria as defined by the original publication [39]. The original critical criteria 9, 11, 13, and 15 were classified as noncritical for the purpose of this umbrella review due to pertaining to meta-analytic steps that none of the included systematic reviews performed. Instead, the following criteria were classified as critical: criterion 5 due to the variety of study designs and target user groups and/or clinical contexts included within the systematic reviews; and criterion 16 due to the context of mHealth usability, where the borders between academic enquiry and commercialization are more blurred and funding could constitute a significant source of bias and/or conflict of interest. A summary rating was produced according to recommendations by Shea et al [39].

Finally, to gauge potential skewing of the data caused by significant overlap of primary studies contained within the systematic reviews included in this umbrella review [40], overlap assessment was achieved via citation matrix [41,42] for the systematic reviews including the System Usability Scale (SUS) as an exemplar. The SUS was chosen because it is one of the most well-known instruments [43] and preliminary searches of the literature demonstrated its frequency of use and reference.

Results

The initial database search returned 1479 results, which were reduced to 1375 after removal of duplicates (see Figure 1). Title and abstract screening resulted in 27 articles being included for full-text screening. A total of 15 of the full-text articles retrieved (see Table S2 in Multimedia Appendix 1) were ineligible because they did not review usability assessment measures, include sufficient detail on usability assessment instruments (eg, including binary information only), include a literature review, or examine nonhealth mobile service categories (see Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.



A total of 12 systematic reviews examining usability assessment instruments were included. Data were extracted (see Table S3 in Multimedia Appendix 1) as per the registered protocol. Across the systematic reviews included, there was coverage of primary studies from the start of records to 2020. Three of the systematic reviews included examined usability assessment instruments within a specific target user group (eg, users with diabetes [44] and users living with a mental health concern [45,46]). The remaining 9 systematic reviews [13,47-54] focused on usability assessment instruments used across different target user populations. Usability models or frameworks referenced included ISO [20] (referenced in [13,44,48,49]), Nielsen [21] (referenced in [45]), and the framework by the Canadian Institutes of Health Research and the Mental Health Commission Canada [55] (referenced in [47]). Three (25%) of the systematic reviews [46,50,51] included in this umbrella review did not refer to any theoretical framework (see Table S3 in Multimedia Appendix 1).

The systematic reviews included identified a total of 32 usability assessment instruments (see Table 1) and a further 66 custom-made usability assessment instruments as well as hybrid custom-made instruments (see Table S4 in Multimedia Appendix 1). The most commonly referenced usability assessment instrument was the SUS [56], followed by the IBM Computer Usability Satisfaction Questionnaire [57] and the Usefulness, Satisfaction, and Ease of Use (USE) Questionnaire [58].

Table 1. Overview of usability assessment scales identified by reviews included within this umbrella review.

Assessment scale	Reference	Systematic review identifying scale	Count	Psychometric properties as identified by systematic reviews included in this umbrella review						
				Internal consistency (Cronbach α)	Reliability (intraclass correlation)	Content validity	Structural validity	Cross-cultural validity	Criterion, convergent, concurrent, discriminant validity	Responsiveness

[a]NR: not reported as part of the systematic reviews included in this umbrella review.

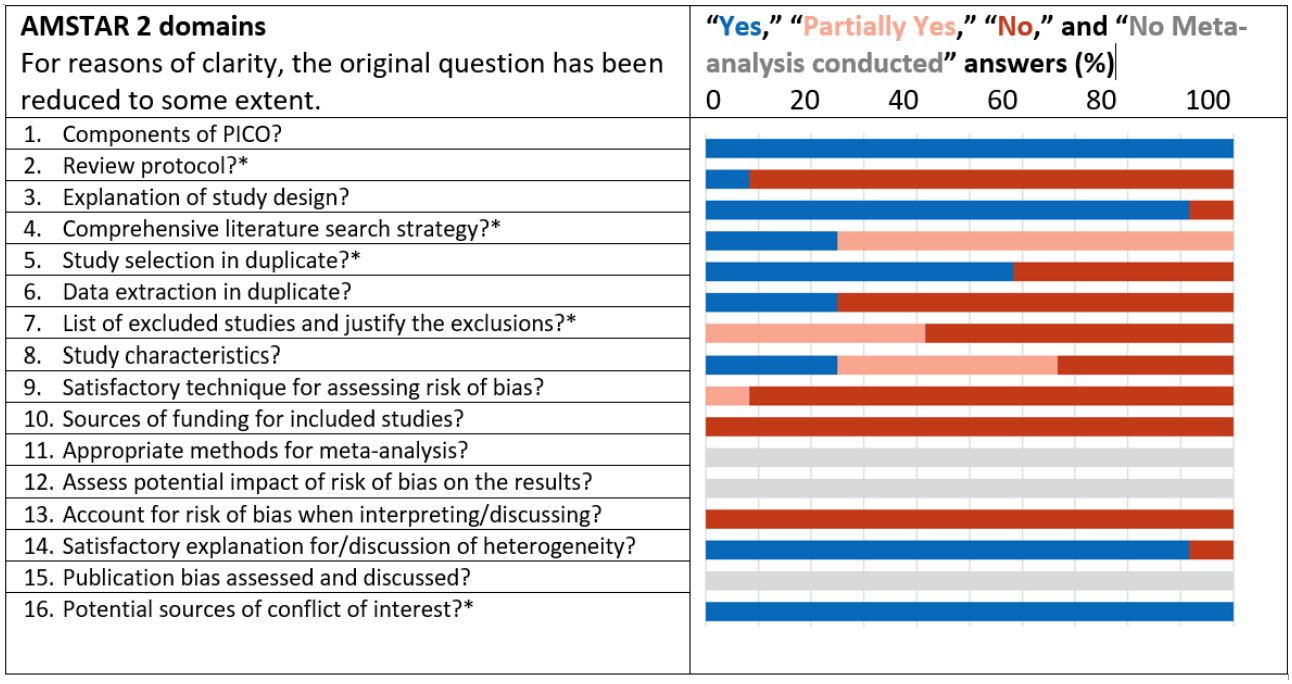
Data regarding the psychometric properties of 9 (28%) instruments [56,57,64,70-72,83,84] were included in the systematic reviews as detailed in Table 1. Internal consistency was generally good across these instruments, content validity was provided through expert panel or focus groups [56,57,64,70,71,83,84], and exploratory and/or confirmatory factor analyses were used in evidence of structural validity [56,64,70,83,84]. Details of convergent validity were included for 3 instruments [64,70,84] (see Table 1). Importantly, there was no evidence of reliability, responsiveness, or cross-cultural validity assessment for the usability assessment instruments referenced most often (ie, SUS, IBM Computer Usability Satisfaction Questionnaire, and USE Questionnaire).

Further, 8 (67%) of the systematic reviews [13,44-46,48-50,54] referred to usability assessment methods other than assessment scales. These included focus groups, heuristic evaluation,

think-aloud protocols, and other methods (see Table S5 in Multimedia Appendix 1).

Quality assessment of the systematic reviews using AMSTAR 2 revealed that 8 (67%) articles [13,44-46,48-50,54] exhibited at least 2 critical weaknesses (see Figure 2), 3 (25%) systematic reviews [47,51,52] were affected by 1 critical weakness, and 1 (8%) review [53] had only noncritical weaknesses. The most frequently unfulfilled assessment criteria included the sources of funding enquiry for the included studies (AMSTAR criterion 10), accounting for risk of bias when interpreting results (AMSTAR criterion 13), use of a satisfactory technique for assessing risk of bias (AMSTAR criterion 9), and inclusion of a review protocol (AMSTAR criterion 2; see Table S6 in Multimedia Appendix 1).

Figure 2. Overview of methodological quality of reviews according to AMSTAR 2 (A Measurement Tool to Assess Systematic Reviews 2). * denotes critical criterion as determined for this umbrella review.



Finally, visualization of citation overlap for systematic reviews including primary studies using the SUS showed minimal overlap with 4 (10%) of 41 primary studies included in 2 of the systematic reviews (see Table S7 in Multimedia Appendix 1). With the exception of the citation of the original publication of the SUS instrument [56], all other references included in the overview were unique to one of the systematic reviews included.

Discussion

Principal Findings

The exponential growth of research evidence related to the effectiveness of mobile solutions for rehabilitation [85-88] and the proliferation of technological solutions that afford new modes of treatment delivery [89,90] underscore the critical need for high-quality mHealth usability evaluation. Usability attributes such as efficiency, learnability, and memorability [21] are particularly important to consider for mHealth users who may face challenges due to neurological compromise [91], age-related issues [23], or limited technology experience [13]. This umbrella review aimed to summarize usability assessment instruments for mHealth researchers, clinicians, and consumers to guide the development, assessment, and selection of high-quality mHealth tools.

The review identified, first, significant diversity and common use of custom-made instruments when usability assessment instruments were employed to evaluate mHealth tools for rehabilitation. Second, there was a notable lack of theoretical grounding for selection of the assessment of usability. Third, a scarcity of psychometric data for widely used instruments for mHealth usability assessment was evident in the systematic reviews included.

Heterogeneity of Instruments, Including Nonstandardized Instruments

Regarding the first critical point, a wide range of different instruments for the assessment of usability was evident across the systematic reviews included. This range included adaptations of preexisting usability assessment instruments for the context of mobile apps [59,66] as well as assessment instruments, such as the Mobile App Rating Scale (MARS) [72], specifically designed for usability assessment of mHealth tools. In addition, both completely custom-made instruments and hybrids [92] of preexisting instruments with custom elements were prevalent in the mHealth usability literature.

Although the use of hybrid assessment instruments and adaptations of preexisting assessment instruments may increase flexibility and thereby possibly improve the experience for respondents, the fact that most studies are limited in sample size prevents validation of hybrid and adapted instruments [51]. Alternative approaches to increasing flexibility and improving respondent experience while ensuring psychometric integrity are needed instead. A good example of this may be seen in the creation of a hybrid version of the SUS with the inclusion of

pictorial elements, which increased respondent motivation [92]. Importantly, acceptable validity, consistency, and sensitivity were also evidenced, allowing future users of the hybrid measure to place greater trust in the quality of the data.

Theoretical Underpinning

Second, and similar to what has been found to be the case for individual-level studies assessing the usability of specific mHealth tools [47], this review revealed that some systematic reviews examining the broader literature related to usability assessment lacked connection to theoretical models of usability. This observation resonates with previous criticisms of the quality of reviews of health-related mobile apps [8] as well as research exploring technology adoption in fields beyond mHealth [93]. The latter exposed a reliance on a wide array of theoretical models of technology adoption in the literature and in some cases several within one review. To address this, it has been suggested that generic models for different service categories (eg, information and transaction) be developed [93]. A theoretically grounded, generic guide for mHealth usability assessment could similarly promote broader adoption and enhance comparison of usability across studies and use cases.

Psychometric Properties and Psychometric Testing

Third, systematic reviews included in our overview also reported significant limitations regarding the psychometric properties of preexisting instruments. For example, the MARS tool, which has been put forward as an instrument for standardized use in mHealth usability assessment [51], lacks structural validity. Moreover, other constructs such as internal consistency and criterion validity have been documented as significant areas of future work for measuring the implementation of interventions [53], with usability assessment playing a significant role.

Although consistent with previous research, this umbrella review did not specifically search for psychometric evaluations of usability assessment instruments; instead, it relied on summaries of psychometric evaluations presented as part of the included systematic reviews. As a result, it is likely that psychometric evaluation of other instruments is available. For example, psychometric evaluation of the popular USE Questionnaire [58] is available and, consistent with our observation, has been shown to be affected by a lack of reliability and validity [94]. Furthermore, outside of the academic literature, there is a still greater portion of mHealth solutions on the market that likely will not have undergone empirical evaluation of usability.

Although some of the acceptable psychometric information was referenced for the SUS [95], both the IBM Usability Satisfaction Questionnaire and the USE Questionnaire appear to lack reliability assessment. Reliability, or the freedom of measurement error [96], may be regarded as crucial with regard to any metrics that are gathered after, rather than during, a user's interaction with an application. The inability to separate true change in users' estimate of the usability of mHealth tools from random variation, or measurement error, originating from recall bias [9,97,98], for example, means that mHealth tool iterations [99] are unable to be evaluated appropriately.

Moreover, the widespread use of custom-made and hybrid assessment instruments leads to the loss of the original instrument's integrity and compromises its already-documented psychometric strengths [100]. Consequently, establishing the validity of results from individual usability investigations becomes challenging, and comparison across studies is difficult. Hence, there is an urgent need to assess the accuracy and appropriateness [101] of individual usability assessment instruments to capitalize on the promise of mHealth tools in rehabilitation [5,6].

Another important psychometric aspect of usability assessment instruments that the systematic reviews included in this umbrella review highlight as missing from the published literature is responsiveness. mHealth development usually involves iterative design and testing cycles [30,99] with associated formative and summative usability evaluation [45]. Across the life of mHealth development, iterative cycles are likely to span different stages of development and be undertaken in different clinical contexts [54,102]. Integrating usability assessment into this process requires instruments that are generic enough to capture user responses to a wide variety of mHealth strategies but also fine-grained enough to possess sufficient responsiveness [96].

Finally, with regard to the argument of lacking psychometric assessment, none of the preexisting mHealth usability assessment instruments referenced as part of the literature included in this umbrella review appear to have been informed by a breadth of cultural perspective or undergone cross-cultural validity testing. Given the global potential of mHealth to address inequities in access to and outcomes from rehabilitation [5,6], it is particularly important to establish cross-cultural validity of the usability assessment instruments employed in mHealth development. In addition, with the pervasiveness of technology, there is a certain element of unpredictability of the context in which mHealth tools will be trialed and used "in the wild" [103,104]. For that reason, an alternative argument could be made for innovative, culturally responsive methodology for mHealth tool design including usability testing [105]. A key difference in such attempts is user participation at multiple stages of development and responsiveness to expanding the stages of development as guided by stakeholders. This process likely includes constant negotiation and may be resource heavy but is arguably needed if the aim is to create mHealth solutions impacting indigenous outcomes, for example [74,106].

Considering the identified issues, including lack of theoretical grounding, common use of custom-made assessment instruments, and the scarcity of psychometric data for widely used mHealth usability assessment instruments, multimethod usability assessment appears paramount. This is consistent with recommendations made by a number of research groups [13,44,102,107] and reinforces the argument often advanced in favor of Ecological Momentary Assessment approaches, which are recognized for their advantage over retrospective assessment [97]. It is therefore proposed that standards be developed that specify the time points in the mHealth life cycle at which usability assessment is completed, with an emphasis on what methods to use. Moreover, these standards should mandate that individual assessment instruments are grounded in a theoretical framework and possess a minimum threshold for psychometric properties [53,108].

Recommendations

The establishment of a universal usability scoring system or algorithm would further facilitate the integration of these assessments into an overall framework [109]. It has been observed that, at present, less than half of existing evaluation frameworks include such a scoring system, but that such systems could support funding decisions [29] and advance the vision of prescribable mHealth apps [10]. Although technological advancement often outpaces academic enquiry necessitating new approaches to mHealth evaluation frameworks [110], usability factors are enduring [16] and investing resources into establishing standards will therefore be valuable.

Limitations

In the context of an area of practice where the lines between commercial and academic work are blurred and usability assessment constitutes a common practice in the global commercial environment [111], this umbrella review is limited to only including English language systematic reviews published within the academic literature indexed in the databases included. Furthermore, the quality of the included systematic reviews was found to be limited, and the fit of the AMSTAR 2 tool with methodological papers is not perfect. However, AMSTAR 2 could be argued to be more detailed than instruments developed for umbrella reviews specifically [31], and, in line with the AMSTAR 2 recommendations [39], the authors modified the list of critical criteria to reflect the specific aim of the overview. Finally, with regard to the review's methodology, 2 limitations are of note. First, although the search syntax for this umbrella review included the keyword "physical exercise," for pragmatic reasons, no validation step was included to confirm that all mHealth tools examined as part of the primary studies included within the systematic reviews included a physical exercise component. Regardless, the observations presented here are valid for mHealth tools for rehabilitation overall and provide valuable guidance to developers, researchers, and clinicians. Second, for practical reasons, data selection could only be performed by the primary author (SH) with a subset of articles being screened by a second author (VS). However, agreement on study selection was high (>80%), supporting the quality of the review.

Conclusions

There is considerable variety in approaches to and instruments for the assessment of usability in mHealth for rehabilitation, many of which lack theoretical foundation. Clinicians are therefore advised to critically evaluate mHealth literature and solutions, paying particular attention to the population in which usability testing was performed and the specific usability assessment instruments were employed. Future research efforts should be focused on producing high-quality systematic reviews and psychometric evaluations of usability assessment instruments. A collaborative effort between researchers, designers, and developers is essential to establish mHealth tool development standards. These standards should emphasize the incorporation of usability assessment instruments underpinned by a robust theoretical base. This umbrella review represents a valuable reference tool in this endeavor. Inclusion of multimethod usability assessment within the wider mHealth development cycle could also be part of these standards, which will ensure that we can capitalize on the widely heralded promise of mHealth to promote access to and outcomes from rehabilitation.

Acknowledgments

The authors thank the wider team of researchers and clinicians at the AUT Research Innovation Centre for workshop and input, and Exsurgo for valuable conversations on usability from a commercial perspective.

Abstract

Background: The use of wearable sensors is being explored as a challenging way to accurately identify smoking behaviors by measuring physiological and environmental factors in real-life settings. Although they hold potential benefits for aiding smoking cessation, no single wearable device currently achieves high accuracy in detecting smoking events. Furthermore, it is crucial to emphasize that this area of study is dynamic and requires ongoing updates.

Objective: This scoping review aims to map the scientific literature for identifying the main sensors developed or used for tobacco smoke detection, with a specific focus on wearable sensors, as well as describe their key features and categorize them by type.

Methods: According to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) protocol, an electronic search was conducted on the PubMed, MEDLINE, and Web of Science databases, using the following keywords: ("biosensors" OR "biosensor" OR "sensors" OR "sensor" OR "wearable") AND ("smoking" OR "smoke").

Results: Among a total of 37 studies included in this scoping review published between 2012 and March 2024, 16 described sensors based on wearable bands, 15 described multisensory systems, and 6 described other strategies to detect tobacco smoke exposure. Included studies provided details about the design or application of wearable sensors based on an elastic band to detect different aspects of tobacco smoke exposure (eg, arm, wrist, and finger movements, and lighting events). Some studies proposed a system composed of different sensor modalities (eg, Personal Automatic Cigarette Tracker [PACT], PACT 2.0, and AutoSense).

Conclusions: Our scoping review has revealed both the obstacles and opportunities linked to wearable devices, offering valuable insights for future research initiatives. Tackling the recognized challenges and delving into potential avenues for enhancement could elevate wearable devices into even more effective tools for aiding smoking cessation. In this context, continuous research is essential to fine-tune and optimize these devices, guaranteeing their practicality and reliability in real-world applications.

KEYWORDS

smoking; tobacco smoke; smoke exposure; cigarette smoking; wearable sensor; public health

Introduction

According to the World Health Organization, tobacco smoke poses a major public health issue, causing approximately 8 million deaths annually worldwide [1]. It is a prominent contributor to noncommunicable diseases, such as cardiovascular diseases, chronic respiratory diseases, cancer, and diabetes, accounting for 1 out of every 6 deaths caused by these diseases [2,3]. In line with the sustainable development goals, reducing tobacco use is an essential requirement to achieve progress in the prevention and control of noncommunicable diseases, as well as for monitoring tobacco control efforts [4]. However,

smoking cessation is often hindered by low awareness of the health risks related to tobacco smoke [2]. In order to tackle this problem, there are multiple strategies available to aid individuals in their journey to quit smoking, and it is crucial to establish regular data collection on smoking habits and individual exposures [5,6].

A number of conventional approaches (eg, portable puff instruments, self-report questionnaires, and ecological momentary assessments) have been employed to monitor smoking habits in epidemiological research [2]. However, these methods have shown limited efficacy in accurately detecting smoke exposures, due to memory biases and underreporting by individuals. For these reasons, they do not offer valuable tools to support effective public health interventions [7]. More recently, wearable sensors have emerged as a potential approach for detecting smoking exposure in individuals. Broadly speaking, these sensors are usually intended to be worn on the body and measure various physiological or environmental parameters and behaviors of smoke exposure. It is intriguing that these devices comprise a blend of distinct sensor modalities (such as electrical, inertial, and acoustic) and a system of multiple sensors [8,9]. However, it is important to note that this field of research is still evolving, indicating that there is currently no single wearable device that exhibits high accuracy in detecting smoking events in all situations, isolating puffs and smoke inhalations, or evaluating smoke exposure.

In this context, the systematic review conducted by Imtiaz et al [2] provides a summary of recent innovative approaches (ie, individual and multisensor combinations, various body locations, and signal processing methodologies) of cutting-edge wearable sensors designed for monitoring cigarette smoking in real-world conditions, including studies published from 1990 to 2019. However, the following years have been marked by the COVID-19 pandemic, a globally impactful event that may have influenced the interest and potential applications of new technologies for monitoring lifestyles. Additionally, given that sensor use is a rapidly evolving field, it is necessary to consistently provide updates in the scientific literature.

Considering this, our scoping review was undertaken to offer an updated summary of studies published until March 2024, presenting the application of wearable sensors for monitoring cigarette smoking and smoke exposure, and focusing on both single-sensor and multisensor approaches.

Methods

The review methodology was employed by following these steps: (1) identifying the research question (RQ); (2) defining the search strategy and protocol; (3) conducting a literature search; and (4) collecting data from the included studies.

Thus, the RQ of our systematic review was as follows: what is the state of the art regarding the development and use of sensors (particularly wearable sensors) for monitoring smoking habits in epidemiological studies? Additionally, what are the main types of sensors and how do they differ in terms of modalities and potential applications?

This scoping review was conducted according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) protocol (Multimedia Appendix 1) [10]. Two authors (GF and AM) independently conducted a literature search and selected potentially relevant articles from inception to March 10, 2024, using the PubMed, MEDLINE, and Web of Science databases. The electronic search strategy consisted of the following keywords: (“biosensors” OR “biosensor” OR “sensors” OR “sensor” OR “wearable”) AND (“smoking” OR “smoke”).

Articles were included in the scoping review if they reported studies describing, developing, or applying sensors for the detection of tobacco smoke exposure, with the potential to be wearable. Thus, articles were included if they met the following criteria: (1) were written in English; (2) involved human participants; (3) described, developed, or applied sensors that could be wearable; (4) analyzed active or passive exposure to tobacco smoke; (5) were conducted in a laboratory or the community; and (6) described protocols according to the RQ of the scoping review. By contrast, articles were excluded if they met the following criteria: (1) did not fit into the RQ of the scoping review; (2) reported studies on sensors that were not or potentially not wearable; (3) did not analyze active or passive exposure to tobacco smoke; (4) presented only the biochemical or biomolecular applications of sensors; and (5) were letters, comments, abstracts, editorials, reviews, systematic reviews, or meta-analyses.

By using a data abstraction form designed for this scoping review, 2 authors (GF and AM) collected the following information from all the included studies: article characteristics (eg, first author, publication year, and country of origin), study characteristics (eg, study design), sensor specifications (eg, type of wearable sensors, parameters that were measured, accuracy, data availability, and autonomous or integrated system), and applications proposed.

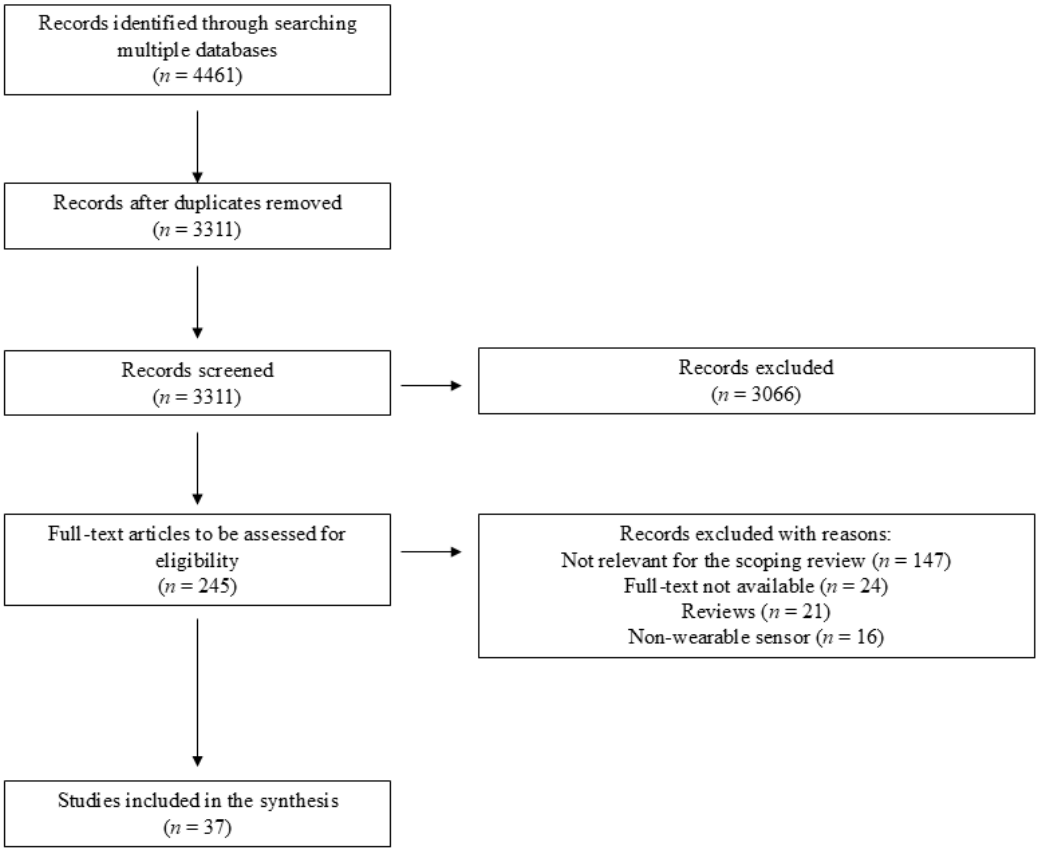
Diverse opinions between investigators were resolved through discussion between the 2 authors or by consulting a third author (AA). The studies were categorized based on the types of wearable devices employed, with particular attention given to distinguishing between single-device applications and combinations or systems of these devices.

Results

Study Selection

Following the removal of duplicates, a total of 3311 articles were initially identified through the literature search. Through the screening process of titles and abstracts, 3066 articles were excluded, leaving 245 full-text articles that were thoroughly evaluated for eligibility. Among these, 208 were excluded for the following reasons: 147 were not relevant for the objective of the current scoping review, 24 were without full text, 21 were reviews, and 16 used nonwearable sensors. Thus, the remaining 37 studies were considered eligible and were included in this scoping review (Figure 1).

Figure 1. Flowchart illustrating the selection of studies included in the scoping review.



Characteristics of the Studies Included

The vast majority of studies included in this scoping review originated from the United States (n=27). In particular, 16 studies described single wearable devices or devices in combination, 15 studies described multisensor systems, and 6 studies described other innovative strategies for the detection of cigarette smoke exposure. All of the studies included in this review were conducted within the general population, with a particular emphasis on individuals who smoke.

In the following sections, we grouped the studies included by the type of wearable sensor considered, as follows: (1) a single elastic band or a combination of elastic bands; (2) multisensor systems (ie, “Personal Automatic Cigarette Tracker [PACT],” “PACT 2.0,” and “AutoSense”); and (3) other alternative strategies.

Wearable Sensors Based on Elastic Bands

Sixteen studies focused on detailing the design or application of wearable sensors [8,11-14] or a combination thereof [15-23] to detect different aspects of tobacco smoke exposure (Table 1). While numerous studies commonly suggested sensors mounted in fixed locations, these approaches did not permit a comprehensive determination of tobacco smoke exposure among specific subgroups of individuals [24]. In this context, tobacco test strips are among the commercially available options for assessing nicotine levels in urine and saliva samples [25].

Table 1. Summary of studies exploring wearable sensors based on elastic bands.

Study	Country	Type of wearable	Application	Sensor modality	Accuracy	Data availability	Autonomous/integrated
Cole et al [26], 2021	United States	Smartwatch and smartphone app	To validate a smartwatch for the examination of smoking temporal patterns	Interpuff intervals and puff duration	—[a]	User and researcher	Integrated with a smartphone app
Dar [19], 2018	Israel	Smartwatch and wristbands	To investigate whether smoker monitoring through the SmokeBeat app would result in a reduction in smoking	Hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone app
Horvath et al [20], 2021	United States	Smartband and smartphone	To propose a protocol for aiding daily smokers in their attempt to quit smoking	Hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone app
Joyce et al [21], 2021	United States	Smartwatch or smartband	To assess the viability, acceptability, and efficacy of a smoking cessation program utilizing smartwatch technology and incentive-based strategies	Hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone app
Lopez-Meyer et al [18], 2013	United States	Wristband	To describe a sensor for monitoring gestures in cigarette smokers	Hand-to-mouth gestures	Sensitivity: 90%	User and researcher	Data logger unit
Maguire et al [15], 2022	United States	Smartwatch and finger elastic band	To develop a smoking detection system to classify presmoking behaviors	Arm, wrist, and finger movements	Accuracy: 80.6%	User and researcher	Integrated with a smartphone app
Morriscey et al [22], 2018	United States	Smartwatch and smartphone app	To determine the sensitivity and specificity of the smartphone app	Hand-to-mouth gestures	Sensitivity: 22.5%-41.7%	User and researcher	Integrated with a smartphone app
Parate et al [12], 2014	United States	Wristband	To design a mobile solution to capture changes in the orientation of a person's arm	Hand-to-mouth gestures	Accuracy: 95.7%; precision: 91%; recall: 81%	User and researcher	Integrated with a smartphone app
Quintana et al [27], 2018	United States	Silicone wristband	To assess the effectiveness of silicone wristbands as personal nicotine samplers	Nicotine level	—	Researcher	Autonomous
Raiff et al [13], 2014	United States	Wrist, elbow, and shoulder bands	To develop and test the ability of inertial sensors to detect cigarette smoking	Arm movements	—	User and researcher	Integrated with a tablet
Schnall et al [23], 2022	United States	Smartwatch and smartphone app	To assess the feasibility and efficacy of the Lumme Quit Smoking mobile app	Hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone app
Senyurek et al [14], 2019	United States	Chest band	To develop and test a machine learning model for smoking recognition	Breathing signals	Accuracy: 80.0%	—	—
Skinner et al [17], 2018	United Kingdom	Smartwatch	To present a system for passive detection of cigarette smoking	Hand-to-mouth gestures	—	—	Integrated with a smartphone
Tai et al [11], 2020	United States	Forearm band	To detect nicotine levels in the sweat of subjects inhaling cigarette smoke	Nicotine level	—	Researcher	Integrate with a computer
Takur et al [8], 2022	India	Wristband	To develop a modeling framework for smoking recognition	Hand-to-mouth gestures	Accuracy: 98.7%	User and researcher	Data logger unit integrated with a computer
Zhai et al [16], 2020	Belgium	A system that includes: an electric lighter, wristband, and chest patch	To reveal temporal patterns of smoking behaviors	Hearth rate, breathing, and hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone app

[a]Not applicable.

Nonetheless, achieving a personalized and real-time assessment of individual exposure remains a challenge, emphasizing the need for further efforts to develop tailored preventive strategies accordingly. In an effort to address this concern, some authors presented a strategy to bridge the gap between fixed tobacco sensors and nicotine test strips. In particular, they proposed a noninvasive and wearable forearm band designed for continuous and real-time monitoring of nicotine levels in human sweat after nicotine inhalation. The device comprised a flexible electrode array connected to an electronic circuit, demonstrating favorable sensitivity and stability in both smokers and nonsmokers alike [11].

A recent study introduced a smoking cessation system aimed at predicting presmoking movements, such as reaching for a pack of cigarettes or lighting a cigarette, which are associated with smoking behaviors. This system utilizes an accelerometer embedded in a smartwatch to capture arm and wrist movements, along with a wearable finger sensor to measure the bending angle of the user's index finger. Their results showed that a model integrating data from both the smartwatch and finger sensor achieved higher accuracy in classifying presmoking activities compared to the model relying solely on the smartwatch. These findings lay the groundwork for developing an effective smoking cessation strategy that utilizes the combined input from these devices [15].

The authors who designed the "RisQ" mobile solution made additional endeavors to differentiate smoking episodes by validating a solution based on a wristband capable of detecting arm and wrist movements during smoking, as well as hand-to-mouth gestures, utilizing a machine learning model. Specifically, the authors compared the performance of 2 different algorithms in accurately identifying hand-to-mouth gestures, puffs, and smoking events. The authors proposed a pipeline aimed at effectively and promptly detecting smoking gestures in real time, yielding favorable accuracy, precision, and recall values [12]. In this context, a study conducted in 2020 assessed recurring patterns of smoking behaviors in real-life settings. The authors proposed a system comprising a wristband (capturing arm movements and skin impedance data), a chest patch (gathering electrocardiogram [ECG] information), and an electric lighter (detecting smoking events) to collect data regarding the contextual aspects in which individuals smoke. Notably, the study revealed intriguing differences in temporal patterns, encompassing weekly, daily, and time-of-day variations, as well as variations in emotional states during smoking episodes [16].

Some researchers introduced an innovative use of wearable devices for the real-time detection of smoking activity. They developed a wearable wristband that integrated 6-axial inertial sensors to gather data on physical activities, such as walking, running, walking upstairs, and walking downstairs, as well as smoking events. Additionally, they leveraged the collected data to create a machine learning model capable of distinguishing smoking activity from various daily activities, demonstrating promising performance [8]. Similarly, another study aimed to assess the capability of 4 inertial sensors (positioned on the wrist, elbow, and arm) to capture arm movements. Interestingly, the authors compared 2 distinct algorithms, namely support vector machine (SVM) and edge-detection–based learning. The results highlighted that the SVM model had superior performance in recognizing smoking events and interpuff intervals [13].

Similarly, a study published in 2019 compared the performance of various machine learning models with a focus on detecting smoke inhalations, utilizing a wearable chest band to capture breathing signals. The findings indicated that novel deep learning approaches may offer a more accurate method for detecting smoke inhalations than conventional machine learning models [14]. A validation study presented a system designed for the detection of passive cigarette smoking. The system consisted of a smartwatch equipped with a combination of accelerometers and gyroscope sensors, enabling the detection of hand movements associated with cigarette smoking [17]. Similarly, some authors validated a wristband that transmitted hand-to-mouth gestures to a receiver positioned on the user's chest. Interestingly, the proposed sensor exhibited good sensitivity and provided a methodology to differentiate hand-to-mouth gestures originating from smokers [18].

Although mobile apps for smoking cessation are becoming more widely accessible, their effectiveness is yet to be proven. In this context, a pilot trial being carried out in the United States is evaluating the potential of utilizing a smartband and smartphone for real-time monitoring, detecting smoking, and delivering concise mindfulness interventions to diminish smoking. The trial protocol seeks to provide insights into the practicability of employing the combined use of a smartband and smartphone [20]. An additional pilot study investigated SmokeBeat, an inventive app tailored for use with smartwatches and wristbands. This app processes information and utilizes embedded sensors in wearables to identify hand-to-mouth gestures in real time. The study's authors highlighted that the SmokeBeat algorithm accurately identified more than 80% of smoking episodes, and participants in the experimental group demonstrated a notable decrease in smoking rates throughout the 30-day trial [19]. SmokeBeat was also employed to assess the feasibility, acceptability, and effectiveness of a smoking cessation program designed for low-income pregnant smokers, utilizing smartwatch technology and incentive-based strategies. Reductions in smoking were noted in both the control and intervention groups across all pilot studies. While the utilization of the SmokeBeat program did not lead to a significant improvement in cessation rates, its feasibility and acceptability were deemed moderately high [21]. Similarly, another study demonstrated SmokeBeat's good sensitivity and specificity in cigarette detection following a learning period [22]. Remarkably, a pilot study indicated outstanding feasibility and acceptability in utilizing the "Lumme Quit Smoking" mobile app in conjunction with a smartwatch, aiming to enhance smoking cessation outcomes among individuals with HIV [23].

In this context, a pilot feasibility study was recently conducted to study temporal patterns and characteristics of smoking among adult smokers in a controlled laboratory setting. The authors compared the agreement of recording smoking characteristics by comparing the Polar M600 smartwatch that recorded accelerometer data to identify the durations of puff and interpuff intervals using Automated Smoking Perception and Recording

(ASPIRE) software and the pocket Clinical Research Support System (CReSS) topography device that uses video observation. The results suggested that the ASPIRE approach is more accurate than the CReSS method for passively monitoring smoking behavior. Moreover, the ASPIRE approach was more accurate than the CReSS method for measuring puff and interpuff intervals. In fact, the ASPIRE approach consistently produced a higher count of puffs and maintained more stable durations of interpuff intervals in comparison to the CReSS method, aligning both methods with the visually observed puff count. After filtering out implausible data from the CReSS method, both the ASPIRE approach and CReSS method provided consistent results for both puff duration and interpuff intervals [26]. A different study has proposed that uncomplicated silicone wristbands could serve as potential passive samplers for monitoring tobacco product exposure in children. Additionally, they have emerged as a noteworthy strategy for epidemiological and intervention studies. The researchers investigated the efficacy of 2 silicone wristbands for sampling personal nicotine levels in children, which were worn for durations of 7 days and 2 days, respectively. To achieve this, they compared the nicotine levels detected by the wristbands to urinary cotinine, a nicotine metabolite, measured in the urine of children exposed to contaminants in tobacco smoke or vapor from electronic cigarettes, as well as those living in nonsmoking households. The nicotine detected in the wristbands worn for 2 days exhibited a high correlation with urinary cotinine concentration, mirroring the correlation found in wristbands worn for 7 days. Moreover, the nicotine amounts recorded in the wristbands for both 2 and 7 days were significantly correlated [27].

Multisensor System: PACT

Five studies used the PACT to monitor tobacco smoke exposure (Table 2). The PACT is a comprehensive system composed of various sensor modalities [2,28-31]. Its primary objective is to track smoking episodes by detecting hand-to-mouth gestures that precede smoke inhalations. The PACT system comprises several components, including a chest module, a wrist or forearm band, an instrumented lighter, and a data logger. Specifically, the PACT system consists of the following elements. First, wearable respiratory inductance plethysmograph (RIP) sensors that are mounted in abdominal and thoracic bands. These sensors capture changes in breath volume, which are indicative of the expansion and contraction of the subject's lungs. Second, a radio frequency (RF) proximity sensor that is used to detect hand-to-mouth gestures. It consists of a transmitter positioned on the wrist and a receiver positioned on the chest. This sensor records the proximity of the hand to the mouth during smoking episodes. Third, a portable data logger that captures and stores the signals from the RIP sensors and RF proximity sensors. Additionally, the PACT system includes a self-report button that allows users to manually register each smoking event [2,32]. This feature enables users to input and record their smoking activities within the PACT system, providing an additional means of tracking and monitoring their smoking behavior [2,32].

Table 2. Studies exploring the Personal Automatic Cigarette Tracker system.

Study	Country	Type of wearable	Application	Sensor modality	Accuracy	Data availability	Autonomous/integrated
Lopez-Meyer et al [29], 2013	United States	Personal Automatic Cigarette Tracker (PACT) system that includes: thoracic, abdominal, and wrist bands; a chest receiver; a portable plethysmograph; and a data logger	To describe the development of a noninvasive wearable sensor system	Hand-to-mouth gestures and breathing	Precision: 87%; recall: 80%	Researcher	Autonomous data logger unit
Lopez-Meyer et al [30], 2012	United States	PACT system that includes: thoracic, abdominal, and wrist bands; a chest receiver; a portable plethysmograph; and a data logger	To apply a machine learning model for identifying cigarette smoke inhalations from wearable sensor data	Hand-to-mouth gestures and breathing	Precision: >87%; recall: >80%	Researcher	Autonomous data logger unit
Patil et al [28], 2013	United States	PACT system that includes: thoracic, abdominal, and wrist bands; a chest receiver; a portable plethysmograph; and a data logger	To apply a machine learning model for detecting cigarette smoke inhalations from respiratory signals	Hand-to-mouth gestures and breathing	Accuracy: 80%	Researcher	Autonomous data logger unit
Patil et al [32], 2014	United States	PACT system that includes: thoracic, abdominal, and wrist bands; a chest receiver; a portable plethysmograph; and a data logger	To analyze the factors affecting the output quality of the abdominal and thoracic bands	Hand-to-mouth gestures and breathing	F-score: 94%	Researcher	Autonomous data logger unit
Sazonov et al [31], 2013	United States	PACT system that includes: thoracic, abdominal, and wrist bands; an airflow sensor; a chest receiver; a portable plethysmograph; and a data logger	To describe the prototype of the sensor system and preliminary results of initial testing	Hand-to-mouth gestures, breathing, and oral and nasal airflow	—[a]	Researcher	Autonomous data logger unit

[a]Not applicable.

A validation study found that the accuracy of the classifier depends on the signals recorded, with abdominal breathing and hand gestures playing a significant role in detecting smoke inhalations. Additionally, the authors evaluated the impact of anthropometric measures on the quality of data captured by the PACT system. They suggested that the BMI and posture of individuals may influence the quality of smoking breathing signals [32]. Furthermore, another study demonstrated the feasibility of detecting smoke inhalation using the PACT system, indicating that each individual has unique characteristics in their response during smoking [28].

In the context of the PACT system, a study demonstrating the feasibility of automatically recognizing smoke inhalations was conducted. By applying the SVM algorithm, the authors found that breathing patterns exhibited individual characteristics. Subject-dependent models showed higher precision and recall values compared to subject-independent models [29]. In a further study, the same authors reported the findings of a subject-independent model for detecting smoke inhalations using data collected through the PACT system. In particular, the SVM model achieved high precision and recall values for detecting cigarette smoke inhalations [30].

A laboratory study proposed an intriguing application of the PACT system for reliable monitoring of smoking episodes in real-life settings. The findings revealed that smoking breathing patterns exhibit individual characteristics and display a strong correlation with hand-to-mouth gestures. As a result, the authors suggested that the PACT system can be employed to automatically assess daily smoking habits and evaluate the efficacy of behavioral and pharmacological interventions [31].

Multisensor System: PACT 2.0

Some studies (n=4) introduced the PACT system version 2.0, an enhanced iteration designed for automated real-time monitoring of smoking behavior (Table 3) [33-36]. Interestingly, the PACT 2.0 system eliminates the need for manual input from users as all smoking events are automatically detected and recorded by the sensors. In addition to capturing smoking data, the PACT 2.0 system collects supplementary information on smoking behaviors, including GPS location data and ECG data. It further offers users real-time feedback on their smoking behavior through a smartphone interface. This advanced system comprises a combination of components, including a chest module, a wrist or forearm module, an instrumented lighter, and a dedicated smartphone app.

Table 3. Studies exploring the Personal Automatic Cigarette Tracker 2.0 system.

Study	Country	Type of wearable	Application	Sensor modality	Accuracy	Data availability	Autonomous/integrated
Imtiaz et al [33], 2017	Switzerland	Personal Automatic Cigarette Tracker (PACT) 2.0 system that includes: a wristband, chest band, and smart lighter	To describe and validate a multisensory wearable system for monitoring cigarette smoking behavior	Hand-to-mouth gestures, breathing, lighting events, and heart rate	—[a]	Researcher	Autonomous data logger unit
Imtaiz et al [34], 2019	United States	PACT 2.0 system that includes: 2 cables and adhesive electrodes	To describe a novel method to identify smoking events	Heart rate, breathing, and hand-to-mouth gestures	Sensitivity: 87%; F-score: 79%	Researcher	Autonomous data logger unit
Senyurek et al [35], 2019	United States	PACT 2.0 system that includes: a wristband and smart lighter	To develop a robust sensor-based monitoring solution to detect smoking events	Hand-to-mouth gestures and lighting events	Accuracy: 84%; F-score: 91%	User and researcher	Integrated with a smartphone app
Senyurek et al [36], 2019	United States	PACT 2.0 system that includes: a wristband and smart lighter	To describe a novel method to identify smoking events	Hand-to-mouth gestures and lighting events	Accuracy: 84%; F-score: 91%	User and researcher	Integrated with a smartphone app

[a]Not applicable.

The chest module of the PACT 2.0 system captures various types of data, including breathing patterns recorded by inductive and bioimpedance respiratory sensors, cardiac activity measured by an ECG sensor, chest movement monitored by a 3-axis accelerometer, hand-to-mouth proximity detected by an RF receiver, and geospatial information obtained through a GPS receiver. On the other hand, the hand module records hand-to-mouth gestures using an inertial measurement unit (IMU) integrated with an RF transmitter. Additionally, the hand module serves as a pedometer, measuring the user's steps. The instrumented lighter within the PACT system is capable of detecting when the user is lighting a cigarette, as well as monitoring the smoking process and detecting when the cigarette is extinguished. To further enhance the user experience, the system is accompanied by a smartphone app that offers real-time feedback on smoking behavior. This includes information, such as the number of cigarettes smoked, the timing of each smoking event, and the associated location [2].

In a study conducted on a sample of 40 smokers in real-life settings, the PACT 2.0 system was developed and validated for monitoring cigarette smoking. The system demonstrated high acceptability and reliability, serving as an effective platform for detecting smoking behaviors [33]. In another investigation, the authors put forth changes in heart rate, along with breathing signals and body motion, as specific indicators of cigarette smoking, by employing the chest module of the PACT 2.0 system for this purpose. Utilizing an SVM model, they successfully developed an automated detection system for smoking events, achieving a high level of accuracy [34].

In another study, a combination of an instrumented lighter and a wrist IMU from the PACT 2.0 system was used in a group of smokers. The results indicated that integrating the IMU and instrumented lighter holds potential for studying smoking behavior in natural settings, resulting in higher accuracy values for the SVM classifier [35]. In a subsequent study, the temporal regularity of hand gestures was identified as a novel approach for detecting smoking events using the wrist IMU and PACT 2.0 lighter. Interestingly, this study revealed a high level of regularity in hand-to-mouth gestures during smoking episodes [36].

Multisensor System: AutoSense

In recent advancements, there have been proposals to leverage multiple wearable sensors in order to enhance accuracy, simplify signal detection, and combine various sensor modalities. Notably, 6 studies have put forth the utilization of AutoSense technology to monitor cigarette exposure and offer real-time feedback to individuals (Table 4) [37-42]. This technology employs a combination of wearable sensors that capture physiological signals associated with cardiovascular, respiratory, and thermoregulatory activities.

Table 4. Studies exploring the AutoSense system.

Study	Country	Type of wearable	Application	Sensor modality	Accuracy	Data availability	Autonomous/integrated
Battalio et al [39], 2021	United States	AutoSense system that includes: a chest band, wristbands, and electrocardiogram (ECG) electrodes	To investigate whether the delivery of a prompt could perform stress management and smoking behaviors	Hearth rate, breathing, and hand-to-mouth gestures	—[a]	User and researcher	Integrated with a smartphone
Chatterjee et al [41], 2016	United States	AutoSense system that includes: a chest band, wristbands, and ECG electrodes	To estimate cigarette craving during smoking abstinence	Hearth rate, breathing, and hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone
Chatterjee et al [40], 2020	United States	AutoSense system that includes: a chest band, wristbands, and ECG electrodes	To automatically detect smoking "opportunity context"	Hearth rate, breathing, and hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone
Hernandez et al [38], 2021	United States	AutoSense system that includes: a chest band, wristbands, and ECG electrodes	To deliver mindfulness-based strategies in real-time among individuals attempting to quit smoking	Hearth rate, breathing, and hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone
Nakajima et al [37], 2020	United States	AutoSense system that includes: a chest band, wristbands, and ECG electrodes	To examine relationships between stress and smoking behavior and lapse among smokers motivated to quit smoking	Hearth rate, breathing, and hand-to-mouth gestures	Sensitivity: 80%	User	Integrated with a smartphone
Saleheen et al [42], 2015	United States	AutoSense system that includes: a chest band, wristbands, and ECG electrodes	To propose and evaluate a new model for detecting a smoking lapse	Hearth rate, breathing, and hand-to-mouth gestures	—	User and researcher	Integrated with a smartphone

[a]Not applicable.

AutoSense integrates various wearable sensors, including (1) a chest band equipped with a RIF sensor to capture respiration patterns and lung volume; (2) two chest ECG electrodes to measure electrical heart activity; and (3) inertial sensors placed on each wrist to detect movement patterns, hand-to-mouth gestures, and changes in body posture. All sensors continuously transmitted the collected data to a mobile phone for analysis and monitoring [2,42].

In a noteworthy study, the use of AutoSense technology was explored to identify stress states (cStress) and to predict first lapse smoking episodes (puffMarker) during a clinical study of smoking cessation. These findings suggested that heart rate and cStress could serve as useful predictors of smoking lapse [37]. Furthermore, this scoping review included a protocol that focused on recruiting motivated individuals who wanted to quit smoking. The protocol outlined a microrandomized controlled trial that would utilize the AutoSense system to deliver mindfulness strategies during the quit smoking attempt [38]. Another trial conducted on 75 smokers who expressed a desire to quit smoking and wore the AutoSense system, provided valuable insights for enhancing just-in-time stress management interventions aimed at preventing smoking relapse [39].

In this scenario, another notable study used data collected by the AutoSense system to identify common contexts of smoking "opportunity" (eg, smoking lapse, overeating or binge drinking, etc), which can either discourage or encourage individuals from engaging in adverse daily-life behaviors [40]. In a related study, the AutoSense system was employed to investigate the phenomenon of cigarette craving during smoking abstinence. Interestingly, individuals who reported high cravings experienced higher levels of stress during the hours of the day when the craving was elevated, compared to those with low cravings [41].

Moreover, a research group proposed the application of the AutoSense system in a population of abstinent smokers to detect the occurrence of a first lapse. By using an SVM classifier, the authors demonstrated the ability to detect the timing of the first lapse in smoking cessation within real-life settings [42].

Other Strategies

In our scoping review, we identified 6 studies that proposed alternative sensor modalities for the detection of smoking behavior (Table 5). One intriguing approach involves leveraging the distinct acoustic characteristics of smoking breaths, which differ from those of nonsmoking breaths. This opens up the potential for utilizing specialized sensors to gain novel insights into assessing smoking in real-life situations. To illustrate, a study explored the use of a wearable acoustic sensor designed to capture smoke-related sounds. The sensor, consisting of a microphone attached to the throat using an adhesive, was employed to record breath sounds. The authors further developed

an algorithm capable of automatically distinguishing between smoking and nonsmoking breaths, offering a promising advancement in smoking detection [43].

Table 5. Studies proposing alternative strategies for the detection of smoking behavior.

Study	Country	Type of wearable	Application	Sensor modality	Accuracy	Data availability	Autonomous/integrated
Cheng et al [44], 2019	China	Surface acoustic wave (SAW) sensor	To develop a sensor to absorb ambient tobacco markers	Gas	—[a]	Researcher	Autonomous
Echebarria et al [43], 2017	United Kingdom	Adhesive microphone	To monitor the acoustic properties of smoking breaths	Breathing acoustic signals	Sensitivity: >70%; specificity: >90%	Researcher	Autonomous
Gurtner et al [45], 2018	New Zealand	Wearable camera	To monitor children's exposure to smoking	Images	—	Researcher	Autonomous
Imtiaz et al [46], 2020	United States	Wearable camera–based sensor	To capture images of cigarette smoking episodes	Images	—	User and researcher	Integrated with a smartphone app
Qiao et al [47], 2019	China	Photoacoustic spectroscopy (PAS)-based carbon dioxide (CO_2) sensor	To demonstrate the applicability of a PAS sensor	Gas	—	—	Autonomous
Rahman et al [48], 2022	Australia	Chemoresistive sensor	To demonstrate the effectiveness of a sensor for nicotine detection	Gas	—	User and researcher	Integrated with a smart electronic device

[a]Not applicable.

With recent advancements in computer vision, there is an opportunity to explore novel approaches using images and video analysis for the detection of smoking episodes. This emerging field offers promising instruments to complement existing methods. Thus, a wearable camera for capturing various aspects of cigarette smoking behaviors (ie, smoking actions, smoking environment, and social interactions) was developed and tested. In this regard, the authors determined that positioning the camera on the eyeglass temple yielded the best results in terms of capturing images related to cigarette smoking while minimizing image blurriness across different body locations [46]. In a similar vein, some authors evaluated the extent and nature of the exposure of children living in households with a smoker, using image data. In this study, children wore wearable cameras around their necks for 4 days, which automatically took pictures every 7 seconds. The wearable camera proposed appears to have high utility for studying health behaviors in private spaces, including smoking episodes both in private spaces (ie, home and cars) and outdoors [45]. Interestingly, in a separate study, a surface acoustic wave (SAW) sensor specifically was designed to detect cigarette smoke in real time by adsorbing ambient tobacco markers [44]. Finally, another study demonstrated the effectiveness of a highly sensitive photoacoustic spectroscopy–based CO_2 trace gas sensor. This sensor holds the potential for detecting carbon dioxide (CO_2) levels resulting from cigarette smoking, among other real-world applications [47]. These advancements in sensor technologies provide promising avenues for further research in the detection and analysis of smoking behaviors.

Another study proposed a chemoresistive sensor for real-time monitoring of nicotine vapor from e-cigarettes in the air. In particular, the authors proposed a vanadium dioxide (VO_2)-based nicotine sensor integrated with an epidermal near-field communication (NFC) interface that enables battery-free operation and data transmission to smart electronic devices to record and store sensor data to detect nicotine at ambient concentrations [48].

Discussion

Principal Results and Comparison With Prior Work

The real-time monitoring of smoking behavior presents a significant challenge for public health research and the development of effective smoking-cessation interventions. However, advancements in mobile health (mHealth) technologies offer promising opportunities to address this challenge [13,16]. Through our scoping review, we have identified 37 studies published between 2012 and 2024 (March 10) that explore the use of wearable devices for assessing tobacco smoke exposure. These studies highlight the ongoing evolution of research in this field. Currently, research in the field predominantly focuses on the utilization of single or combined sensors to detect behaviors associated with smoking episodes. The inclusion of wearable sensors, particularly those integrated into elastic bands, has emerged as a noninvasive and mobile approach that enables continuous monitoring of smoking exposures. These advancements in sensor technology offer valuable insights for the development of targeted preventive measures and policies. In general, traditional smoking cessation programs, whether delivered in-person or via a smartphone, have proven efficacy but are constrained in their reach and utilization. In contrast, digital solutions exhibit greater potential for widespread accessibility, and there is evidence suggesting

their efficacy. However, only a limited number of scientifically validated apps have been developed for commercial purposes, limiting their full potential for reach. Moreover, most digital solutions for smoking cessation have predominantly relied on a single form of technology, such as text messaging or an app. Mobile apps hold great promise in supporting patients in health care and promoting healthy behavioral changes. However, the success of these apps is largely determined by their features, influencing patients' attitudes toward their use. In this context, the varied range of wearable sensors and studies highlighted in our scoping review have the potential to provide individuals with valuable approaches that fulfill both educational and motivational purposes. Furthermore, these wearable sensors can be smoothly integrated into evidence-based smoking cessation initiatives, thereby improving the overall effectiveness of such programs and encouraging a heightened interest in participating in cessation programs [49,50].

The studies included in our analysis demonstrate the efficacy of wearable sensors in monitoring smoking exposure. These sensors, deployed in various wearable bands, facilitate the detection of hand-to-mouth gestures, arm movements, and smoke inhalation during smoking episodes [12-14]. These sensors have also been employed to classify presmoking episodes [15] and evaluate temporal and emotional patterns associated with smoking behaviors [16]. Of particular interest is the use of a wearable forearm band, which allows for the monitoring of nicotine levels in sweat. This novel approach addresses the limitations of existing smoke monitoring devices and provides the potential capability to assess tobacco smoke exposures [11].

Overall, our findings highlight the ongoing challenges in achieving a personalized assessment of tobacco smoke for individuals in real-life settings. This suggests the need for further efforts to implement the proposed applications and enable a more precise evaluation of tobacco smoke exposure. It is crucial to consider personal factors, such as gender, age, and BMI, as well as contextual information including location, activity, and social context, in order to deeply characterize smoking patterns.

The focus of research in this field is shifting toward the utilization of complex systems comprising various types of sensors. For example, the integration of accelerometers and gyroscope sensors in a wearable smartwatch, along with wrist and chest bands, has demonstrated potential in detecting both active and passive tobacco smoking [17,18]. Some studies have explored noninvasive wearable devices that continuously collect real-time data on multiple physiological and environmental parameters, such as breathing patterns, chest movement, hand-to-mouth gestures, and lighting events. Among these innovative systems, the PACT system stands out, incorporating a comprehensive array of sensor modalities. This includes a chest module, a wrist or forearm band, an instrumented lighter, and a data logger. The findings from these studies have indicated that anthropometric measures of individuals can impact the signals collected by the PACT system. Additionally, they have suggested that breathing patterns show individual characteristics and are closely associated with hand-to-mouth gestures [28,29,31,32].

Several studies have introduced an advanced version of the PACT system, known as PACT 2.0, which offers several advantages and additional features. This upgraded system collects additional information, including GPS data, bioimpedance data, and heart activity, providing users with real-time feedback through a mobile app. Remarkably, the PACT 2.0 system has undergone development and validation to ensure its effectiveness in monitoring tobacco smoking in real-life situations, achieving a high level of acceptability [33]. Furthermore, it has been found that heart rate parameters can serve as an additional indicator of cigarette smoking, adding to the system's capabilities [34]. The implementation of the PACT 2.0 system has yielded promising results among smokers, presenting opportunities for various applications in the field of public health research [35]. Notably, data collected through the PACT 2.0 system have revealed that hand-to-mouth gestures exhibit a high degree of regularity during smoking events. This finding suggests that the system can serve as a valuable tool for accurately identifying smoking episodes amidst various daily activities [36].

One notable advantage of these approaches is their ability to monitor without relying on self-reporting by smokers. This eliminates potential biases caused by underreporting. Moreover, the use of the PACT system only requires the cooperation of subjects in wearing the system, offering the potential to capture smoke exposure parameters that are not accessible through other methods. In addition, the information recorded by the PACT system can enhance our understanding of the health consequences associated with smoke exposure by evaluating the relation between biomarkers (eg, blood levels of CO_2 and cotinine) and individual smoking behaviors. The PACT system also provides a unique advantage in its ability to capture comprehensive data on the complete breathing cycle during smoking, including puff, smoke inhalation, smoking apnea, and smoke exhalation. This is in contrast to traditional puff topography devices that only measure and analyze the air drawn through a cigarette during a puff. This comprehensive data can offer valuable insights into smoking behavior and its effects on health outcomes.

However, it is important to acknowledge some limitations of these systems. One such limitation is the relatively large size of the sensors, which are typically mounted on garments or vests. To overcome this limitation, there is a need to significantly miniaturize the sensors and integrate them into a fully wearable device, ensuring greater comfort and convenience for users. Overall, while these systems show promise in improving the monitoring of smoke exposure, it is essential to address the limitations by developing more compact and integrated sensor solutions for enhanced usability and effectiveness.

In this context, the AutoSense system emerges as a valuable combination that can capture a range of information, including heart rate, respiration, skin conductance, and physical activity. Its versatility opens up promising applications in various settings such as health care, workplaces, and communities. AutoSense not only enables the collection of physiological measurements but also offers particular potential in assessing stress response.

The real-time transmission of data to a smartphone allows for the monitoring of physiological responses to real-life stressors and the continuous estimation of stress levels. This capability positions AutoSense as a valuable tool for evaluating behaviors associated with stress, such as drinking, smoking, physical activity, movement patterns, and conversations. Furthermore, it provides insights into physical, behavioral, and mental health conditions. Looking ahead, ongoing research in this field holds the promise of developing effective prevention and intervention strategies. The ability to deliver these strategies directly on smartphones aligns with the vision of mHealth, empowering individuals to proactively manage their health and well-being. By harnessing the potential of AutoSense, we can anticipate advancements that contribute to improved health outcomes and enhanced quality of life.

Some authors thoroughly discussed user behavior, comfort levels, and compliance with the use of wearable sensors in real-world settings [8,13,33,37,46]. To address this, brief acceptability questionnaires were administered to gauge users' personal experiences with the wearable sensors. For instance, the results from these assessments indicated a strong inclination among participants to continue wearing the wearable camera for any subsequent multiday experiments [46]. This positive sentiment also encompassed other wearable accessories, such as elastic bands [13], and the PACT 2.0 system [33], highlighting that these devices were not only comfortable but also considered acceptable for prolonged use beyond the laboratory setting. Participants expressed contentment with the ease of wear for these technologies over extended periods.

As denoted in our work, there has been significant interest in sensors as a potential solution to address challenges related to the detection of tobacco smoke exposures. However, it is essential to highlight that no single wearable method has demonstrated 100% accuracy in detecting smoking events under all circumstances, with certain technologies that may be effective in specific environments and others that may not yield satisfactory results in the same context. To address this issue, it is evident that no single device currently offers a complete and accurate solution. Moreover, sensor responses are often influenced by ambient factors, such as motion and clothing. Although we described various single-sensor and multisensor approaches, our work denoted a lack of comparative analyses of their respective efficacies. To date, indeed, there has been no comprehensive survey or comparison study conducted on these approaches, elucidating the strengths and limitations of sensing technologies and their applicability in real-world settings. Furthermore, there has been limited evaluation of the underlying detection algorithms and their comparative accuracy.

In our research, only the study conducted by Imtiaz et al [46] addressed specific ethical considerations related to wearable camera research. They recommended that researchers involved in such studies actively protect the rights, privacy, dignity, and well-being of the individuals being studied. Emphasizing the importance of voluntary informed consent, research efforts should strive to ensure that participants willingly agree to take part. Additionally, research participants should be informed about the level of anonymity and confidentiality guaranteed during the publication and dissemination of findings, along with the potential for data reuse. To adhere to these ethical principles, participants throughout the study were instructed to remove the sensor system in situations where privacy was expected, such as restrooms, during activities causing discomfort (like sports and water-related events), and upon requests by individuals in their vicinity [46].

In general, wearable sensors described in our work are commonly characterized by their lightweight, mobile, and convenient design. However, as of today, there is a notable gap in the literature regarding a comprehensive analysis of their cost-effectiveness. While the advantages of wearables, such as ease of use and adaptability to various settings, are frequently acknowledged, there remains a critical need for research that delves into the economic aspects of implementing these technologies. Understanding the cost-effectiveness of wearable sensors is crucial for widespread adoption and integration into various domains, including health care and environmental monitoring.

Future studies could explore not only the initial investment and production costs but also the long-term economic benefits, considering factors such as durability, maintenance, and the potential impact on health outcomes or performance improvements. A thorough cost-effectiveness analysis would provide valuable insights for decision-makers, researchers, and industries looking to leverage wearable sensor technologies while considering the economic implications of their adoption.

Limitations

Our findings indicate that wearable devices for detecting cigarette smoking and assessing smoke exposure are still in the early stage of development and require further advancements. Therefore, it is crucial to acknowledge certain limitations when considering the implications of our review. First, the included studies evaluated various behavioral and physiological characteristics, such as hand gestures, breathing, and lighting, using wearable sensors during smoking episodes. However, there is a need for future research to explore the integration of wearable chemical sensors for detecting smoking and measuring exposure to both traditional and electronic cigarette smoke.

Second, the included studies did not extensively explore how external environmental factors might impact the accuracy and reliability of these wearable sensors. A thorough investigation into how factors, such as ambient smoke, weather conditions, and other pollutants, could influence sensor readings would provide valuable insights. Third, it is important to note that our review primarily focused on wearable device development and validation, involving a limited number of participants, which included both smokers and nonsmokers. Fourth, the considerable heterogeneity between the studies precluded the possibility of conducting a meta-analytical approach, thereby hindering the ability to synthesize data, as well as to offer a quantitative perspective on the efficacy or cost-effectiveness of the wearable sensors explored. On the one hand, this represents a limitation of existing studies, but on the other hand, it represents an important perspective for future research.

Finally, the potential for biases in the selection of studies, which could impact the representativeness and generalizability of the

obtained results, needs to be considered. Addressing these biases could enhance the overall robustness and reliability of our scoping review's conclusions.

Conclusions

Our scoping review highlights existing evidence about single-sensor or multisensor wearables in the context of tobacco smoke detection. While their potential is evident, further advancements and investigations are necessary to deeply evaluate their full potential and assist both individuals and health care professionals in addressing smoking-related health issues, as well as designing effective public health strategies.

Overall, wearable sensors may hold great promise in assisting individuals in their journey to quit smoking by offering real-time feedback on their exposures and smoking behaviors, empowering them to make informed decisions and take control of their habits. Through our scoping review, we have identified both the challenges and possibilities associated with wearable devices, which can serve as valuable guidance for future research endeavors. By addressing the identified pitfalls and exploring the potential avenues of improvement, wearable devices may become even more valuable tools in supporting smoking cessation efforts. In this scenario, ongoing research is crucial to refine and optimize these devices, ensuring their practicality and reliability in real-world settings.

Indeed, further research is needed to enhance the accuracy and usability of these devices, enabling researchers and health care professionals to gain a better understanding of the health implications related to smoking and to develop effective preventive interventions. In addition, future studies should examine factors such as comfort, adherence, and acceptability of wearable sensors. In fact, while many wearable sensors have been validated and tested in controlled experimental settings, there is a scarcity of research on their accuracy and applicability in real-life contexts.

Abstract

Background: Personal safety is a widespread public health issue that affects people of all demographics. There is a growing interest in the use of mobile apps for enhancing personal safety, particularly for children and youth at risk, who are among the most vulnerable groups in society.

Objective: This study aims to explore what is known about the use of mobile apps for personal safety among children and youth identified to be "at risk."

Methods: A scoping review following published methodological guidelines was conducted. In total, 5 databases (Scopus, SocINDEX, PsycINFO, Compendex, and Inspec Archive) were searched for relevant scholarly articles published between January 2005 and October 2023. The gray literature was searched using Google and Google Scholar search engines. The results were reported using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. For summarizing the features and users' experiences of the apps, a published framework for evaluating the quality of mobile health apps for youth was used.

Results: A total of 1986 articles were identified, and 41 (2.1%) were included in the review. Nine personal safety apps were captured and categorized into 4 groups based on the goals of the apps, as follows: dating and sexual violence prevention (n=4, 44% of apps), bullying and school violence prevention (n=2, 22% of apps), self-harm and suicide prevention (n=2, 22% of apps), and homeless youth support (n=1, 11% of apps). Of the 41 articles, 25 (61%) provided data solely on app descriptions and features, while the remaining 16 (39%) articles provided data on app evaluations and descriptions. Outcomes focused on app engagement, users' experiences, and effectiveness. Four articles reported on app use, 3 (75%) of which reported relatively high app use. Data on users' experience were obtained from 13 studies. In general, participants found the app features to be easy to use and useful as educational resources and personal safety tools. Most of the views were positive. Negative perceptions included redundancy of app features and a lack of usefulness. Five apps were evaluated for effectiveness (n=2, 40% dating and sexual violence prevention; n=2, 40% self-harm and suicide prevention; and n=1, 20% bullying and school violence prevention) and were all associated with a statistically significant reduction (P=.001 to .048) in harm or risk to participants at the 95% CI.

Conclusions: Although many personal safety apps are available, few studies have specifically evaluated those designed for youth. However, the evidence suggests that mobile safety apps generally appear to be beneficial for reducing harm to at-risk children and youth without any associated adverse events. Recommendations for future research have been made to strengthen the evidence and increase the availability of effective personal safety apps for children and youth.

Introduction

Background

Interpersonal violence is a global public health and human rights challenge, having effects at the family, community, and national levels, with impacts reverberating across generations [1]. Physical violence, psychological violence, verbal abuse, and sexual assault or harassment are common forms of interpersonal violence [2]. More specific examples are child abuse, dating violence, domestic violence, human trafficking, stalking, hazing, bullying, and older person abuse [3]. It is a leading cause of not only physical and psychological harm but also early mortality and is therefore a significant threat to personal safety [1,4]. Interpersonal violence, therefore, has considerable societal consequences, including significant economic burden due to health care provision, loss of productivity, criminal justice involvement, and antiviolence campaigns and interventions [4,5]. The total economic cost of violence has been estimated to be in the billions for many countries worldwide, including Canada [6,7], the United States [8], and the United Kingdom [5,9].

While every age demographic experiences interpersonal violence, children and youth constitute a particularly important sector. This is because such violence, which can reoccur throughout an individual's life, has enduring consequences, increasing one's lifelong vulnerability to a myriad of emotional and physical health problems and negative health behaviors such as substance misuse and risky sexual behaviors [1,10,11]. In 2020, it was estimated that 1 billion children (1 out of every 2 children worldwide) experience some form of violence each year. When aggregated across billions of people, the effects of violence against children can have detrimental effects on economic development [12]. It has been reported that individuals between 12 and 34 years of age are at the highest risk for sexual assault [13]. In a study involving 8629 participants in the United States, violent childhood experiences were reported to double the risk of experiencing intimate partner violence (IPV) in adulthood for women and double the risk of IPV perpetration in men [14]. Studies such as this show that the impacts on younger populations can be more devastating, affecting individuals, families, communities, and society as a whole. It has been shown that children and youth are among the sectors of society that are at greatest risk of violence, sexual abuse, and going missing [15,16]. Among other factors, youth and young adults are at increased risk of victimization, as they are more likely to be single, have lower income, and engage to greater extents in nighttime activities [4].

In addition to harm from older adults, children and youth are also at risk from their peers through incidents such as dating violence, sexual violence, and bullying [10,17,18]. A Youth Risk Behavior Survey conducted in 2019 among high school students in the United States revealed that 25% of students reported bullying victimization and approximately 12% reported dating violence (physical or sexual) [10]. Furthermore, interpersonal violence is one of the main causes of death among adolescents and young adults in most countries worldwide [1].

Youth personal safety is not only impacted by interpersonal violence but also by the risk of self-harm. Mental health issues such as depression, anxiety, and suicide pose significant threats to the lives and well-being of individuals between 10 and 24 years of age worldwide [19]. The World Health Organization describes children as persons aged <18 years and youth as persons between 15 and 24 years of age [19,20]. With people aged <25 years accounting for 42% of the world population and being among the most vulnerable [21], measures to protect their lives and well-being are of utmost importance.

Addressing the issue of violence requires a multifaceted approach involving various levels of society. Mobile technology greatly expands the possible range of available options for addressing these issues [22]. Increasingly, health and human service organizations, policy makers, as well as practitioners across the world have recognized the potential of smartphone apps in helping to address social issues including interpersonal violence and mental health issues at both individual and community levels [5]. The global increase in smartphone ownership makes this option even more potentially useful. The number of smartphone users worldwide has continuously increased from approximately 1 billion in 2014 to 4.88 billion in 2024 and is forecast to reach 6.4 billion by 2029 [23]. There were almost 7 billion smartphone mobile network subscriptions worldwide in 2023, and this number is expected to exceed 7.7 billion by 2028 [24]. Smartphone apps are a particularly important avenue for addressing youth's issues, as youth tend to be more open to technological services compared to the more traditional approaches [25]. The prevalence of smartphones among the younger demographic is well known [26], with smartphones being ubiquitous among youth and young adults. As of January 2024, a significant 98% of Gen Z (people born between 1997 and 2012) own a smartphone [27]. In April 2022, a significant 87% of teenagers between 12 and 17 years of age in Canada were using smartphones; half of the children between 7 and 11 years of age and 39% of children between 2 and 6 years of age were reported to use a mobile device [28]. Similarly, in the United States, 88% of teenagers aged between 13 and 18 years owned a smartphone in 2021; among younger kids between 8 and 12 years of age, ownership of tablets (57%) was more prevalent than smartphone ownership (43%) [29].

Widespread access to mobile phones opens up opportunities for their use as tools to mitigate the risk of harm to children and youth, improving outcomes in instances when such incidences occur. There has been a growing interest in the use of mobile apps for enhancing personal safety; however, there is a lack of evidence on the use and effectiveness of such apps that are specifically geared toward protecting children and youth. Most of the literature on mobile apps has been focused on health and fitness [4,30-38]. There are also some studies on personal safety

apps, but most of them either cover a wide age demographic, are focused on sexual violence against women (with no youth focus), or are focused solely on app development with no associated evaluation [5,39-43]. Furthermore, evidence on apps intended for autonomous use by children and youth is lacking in the literature. Ford et al [5] published an overview of smartphone apps available in the United Kingdom. Of the 86 apps included in the study, 52% targeted the general population, 26% targeted women, and 13% targeted families. None of the studies specifically targeted youth. Nonetheless, that research found that app functionality included providing an alarm (22%), sending alerts to predesignated contacts (71%), providing evidence capture (34%), and offering educational information (26%). More than 70% of apps had a user rating of at least 4 out of 5. Key aspects included positive consequences of app use, technical issues, dissatisfaction with the financial cost of some features, and ethical issues [5]. The effectiveness of the apps was not evaluated.

Most of the literature on personal safety apps is focused on preventing sexual violence or domestic violence, particularly against women. This is not surprising, considering the high prevalence of sexual violence victimization in women globally. For example, in Canada, the rate of IPV was >3 times higher among women and girls compared to men and boys in 2022 [15]. Doria et al [39] identified 3 themes in their review on women's experience with safety apps: security, accessibility, and knowledge. Although there was no evaluation of effectiveness, a common thread among most of the app users was their view that the apps were acceptable, user-friendly, and useful [15]. The review highlighted the potential of smartphone interventions to become a valuable tool for preventing sexual violence in women. Sumra et al [44] conducted a systematic review that included 136 smartphone apps that targeted domestic violence prevention. They found that over two-thirds of the apps (71%) were released between 2020 and 2022, with almost a half of them (46%) being from northeast America. Five app categories were described: emergency assistance (44%), avoidance (21%), informative (21%), legal information (7%), and self-assessment (5%) [44], which were similar to those identified by other researchers [45]. Unique features among the apps included geo-fences, shake-based alert, accelerometer-based alert, alert auto cancelation, anonymous communication, and data encryption [44]. None of the apps had automated alerts or used artificial intelligence to help potential survivors. There was no focus on youth and no evaluation of effectiveness. A 2016 systematic app search for intimate partner and sexual violence prevention and response apps found that, of the 132 unique apps identified, 66% targeted adults, 24% targeted the general population, 27% targeted young adults, 10% targeted teens, and 2% targeted children aged <12 years. However, the app categories were not mutually exclusive, and the specific apps were not identified. As a result, it is impossible to determine what proportion of the apps specifically targeted the younger demographic or to identify them [13]. The apps were found to vary greatly in quality, and sharing information or resources was the primary purpose of most of the apps (76%).

Draughon Moret et al [13], who were experienced forensic examiners, reported that there were only a few apps that they would use as clinicians or recommend to their patients after a physical or sexual assault. The apps focused largely on education and information sharing; therefore, it was thought that they may not successfully meet their desired goal. In addition, they experienced difficulty in finding the apps, as searches for violence prevention and response apps yielded many disturbing apps (zombie-killing games, dating sims, etc), which could potentially retraumatize patients. Furthermore, there was a lack of quality and evidence base among the apps [13].

Reviews focused on sexual violence or domestic violence prevention have found that most of the apps addressed emergencies, with a large proportion of apps focusing on avoidance or education [44-46]. They concluded that further research on app development should focus on automation, making better use of artificial intelligence, speech recognition, and pitch detection to assist in live analysis of the situation and for accurately generating emergency alerts [44]. Other recommendations for further research include a greater focus on app efficacy, sustainability, and data security [45].

Despite widespread access to mobile apps and the growing interest in their use for enhancing personal safety, there is a lack of evidence on the use and effectiveness of such apps that are specifically geared toward protecting children and youth.

Objective

This review aimed to understand what is known about the use of mobile apps for personal safety among at-risk children and youth.

Methods

Overview

A scoping review was conducted following published methodological guidelines by Arksey and O'Malley [47]. They comprise the following 6 steps: identifying the research question; consulting with stakeholders (an optional step in the framework); identifying relevant studies; selecting studies; charting the data; and collating, summarizing, and reporting the results [47]. A scoping review was conducted, as this type of review is particularly useful for mapping the scope, range, and character of the literature and identifying any potential gaps in the body of knowledge on a given topic [48]. Multimedia Appendix 1 [49] provides the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist [49]. No protocol for this review was previously published. The term "at-risk children and youth" refers to those who are in physical or mental danger [50].

The main categories of the theoretical framework developed by Jeminiwa et al [51] for evaluating the quality of mobile health (mHealth) apps for adolescent users were used to provide an overview of app features. The framework has 5 categories (technical quality; engagement; support system; autonomy; and safety, privacy, and trust). However, the authors of this paper modified it to include "esthetics" (included as a subcategory of "engagement" in the framework by Jeminiwa et al [51]) as a distinct category to cover layout, graphics, and visual appeal. In addition, a "subjective quality" category was added to cover

concepts such as usefulness and recommendability. The modifications were guided by the features of the validated Mobile App Rating Scale [52,53], and "personal safety" was also added by the authors to capture features such as self-tracking and a panic button (Multimedia Appendix 2 [51,52]).

Identifying the Research Question

The research question was as follows: "What is known about the use of mobile apps to ensure personal safety among at-risk children and youth?"

Consulting With Stakeholders

To inform the research, a police service division in Alberta planning to develop a personal safety app for at-risk children and youth provided information on important issues to consider. Topics such as app features, use, users' perceptions, and effectiveness were discussed. Issues related to privacy and security were also discussed. A computing science professor from the University of Saskatchewan with expertise in the development of apps also offered insights into key aspects of personal safety apps for youth.

Identifying Relevant Studies

Both peer-reviewed and gray literature sources were included in this review. As non–peer-reviewed sources (eg, reports and app-specific websites) can provide valuable insights and perspectives that may not be captured solely through peer-reviewed literature, these sources were included. In particular, they provided useful information on the characteristics of the various apps. With support from an experienced research librarian, a search strategy for scholarly literature was developed and tested iteratively. In total, 5 databases were searched: Scopus, SocIndex (EBSCO platform), PsycINFO (Ovid platform), Compendex, and Inspec Archive (both Engineering Village platforms). The searches were performed from July 19 to July 30, 2023, using combinations of relevant terms, such as "at-risk," "youth," "children," "safety," and "mobile application." Keywords included "homeless teenagers," "runaway children," "abandoned children," "street youth," "school-aged," "Indigenous youth," "poor children," "juvenile offenders," "LGBTQ+," "sexually abused teenagers," "domestic violence," "protect," "prevent," "safety app," "mobile-based," and "smartphone." Adjustments to the search strategy across different databases were made due to database-specific indexing or features. For example, both APA PsycINFO (Ovid platform) and SocINDEX (Ebsco platform) include extensive but differing controlled vocabularies for children who are abused, fostered, homeless, or neglected and their care. APA PsycINFO uses terms such as "foster care," "child neglect," and "protective services," whereas SocINDEX uses "foster home care," "child abuse," and "child protection services." Where possible, equivalent free-text terms were used across all the databases. Syntax was adjusted according to the specifications of each database or platform. All citations were imported into EndNote version 9.3.3 (Clarivate Analytics, Inc), and duplicates were removed. For the gray literature, Google and Google Scholar were searched using similar terms to those applied to the peer-reviewed strategy.

Study Selection

Included articles satisfied the following criteria: (1) participants were at-risk children or youth; (2) the article focused on mobile apps designed for personal safety; (3) the children and youth had autonomous control of the app; (4) the article was published between 2005 and 2023, as the use of mobile apps for safety applications has been fairly recent; and (5) the evaluation study assessed app users' experience, app engagement, or app impact. Articles intended to be used for characterizing the apps did not need to be evaluation studies. As the terms "children" and "youth" are variously described in the literature, no strict age limits were applied for inclusion; rather, if the target or study population was described using descriptors for children and youth such as "teenagers," "adolescents," or "college students," the study was included. Due to the paucity of available articles, studies focused on participants not strictly considered "at risk" were also included, as long as they focused on children and youth. If ≥1 of the abovementioned criteria were not satisfied for a given app, the articles were excluded. Bullying prevention apps focusing solely on cyberbullying were outside of the scope of this project and were therefore excluded, as were articles not available in English.

For the peer-reviewed literature search, 2 researchers (CB-F and TK) independently screened the titles and abstracts of the identified articles. For quality assurance, a portion of the articles was reviewed by both researchers. Conflicts were resolved through discussion. In cases of disagreement, a third researcher (DM) arbitrated. For the gray literature search, the same 2 researchers systematically searched Google and Google Scholar using similar keywords to those applied to the peer-reviewed search and scanned the first 50 "hits" generated from applying the search terms. Excel software (Microsoft Corporation) was used for data management.

Charting the Data

Information collected from papers was extracted using a standard template. The data extracted included the following elements: goal of app, operating system, date launched, provider or developer, target users, general description, features, app funding, study aim, study type, study period, methods, participants, outcomes measured, findings, facilitators and barriers to app use, app limitations, and conclusions and recommendations. The data extraction tables were piloted and revised as necessary. To ensure consistency in data extraction, CB-F and TK each independently extracted data from a single article and then reviewed each other's work to establish a consistent approach to charting. The researchers met several times during the screening process to ensure a consistent data charting approach.

Collating, Summarizing, and Reporting the Results

The apps were categorized into 4 groups based on app goals and target populations. A descriptive analytical approach was then used to summarize the findings. This involved using common analytical frameworks for summarizing different aspects of the included articles and collecting standard information from each of them [47]. For example, to summarize app features and users' perceptions, a modified version of the

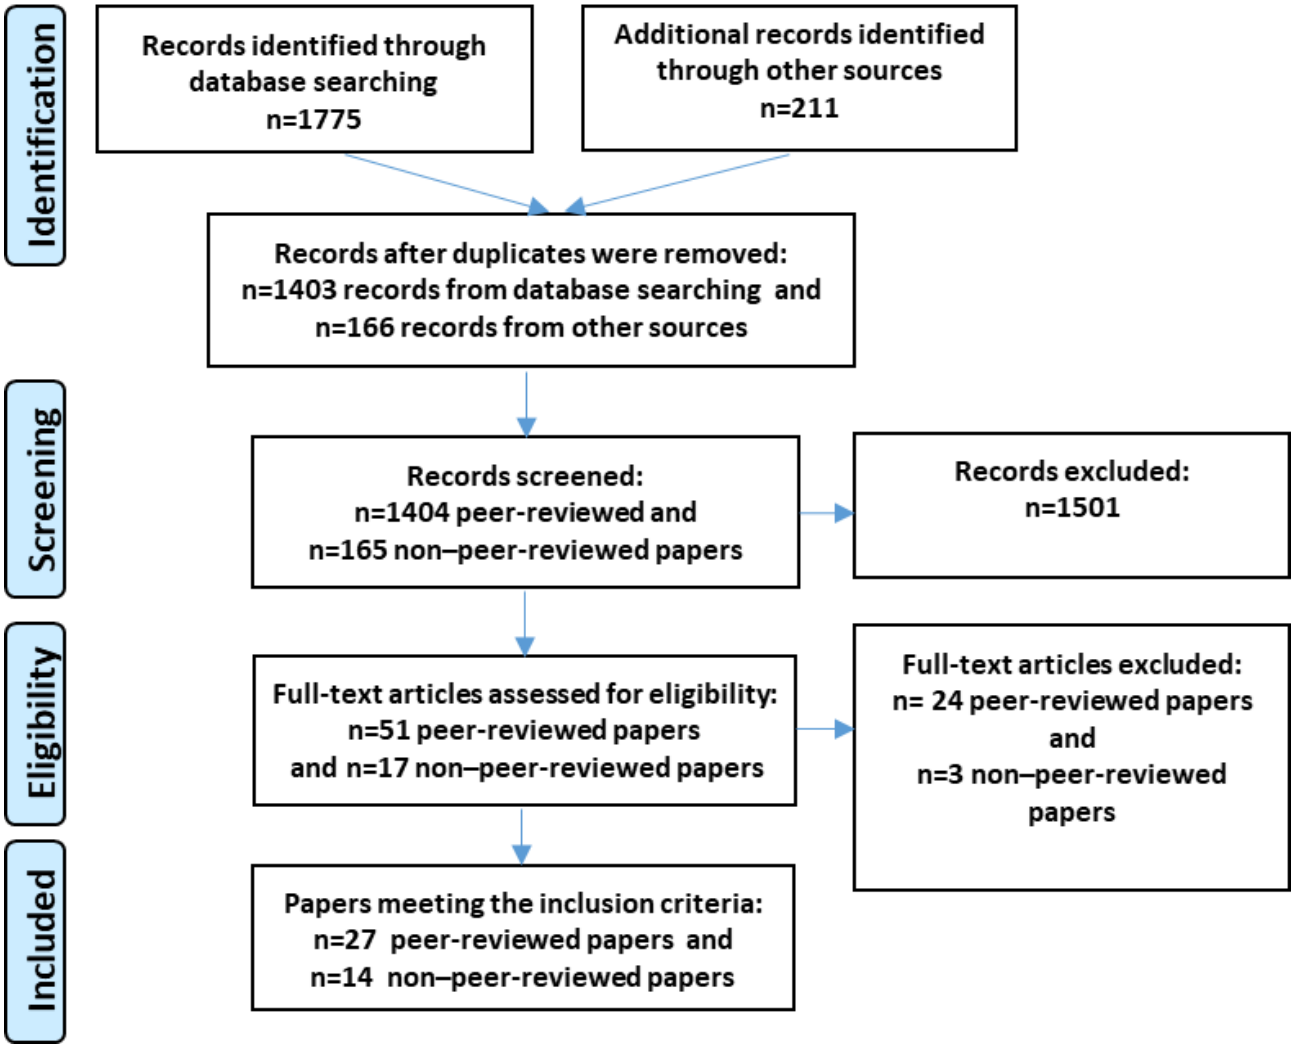
framework developed by Jeminiwa et al [51] was used. For app features, 6 categories were captured: engagement; esthetics; support system; personal safety; autonomy; and safety, privacy, and trust. Four categories were captured for users' perception: engagement; esthetics; safety, privacy, and trust; and subjective quality. Evidence on the effectiveness of the apps was organized by outcomes, such as IPV and other sexual violence, school violence and bullying, and suicide ideation and suicide risk. Data on app evaluation were summarized in Microsoft Excel spreadsheets.

Results

Results of Literature Search

A total of 1986 articles were identified through peer-reviewed (n=1775, 89.37% articles) and gray literature searches (n=211, 10.62% articles). Most of the identified literature on mobile apps primarily focused on health and fitness [4,30-37]. There were also some studies on personal safety apps; however, most either covered a broad or older demographic, focused on sexual violence against women, or solely addressed app development without evaluation [5,38-42]. Consequently, of the 1986 articles, only 68 (3.42%) were eligible for full-text screening. Finally, 41 articles (n=27, 66% peer-reviewed and n=14, 34% non–peer-reviewed) met the inclusion criteria and were included for data extraction. Collectively, these 41 articles provided data on the features and evaluation of 9 apps that met our inclusion criteria. Several studies reported on various aspects or phases of the app development and evaluation process in different articles. For example, for 1 app, acceptability and impact were captured in 2 separate articles [54,55]. The non–peer-reviewed literature primarily provided detailed information on app characterization, including descriptions, features, and functionalities. The results of the screening and selection process are presented in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1).

Figure 1. PRISMA (Preferred Reporting Item for Systematic Reviews and Meta-Analyses) flow diagram of study selection. Additional records identified through other sources include both non–peer-reviewed and peer-reviewed articles. Reasons for exclusion of studies include the following: not focused on children or youth; not focused on personal safety apps; no information on app use, users' perception, or app impact; published before 2005; and non-English.



Basis of App Development and Stakeholder Engagement

All 9 apps identified through the included articles are summarized in Table 1, and further details are provided in Multimedia Appendix 3 [54-91]. In addition to the language used in the respective articles to describe the type of app, the descriptors from the typology of crime prevention apps by Wood et al [56] were also used. For example, some apps were described as decision aid apps, which are apps designed to help individuals in making decisions based on high-quality evidence [56]. The use of a relevant theory as a basis for development was noted for 3 (33%) of the 9 apps: ambivalent sexism theory and romantic love myths for Liad@s (Universitat de València) [57,58], cognitive behavior theory and dialectic behavior therapy for BlueIce (Oxford Health NHS), and acceptance and commitment therapy for iBobbly (Black Dog Institute). In addition, myPlan (Johns Hopkins University School of Nursing) was developed based on literature on empowerment, internet safety decision aid, and safety planning [59]; +FORT (AXEL; University of Montréal) was developed based on a coordinated sequence of 4 mechanisms of action central to problem-solving [60]; and organizations focused on domestic and sexual violence were consulted in the development of uSafeUS (University of New Hampshire) [61]. The development of the YTH Street Connect prototype app (Santa Clara University Frugal Innovation Hub) was based on information obtained from formative research on homeless or unstably housed youth and mHealth apps and in consultation with homeless or unstably housed service providers [62]. Collaborators from multiple sectors were involved in the development of most of the included apps (7/9, 77%). They included universities (7/9, 77%), schools (2/9, 22%), target users (7/9, 77%), parents (3/9, 33%), companies or organizations (3/9, 33%), and mental health professionals (2/9, 22%). In total, 7 (77%) of the 9 apps are available in English only, while 1 (11%) is available in English and French (+FORT) and 1 (11%) is available in Spanish (Liad@s). In total, 6 (66%) of the 9 apps are currently available, 5 (56%) of which may be freely downloaded and 1 app, 1 (11%) is available only by prescription from child mental health services [54,55]. Of the 3 apps that are not currently available, 2 (67%) were simply prototype apps (YTH StreetConnect) [62] and Circle of 6 [Co6] (Youth Tech Health; Kliq) [63]) and 1 (33%; iBobbly) was recently discontinued [92]. On the basis of an official statement of the First Nations team at the Black Dog Institute (iBobbly developers) in New South Wales, Australia, iBobbly was decommissioned in response to evolving community needs, with the focus now being on providing and recommending best-in-market products (email, November 12, 2023).

App Characteristics

The apps were categorized into 4 groups based on app goals and target populations: homeless youth support (1 app), dating and sexual violence prevention (4 apps), bullying and school violence prevention (1 app), and self-harm and suicide prevention (2 apps). A more detailed description is provided in Multimedia Appendix 3. All 9 apps were designed for the autonomous use of youth. They all featured goal-specific educational content and were available on both iOS and Android devices.

Homeless Youth Support

YTH StreetConnect is a decision aid mobile phone app developed in 2016 with the goal of connecting homeless or unstably housed youth in Santa Clara County, California, United States, to health and vital resources [62]. YTH StreetConnect Pro is a companion tablet app for providers who serve these youth [62]. Both are discussed as a single app for the purpose of this review. YTH StreetConnect has features such as a location-based database, interactive mapping, and emergency hotlines. The app helps youth locate services using visual enhancements. Youth have access to sexual health information and weekly health tips via SMS text messaging. YTH StreetConnect Pro features include a referral function and a medical questionnaire to assess clients' homelessness vulnerability and sexual risk [62].

Dating and Sexual Violence Prevention

Four dating and sexual violence prevention apps were identified, 3 (75%) of which were developed in the United States (Co6, myPlan, and USafeUS) and 1 (Liad@s) in Spain [57,61,63,66-68,79,93]. Liad@s targets adolescents, USafeUS targets college or university students, and Co6 and myPlan

target people at risk of sexual violence. Two of the apps have decision aid or personalized action plan features (myPlan and uSafeUS), and 1 app has an interactive game format (Liad@s). Two apps have an emergency text or a fake-a-call or text feature (Co6 and USafeUS, respectively), and 1 (USafeUS) app has an incident reporting feature. Co6, which was a pilot app, is not currently available on the market [80].

Bullying and School Violence Prevention

Two apps were identified in the bullying and school violence prevention category: +FORT (Canada) [60,69,81] and uSafeHS (University of New Hampshire; United States) [70,71]. +FORT, developed in Quebec, was first available in French and was subsequently made available in English. Both apps target high school students, with +FORT aimed at preventing bullying victimization. uSafeHS aims to prevent school violence in general, including bullying (Multimedia Appendix 3). +FORT allows youth to journal their bullying victimization experiences and compiles the information in simple graphs, which youth may use to enhance their safety awareness [60,81]. uSafeHS has an administrative platform, incident reporting, and an interactive game feature to facilitate social and emotional learning [70,71].

Self-Harm and Suicide Prevention

BlueIce [54,55,72,73,82-85] and iBobbly [74-78,86,87] are self-harm and suicide prevention apps that were identified. BlueIce targets young people attending Child and Adolescent Mental Health Services across the United Kingdom and aims to help them reduce urges to self-harm. iBobbly targeted Aboriginal and Torres Strait Islander Australians aged ≥15 years (youth, in particular) and aimed to tackle suicide prevention in a culturally appropriate way. Both have emergency call or text, diary or self-check, and activities that youth may engage in as features.

Characteristics of App Evaluation Studies

A total of 14 studies conducted between 2013 and 2022 were identified and reported in 16 peer-reviewed papers. In total, 15 papers reported on experimental study designs (3 randomized controlled trials [RCTs] [59,74,76], 9 single-arm design [54,55,61-63,65,66,70,79], 2 quasi-experimental design [57,64], and 1 that used single-arm and quasi-experimental designs in 2 phases [60]). One paper reported on a cross-sectional study [93]. All the studies included self-reported data. The studies were conducted in the United States (5 apps and 9 papers [59,61-63,65,66,70,79,93]), Australia [74,76], Canada [60], Spain [57,64], and the United Kingdom [54,55] (1 app each).

The 14 studies were conducted across several different settings as follows: 6 (43%) in college or universities [59,61,63,65,66,79,93]; 3 (21%) in high schools [60,70], and 1 (7%) each in mental health services for children [54,55], childcare homes [57], Aboriginal and Torres Strait Islander communities [74,76], the homeless youth context [62], and dating locations [63].

The duration of app use ranged from 20 to 40 minutes in 1 single-arm qualitative study [65] to 12 months in an RCT. For 7 (50%) of the 14 studies (corresponding to 6 apps), the apps were used for at least 6 weeks.

Characteristics of Participants

The reviewed studies included >3800 children and youth, but demographics were not consistently reported. Reported average age ranged from 14 to 27 years; in 1 study, one-third were aged ≥26 years [93], and in another study, the age range was 19 to 29 years [74]. Where information on sex was reported, only 1 study had more men than women [57] (in a childcare home), and in 2 studies evaluating dating and sexual violence prevention apps, only women were enrolled [59,63]. Only 3 studies captured information on sexual orientation [62,63,79]. Where reported, the proportion of White participants ranged from 33% (2/6) [62] to 71.3% (122/171) [59,62].

In addition to children and youth, other stakeholders (eg, parents, app administrators, and police officers) were included as participants in the evaluation of 4 apps [54,55,60,61,70].

Study Outcomes and Measurement Approaches

Table 2 provides a summary of the outcomes and associated measurement tools used in the included studies. Outcomes comprised app engagement (4/9, 44% apps), users' experiences (9/9, 100% apps), and effectiveness of the app (7/9, 78% apps; Multimedia Appendix 4 [54,55,57,59-66,70,74,76,79,92,93]). Effect measures were safety behavior, bystander behavior, sexism, IPV, self-harm, suicide risk, depression, anxiety, and bullying victimization. A wide range of tools was used for measuring outcomes. Self-reported measures were used for all 3 types of outcomes reported (app use: 2/4, 50% apps, users' experience: 9/9, 100% apps, and effectiveness: 7/7, 100% apps). Validated tools were used in the evaluation of effectiveness of 86% (6/7) of the apps. For the remaining app (+FORT), even though no validated tool was used for measuring effectiveness, the app itself uses items adapted from the validated Olweus Bullying Questionnaire for logging information about users' bullying experiences to help users identify more effective strategies to deal with bullying victimization [60]. Objective measurements were used for measuring app use for 2 (50%) out of 4 apps and for measuring the effectiveness of 1 (14%) out of 7 apps. For example, for the BlueIce app, the change in users' frequency of self-harming was determined by comparing historical clinical data with the self-reports of postintervention self-harming incidence [46]. For 3 apps, the general internet use of app users was also assessed, and self-reported, unvalidated measures were used [54,55,62,70]. Further details on study outcomes and measurement approaches are provided in Multimedia Appendix 4.

Table 2. Study outcomes and measurement approaches.

Outcomes and tool name and/or description	Mode of measurement	App	Study
General internet use			
Question, questionnaire, survey, or interview	Self-reported and unvalidated	iBobbly, uSafeHS, and YTH StreetConnect	[62,70,74]
App engagement (downloads, frequency of use, features used, etc)			
Mobile device download data	Objectively measured	iBobbly	[74]
Administrative dashboard analytics	Objectively measured	usSafeHS	[70]
Question, questionnaire, survey, or interview	Self-reported and unvalidated	Circle of 6	[63]
Question, questionnaire, survey, or interview	Self-reported and unvalidated	uSafeUS	[93]
Users' experience (perception, feasibility, acceptability, or subjective value)			
Question, questionnaire, survey, or interview	Self-reported and unvalidated	BlueIce, Circle of 6, +FORT, Liad@s, iBobbly, myPlan, uSafeHS, uSafeUS, and YTH StreetConnect	[54,57,59-63,65,66,70,74,79,93]
Effectiveness			
Decisional conflict: Decisional Conflict Scale (modified)	Self-reported and validated	myPlan	[59]
Safety behaviors: question, questionnaire, survey, or interview (number of safety behaviors tried on app)	Self-reported and validated	myPlan	[59]
Bystander behavior: Banyard's Bystander Scale	Self-reported and validated	Circle of 6	[63]
Intention to help: 10-item modified Intention to Help Scale	Self-reported and validated	Circle of 6	[63]
Sexism (hostile sexism and benevolent sexism): Ambivalent Sexism Inventory-Adolescents	Self-reported and validated	Liad@s	[57,64]
Ambivalence toward men: Ambivalence toward Men Inventory	Self-reported and validated	Liad@s	[57]
Distortions about romantic love: Myths, Fallacies, and Erroneous Beliefs about the Ideal of Romantic Love Scale	Self-reported and validated	Liad@s	[57]
Sexual victimization: 11 item-Revised Sexual Experience Survey	Self-reported and validated	Circle of 6	[63]
Intimate partner violence: Composite Abuse Scale	Self-reported and validated	myPlan	[59]
Intimate partner violence: traumatic brain injury (questions or questionnaire)	Self-reported and unvalidated	Liad@s	[57]
Intimate partner violence: digital abuse (questions or questionnaire)	Self-reported and unvalidated	myPlan	[59]
Intimate partner violence: reproductive coercion (questions or questionnaire)	Self-reported and unvalidated	myPlan	[59]
Substance use: frequency of alcohol use	Self-reported and unvalidated	Circle of 6 and myPlan	[59,63]
Substance use: frequency of getting drunk	Self-reported and unvalidated	myPlan	[59]
Substance use: frequency of binge drinking	Self-reported and unvalidated	myPlan	[59]
Substance use: any marijuana use	Self-reported and unvalidated	myPlan	[59]
Substance use: any drug use other than marijuana	Self-reported and unvalidated	myPlan	[59]
Substance use: feeling of intoxication	Self-reported and unvalidated	Circle of 6	[63]
Self-harm: clinical data	Objectively measured	BlueIce	[63]
Self-harm: question, questionnaire, survey, and interview	Self-reported and unvalidated	BlueIce	[63]
Bullying victimization: Multidimensional Peer-Victimization Scale	Self-reported and validated	+FORT	[60]
Depression: Center for Epidemiologic Studies Depression Scale Revised	Self-reported and validated	myPlan	[59]
Depression: Mood and Feelings Questionnaire	Self-reported and validated	BlueIce	[54,55]
Depression: Patient Health Questionnaire 9	Self-reported and validated	iBobbly	[74,76]
Anxiety: Revised Child Anxiety and Depression Score	Self-reported and validated	BlueIce	[54,55]

Outcomes and tool name and/or description	Mode of measurement	App	Study
Psychological distress: Kessler Psychological Distress Scale	Self-reported and validated	iBobbly	[74,76]
Impulsivity: Barratt Impulsivity Scale	Self-reported and validated	iBobbly	[76]
Behavior: Strengths and Difficulties Questionnaire	Self-reported and validated	BlueIce	[54,55]
Suicide risk: Center for Epidemiologic Studies Depression Scale	Self-reported and validated	myPlan	[59]
Suicidal ideation: Depressive Symptom Inventory–Suicidality Subscale	Self-reported and validated	iBobbly	[74,76]

App Engagement

Four studies reported data on the use of 4 apps: 2 on dating and sexual violence prevention (Co6 [63] and uSafeUS [93]), 1 on bullying and school violence prevention (uSafeHS) [60], and 1 on self-harm or suicide prevention (iBobbly) [74]. Multimedia Appendices 4 and 5 [54,55,57,59-66,70,74,76,79,92,93] provide details on the characteristics and the findings of the included evaluation studies. On the basis of app download and use, the findings of 2 studies indicated that there is a high level of app use among high school students (uSafeUS) [70] and Aboriginal and Torres Strait Islander youth (iBobbly) [74]. Two studies involving college students found generally low app engagement [63,93]. The findings indicated that younger app users had higher engagement levels than older users, and women were more engaged than men [93]. The reasons for low app use among college students included the perceived redundancy with existing smartphone features, college women's discomfort with group messaging (Co6) [63], and the opinion among older college students that the app was not relevant to their needs (uSafeUS) [61].

App Users' Experience

Data on users' experience of the apps were obtained from 13 studies, with all 4 app categories being covered (Tables 3 and 4; Multimedia Appendices 4 and 5) [54,57,59-63,65,66,70,74,79,93]. In general, participants liked the app features and perceived the apps to be easy to use and effective. One dating and sexual violence prevention app (myPlan), 1 self-harm and suicide prevention app (iBobbly), and 1 bullying and school violence prevention app (+FORT) were perceived to be judgment free by youth [60,66,74]. Among the 9 apps, the features perceived to be the most useful included map features, personalized action plan, mood diary, and bullying prevention strategies. The appealing features, confidentiality, accessibility, ease of use, and useful resources were common facilitators of app use among youth. In addition, the judgment-free nature of some apps facilitated their use. By contrast, the repetitive, redundant nature and lack of specific resource information were among the reported barriers to app use.

Table 3. Youth's perceptions of mobile personal safety apps.

Users' perception and descriptors	Homeless youth support	Dating and sexual violence prevention				Bullying and school violence prevention		Self-harm and suicide prevention

[a]No or not reported.

Both the youth and service providers who participated in evaluating the homeless youth support app, YTH StreetConnect [62], enjoyed using the app and considered it to be accessible, appropriate, and confidential for locating services. None of the evaluation studies analyzed the privacy or confidentiality of the apps.

For the dating and sexual violence prevention apps, the views of youth and other stakeholders, including college campus administrators and crisis center advocates, were captured [59,61,63,65,66,79,93]. Participants generally had positive perceptions of the apps' sexual violence–related resources and supporting features. For example, Lindsay et al [66] found that women survivors of dating violence who attended college found myPlan to be "useful, innovative, and effective" in conveying information regarding dating violence and relationship safety. In particular, the "My Plan" (personalized safety plan) feature was found to be the most useful feature [66]. By contrast, Debnam and Kumodzi [79] found that among participants who represented a sexually diverse group of adolescents, there was an intolerance to gender-conforming language in the app, which targeted females only. They strongly believed that men can be victims too, and that conversely, women can also be perpetrators. Consequently, participants recommended that the app be modified to reflect a more inclusive group to users with diverse sexual orientations and to have a greater focus on safety dilemmas faced by youth, such as emotional or psychological abuse and power imbalance induced by age difference. Because of that research, a lesbian, gay, bisexual, transgender, queer (LGBTQ) version of the myPlan app was developed and later released [79]. In addition, Potter et al [61] found that while most college students and other stakeholders who used uSafeUS agreed on the need of mobile apps to protect against sexual violence, most of the graduate students (particularly older students) as well as commuter students indicated that they did not perceive the app as being applicable or relevant to their needs.

Across the 2 studies that evaluated bullying and school violence prevention apps among high school students, participants found the app features to be favorable and felt that the apps were useful personal safety tools [60,70]. For example, all the survivors of bullying who used +FORT felt that it may be a beneficial tool, with 1 participant stating, "We talked about it [bullying] during three hours at school and I learned more about it with Stronger than Bullying (as the app was initially called) in five minutes" [60]. uSafeHS users felt that the app could serve as a useful tool for high school students, with all participants who completed the gamified social emotional learning educational modules expressing that their knowledge had improved [70].

Both self-harm and suicide prevention apps were found to be acceptable and helpful to users [54,55,74,76]. In particular, iBobbly was considered culturally appropriate by Aboriginal and Torres Strait Islander youth [74,76]. Although 2 users of BlueIce reported initial concerns that seeing their mood diary full of negative days might not help them, they felt that overall, self-monitoring was beneficial [55].

Evidence by Outcome

The effect of app use on substance use; decisional conflict; safety behaviors; protective behavior; sexism; ambivalence toward men; love myths; sexual violence; bullying victimization; and mental health issues, such as depression, anxiety, self-harm, and suicide risk, were evaluated in 6 studies (8 articles). All the studies that evaluated effectiveness reported positive outcomes associated with app use in at least 1 outcome measure.

Substance Use

Two studies reported on substance use, but only 1 assessed the impact of the app on this outcome. A 12-month RCT study involving college women found that there was a reduction in the frequency of alcohol use, getting drunk, binge drinking, and nonmarijuana drug use over time in both the intervention and control groups. However, only the reduction in drunkenness frequency achieved statistical significance (P=.001), but there was no significant difference between both groups. Interestingly, there was a slight increase in marijuana use in both groups over time [59]. Although the feasibility and acceptability of Co6 among college women who drink alcohol were assessed, its effects on alcohol and the risk of sexual violence were not assessed. Rather, how app users perceived the app as a sexual violence risk reduction tool was assessed [63].

Decisional Conflict and Safety Behaviors

One study that evaluated decisional conflict and safety behaviors in college women reported statistically significantly greater improvement in preparedness to make better safety decisions in the intervention group compared to the control group [59]. There were immediate improvements in all decisional conflict subscales in both groups. In particular, participants in the intervention group were statistically significantly better able to weigh the risks and benefits of different safety options compared to those in the control group (P=.02). It was found that the number of helpful safety behaviors used on the app increased over time, although there was no statistically significant difference between the intervention and the control groups. There was a statistically significant association between the number of safety behaviors tried and IPV reduction in the intervention group only (P<.001) [59].

Protective Behavior

Four studies that evaluated protective behavior or had themes surrounding that topic found that youth were generally willing to help their friends in risky situations [63,65,79,93]. In 1 study, users of Co6 app expressed almost 3 times more protective behavior in sexually aggressive situations toward friends compared to strangers at 2-month follow-up [63]. Of note, they also expressed greater intention to help friends than strangers at the start of the study. In another study, the myPlan app helped friends of survivors of IPV to understand abusive relationships better and helped them to better understand the severity of violence, identify resource options, and know possible ways to intervene [65]. In evaluating the reasons for downloading uSafeUS, it was found that 90% of college women felt confident that it would provide sufficient resources to help them support a friend who disclosed that they had been sexually assaulted [93]. In another study on the myPlan app, while adolescents expressed willingness to help protect their friends who experience dating violence, they also described the moral distress they experienced regarding protecting themselves over their friends in risky situations [79].

Sexism, Ambivalence Toward Men, and Love Myths

Sexism was measured in 2 quasi-experimental studies evaluating the Liad@s app. One involved a 2-week intervention involving residents of childcare homes in Spain, who ranged in age from 11 to 18 years [57], and the other involved a 2-hour intervention involving high school students aged 13.9 years, on average [64]. Ambivalence toward men and love myths (distortions about romantic love) were measured only in the study involving residents of childcare homes in Spain [57]. Across the 2 studies, the app was found to be effective in reducing sexism, ambivalence toward men, and love myths. Participants experienced a statistically significant reduction in hostile sexism (P=.009) and benevolent sexism post intervention relative to pre intervention (P<.001), with greater reductions observed in these variables in the intervention group compared to the control group. The difference was statistically significant only in the study involving high school students [64]. Similarly, there was a significant reduction in ambivalence toward men and distortions of romantic love postintervention relative to pre intervention among residents in a childcare home (P=.02 and P<.001, respectively) [57]. A statistically significant pre-post difference in distortions of romantic love was observed in the intervention group only. There were no significant gender differences in sexism or myths about romantic love. A statistically significant decrease in hostile sexism with increasing age was observed, and there was also a decrease in paternal resentment with age [57].

IPV and Other Sexual Violence

One RCT study that evaluated the impact of a personal safety app (myPlan) on IPV among college-going female survivors of IPV between 18 and 24 years of age found that after 12 months of using the app, there was a statistically significant decrease in IPV in both intervention and control groups in all 4 subscales measured (Composite Abuse Scale, traumatic brain injury–related IPV, digital abuse, and reproductive coercion) [59]. The intervention group, however, experienced a statistically significantly greater reduction in reproductive coercion compared to the control group (P=.02). In 1 mixed methods study that evaluated sexual victimization among college women, 23% (10/44) of participants who used Co6 reported sexual victimization at 2-month follow-up, which involved unwanted sexual contact (5/10, 50%), completed rape (3/10, 30%), and attempted rape (2/10, 20%) [63]. Most of the perpetrators were friends or acquaintances 44% (4/9), while 33% (3/9) were strangers and 22% (2/9) were their boyfriends. The participants had mixed views on whether the app made them feel safer from sexual violence. App use was low due to perceived redundancy with existing smartphone features and college women's discomfort with group messaging [63] (Multimedia Appendices 4 and 5).

School Violence and Bullying Victimization

One study that reported on bullying victimization among high school students found a 2-fold reduction in bullying victimization, which occurred after 4 to 6 weeks of app use (P<.001). The reduction in victimization was 16 times greater for the intervention group compared to the control group, who did not receive the app. None of the 5 parents or educators involved in the study believed that the app could jeopardize or conflict with existing services [60]. One study that gathered participants' input and feedback on the development and testing of a school violence prevention app (uSafeHS) found that the app was well received by youth and appeared to be a useful tool in streamlining all services for homeless or unstably housed youth and their service providers. The impact on safety was, however, not evaluated [70].

Depression

All 3 studies that reported on depression (2 on self-harm or suicide prevention apps and 1 on a dating and sexual violence prevention app) found a statistically significant reduction among youth who used personal safety apps (P<.001 to .02) [55,59,76]. For 1 app (myPlan), there was no difference between the intervention and control arm, whereas for another (iBobbly), the difference between arms was statistically significant. Interestingly, a follow-up study involving participants of the initial iBobbly RCT study found a nonstatistically significant reduction in depression over time [74]. Of note, the sample size of the follow-up study was much smaller than that of the initial study (13 compared to 61).

Anxiety, Psychological Distress, and Impulsivity

Two studies (3 articles) on self-harm or suicide prevention apps that reported on anxiety-related outcomes found statistically significant reductions in anxiety and psychological distress over time [55,74,76]. One noncontrolled study on BlueIce found a statistically significant reduction in overall scores across all 5 Revised Child Anxiety and Depression Score subscales: panic disorder, separation anxiety disorder, generalized anxiety disorder, social anxiety disorder, and obsessive compulsive disorder (P<.001). One RCT on iBobbly reported statistically significant reductions in psychological distress (P=.02), which was statistically different from the control (waitlist) arm. However, a follow-up report on iBobbly found nonstatistically significant reductions in psychological distress and impulsivity [74].

Self-Harm

A pre-post mixed methods study on a self-harm and suicide prevention app found a reduction in self-harming incidents among 33 youth between 12 and 17 years of age who attended mental health services in the United Kingdom [54,55]. The app helped individuals to not act on their urges to self-harm, with 15% (4/26) of those who self-harmed before the study stopping that practice, and a further 58% (15/26) self-harmed less frequently after using the app [55]. A total of 308 incidents of self-harm were prevented during the study, based on historical clinical data and self-reported rates after app use. In total, 27% (7/26) of participants had no reduction in self-harming behavior. No app user felt that the app would increase their thoughts of self-harming, and no adverse events were reported [54].

Suicide Ideation and Suicide Risk

The 2 studies that evaluated suicide risk–related outcomes among youth reported a reduction after using personal safety apps [59,74]. For 1 dating and sexual violence prevention app, which was used for 12 months, there was a reduction in suicide risk, which was significantly greater in the intervention group relative to the control group (P=.048) [59]. For a self-harm or suicide prevention app, which was used for 6 weeks, the reduction in suicide ideation was nonsignificant. In addition, a third study, which evaluated the safety of another self-harm or suicide prevention app, found that no clinician withdrew any participant from the study because of escalated or emergent risk of suicide planning or attempt [55]. The effectiveness of the apps was attributed to several factors, including the provision of distractions and emotional outlets, tracking and recognizing mood patterns, identifying triggers for negative emotions, gaining new perspectives and coping strategies, improving interpersonal communications, and quick access to emergency numbers [54,74].

Discussion

Principal Findings

This scoping review identified, categorized, and characterized mobile apps used for personal safety among at-risk children and youth and summarized the findings on app use (engagement), users' perception, and effectiveness. To the best of our knowledge, this is the first review that provides this type of information on personal safety apps intended to be used autonomously by children and youth. Six (86%) of the 7 studies that evaluated effectiveness reported positive outcomes associated with app use in at least 1 outcome measure, with statistically significant reductions in drunkenness frequency [59], sexism, ambivalence toward men, love myths [57,64], IPV [59], bullying victimization [57], depression [55,59,76], anxiety [54,55], and suicide risk [59] reported over time. In addition, statistically significant differences between intervention and control arms were reported for sexism [57], reproductive coercion (a measure of IPV) [59], and suicide risk [59]. Furthermore, no study reported an increase in harm to participants. These are promising results, which suggest that mobile personal safety apps may be a viable tool for enhancing the safety of children and youth.

From a global personal safety perspective, 100% (13/13) of the included studies were conducted in high-income countries, a reflection of the concentration of mobile app development in such countries. This is highly disproportionate to the high global prevalence and trends in sexual violence, depression, and anxiety in low-income countries [94-96]. A study of global crime patterns during the period 2006 to 2019 revealed that African and Latin American countries experienced the highest levels of various types of crime, followed by Asian countries. Intermediate or relatively low levels of most types of crime were reported for European, North American, and Australian countries [97]. The abovementioned findings demonstrate that more research needs to be undertaken in low- and

middle-income countries (LMICs), particularly in areas where mobile phone app use is known to be prevalent. Ding et al [98] had similar findings from their review of mHealth and youth mental health. Furthermore, Madonsela et al [99], in a scoping review on the development and use of mHealth interventions in LMICs, identified only 6 relevant studies from 5 countries. Only 2 of the studies were focused on smartphone apps, and 1 study involved multiple intervention types, including smartphone interventions. Only 1 study that involved a SMS text messaging intervention was focused on self-harm or suicide. The authors concluded that more research is needed to build the evidence base in LMICs to develop this field [99]. Decker et al [100] have made progress in increasing research in LMICs through their RCT to evaluate the efficacy of a culturally and linguistically adapted version of the myPlan app used by women at risk of and experiencing IPV in Nairobi, Kenya. The study, however, had a short duration (3-month follow-up) and was not focused on youth [100].

Considering that only 9 apps met the inclusion criteria, this review suggests that despite the growing number of personal safety apps available on the market, very few are specifically geared toward autonomous use by children and youth. This represents a gap in the mobile personal safety app industry. Many apps are available for use by parents and guardians to track their children, and these have their purpose. However, with a high premium placed on their autonomy, youth generally prefer to use apps that they completely control. As it is for mHealth apps [100], the field of personal safety apps offers both opportunities and risks. For any app, but particularly for personal safety apps geared toward autonomous youth control, it is important that the development be undertaken with target user engagement and for the app to be based on scientific evidence and be well validated. The review found that for most of the apps (8/9, 89%), relevant theories or expertise were used in their development. This indicates that, in general, measures are being taken to ensure that personal safety apps for youth are developed based on sound theories and evidence.

A common feature among the 9 apps is the inclusion of educational content. Interestingly, for 2 apps—1 bullying and school violence prevention app [70] and 1 self-harm and suicide prevention app [74]—youth desired more educational content. In contrast, for the evaluation of 1 dating and sexual violence prevention app, college women found the explanatory video for first-time users “cumbersome” and suggested using dialogue boxes with brief instructions that pop up [61]. The review findings suggest that while younger youth generally have positive perceptions of personal safety apps and highly value them, older youth tend to find them less valuable. As victimization oftentimes begins during adolescence and prevails into adulthood [10], and with the appetite for personal safety apps apparently lessening with age, it may be prudent for more research and development to be focused on the younger segment of the youth demographic [10].

The features perceived to be the most useful included map features (homeless youth support), personalized action plan and myth-debunking sections (dating and sexual violence protection), bullying prevention strategies (bullying and school violence prevention), mood diary, and emergency numbers (self-harm and suicide prevention). The danger assessment tool featured in the myPlan app is unique among the included apps. This user-preferred app feature is a validated tool which provides both numerical and graphical displays of the assessed risk for repeated severe IPV [59,65,66]. Such a feature is potentially very valuable in sexual violence prevention. Common facilitators of app use among youth were the appealing features, confidentiality, accessibility, ease of use, and useful resources. However, the repetitive, redundant nature and lack of specific resource information were barriers to app use. For example, for the YTH StreetConnect app, homeless youth found the lack of specific information such as the number of available beds available at a given shelter to be a barrier to app use [62]. Features that youth suggested for app development or improvement included ambiguous name and branding, an easy delete option, a panic button option, bystander-focused intervention for reducing dating violence, and gamification (Multimedia Appendix 5 [54,55,57,59-66,70,74,76,79,92,93]). As target users’ perception is of utmost importance to app development, these findings are of relevance for app developers.

In 5 (38%) of the 13 included evaluation studies, the period of app engagement did not extend beyond 6 weeks [57,60,63,64,74,76]. In 1 study on users’ experience, app use was as short as 20 to 40 minutes [65]. The longest period reported was 12 months in an RCT study [59]. This reveals that a high proportion of the evaluation studies involved very short app engagement periods, which leaves us to wonder to what extent the results can be related to the real-life context. In particular, no conclusion can be drawn about the long-term effectiveness of personal safety apps for children and youth based on this review. Further studies involving longer app engagement periods and follow-up times need to be undertaken to shed light on effectiveness in the long term.

Regarding measurement outcomes, self-reported measures were used for all but 3 distinct outcomes measured (2 on app use and 1 on self-harming frequency) among all the included studies. While self-reported measures are a valuable tool in public health research, they can inadvertently be affected by various biases, particularly information bias. The use of validated tools, however, can markedly strengthen the validity of self-reported measurement tools. Most of the included studies incorporated the use of validated measures for evaluating effectiveness (6/7, 86% apps). However, only 2 (22%) of the 9 validated measures used were specifically geared toward youth, namely, the Multidimensional Peer-Victimization Scale [60] and the Revised Child Anxiety and Depression Score [54,55]. It may be beneficial for future research to focus on developing and validating tools for evaluating mobile personal safety apps specifically for youth to improve the validity of such research involving youth. In addition, the outcome measurements directly related to victimization or risky behavior were generally based only on a reduction in frequency. Although these measures are useful, the incorporation of measures of the nature or severity of victimization and risky behavior would only serve to improve upon the quality of research conducted.

Limitations

This review was conducted in accordance with best practices in conducting scoping reviews. However, some limitations exist. Only articles written in English were included; therefore, some relevant articles could possibly have been missed. In addition, a systematic app search was not a part of the search process. Such a search could have potentially identified apps that could have directed the search for evaluation studies. As apps with no available information on users' experience, app engagement, or impact were outside the inclusion criteria, we believe that a targeted database search along with a search of the gray literature was sufficient and effective in yielding relevant articles. A broad range of study designs and methodologies were included; hence, no quality assessment of included articles was done. However, quality assessment is not a requirement of scoping reviews. The short durations of app use for most of the studies limit the strength of the review findings. In addition, all the evaluation studies used self-reported data, which are more subject to bias than objectively determined measures. The inclusion of validated tools in evaluating all the apps, however, counteracts this limitation to some extent. It is challenging to realistically compare the use, users' perception, and impact of the apps due to the variability of outcome measures and methodologies. Finally, the generalizability of the findings is limited due to the heterogeneity in participant characteristics across different apps and studies, variations in intervention durations, a small number of apps within each category, and the small sample sizes in several studies.

Implications for App Development and Future Research

This review sheds light on youth's experience and perception of personal safety apps geared toward their use. As target users' perception is of critical importance to app development, these findings are of relevance for app developers. The features perceived to be the most useful included maps, personalized action plans, mood diaries, violence prevention strategies, and emergency numbers. Appealing features, confidentiality, accessibility, ease of use, and useful resources motivated youth to use the apps. Of note, the inclusion of validated danger assessment tools such as the one included in the myPlan app [59,65,66] may be a very useful feature for personal safety apps in general. With the constant evolution of technology, the information included in apps can quickly become obsolete. Therefore, co-design methodologies are essential for increasing and sustaining youth engagement as well as increasing the likelihood of universal acceptability [101]. App developers should, therefore, ensure that youth collaborate in app design and development and that app information is regularly updated, including specific details on helpful resources for at-risk youth. In addition, it may be prudent for more research and development to focus on the younger segment of the youth demographic, given that this group of youth appears to value personal safety apps more compared to older ones [10].

All 9 included apps featured educational content. Inclusion of a test-retest knowledge assessment would be a useful feature to provide basic data on the effectiveness of the apps in increasing knowledge [13] and should be considered in developing these apps. A noteworthy, but not surprising, finding of this review is that youth are generally willing to help their friends in risky situations [63,65,79,93]. This information can be harnessed by app developers. It is potentially very useful to routinely develop companion apps for personal protection apps that target friends of at-risk youth or include features in the apps that allow them to be customized for friends of at-risk youth.

Despite the availability of personal safety apps, the scoping literature review found that there were not many that specifically target youth. Furthermore, all the included studies were conducted in high-income countries, and a high proportion of the evaluation studies had short durations. Most of the evaluation measures were self-reported, and the validated tools were generally not specifically geared toward youth. In addition, some of the outcome measurements were based only on a reduction in frequency. Importantly, the review found that the interest in personal safety apps appears to diminish with age. In light of the abovementioned findings, to better serve the global youth population and to more robustly determine effectiveness, including over the long term, future studies should be conducted as follows: (1) increase focus on development of apps that target youth, particularly the younger demographic; (2) conduct longitudinal studies to determine long-term effectiveness; (3) conduct studies in LMICs; (4) incorporate objective outcome measures into studies; (5) develop standardized measures for evaluating the effectiveness of apps specifically geared toward youth; and (6) include outcome measures that are focused on extent or severity (in addition to frequency of occurrence).

Implications for Policy Making

Smartphone personal safety apps cannot be considered the panacea for violence against children and youth. Nonetheless, the limited studies available suggest that if personal safety apps are designed based on strong evidence, integrated appropriately into existing interventions, and used effectively, they have the potential to serve as valuable tools for personal safety and, by extension, global health. As is true for personal safety apps for the older demographic, few studies have associated evidence on effectiveness, and among those that do, numerous limitations reduce their generalizability. In addition, there was no focus on privacy and confidentiality in the included evaluation studies. Strong evidence on the effectiveness and security of personal safety apps is needed for them to be fit for integration into interventions used in school, clinical, police, community services, and other settings. As has been recommended for mHealth apps, stringent standards for providing personal safety apps should be established and incorporated into the submission processes used by app stores. In addition, it is imperative that experts in the various fields (education, health care, social security, etc) play a more central role in developing, recommending, and distributing these apps. Furthermore, systematic frameworks to facilitate the translation of personal safety apps into schools, clinical settings, etc would be required.

Conclusions

The results of this scoping review indicate that mobile personal safety apps generally seem to be effective in reducing harm to at-risk children and youth, with no associated adverse events.

Although the findings are promising, several factors limit the robustness of the evidence. Recommendations for future research to improve upon the current state of evidence and availability of effective personal safety apps for children and youth have been made, such as the development of apps that specifically target youth, undertaking studies in LMICs, conducting longitudinal studies, and incorporating objective outcome measures into studies such as the number and nature of reports of victimization to authorities and pre-post professional psychological assessments of risk for self-harm or suicide. Recommendations for app development include incorporating features such as maps, personalized action plans, mood diaries, violence prevention strategies, test-retest knowledge assessments, and validated danger assessment tools. Another recommendation is for app developers to develop companion personal safety apps that target friends of at-risk youth or include features that allow them to be customized for friends' use, in light of the willingness of youth to help their friends in risky situations. Strong evidence on the effectiveness and security of personal safety apps is needed for them to be fit for integration into interventions used in school, clinical, police, community services, and other settings. There is yet a far way to go in that regard.

Abstract

Background: Living with a diagnosis of dementia can involve managing certain behavioral and psychological symptoms. Alongside cognitive decline, this cohort expresses a suppression in melatonin production which can negatively influence their alignment of sleep or wake timings with the 24 hour day and night cycle. As a result, their circadian rhythms become disrupted. Since daylight has the capacity to stimulate the circadian rhythm and humans spend approximately 90% of their time indoors, research has shifted toward the use of indoor lighting to achieve this same effect. This type of lighting is programmed in a daylight-simulating manner; mimicking the spectral changes of the sun throughout the day. As such, this paper focuses on the use of a dynamic lighting and sensing technology used to support the circadian rhythm, behavioral and psychological symptoms, and well-being of people living with dementia.

Objective: This study aimed to understand how dynamic lighting, as opposed to static lighting, may impact the well-being of those who are living with dementia.

Methods: An ethically approved trial was conducted within a care home for people with dementia. Data were collected in both quantitative and qualitative formats using environmentally deployed radar sensing technology and the validated QUALIDEM (Quality of Life for People With Dementia) well-being scale, respectively. An initial 4 weeks of static baseline lighting was used before switching out for 12 weeks of dynamic lighting. Metrics were collected for 11 participants on mood, social interactions, agitation, sense of feeling, and sleep and rest-activity over a period of 16 weeks.

Results: Dynamic lighting showed significant improvement with a moderate effect size in well-being parameters including positive affect (P=.03), social isolation (P=.048), and feeling at home (P=.047) after 5 - 10 weeks of dynamic lighting exposure. The results also highlight statistically significant improvements in rest-activity–related parameters of interdaily stability (P<.001), intradaily variation (P<.001), and relative amplitude (P=.03) from baseline to weeks 5 - 10, with the effect propagating for interdaily stability at weeks 10 - 16 as well (P<.001). Nonsignificant improvements are also noted for sleep metrics with a small effect size; however, the affect in agitation does not reflect this improvement.

Conclusions: Dynamic lighting has the potential to support well-being in dementia, with seemingly stronger influence in earlier weeks where the dynamic lighting initially follows the static lighting contrast, before proceeding to aggregate as marginal gains over time. Future longitudinal studies are recommended to assess the additional impact that varying daylight availability throughout the year may have on the measured parameters.

Introduction

Experiencing life with an atypical body clock can often materialize as a result of living with dementia. In fact, studies have shown that the relationship between atypical body clocks and dementia may even be bidirectional [1]. This means that the disruption of one's body clock may catalyze their progression of dementia and vice versa. The combined effect of this can lead to disjointed rest-activity patterns and poor sleep quality, which then impacts mood and well-being in the longer term [2,3].

At present, there are over 55 million people living with dementia around the world [4]. This is 55 million people living without a cure for their diagnosis. As a result of this, society places great importance on research which can either predict the diagnosis in advance or alleviate the symptoms after the fact in a preventative versus reactionary approach [5].

This paper focuses on the latter approach, exploring means to alleviate symptoms of dementia to improve well-being. To expand the above content, a disrupted body clock (aka circadian rhythm) is a common factor of natural ageing, and is heightened in people living with dementia [6]. This disruption lends itself to poor sleep quality. In turn, this misaligns the typical timing of one's sleep and wake cycle with the timing of sunset and sunrise which acts as our inherent, evolutionary alarm clock. Alongside this 24 hour cycle of light and dark, our bodies experience a diurnal cycle of the hormones melatonin and cortisol [7]. Melatonin is a hormone which encourages relaxation and sleep while cortisol is commonly named the "stress hormone" and governs the alerting response in the body. In a typical body clock aligned with sunlight cues, melatonin levels will begin to rise in the evening hours at the onset of darkness, and cortisol levels peak in the afternoon when sunlight is wholly available [8]. With dementia, the disrupted body clock suppresses this cycle of melatonin to cortisol and there becomes a discrepancy between the signals within the body, which should control our sleep-wake rhythm at these predefined times of the day. When sleep and hormone cycles are not in synchronization, the interlocking of these mechanisms becomes chaotic and thus a disrupted circadian rhythm and its symptoms ensue [8]. Since the circadian rhythm is responsible for controlling mood, body temperature, appetite, sleep-wake cycles, rest-activity levels among other factors, ensuring its synchronization is essential for supporting well-being for people living with dementia.

Objectively, it is known that light is the strongest zeitgeber (german for time-giver) for the human body and its circadian rhythm [9]. The circadian rhythm is governed from the suprachiasmatic nucleus in the brain, which is accessed via pathways from the eye. Within the eye, there are rods and cones which receive lighting spectra and translate this into a visual response. However, the discovery of the intrinsically photosensitive retinal ganglion cells (ipRGCs) in 2002 supported the theory that light delivers both photopic and melanopic contributions within human systems [10]. In other words, light is not only necessary for visual purposes (photopic) but also for aligning the circadian rhythm (melanopic). These ipRGCs exhibit varying sensitivity to different wavelengths of light, peaking at 480 nanometers (blue colored light) [10]. This means that the incorporation of dynamic lighting as opposed to static lighting may be critical for attuning the circadian rhythm with the analogous varying properties of daylight with which we have evolved.

Although, however inherent the need for lighting is to align the human circadian rhythm, the extent to which this applies in dementia is largely uncertain [11,12]. Typically, this is because the nature of the disease varies largely on factors such as the state of progression of dementia, alongside different factors that affect the response to lighting: chronotype, age, gender, and previous lighting exposures [13]. Additionally, the methods for obtaining the amount of lighting one is exposed to are commonly not accounted for, and the units of the lighting spectra trialled are far from systematic [14]. This makes comparison of lighting trials and studies within dementia cohorts difficult, resulting in a critical gap in knowledge within this field. This study aims to address some of these gaps by monitoring aspects of well-being and correlating this with commonly reported lighting metrics.

In order to monitor the above, it is critical to collect information on the daily activity and well-being of people living with dementia [15]. As such, this study makes use of integrated, environmentally deployed sensors to enrich this dataset in a nonintrusive manner. This setup allows for the formation of a technology, which can deliver circadian-aligned lighting and simultaneously monitor any resultant changes to well-being. Additionally, validated questionnaires are used to collect information on certain behavioral symptoms, which the sensors cannot themselves generate. Collaboratively, this information will provide informatics in response to dynamic lighting systems for people living with dementia. This study therefore hypothesizes that all measured parameters of well-being will benefit from exposure to dynamic lighting as opposed to static lighting over time.

Methods

Study Design

A combined lighting and sensing intervention was carried out from March to July 2023 for a period of 16 weeks, whereby participants with dementia experienced a change in their received lighting output. The technology is designed to deliver dynamic lighting to support the circadian rhythm of people living with dementia.

Simultaneously, it is designed to monitor the change to certain aspects of their circadian rhythm and well-being that are expected to be impacted by changes in the lighting spectra. The trial invoked a baseline-intervention strategy on the same group of individuals to obtain repeated measures at several key points throughout this study.

Ethical Considerations

This study has been approved by the Office for Research Ethics Committees Northern Ireland under Integrated Research Application System ID 311547. Recruitment of participants was managed via the care home manager acting as gatekeeper. With consideration of the inclusion criteria, a dementia-friendly information leaflet was circulated by the care home manager to

the residents and family members of people living with dementia. A similar leaflet was delivered to the care staff. Those who were interested in participating were invited to a presentation afternoon in the care home where 2 members of the research team brought the luminaire or sensor prototype to the care home and explained this study's requirements for all involved parties.

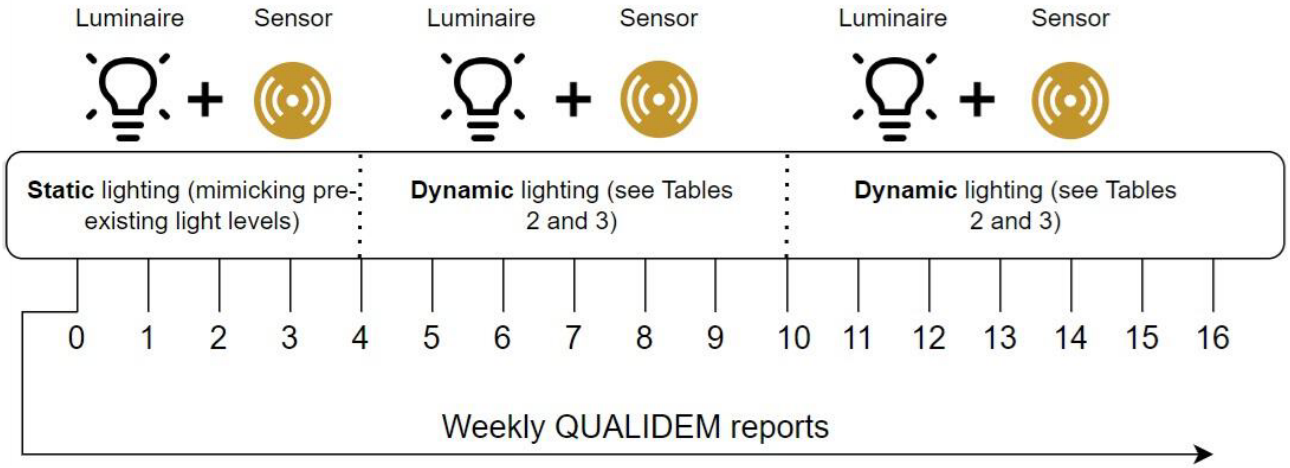
Care staff were shown the questionnaire and user guide and offered to take part. After this, for those who were willing, initial consent was obtained and reaffirmed verbally throughout this study. In addition to care staff providing informed consent for their contribution to questionnaires, family members were asked to provide proxy consent on behalf of the selected residents recruited by the care home manager. For the residents living in this unit, all of their families possessed the legal right to consent to matters on their behalf that relate to their everyday life and well-being. This was communicated to the researchers by the care home manager. Since all participants had moderate-to-severe stages of progression of dementia and the fact that this was a pilot study requiring only passive interactions with the technology, it was deemed appropriate by family members, researchers, and the care home manager to gain initial consent via proxy at this stage of this study. A paper copy of a consent form was given to the participant's proxy to be signed. If consent has been given, the participants data will be collected and analyzed by the research team. If at any point a participant proxy retracts their consent or the resident with dementia indicates they do not wish to be part of this study (verbally or otherwise), the data up until that point will have been collected and analyzed, and any data collected after this may be stored but not used for analysis, or exempt from collection altogether if requested. Proxies for participants were informed should they wish, to opt in and opt out at any point by informing the care manager, care staff, or chief investigator.

Study Protocol

This study was implemented using the following protocol as seen in Figure 1.

- Weeks 1 - 4 : baseline lighting and static lighting
- Weeks 5 - 16: dynamic lighting

Figure 1. Baseline lighting was static in nature and was used as a control for 4 weeks. Dynamic lighting was introduced from weeks 5-16 inclusive. Sensor metrics were collected 24/7 for all 16 weeks with QUALIDEM reports completed on a weekly basis. QUALIDEM: Quality of Life for People With Dementia.



The baseline lighting was used as a control for 4 weeks to generate differences in well-being attributed to the dynamic lighting. After these 4 weeks, the lighting program was changed to exhibit the dynamic lighting spectra. The period of 12 weeks to trial the dynamic lighting was chosen due to the fact that it is estimated to take approximately 2 - 5 weeks to realign a circadian rhythm, therefore providing ample opportunity to witness potential progression over time [16]. As such, a baseline (weeks 1 - 4), midpoint (weeks 5 - 10), and end of intervention (weeks 10 - 16) approach for analysis was used on the results to observe the progression in well-being throughout the trial. Alongside the sensing metrics collected, the trial required insight into additional well-being parameters that could not be collected via the sensors. As such, a validated well-being questionnaire (QUALIDEM) was also completed by care staff on a weekly basis [17]. The QUALIDEM scale represents the "Quality of Life for People With Dementia" and is a validated measure of quality of life and well-being for people living with dementia [17]. It is used to understand the behavior and attitude of people living with dementia on a weekly basis. The scale measures 10 aspects of quality of life; (A) care relationship, (B) positive affect, (C) negative affect, (D) restless tense behavior, (E) positive self image, (F) social relationships, (G) social isolation, (H) feeling at home, (I) occupation, and (J) other questions for further research. For this study, the latter two parameters (I and J) are presented within the report but excluded from analysis as these are not factors anticipated to be impacted by the circadian rhythm in response to lighting. The QUALIDEM scale is to be completed by care staff on behalf of the residents with dementia. Although there may be unintentional bias on reporting scores, it was deemed suitable for multiple care staff to complete the QUALIDEM scales due to its high Inter Rater Reliability score [18]. This also facilitated the reduction in caregiver workload and burden during the week.

Each resident was free to enjoy their daily routines normally and no constraints on their activity was requested. The sole hypothesis tested in the trial was the changes to various aspects

of well-being under exposure to static versus dynamic lighting spectra.

Hardware and Architecture

The bespoke device deployed within the care home can be seen in Figure 2. It has been designed to integrate both lighting and sensing components of the technology in a feedback setup. The lighting output is produced by the dimmable, tuneable-white LED boards which can change in intensity and color temperature. The integrated sensor is a radar sensor, which can track movements on a frame-by-frame basis at fine-grained resolution. The sensor and luminaire have bidirectional communication pathways with a cloud storage, enabling data-driven feedback to inform the lighting. This means that the luminaire is bespoke in the fact that it has the capacity to actuate changes in the lighting spectra based on data-driven insights. For example, if a resident is observed to frequent their bed during the day for a nap, it could be possible to create a more "alerting" lighting environment (more blue output at higher intensities) to help aid their wakefulness in the day and resultantly promote their sleep during the night. However it should be noted that this pilot study is comparing a predetermined dynamic spectra (consistent with the daylight spectra) to a static lighting spectra in order to generate an initial foundation for how lighting impacts well-being for people living with dementia in order to ensure that the future data-driven actuation will be suitable for each individual.

The device communicates via Bluetooth protocol to the next device or node in the network, creating a mesh network of the lighting and sensing devices. This mesh then interacts with an edge node operating as a Bluetooth low energy gateway and transferring data to a 3rd party cloud platform. From here, the data is accessed via WebSockets (IETF) and consumed by the backend logic for processing and visualization. The entire architecture can be seen in Figure 3.

The data collected include both lighting and sensor data harvested from the network, in 15 minute intervals and real time, respectively. Due to the range of Bluetooth protocol, several repeater nodes had to be included at regular distances to bridge the communication between devices. Figure 3 demonstrates the Internet of Things architecture for the home implementation. The real time sensor data is filtered and consumed by the metric generator. This generator invokes algorithms which search for the activity levels for the previous 15-minute interval alongside the sleep-wake metrics for each day and night (see further detail in the Sensing Component section). In addition, the live location is also assessed and reported to the influx database for access on the visualization platform.

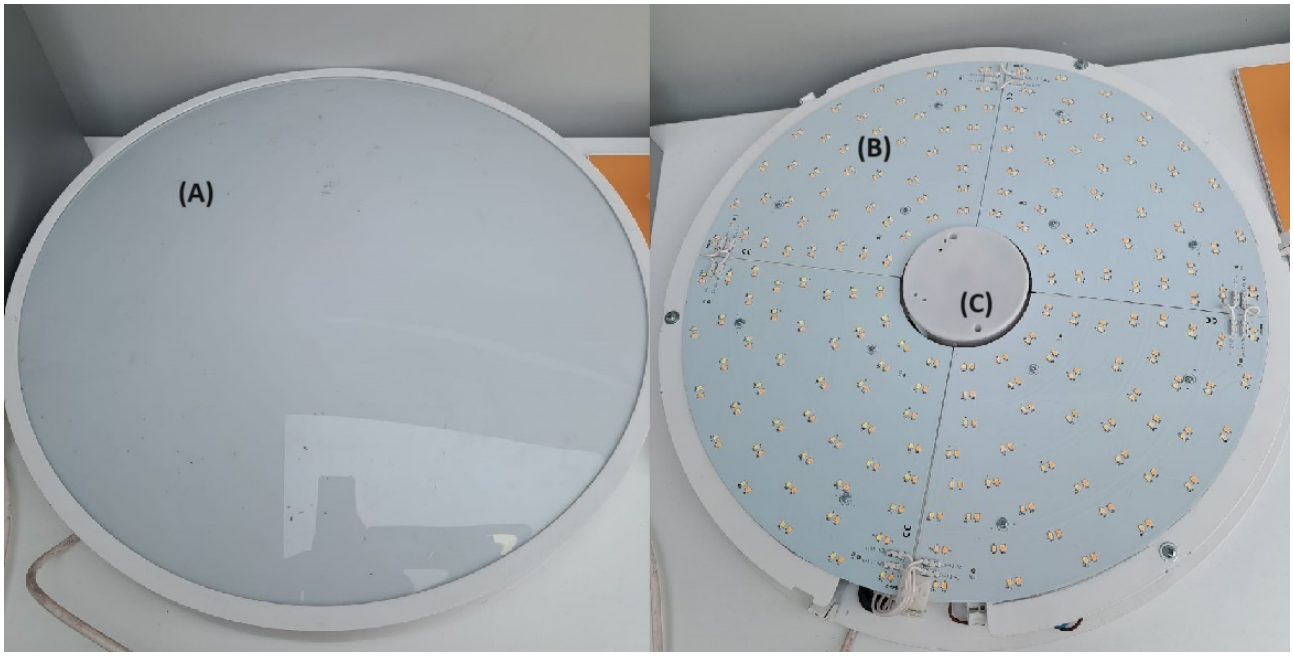

Figure 3. IoT architecture of smart care environment. Data is transferred across the network to storage and accessed by algorithms performing metric generation for visualization. BLE: Bluetooth low energy; DB: database; IoT: internet of Things.

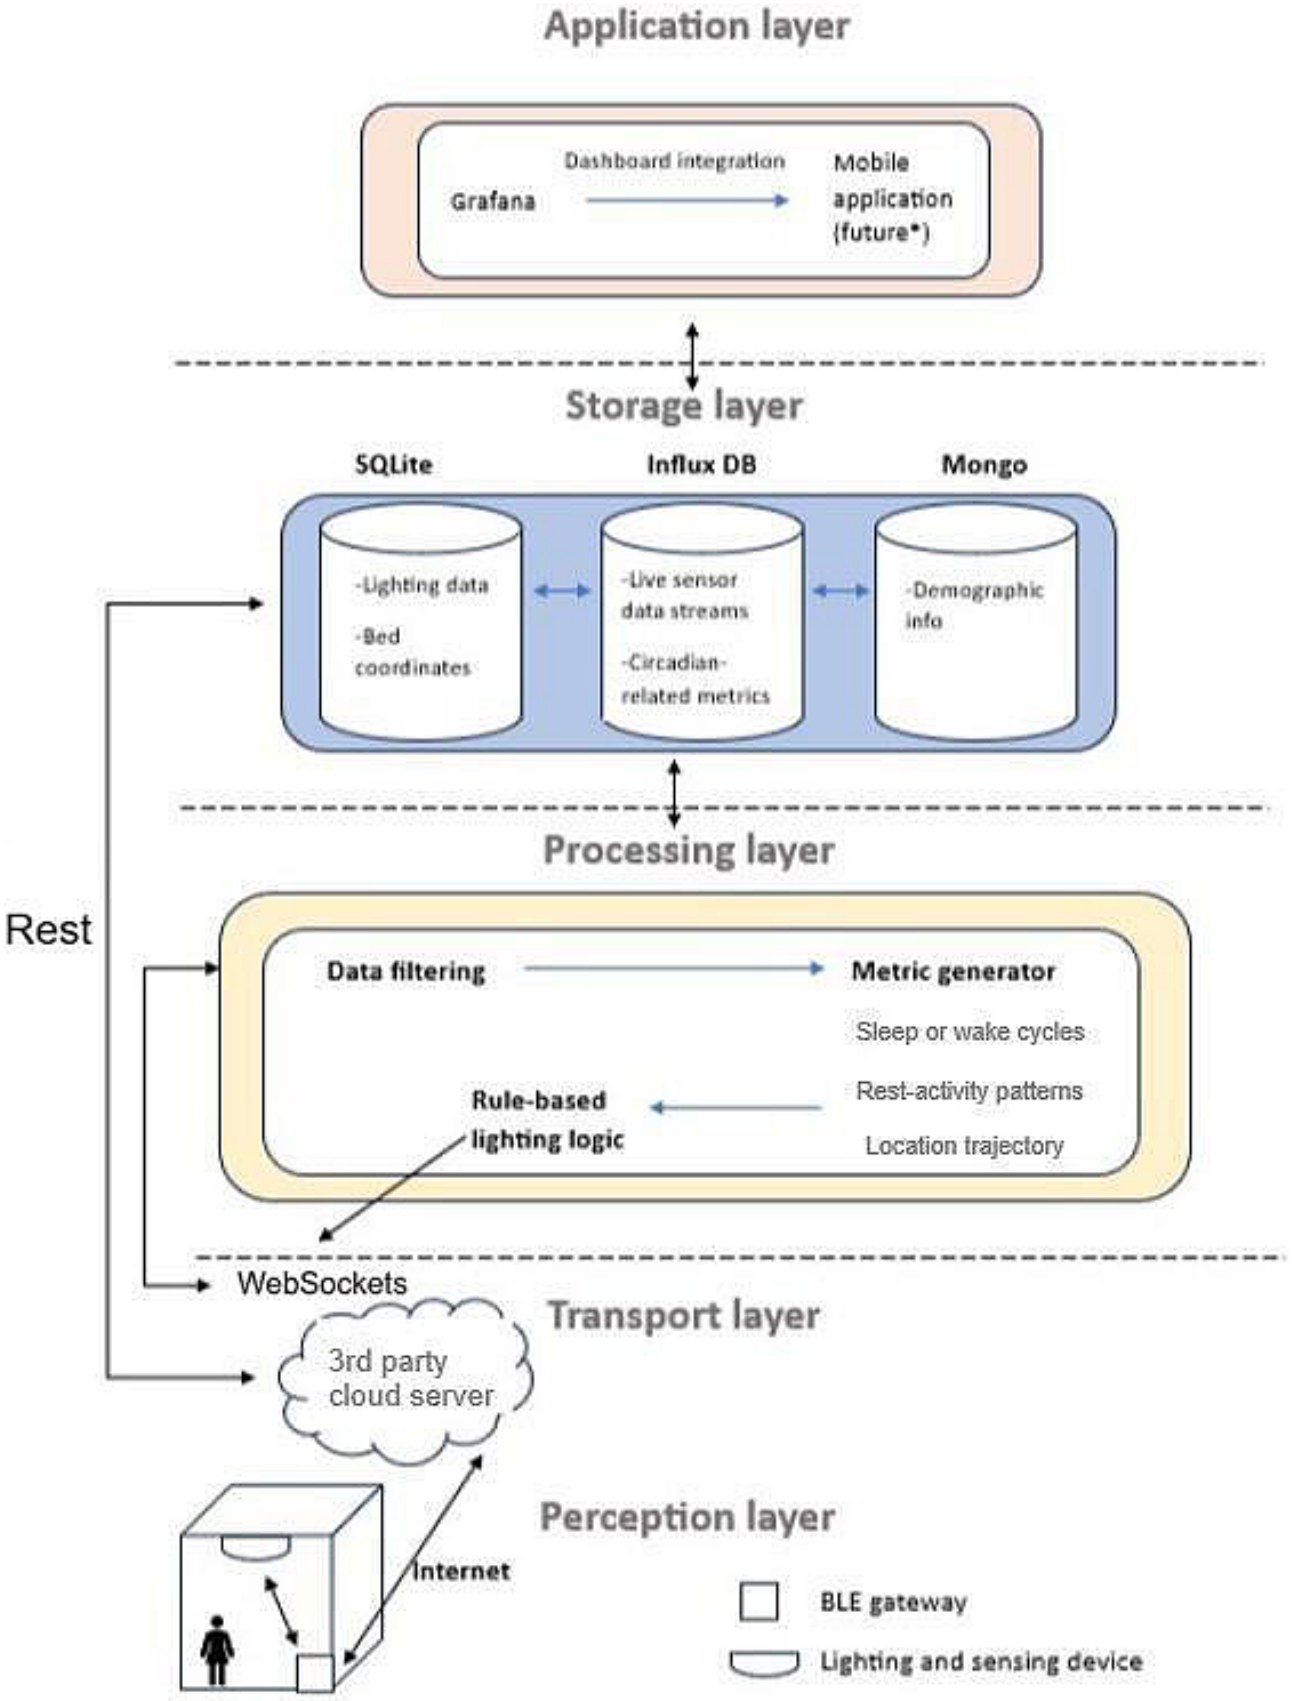
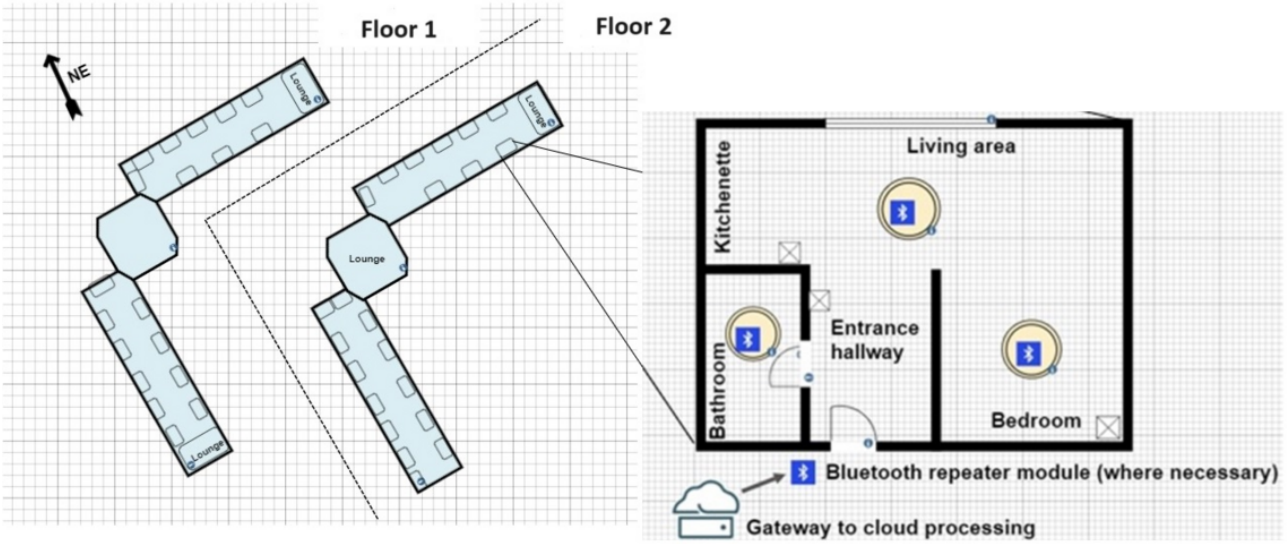


Site

The technology was trialled in a care home within the United Kingdom. The site accommodates up to 42 residents with a dedicated wing for dementia care. Various rooms were included in this study between the upper and lower corridors, totaling 11 rooms. Five rooms faced northeast, 3 rooms faced southwest, 2 rooms faced northwest, and 1 room faced southeast. Each room is an independent living quarter for every person with dementia, with a shared common area for each wing where one can dine and watch television, as shown in Figure 4. All rooms experienced a similar deployment, with a device in each of the kitchenette and living area, bedroom, and bathrooms. The common areas were also equipped with several dynamic lighting devices but with the sensors removed to compensate for those present within these areas who had not consented to data collection.

Figure 4. Floor plan of the care home. Individual flats contained a kitchenette, living area, bathroom and bedroom with access to communal lounges or common areas in each wing. Further, 3 lighting and sensing devices were placed in each flat. NE: northeast.



Participants

Eleven residents participated in the intervention as seen in Table 1; all with a diagnosis of dementia. Each individual's type of dementia and Mini-Mental State Examination was not logged, however all participants were known to exhibit a moderate-severe state of progression. Participants were included based on the criteria that they reside at the care home and had a diagnosis of dementia. Participants were excluded on the basis that they experience schizophrenia, epilepsy, restless leg syndrome, serious eye disease such as retinitis pigmentosa or cataracts or blindness, mania, historical head injuries, diabetes, or any physical disability which would restrict the participant to their bed. These criteria were assessed by the care home manager and relevant participants selected for recruitment. Upon recruitment, 13 participants were identified and consented to this study. Eleven participants were included in the final trial due to the layout of the building and restriction in the Bluetooth range between large distances with concrete walls between. During this study, participants could live their lives as they would prior to the lighting trial. The care home has a scheduled time for breakfast, lunch, and dinner with the option to have a staggered start to accommodate all residents; aside from this, residents are given autonomy to settle in any area of the care home wing including a connected outdoor or indoor walkway, their flatlets, common areas, or their neighbor's flatlets. At night, residents are encouraged by care staff back to their flatlets and into bed and are checked on in 2 hourly intervals.

Table . Participant details.

Variable		Details
Participants, n		11
Female, n		11
Male, n		0
Age (years), mean (SD)		87.45 (2.05)
Weight (kg), mean (SD)		57.45 (1.72)
Medications, n		
	Diazepam (anxiety)	2
	Memantine (dementia)	9
	Risperidone (antipsychotic)	6
	Donepezil (dementia)	4
	Circadin (sleep)	1
	Sertraline (antidepressant)	4
	Mirtazapine (depression and anxiety)	1
	Melatonin (sleep)	1
	Citalopram (low mood)	1

Lighting Component

First, the dynamic lighting was designed to align with the photopic lighting requirements known for the ageing population from existing lighting guidance [19]. These are typically reported as illuminance at eye level measured in lux alongside measurements for the correlated color temperature of the lighting reported in Kelvin. Second, the lighting was required to be of significant spectra to ensure a melanopic response would be invoked [14,20,21]. This response is most recently reported in terms of either circadian stimulus (CS) or the α-opic Melanopic Equivalent Daylight Illuminance (M-EDI) lux [20,21]. The former is defined as the "effectiveness of the spectrally weighted irradiance at the cornea from threshold (CS=0.1) to saturation (CS=0.7)" [20]. The latter refers to International System of Units–compliant metrics as supported by the International Commission on Illumination, which converts multiple spectral inputs to ipRGC-relevant quantities [21]. We have used this to obtain additional values of M-EDI lux according to the LED spectral distribution and melanopic ratio of the lighting. The LED board is bespoke and has been designed to optimize the melanopic response.

In this trial, the illuminance was measured using a lux meter and the color temperature was obtained from the luminaire network. The calculations for the melanopic metrics were completed using the spectral power distribution values from our LED datasheet [22] and the lux intensities from Table 2, with the aid of open access 3rd party software for both CS and M-EDI lux calculations [20,23]. The melanopic ratio does not change throughout this study. The previously installed static lighting for the care home's bathrooms, bedrooms, kitchennette and living space, and common areas exhibit mean illuminance of 99 (SD 49), 75 (SD 12), 59.33 (SD 15.41), and 147 (SD 60.42) lux, respectively. In contrast, the dynamic intervention metrics are shown in both Tables 2 and 3.

The intervention lighting was programmed to simulate the varying properties of the sunlight cycle throughout the day as depicted in Figure 5. Warmer color temperatures were present in the early mornings and evenings with cooler color temperature in the middle of the day. The capacity to switch on or off the lighting was maintained by the residents or the care staff according to preference and was also logged in the network. This then allows for metrics on actual lighting exposures to be calculated.

Table . Photopic lighting intervention parameters.

Intensity (lux)	Correlated colour temperature (K)	Output (%)[a]	Time
300	3350	90	7 AM to 8 AM
550	4000	100	8 AM to 8:30 AM
550	5200	100	8:30 AM to 9 AM
550	6500	100	9 AM to 2:30 PM
300	4200	90	2:30 PM to 3 PM
260	3400	90	3 PM to 4 PM
300	2700	90	4 PM to 6 PM

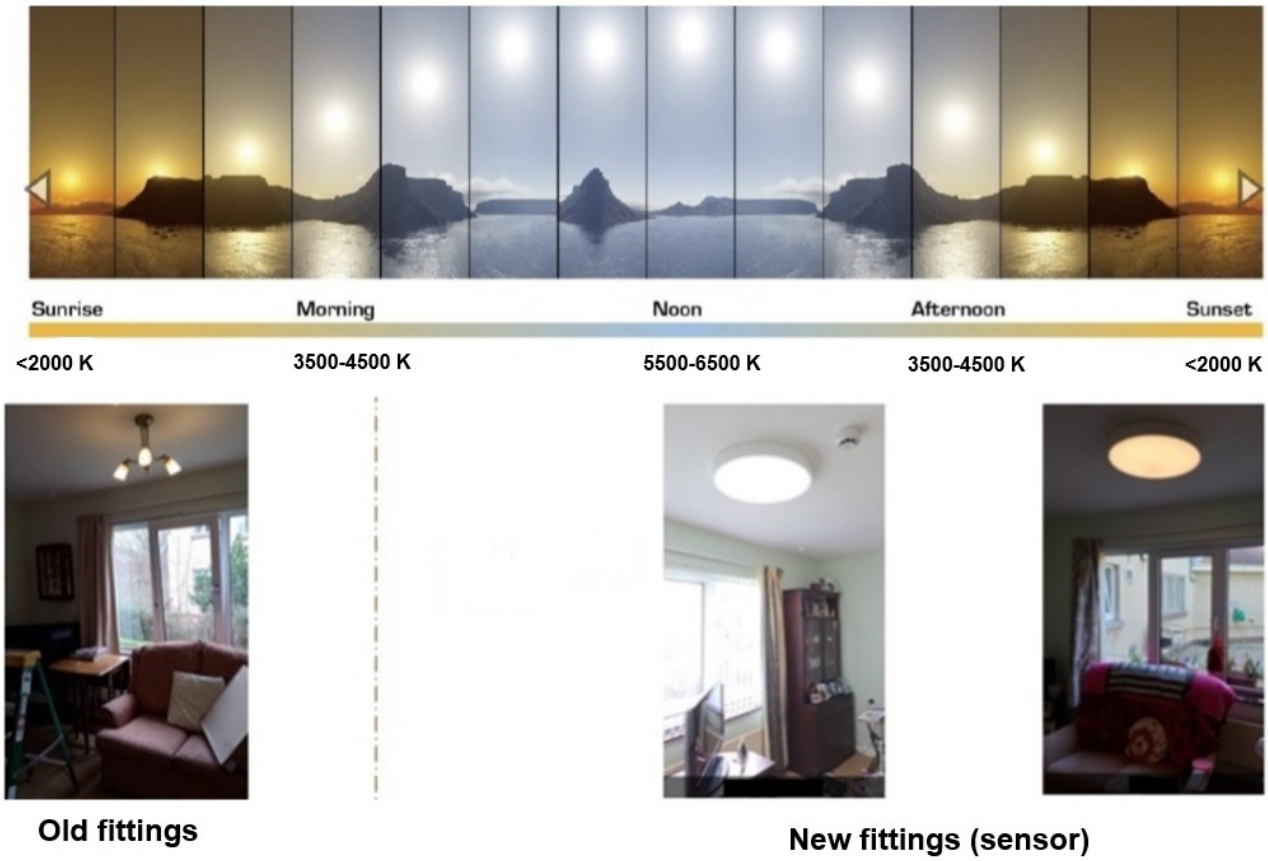
[a]The output is from the luminaire manufacturer and is only expressed in percentages. The actual values are not available. The “intensity (lux)” column states what the authors can measure at eye level that reflects what the percentages give us at this amount of distance from the lighting.

Table . Melanopic lighting intervention parameters.

Intensity (lux)	Circadian stimulus	M-EDI[a] lux
260	0.404	331
300	0.431	382
550	0.532	700

[a]M-EDI Melanopic Equivalent Daylight Illuminance.

Figure 5. Lighting before and after intervention highlighting the variation in spectra throughout the day.



Sensing Component

The sensor is an environmental sensor integrated inside the luminaire and concealed by the diffuser. It is a depth sensing radar sensor, which can perceive the averaged 3D coordinates of an individual in a privacy-friendly manner. The sensor is deployed to track the location, rest-activity, and night activity metrics of the residents with dementia; all parameters expected to be influenced by changes to the circadian rhythm. Frame-by-frame x-y translations were captured at 8 Hz and the total magnitude calculated over 15-minute intervals. This was

normalized by the maximum total translation in the current 15-minute window in order to give activity levels as a percentage. As such, the pseudocode below Figures 6 and 7 demonstrates the type of information collected about each resident.

Figure 6. Algorithm 1: activity metrics.

Algorithm 1: Activity metrics

```
Data: rooms
Result: activity 15min(activity 15, max activity 15, scaled activity)
for room in rooms do
    Get last 15 minutes of x, y data;
    Isolate by single sensor contribution;
    Resample at 1s resolution;
    Assess intervals of sensor overlap (if any);
    if overlap exists then
        Average out the overlapping contributions;
        Combine data;
    else
        Combine data;
    Calculate and store the activity magnitudes per second: |activity|/s;
    activity.append(|activity|/s);
    Calculate activity per 15 minutes:;
    activity_15 = sum(activity);
    Calculate max activity per 15 mins:;
    max_activity = max(activity);
    max_activity 15 = (60 × 15) × max activity;
    Scale the 15 minute activity data to the maximum activity for that time interval:;
    scaled_activity = activity 15 / max_activity 15;
    Return activity 15min(activity 15, max activity 15, scaled activity);
```

Figure 7. Algorithm 2: sleep metrics.

Algorithm 2: Sleep metrics

```
Data: rooms
Result: bed coords(x min, x max, y min, y max, z min, z max)
for room in rooms do
    Collect 1 week of x, y, z position data;
    Isolate between hours of 11pm-5am;
    Calculate mode of x, y, z ± n*ϑ;

Return sleep metrics(sleep start, sleep wake, no of disturbances, bout length));

for room in rooms do
    Pull bed_coords;
    Get last 24 hours of x, y, z position data;
    Generate 1 minute windows of average x, y, z values;
    Assess if each window within bed coord boundaries;
    Put status flag as 'in bed' or 'out of bed' based on above criteria;
    Re-write rules if < 2 consecutive 'out of bed' occurrences present as likely to be noise;

Return bed_status('in bed' — 'out of bed');

for room in rooms do
    Pull bed_status for last 24 hours;
    Isolate from 18:00 (reasonable minimum bed time);
    If > 10 minutes of consecutive 'in bed' occurrences:;
        sleep_start = start time of window;
    Isolate from 05:00 (reasonable minimum wake time);
    If > 10 minutes of consecutive 'out of bed' occurrences:;
        sleep_wake = start time of window;
    Get bed_status between sleep_start and sleep_wake;
    Count consecutive 'out of bed' occurrences and their durations:;
        no_of_disturbances = total no of bed leaves;
        bout_length = average length of time spent 'out of bed' during these hours;

Return sleep_metrics(sleep start, sleep wake, no of disturbances, bout length);
```

Data Analysis

Data analyses was undertaken using SPSS software [24]. All datasets were tested for normality using the Shapiro-Wilk test since the cohort was less than 50 participants. If the data was parametric, paired samples *t* tests (2-tailed) were used to determine statistical significance. If the data exhibited a nonparametric distribution, the Wilcoxon-Signed rank test was used between related samples. Effect sizes were calculated using Cohen *d* and Cliff δ for parametric and nonparametric data, respectively. All measured parameters of well-being were determined parametric with significant deviation from normal and detected solely for 2 parameters of the QUALIDEM scale (E and H: positive self-image and feeling at home). These were therefore analyzed according to the nonparametric methodology highlighted above. Due to the heterogeneity in the sleep metrics obtained, the median of the datasets was calculated to allow for less skew that would arise from taking an average.

Results

Lighting

The lighting metrics were harvested from the network to estimate how much time a resident spent under the dynamic lighting intervention over the duration of the trial. This can be seen in Figure 8. The blue line represents the amount of time spent in their rooms. The orange line indicates that while in their rooms, this is the average percentage of time that the lights were switched on and they were in fact receiving the dynamic lighting intervention. Green lines represent the percentage exposure to dynamic lighting. Typically, the care staff note that common room lighting is generally switched on during the hours of 8 am to 8 pm and all resident lighting is switched on upon wake up time and altered at their discretion throughout the day.

A group analysis of Figure 8 can be seen in Figure 9. The amount of time spent in their rooms generally decreased meaning the amount of time assumed spent in common areas

increased. Although both the blue and orange lines are decreasing, they are converging.

Assuming the times not spent in their rooms were considered to be under common area fully dynamic lighting, the general percentage exposure to dynamic lighting from baseline to weeks 5 - 10 to weeks 10 - 16 increased from the following:

- Baseline: 0% exposure as fully static lighting
- Weeks 5 - 10: 37.48% exposure (SD 2.77%)
- Weeks 10 - 16: 53.08% exposure (SD 4.07%).

Figure 8. Lighting exposure per participant. Blue represents the percentage time in sensor areas, orange is the percentage time while in these areas with lighting switched on, and green represents the percentage time of exposure to dynamic lighting.

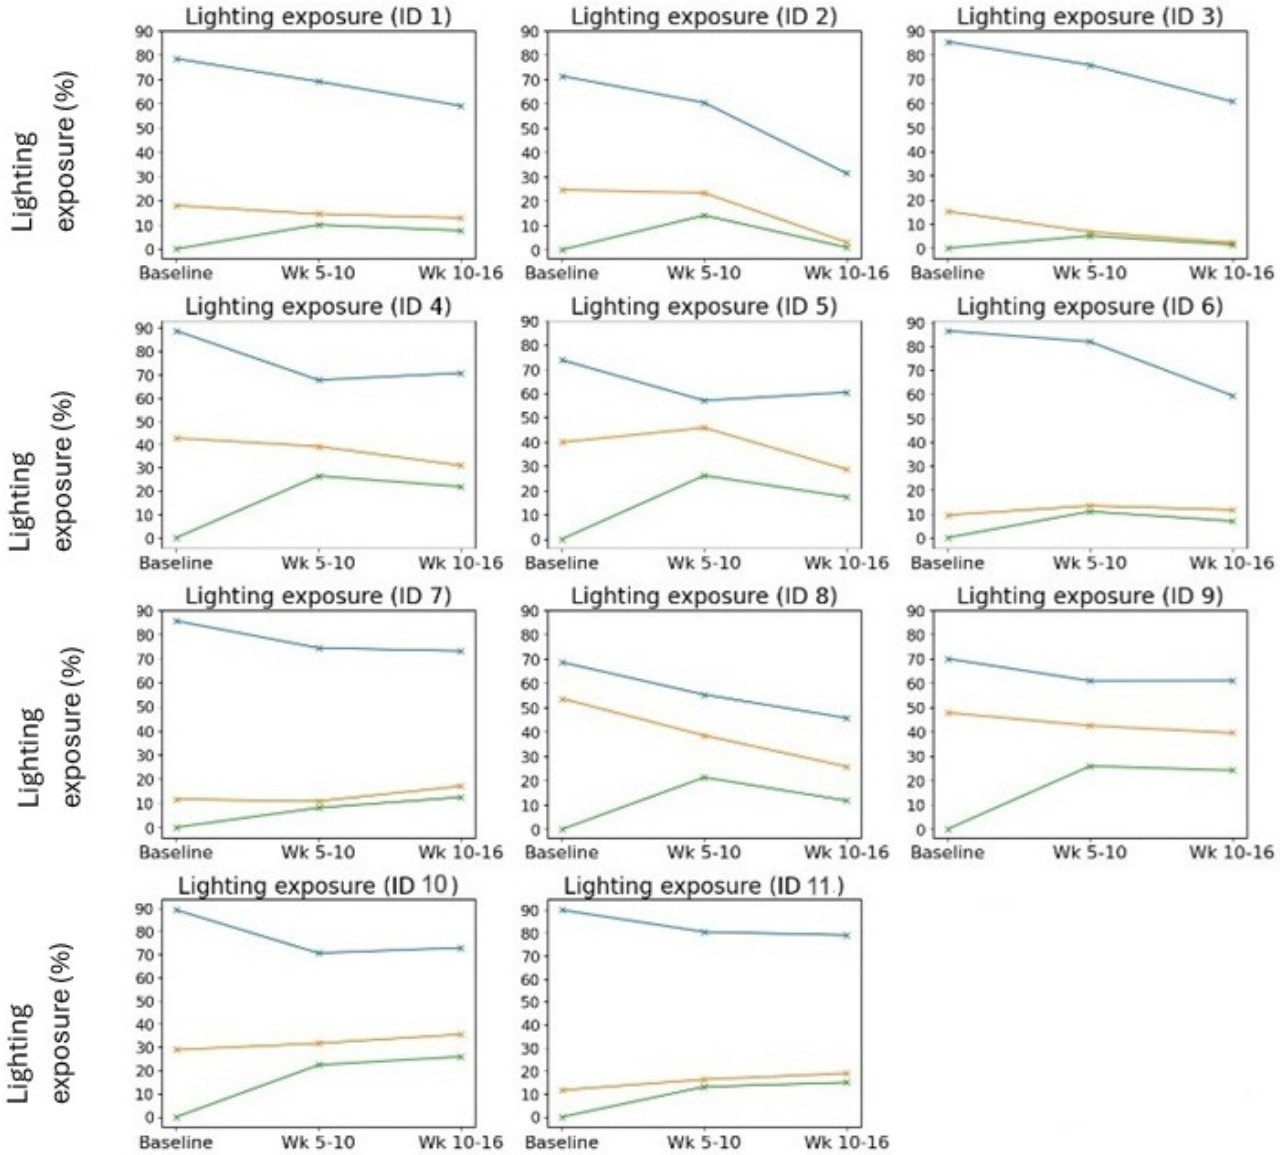


Figure 9. Time spent with lights on as a group trend. The lighter lines indicate error boundaries.

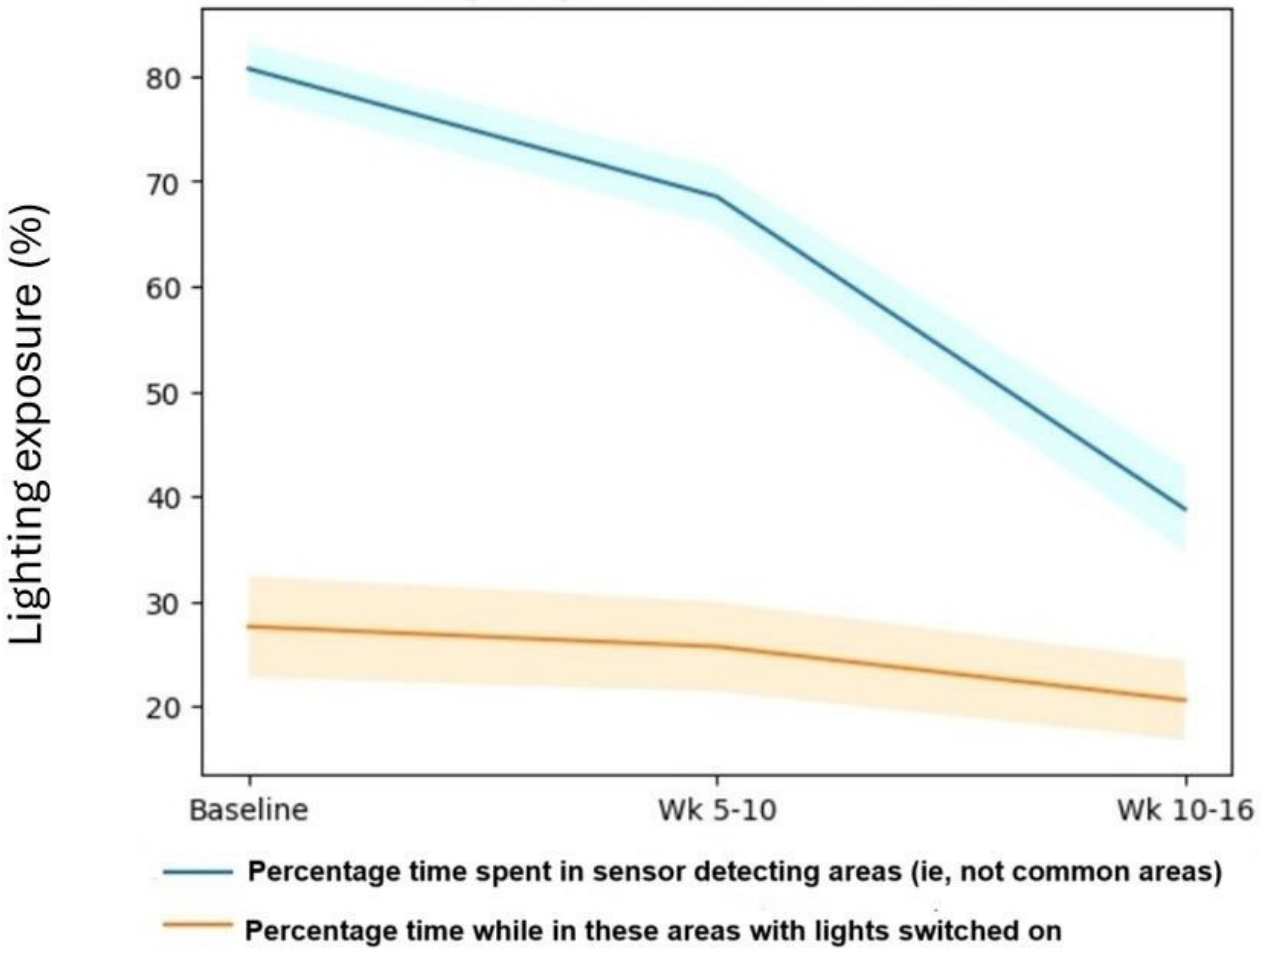
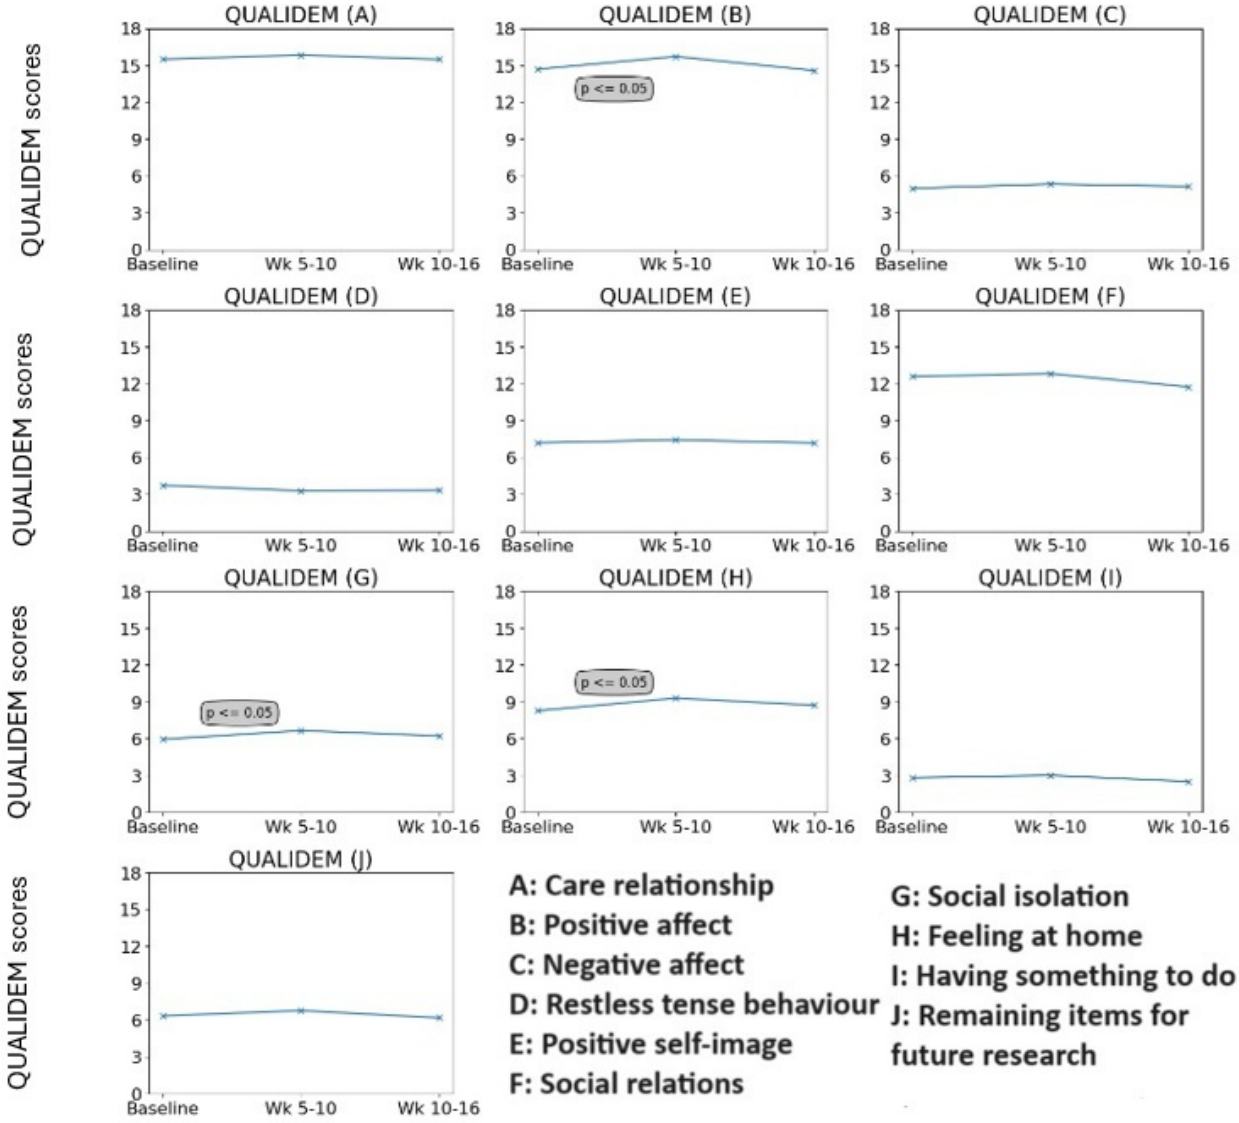


QUALIDEM

Figure 10 shows the QUALIDEM parameters analyzed independently in accordance with the documentation. The results show that from baseline to weeks 5 - 10, there was a statistically significant improvement in B, G, and H with values of *P*=.03, *P*=.048, and *P*=.047 and a moderate effect size. This corresponds to statistically significant improvements in positive affect, social isolation, interdaily stability (IS), and feeling at home.

Figure 10. QUALIDEM scores as a group analyses during both baseline (static lighting) and weeks 5-10/10-16 (dynamic lighting). Note items I and J are not analyzed in this study. Larger values indicate improvement. QUALIDEM: Quality of Life for People with Dementia.



Activity

Commonly reported metrics used in rest-activity studies are the outputs of IS, intradaily variation (IV), and relative amplitude (RA) [25]. IS is an indicator for the synchronization to light and other metabolic cues that inform the body clock. It takes a value between 0 and 1 with the larger number indicating better synchronization. IV gives an indication of body clock disruption and sleep efficacy, with possible values between 0 and 2. The lower the value the better sleep efficacy. RA gives an indication of the robustness of the daily rest-activity rhythm, with higher values equating to a more robust cycle [25].

On a group level, the IS and IV both experience a significant improvement from baseline to weeks 5 - 10 with values of $P \leq .001$ for both variables (Figure 11). The IS also reflects this from baseline to weeks 10 - 16 with a significance of $P \leq .001$. The IV increases from baseline to weeks 10 - 16 but not significantly with a P value of .22.

Figure 12 shows the individual RA. From baseline to weeks 5 - 10, there was a significant improvement in the RA, which means the participant experiences a more robust 24 hour rhythm. The P value for this period was .03. The baseline to weeks 10 - 16 was not significant, but it follows a general upward trend on a group analysis.

An assessment was also carried out of activity levels during typical sundowning hours. The 4 hours before sunset (8 PM, 9 PM, and 10 PM for baseline, weeks 5 - 10, and weeks 10 - 16, respectively) were analyzed as seen in Figure 13. The activity levels increased significantly from baseline to weeks 5 - 10 ($P \leq .001$) but then decreased significantly from baseline to weeks 10 - 16 ($P = .01$). If we take the sunset activity as an analogy to activity during the sundowning hours in dementia, we can see that activity during sundowning hours seems to have increased at weeks 5 - 10 and decreased at weeks 10 - 16.

Figure 11. Box plots for rest-activity metrics as a group analysis, including interdaily stability, intradaily variation, and relative amplitude.

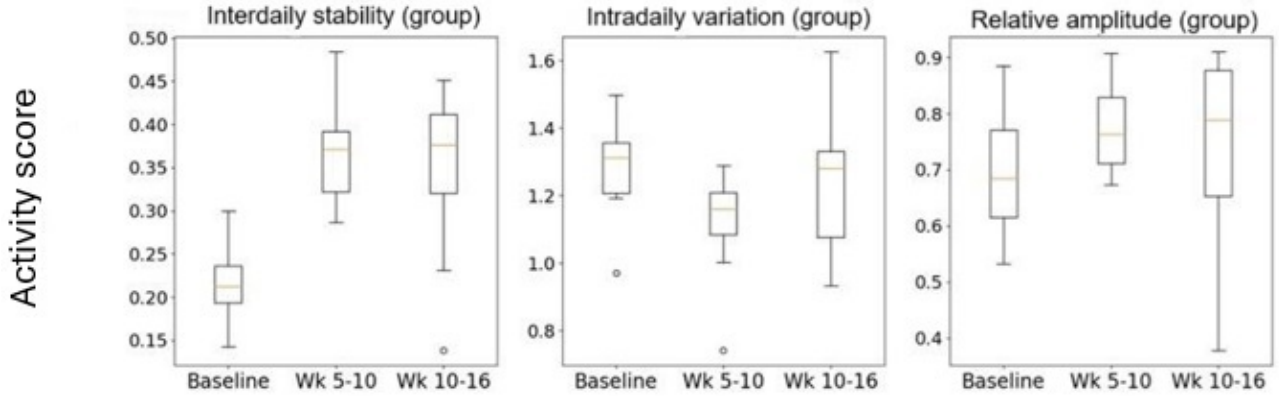


Figure 12. Line plots for rest-activity metrics for an individual analysis, including interdaily stability, intradaily variation, and relative amplitude.

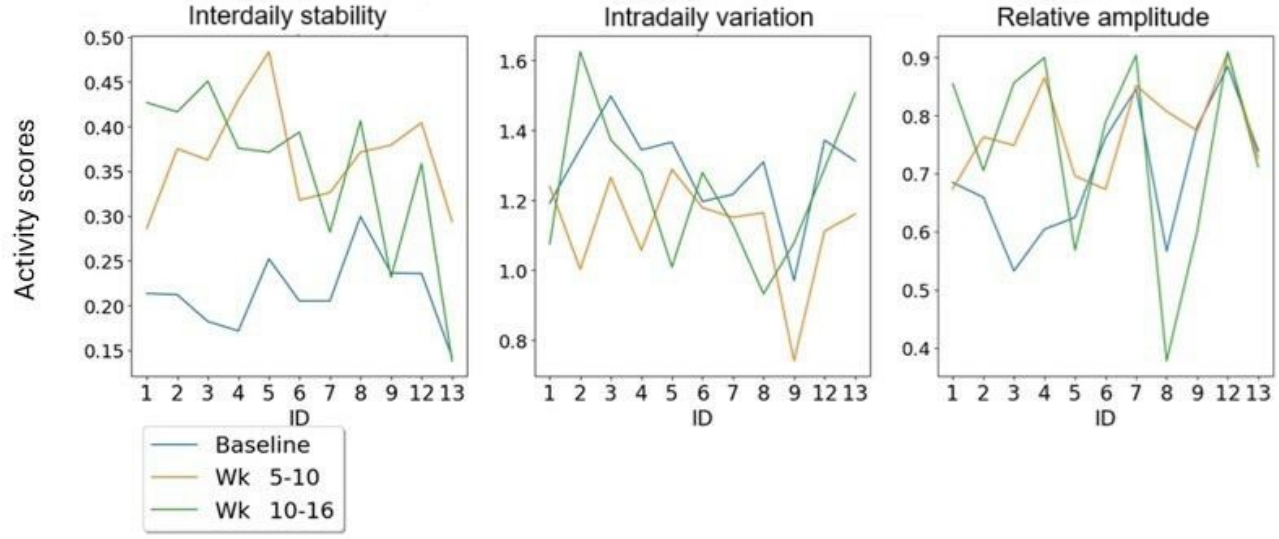

Figure 13. This is the percentage activity levels in the 4 hours before sunset during the trial under different lighting exposures. These data were analyzed with a view to compare with sunset activity or sundowning.

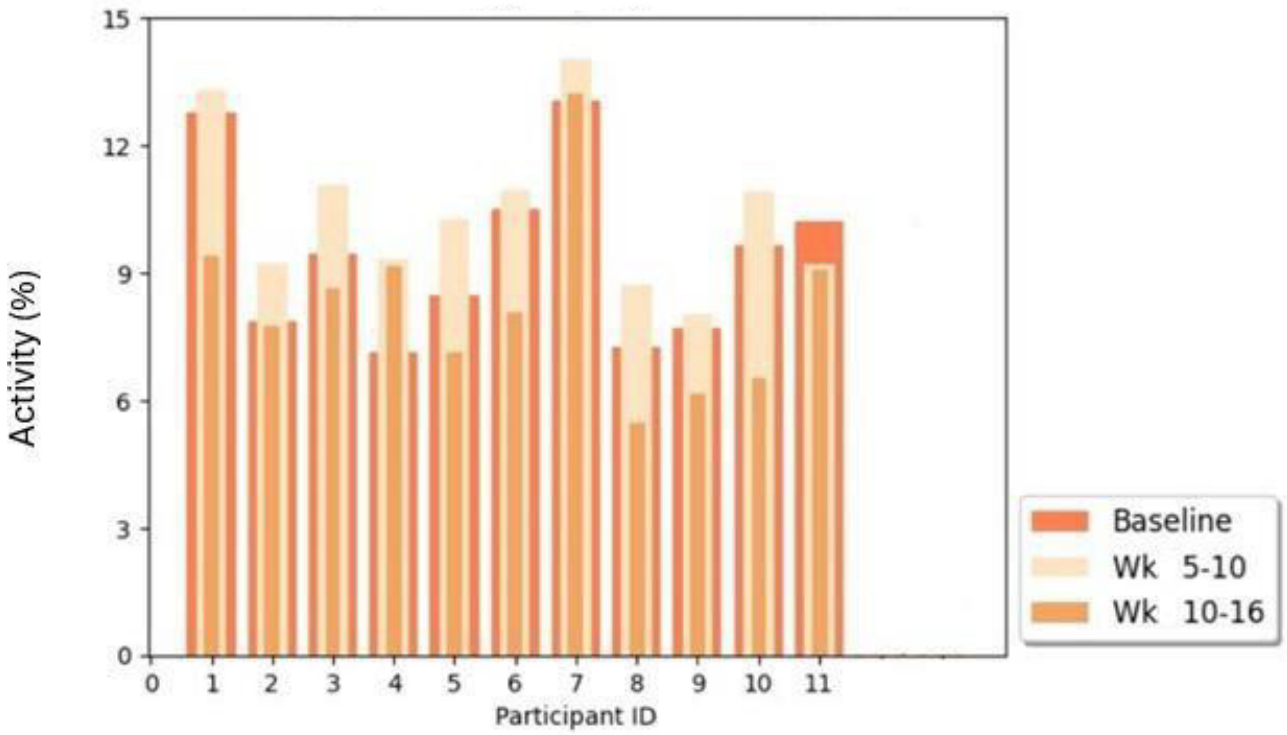


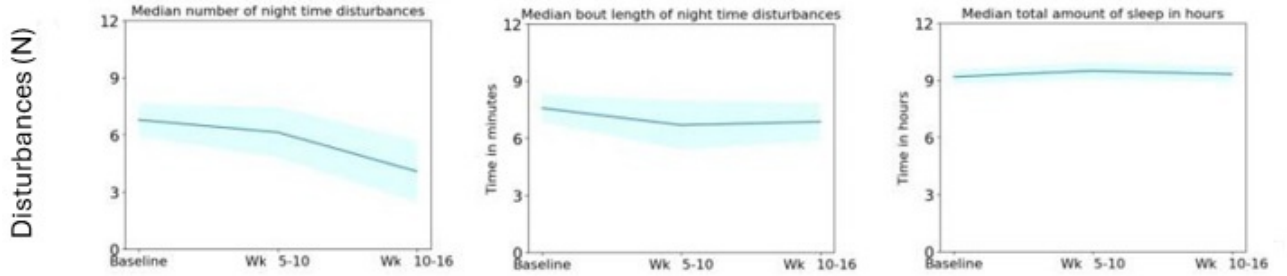
Sleep

Figure 14 shows the median number of sleep disturbances as a group decreased from both baseline to weeks 5 - 10 and from baseline to weeks 10 - 16; however, this did not reach statistical significance.

It should be noted that the highest number of disturbance counts throughout the night on average happened to participant 5 who is the sole one on sleeping medication. If the paired *t* test is repeated for the group without participant 5's data, the reduction in sleep disturbances becomes statistically significant from baseline to weeks 10 - 16.

Figure 14 shows the median length of time that these disturbances lasted for (bout length) also decreased from both baseline to weeks 5 - 10 and baseline to weeks 10 - 16; however, this did not reach statistical significance.

Figure 14. This is the sleep-related metrics recorded on a group level, highlighting the median number of night-time disturbances, bout length of these night-time disturbances, and the total amount of sleep in hours.



Summary

Table 4 shows the *P* values and effect sizes for the statistically significant well-being parameters. Using G*Power (Heinrich Heine University Düsseldorf) software to deduce the required sample size for a medium effect size (0.5), the optimum number of participants to recruit for a future study would be 34.

Table . *P* values and effect sizes for statistically significant well-being parameters.

	P values	Cohen *d*/ Cliffδ**	Summary
QUALIDEM[a] (B)[b]			
Wk 5 - 10	.03	0.639	Significant with medium effect
QUALIDEM (G)[c]			
Wk 5 - 10	.048	0.552	Significant with medium effect
QUALIDEM (H)[d]			
Wk 5 - 10	.047	0.289**	Significant with high overlap
Activity (IS)[e]			
Wk 5 - 10	<.001	2.601	Significant with large effect
Activity (IS)			
Wk 10 - 16	<.001	1.517	Significant with large effect
Activity (IV)[f]			
Wk 5 - 10	<.001	1.314	Significant with large effect
Activity (RA)[g]			
Wk 5 - 10	.03	0.621	Significant with medium effect

Discussion

Principal Findings

This study was conducted to determine the effect of dynamic lighting on well-being for people who are living with dementia.

Social Isolation

Previous studies have highlighted that the exposure to dynamic lighting is not well documented [26-29]. The results from this study highlight that the amount of exposure to dynamic lighting as a group increased from baseline to weeks 5 - 10 and 10 - 16 by 37.48% and 53.08% respectively. Moreover, the amount of times spent in the common areas increased in comparison to the amount of time spent within their own living quarters. Interestingly, by looking at the QUALIDEM scale for parameter "G" as seen in Figure 10, significant improvements to social isolation were found at weeks 5 - 10. This may indicate that exposure to dynamic over static lighting may be responsible for the positive implications found for social isolation. This is in agreement with similar studies conducted by Sust et al [30] who found that residents with dementia experienced improved communications and frequency of participation in activities under dynamic lighting compared to static baseline lighting. Their results were particularly noticed under higher illuminances than delivered in this study (300 - 2200 lux), but with dynamic changes to color parallel with those within this study [30].

The reduction in social isolation within our study continued into weeks 10 - 16 from baseline but did not reach statistical significance. The reason for the subdued progress may be due to the contrast in lighting within a "circadian synchronization period." A "circadian synchronization period" refers to the amount of time it takes for the body to adapt to changes in the circadian rhythm; commonly reported as a period of 2 - 5 weeks [16]. From baseline to weeks 5 - 10, the contrast in lighting transitions is from static lighting to dynamic lighting, whereas there is no contrast introduced in weeks 5 - 10 to weeks 10 - 16; it is simply a continuance of the dynamic lighting parameters. This dampening in the significant improvement from weeks 5 - 10 to nonsignificant improvement in weeks 10 - 16 is interesting to consider when comparing with studies by Wong et al [31]. They deciphered that the exposure to previous lighting histories exhibits a huge impact on an individual's response to lighting [31]. For example, Wong et al [31], found that there is a greater response to lighting interventions upon prior exposure to dark stimuli than bright stimuli, perhaps providing an example of how the larger the contrast in lighting between circadian synchronization periods, the larger the expected impact to the alleviation of certain symptoms. It could be that upon extending our study past 16 weeks, we would have continued to observe a slower paced improvement to social isolation. A further indicator that this might be the case is provided by a study by Figueiro et al [32] who found that symptoms such as agitation, sleep quality, and depression after exposure to dynamic lighting experienced greater alleviation as time progressed in the 25 week study [32].

Sleep

There is a recurring theme with a lot of our findings in that the most significant improvements are observed from baseline to weeks 5 - 10 of dynamic lighting exposure. In most parameter's cases, this improvement from baseline continues into weeks 10 - 16 but at a much lesser and nonsignificant effect than the initial phase. Consider the sleep metrics within this study; the total amount of sleep in hours as highlighted in Figure 14 experiences a progressive increase from baseline to weeks 5 - 10 and 10 - 16. Again, this improvement follows a steeper incline in the first phase of this study in comparison to the second phase. The aforementioned study by Figueiro et al [32] also demonstrates that between the first 3 weeks and 9 weeks of dynamic lighting exposure there is an improvement from baseline, but with the former interval marginally exceeding the 9 week interval. Since weeks 5 - 10 and 10 - 16 within our study refer to the first 5 and 11 weeks of dynamic lighting exposure, respectively, our findings would align with the findings from this study [32]. However, it should be noted that there are other studies which have monitored the impact to sleep after exposure to dynamic lighting and found improvements become progressively larger as the exposure interval increases. For example, Hjetland et al [28] found improvements to proxy-rated sleep after 16 and 24 weeks but not after 8 weeks. One reason these results may contrast is that both our study and Figueiro et al [32] placed dynamic lighting in every vicinity that a resident may frequent within a care home, however Hjetland et al [28] solely placed luminaires in the living space. This could suggest that the absence of a positive implication in sleep parameters witnessed by Hjetland et al [28] after 8 weeks of dynamic lighting could be due to the fact that the exposure amounts were not sufficient enough and therefore the impact to the sleep response would take longer to synchronize. Further exploring the sleep data in our study, Figure 14 observes that the number of sleep disturbances reduced from baseline to both phases of the dynamic lighting exposure. Interestingly, it should be noted that participant 5 was the sole resident on sleeping medication and that if this participant's data are removed from the cohort, the reduction in sleep disturbances at the 10 - 16 week dynamic lighting interval becomes significant. This could indicate that people with dementia on sleep medication may require more tailored dynamic lighting to reflect upon their intensified circadian disruption. This is in alignment with studies suggesting that intense sleep disruption leads to a more rapid cognitive decline and more disrupted circadian rhythms acting in a self-depreciating cycle [1].

Sundowning-Analogous Behavior and Agitation

In terms of sundowning, for most of the participants in our study the percentage of sundowning-analogous activity as seen in Figure 11 demonstrates that after 10 - 16 weeks, the majority of participants experience a nonsignificant reduction in sundowning compared to baseline lighting. The sole participants who experienced an increase in this sundowning behavior at this time interval were participants 4 and 7. Interestingly, when calculating the median wake times for residents, these same participants were the latest to wake with times commencing from 8:25 AM and 9:29 AM, respectively. During these times, it is likely that the first lighting these residents will receive is

of maximum CS and of blue (peak melanopic) wavelength as seen in Tables 2 and 3, as opposed to a general build up to this level the other residents will have experienced at wake times prior to 8 AM. Considering a study by Colenda et al [33] used bright light therapy for participants immediately as they woke, they found that only 1 of 5 participants experienced positive implications on sleep and agitation measurements [33]. Although a much stronger illuminance was used in their study, it should be considered that timings for peak melanopic lighting immediately upon waking may not be of maximum benefit for well-being.

In addition to this, sundowning seems to be a parameter that progressively improves over time. Again looking at Figure 11, it seems sundowning occurrences seem to increase after a period of 5 - 10 weeks before decreasing after a period of 10 - 16 weeks. Similar studies by Baandrup and Jennum [34] and Saidane et al [35] have monitored agitation and found no change to agitation after 4 weeks of dynamic lighting and a reduction in the frequency of agitation after 6 months of dynamic lighting intervention [29,34]. This suggests that longer exposure durations may be needed to positively impact this parameter of well-being in dementia. Additionally, a study by Burns et al [36] observed that the reduction in agitation was significantly correlated to the increase in day length, and so may explain why reductions in activity levels during sundowning hours were larger in later weeks as they occurred over the month of June when the summer solstice occurs [36]. In contrast, the QUALIDEM reported agitation scores (parameter D in Figure 10) highlights a nonsignificant increase in agitation from baseline to weeks 5 - 10 and 10 - 16; however, these results exhibit a nonsignificant decrease in agitation from weeks 5 - 10 to 10 - 16 of dynamic lighting exposure. Once again, the pattern of larger impacts to symptoms becoming present in the transition from static to dynamic lighting phases compared to marginally extended dynamic lighting phases is apparent. The results of the parameter of agitation are complex to analyze due to the contrasting behaviors in sundowning-analogous and QUALIDEM-reported metrics in our study. Reassuringly, it is commonly reported in the literature that the parameter of agitation in dementia in response to lighting is not well understood. In a 2014 lighting review by Forbes et al [37], they found no significant findings for bright light therapies reducing agitation with one study even contributing to a worsening of symptoms in 5 participants [37,38].

Positive Affect and Feeling at Home

Our study found significant improvements in both the well-being parameters of “feeling at home” and “positive affect” during weeks 5 - 10 of dynamic lighting as seen in Figure 10. Positive affect can be likened to positive mood and similar results after exposure to dynamic lighting have been published by Bromundt et al [39], Figueiro et al [32], Kolberg et al [40], and van Lieushout-van Dal et al [41]. It is interesting to consider whether several parameters within the QUALIDEM scale influence the progression of other parameters; for instance does positive affect influence social isolation or sense of feeling at home? Nevertheless, the positive impact on sense of feeling at home (parameter H in Figure 10) has been replicated in other qualitative studies which have researched the opinion on lighting interventions in dementia [42]. The impact to this parameter of well-being after exposure to dynamic lighting may be less surprising, as is seems unanimous in studies designed to reflect on the environmental opinion of dynamic lighting systems that it is better received than that of static lighting [43,44].

Rest-Activity

Our study also monitored the changes to rest-activity rhythms upon exposure to dynamic lighting, reporting findings on IS, IV, and RA (see Figures 2 and 11). All three activity metrics experience significant improvements from baseline to weeks 5 - 10, with IS reporting significance from baseline to weeks 10 - 16 as well. Since these metrics demonstrate adherence of circadian rhythm stability and robustness to light or dark stimuli, it is interesting to consider how the transition to dynamic lighting has impacted them. For example, if we look at Figure 8, which highlights the individual exposures to dynamic lighting, we observe that from weeks 5 - 10 to weeks 10 - 16 for participants 2, 5, and 8, that they experienced the largest reduction in exposure to dynamic lighting, indicating a suboptimal percentage exposure to dynamic lighting. Consequently, if we look at Figure 10 in the RA plot, we can see that there are spikes at lower values than the trend (green line) for participants 2, 5, and 8. This indicates that insufficient exposure to dynamic lighting can significantly impact the robustness of the circadian rhythm.

Furthermore, these significant improvements in rest-activity upon exposure to dynamic lighting are in agreement with studies undertaken by Arden-van Delft et al [27] who concluded that there may be stabilization in activity after using dynamic lighting over a period of 5.5 months in a recurring control-intervention approach with phases spanning between 28 and 42 days [27]. Other studies such as Baandrup et al [34] found that there was no significant changes to rest-activity after exposure to dynamic lighting over 4 weeks [34]. The reasons for the larger improvement in rest-activity witnessed in our study may be due to the fact the dynamic lighting was provided in a completely ambient fashion even in external common areas. However, it may also be attributed to the fact that rather ironically our activity results are being provided by sensors which are environmentally deployed within their living quarters only (not ambient in common areas), and they are therefore not able to capture rest-activity at times when participants are in the common areas.

Summary

It seems possible that prolonged use of dynamic lighting for people living with dementia would lead to aggregated improvements to their well-being over time. In this study, the first phase after baseline (weeks 5 - 10) experienced a 37.48% increase in dynamic lighting exposure, while the transition from phase 1 (weeks 5 - 10) to phase 2 (weeks 10 - 16) experienced an additional exposure of 15.6%, which is less than half of the initial static to dynamic transition. Perhaps the lack of statistical significance continued into weeks 10 - 16 can be explained by the fact that the dynamic lighting exposure amounts have not increased as much as they did in the first instance; from static (no dynamic exposure) to weeks 5 - 10. Since this effect of larger statistical significance is demonstrated in QUALIDEM

parameters, rest-activity, and sleep at weeks 5 - 10 and not at weeks 10 - 16, it seems plausible that insufficient exposure to dynamic lighting could be the cause.

Study Limitations and Future Work

An overall viewpoint of the technology was communicated by the care home manager who supported its use and benefits. One suggestion was for a central control unit to be introduced whereby the care staff could have control over the light switches in resident's rooms. This was suggested so that the residents could obtain the majority exposure to the dynamic lighting but may cause issues in implementing due to the fact that it could take the autonomy away from the residents with dementia. The lack of sensors within the light fittings in common areas may have limited the amount of activity data that could be attributed to each individual throughout the day. In future studies, it would be beneficial to request the consent of the use of sensors in these areas and to introduce sensor processing techniques to distinguish between residents within these areas. In addition, the number of participants within this study was small, and undoubtedly a larger cohort (34 participants) would have provided more applicable effect sizes. Implementing a randomized controlled trial to definitively distinguish cause and effect would be the ideal future pathway for research.

Another limitation to this study was that the 16 week trial period took place from March to July which can be considered a "sunny period"; hence, there is the possibility that the changes observed were due to the natural daylight impact. However, the authors carefully considered the 4 week baseline period in order to ensure that the changes that each individual exhibited could always be compared to a baseline for that individual. In this way, even if all months are "sunny periods," there would be a comparison between static indoor and dynamic indoor lighting. There is a similar argument to be made for the different sun exposures in each room. Since each individual is their own control, these differences are present in both the baseline and intervention measurements and are therefore considered to have minimal impact on any changes observed over the baseline and intervention transition. However as this is a pilot study, future work involves the extension of this study into the winter months to account for external seasonal differences as well.

Additionally, there will be differences in daylight exposure between the equinox in March and the summer solstice in July. The impact of this was not measured but the effect this may have had on study participants cannot be ignored. Again, the authors recommended elongating this study across multiple seasons to gain insight into any potential impact this may administer.

The care home that took part in this study was chosen due to its location within an accessible geographic region for the research team to attend when necessary. Due to the small number of people living with dementia in these facilities, the authors chose to recruit all residents who met the inclusion criteria in favor of random sampling. As a result, the trial was conducted using convenience sampling. The authors note that random sampling may have provided a better representation of the cohort of people living with dementia, but due to the piloting of the trial and the challenges involved in the recruitment of vulnerable adults the authors decided to include all participants. Another limitation was that the type of dementia was not logged. Since several lighting studies have demonstrated that the impact to well-being may be more prominent depending on the type of dementia, this is a parameter that should be logged in all future studies of this type. The authors appreciate that logging this information may provide additional insight into these results.

Conclusion

A 16-week study trialling dynamic lighting for supporting well-being in a care home for residents with dementia was carried out from March to July 2023. The results found that the use of dynamic lighting over static lighting statistically and significantly improved positive affect, social isolation, sense of feeling at home, and rest-activity within 5 weeks of initial exposure. Nonstatistically significant improvements to sleep amount and disturbances were also recorded and extended even 12 weeks into this study; however, improvements were not observed for the well-being parameter of agitation.

Acknowledgments

The authors would like to acknowledge the participants, families and staff from the care home for helping to facilitate this research. They would also like to express thanks to the Royal Commission for the Exhibition of 1851 in their support for this research.

Abstract

Background: Understanding the causes and mechanisms underlying musculoskeletal pain is crucial for developing effective treatments and improving patient outcomes. Self-report measures, such as the Pain Drawing Scale, involve individuals rating their level of pain on a scale. In this technique, individuals color the area where they experience pain, and the resulting picture is rated based on the depicted pain intensity. Analyzing pain drawings (PDs) typically involves measuring the size of the pain region. There are several studies focusing on assessing the clinical use of PDs, and now, with the introduction of digital PDs, the usability and reliability of these platforms need validation. Comparative studies between traditional and digital PDs have shown good agreement and reliability. The evolution of PD acquisition over the last 2 decades mirrors the commercialization of digital technologies. However, the pen-on-paper approach seems to be more accepted by patients, but there is currently no standardized method for scanning PDs.

Objective: The objective of this study was to evaluate the accuracy of PD analysis performed by a web platform using various digital scanners. The primary goal was to demonstrate that simple and affordable mobile devices can be used to acquire PDs without losing important information.

Methods: Two sets of PDs were generated: one with the addition of 216 colored circles and another composed of various red shapes distributed randomly on a frontal view body chart of an adult male. These drawings were then printed in color on A4 sheets, including QR codes at the corners in order to allow automatic alignment, and subsequently scanned using different devices and apps. The scanners used were flatbed scanners of different sizes and prices (professional, portable flatbed, and home printer or scanner), smartphones with varying price ranges, and 6 virtual scanner apps. The acquisitions were made under normal light conditions by the same operator.

Results: High-saturation colors, such as red, cyan, magenta, and yellow, were accurately identified by all devices. The percentage error for small, medium, and large pain spots was consistently below 20% for all devices, with smaller values associated with larger areas. In addition, a significant negative correlation was observed between the percentage of error and spot size (R=−0.237; P=.04). The proposed platform proved to be robust and reliable for acquiring paper PDs via a wide range of scanning devices.

Conclusions: This study demonstrates that a web platform can accurately analyze PDs acquired through various digital scanners. The findings support the use of simple and cost-effective mobile devices for PD acquisition without compromising the quality of data. Standardizing the scanning process using the proposed platform can contribute to more efficient and consistent PD analysis in clinical and research settings.

Introduction

Musculoskeletal pain is a frequent problem that affects a significant portion of the population and can have a major impact on quality of life [1]. Understanding the causes and mechanisms underlying musculoskeletal pain is crucial for the development of effective treatments and enhancement of patient outcomes. Moreover, investigating musculoskeletal pain contributes to the advancement of our understanding of anatomy, physiology, and pain mechanisms, with potential implications for comprehending and managing pain [2,3].

There are several methods for measuring muscle pain, including self-report measures, behavioral measures, and physiological measures [4]. Self-report measures involve asking the person to rate his or her level of pain on a scale, such as the Visual Analog Scale or the Numeric Rating Scale [5]. A promising way of evaluating pain using drawings is known as the Pain Drawing Scale [6-10].

Digital technologies have had a significant influence on the evolution of pain drawings (PDs), with different applications in the field of medical apps [11].

The fields of application of PDs include diagnosis of low back pain disorders; paresthesias evoked by implanted neurological stimulators; depiction of orofacial pain, such as headaches and toothaches; and evaluation of users of electric wheelchairs with pain located in the back, buttocks region, and so forth.

Body charts can also illustrate other types of sensory experiences such as numbness, tingling, hypoesthesia, or allodynia [12].

While digitally acquired PDs offer advantages, many studies demonstrate sophisticated analyses of scanned or digitized pen-and-paper PDs, showcasing the versatility of digital image processing. This capability enables the digitization and analysis of extensive collections of pen-and-paper pain diagrams, making it adaptable to various settings and needs.

In this technique, the individuals are instructed to color the area where they are experiencing pain, and the picture is then rated on a scale based on the amount of pain depicted [13]. This can be a useful tool for measuring pain in individuals who have difficulty verbalizing their pain experience, such as young children or nonverbal individuals [14]. However, it is important to keep in mind that PDs can be subjective and may be influenced by factors such as the person's cultural background or level of education [15]. PDs typically consist of body charts with different views of the human body (dorsal, ventral, and side) or subportions (head, hand, etc), and patients are instructed to color with a marker the area where they experience pain. The body charts can be divided into regions such as the Margolis regions [16]. This technique is used to describe and categorize the location of musculoskeletal pain in the body. The regions are based on anatomical divisions of the body, including the neck, upper extremities, low back, and lower extremities [17].

The purpose of the Margolis regions is to provide a standardized and easily understood way to describe the location of musculoskeletal pain, which can help with diagnosis and treatment planning [18,19].

PDs can be analyzed in a variety of ways, depending on the purpose of the analysis and the method used to create the drawings. The most common method of analyzing PDs is the measurement of the size of the pain region. This can be done using computer software or manual measurement techniques [20].

There are different software programs available for analyzing PDs [21-25]. These programs can be used to perform both qualitative and quantitative analyses of PDs, depending on the specific software and the features it offers [26]. Some researchers also introduced sex-specific body charts in order to facilitate the communication of pain for women [17,27,28].

Some of the features offered by pain analysis software may include image digitization (allowing the conversion of traditional paper drawings into digital format for analysis), image scaling (allowing the adjustment of the size of the PDs to match a reference scale), image analysis (using algorithms to automatically identify and quantify features of the PD, such as the size and shape of the pain region), and data visualization (displaying the results of the analysis in a clear and easy-to-understand format, such as graphs or heat maps).

Submitting paper PDs to patients is simpler than using drawing applications running on tablets. Anyway, the use of PDs is not indicated in patients with vision impairment or in preschool children, although some studies investigated the application in teenagers. Being a self-assessed measure the patients should not have cognitive impairments, or diseases including misperception of their body.

While digital drawings can be easily edited and manipulated, and the tools available on a tablet can offer a wider range of color options and effects, paper PDs are largely used in clinical settings. This preference stems from the fact that many patients feel more comfortable using the pen-on-paper approach rather than digital devices [29-31].

There are different methods for scanning PDs, including using a flatbed scanner, a device that scans flat, thin documents placed on a glass window; a handheld scanner, a portable device that can scan images while being moved over them; a drum scanner, a high-end scanner that uses a rotating cylinder to capture the image; a multifunctional printer scanner, a printer that also includes a scanner function; and a virtual scanner, a software that can use a camera to scan images.

To date, there is no standardization in scanning PDs. The existing softwares for PD acquisition work with specific body charts and do not allow a direct comparison between using the same drawing. The aim of this study was to evaluate the accuracy of PD analysis performed by a web platform using different digital scanners. The objective of this study was to demonstrate that simple and relatively cheap mobile devices can be used to acquire PDs without loss of information.

Methods

Ethical Considerations

We did not involve patients, subjects, or animals. The data set was generated through a computer simulation; thus, there was no need to have ethical approval.

Sketch Your Pain Platform

The proposed analysis was performed using a web platform. The main features of this distributed web application (currently available on a local server [32]) are as follows:

1. *Knowledge-base management*: the platform allows the collection of patient's data (biometric, pain history, applied therapies, diagnoses, etc).
2. *PD acquisition*: PDs can be uploaded both digitally and from paper (see details in the following section).
3. *Basic PD analysis*: each pain spot is analyzed individually (ie, number of pixels, barycenter, etc).
4. *Smart analysis services*: the platform provides a plug-in–based mechanism that allows the implementation of additional analysis within the platform. In this way, researchers can apply specific innovative tools to the PDs stored in the database [33].

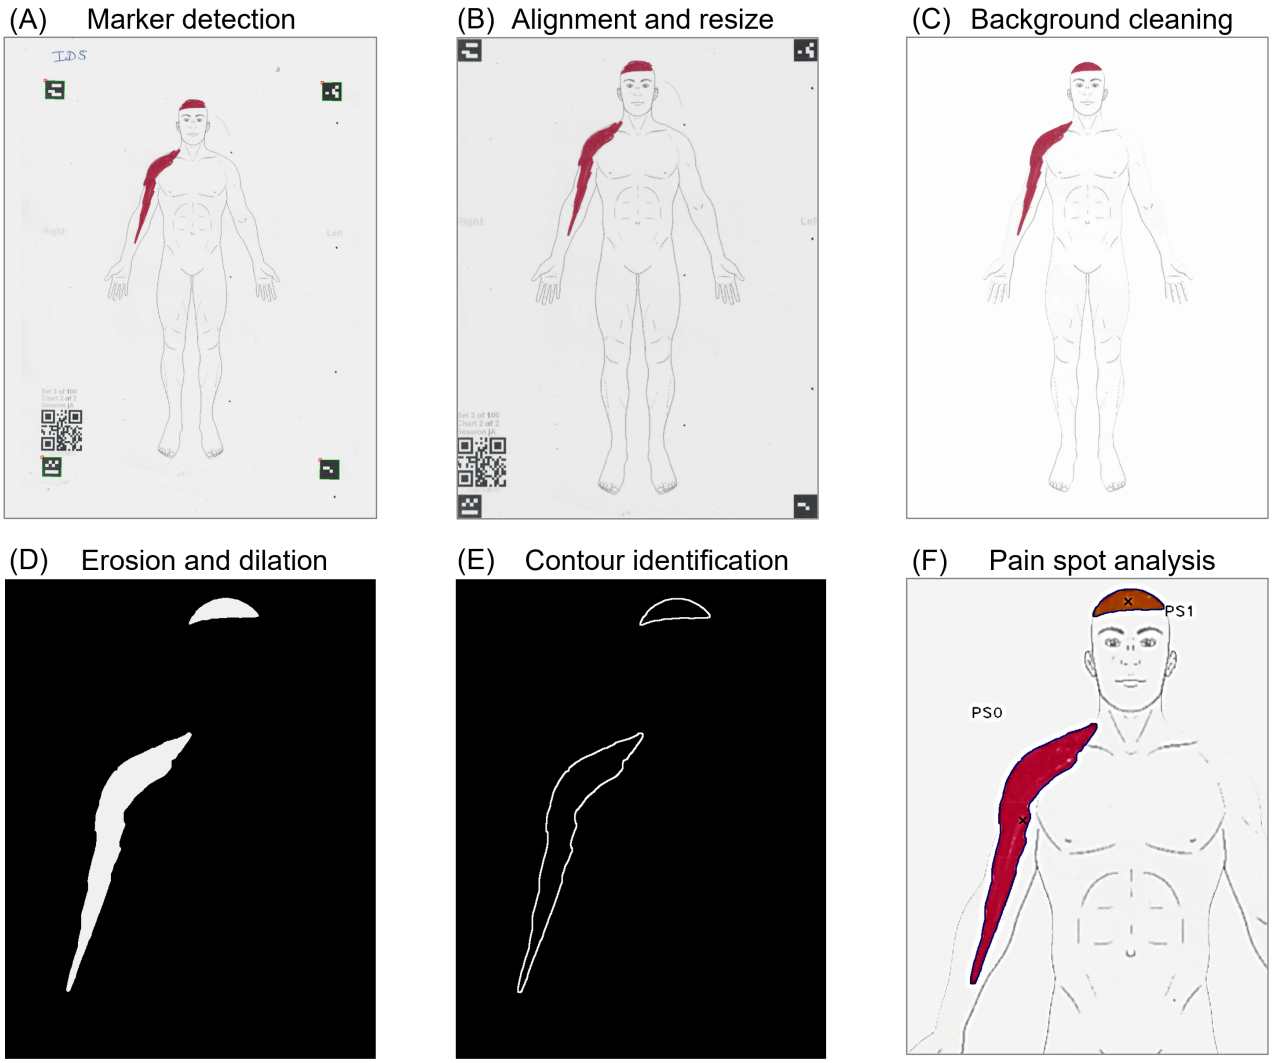
A paper PD can be imported in two ways: (1) it can be digitally imported by using the specific acquisition tool that allows for drawing directly on a tablet, using a digital pen on the touch screen (available on a local server [34]), or (2) it can be manually imported as a PDF file (the platform allows one to download a PDF file including empty body charts with a unique QR code, which can be printed, filled manually using a color marker, and scanned as a PDF file).

When a PD is generated digitally, it is already aligned with the body charts, while for the paper drawings, the process is more complex and can be summarized as follows. The body chart and all related information are identified thanks to the QR code, including the information of the protocol, subject ID, gender, and view of the body chart, and are stored in a database. The platform code and data are stored on a local server. The patient names and sensitive data are anonymized using codes that are available only to the operators.

The scanned image is aligned and cropped using the 4 markers at the corners as pivots (Figure 1A).

The image is resized in order to have the same number of pixels of the body charts stored in the platform (ie, 2048×1536 pixels; Figure 1B). The areas outside the body chart are removed using a mask image. This step also allows for the removal of all possible out-of-body staining errors (Figure 1C). The pain spots (that should be drawn in color and not in any shade of gray) are identified and isolated from the body chart by computing the SD of each pixel (in this way, the SD of black pixels [0, 0, 0] and white pixels [255, 255, 255] is equal to 0, while a red pixel [255, 0, 0] has an SD of 147.2). The optimal threshold for the minimum SD (based on preliminary tests) that works best in extracting pain spots from the body chart with different conditions of light and colors is 25. In this way, the color image is converted into a Boolean matrix where ones correspond to pixels with pain. An algorithm for extrusion and subsequent erosion is applied to the Boolean image in order to fill possible gaps that can happen when the user is using a sharp marker (Figure 1D). All contours of the pain spots and the potential holes in them are identified by means of the Canny edge detection algorithm [35]. The pain spots whose contours contain fewer than 20 points/pixels are removed. Likewise, the holes present in the spots, whose contours contain less than 15 points/pixels, are removed. Further, the pain spots smaller than 100 pixels are removed. Likewise, the holes smaller than 150 pixels are removed (Figure 1E). The individual pain spots are identified by an image segmentation algorithm, and for each spot, the area in pixels and the coordinates of the centroid are computed. The final result of the process is shown in Figure 1F.

Figure 1. Pain spot detection process. (A) The 4 markers at the corners and the QR code are identified. (B) The pain drawing is aligned and scaled. (C) The areas outside the body chart are removed. (D) Pain drawings are separated from the background and eroded in order to correct the imperfections due to pen drawing. (E) Pain spot contours are identified and small holes are removed. (F) Each pain spot is analyzed to extract area and position. PS: pain spot.



Generation of Artificial PDs

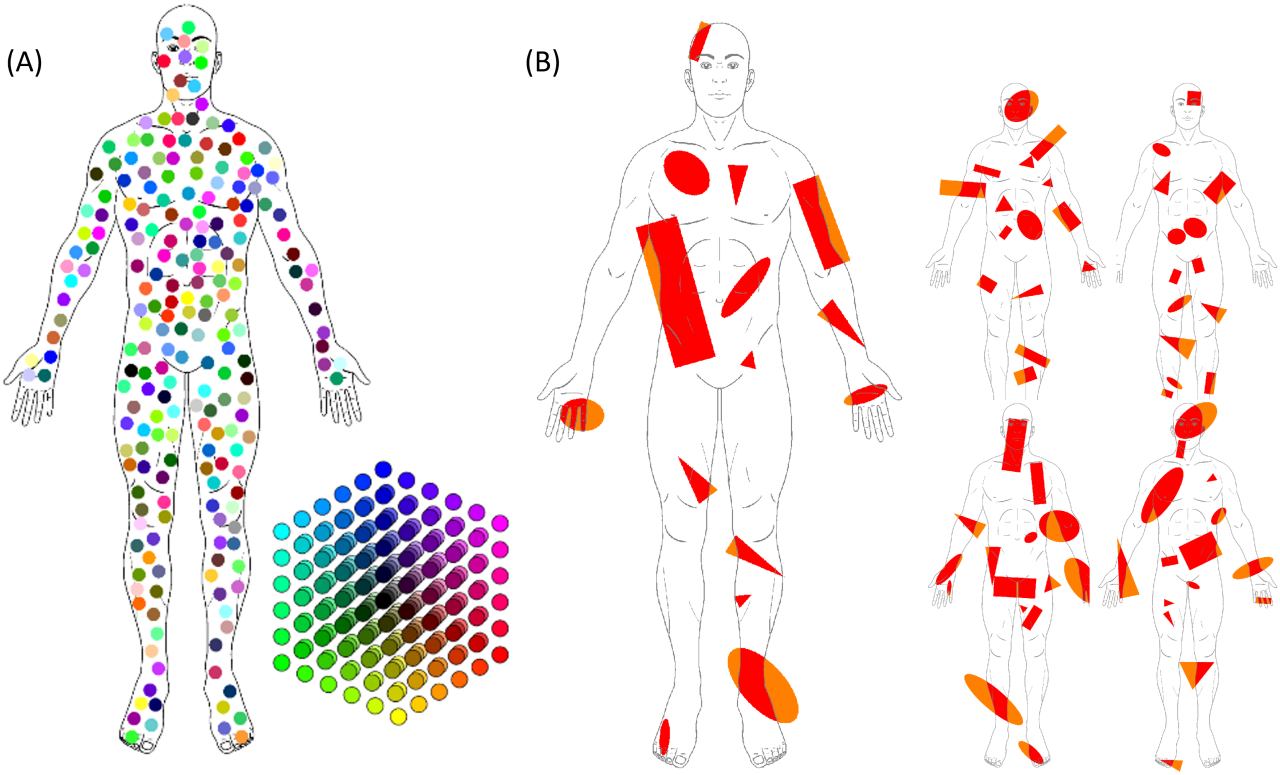
For the present protocol, 2 sets of PDs were generated with a homemade MATLAB (MathWorks) code. We decided to test the platform by using artificial PDs in order to have complete control of the process and of the analysis. For each of the pain spots generated randomly, we had information on pain location (barycenter of the pain spot), area in square pixels, and shade of color in the red, green, and blue (RGB) scale, and with these data, we could assess the performance of each of the scanning devices. A preliminary study was conducted on the platform using different scanning devices on PDs of real patients with similar results [36].

The body chart selected was a male frontal body chart, representing the contours of a full male body in frontal view (dimensions: 1536×2048 pixels).

Color Analysis

The first artificial PD was generated, adding 216 colored circles, which were 33 pixels in diameter, within the body chart map. The circles were randomly positioned within the body chart in order to be nonoverlapping and not touching each other. The colors were chosen in order to uniformly span the RGB color cube, using 6 different intensities for each color. Since the color depth was defined on a range from 0 to 255 (1 byte), the values of each color were 0, 51, 102, 153, 204, and 255. In this way, the total number of colors was 6^3=216, ranging from black (0, 0, 0) to white (255, 255, 255) and including all combinations of RGB (ie, [0, 0, 0], [0, 0, 51], [0, 0, 102],…[51, 0, 0],…[255, 255, 255]; Figure 2A).

Figure 2. Representation of the artificial pain drawings generated with MATLAB. (A) A total of 216 colored circles with a 30-pixel diameter were randomly located within the area of the body chart. The colors were uniformly distributed in the RGB color cube. (B) Five body charts with randomly generated shapes. RGB: red, green, and blue.



Area and Location Analysis

The second set of PDs was composed of 5 artificial PDs generated by adding several red shapes (ellipses, rectangles, and triangles) to the same body chart; the shapes were generated with random sizes, orientations, and positions and could overlap and be partially outside the body chart mask (Figure 2B). The red color was chosen mainly because it can be easily associated with pain in a body chart; in addition, in the RGB cube, the red color is located in one of the vertices (ie, it has the highest SD value among triplets of RGB values, together with yellow, magenta, cyan, blue, and green), and it is easy to find red pens or markers in common shops.

Each of the 2 sets was printed in color, using the same printer (Sharp MX-7580) to print 11 copies; markers were added at the 4 corners, and a QR code was added at the bottom left side. The markers and the QR code were included in order to allow the platform to align the images and add the PDs to the internal database.

Selection of Scanning Devices

The 11 sets of drawings were then scanned using different devices and apps (Table 1).

We selected 3 flatbed scanners with different sizes and prices: 1 professional office printer or scanner that was available in our university (Sharp MX-4070; price about US $5000), 1 portable flatbed scanner (Canon Lide 220; ~US $50), and a home printer or scanner (HP Envy 4500; ~US $300).

In addition, we selected 3 smartphones with different price ranges: iPhone 12 (~US $1000), Samsung Galaxy (~US $400), and Ulefone Armor (~US $100). All the 3 devices were using the same app for scanning images (vFlat scan), in order to compare only the hardware of the devices.

Moreover, for the cheapest smartphone, we selected 6 free apps available in the android apps Google Play repository. The apps were selected according to their popularity and ranking based on users' comments.

For each scanner, a PDF file was generated including the corresponding set of images (1 with colored circles and 5 with red shapes). The PDF files were uploaded in the sketch your pain platform [32].

Table . List of devices used to scan the artificial pain drawings[a].

Type	Device model	Resolution	Price (US $)	App
Flatbed	Sharp MX-4070	300 dpi[b]	~5000	—[c]
Flatbed	Canon Lide 220	300 dpi	~50	—
Flatbed	HP Envy 4500	300 dpi	~300	—
Smartphone	iPhone 12	12 Mpx[d]	~1000	vFlat Scan
Smartphone	Samsung Galaxy S10 Lite	32 Mpx	~400	vFlat Scan
Smartphone	Ulefone Armor-X	13 Mpx	~100	vFlat Scan
Smartphone	Ulefone Armor-X	13 Mpx	~100	TapScanner
Smartphone	Ulefone Armor-X	13 Mpx	~100	Simple Scan
Smartphone	Ulefone Armor-X	13 Mpx	~100	Fast Scanner
Smartphone	Ulefone Armor-X	13 Mpx	~100	CamScanner
Smartphone	Ulefone Armor-X	13 Mpx	~100	TurboScan

[a]The flatbed devices generated the PDF files using proprietary software, while smartphones needed an app to generate the PDF using the camera.

[b]dpi: dots per inch.

[c]Not available.

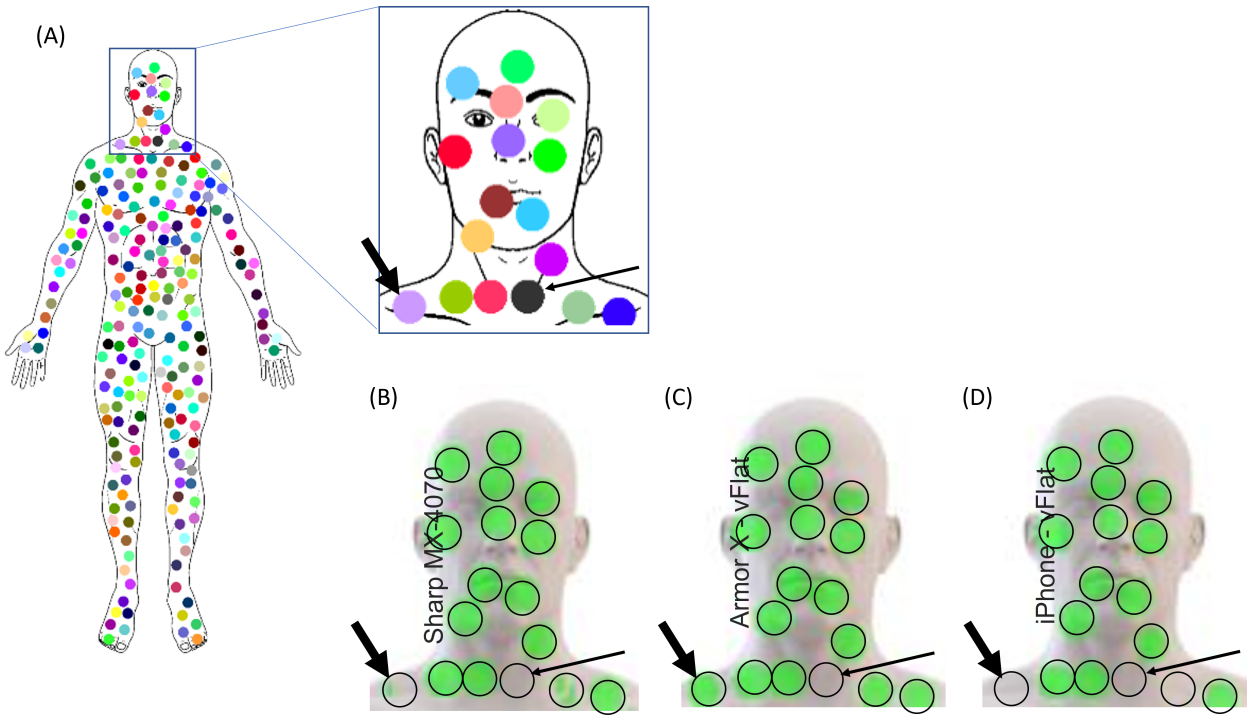
[d]Mpx: megapixels.

Image Processing

The original area of each pain spot generated with MATLAB was computed as well as the coordinates of the centroid of each pain spot. The sketch your pain platform identified the QR codes and allowed the processing of each identified pain spot, providing area in pixels and coordinates of the centroid.

For the analysis of colors, we analyzed whether the platform was able to identify a pain spot corresponding to each of the locations where colored circles were generated. If the area of the identified pain spot was larger than a fixed threshold (90% of the theoretical area; eg, 450 out of 500 pixels), then the pain spot was counted (Figure 3).

Figure 3. Examples of identification of pain spots from colored circles. (A) The original drawing and the output of the platform algorithm for 3 different devices are shown. The green color represents an identified pain spot. The purple circle on the bottom left corner (indicated with the thick arrow) was not identified by the iPhone (D) and Sharp scanner (B), but it was identified by the Armor phone (C). The black circle on the neck (indicated with the thin arrow) was not identified by any of the devices.



Statistical Analysis

The variables used for the statistics were the area (A) of pain spots in square pixels and the coordinates of the centroid (x, y) of each pain spot in pixels. The variables computed for each scanning device were compared with the variables computed for the corresponding pain spots on the original artificial PDs generated with MATLAB. The percentage area error (E) was computed as the difference between the 2 areas divided by the area computed on original PD and expressed as a percentage. The distance (D) between the theoretical centroid of the pain spot computed on original image and the centroid of the pain spot identified by each device was also computed and expressed in pixels.

Intraclass correlation coefficient (ICC) estimates (and their 95% CIs) of pain area and barycenter coordinates were calculated using MATLAB and a 1-way mixed-effects model.

In addition, standard error of measurement (SEM) and minimal clinical differences were computed for pain area and barycenter position.

Descriptive statistics is presented with box and whisker plots with median and IQR values.

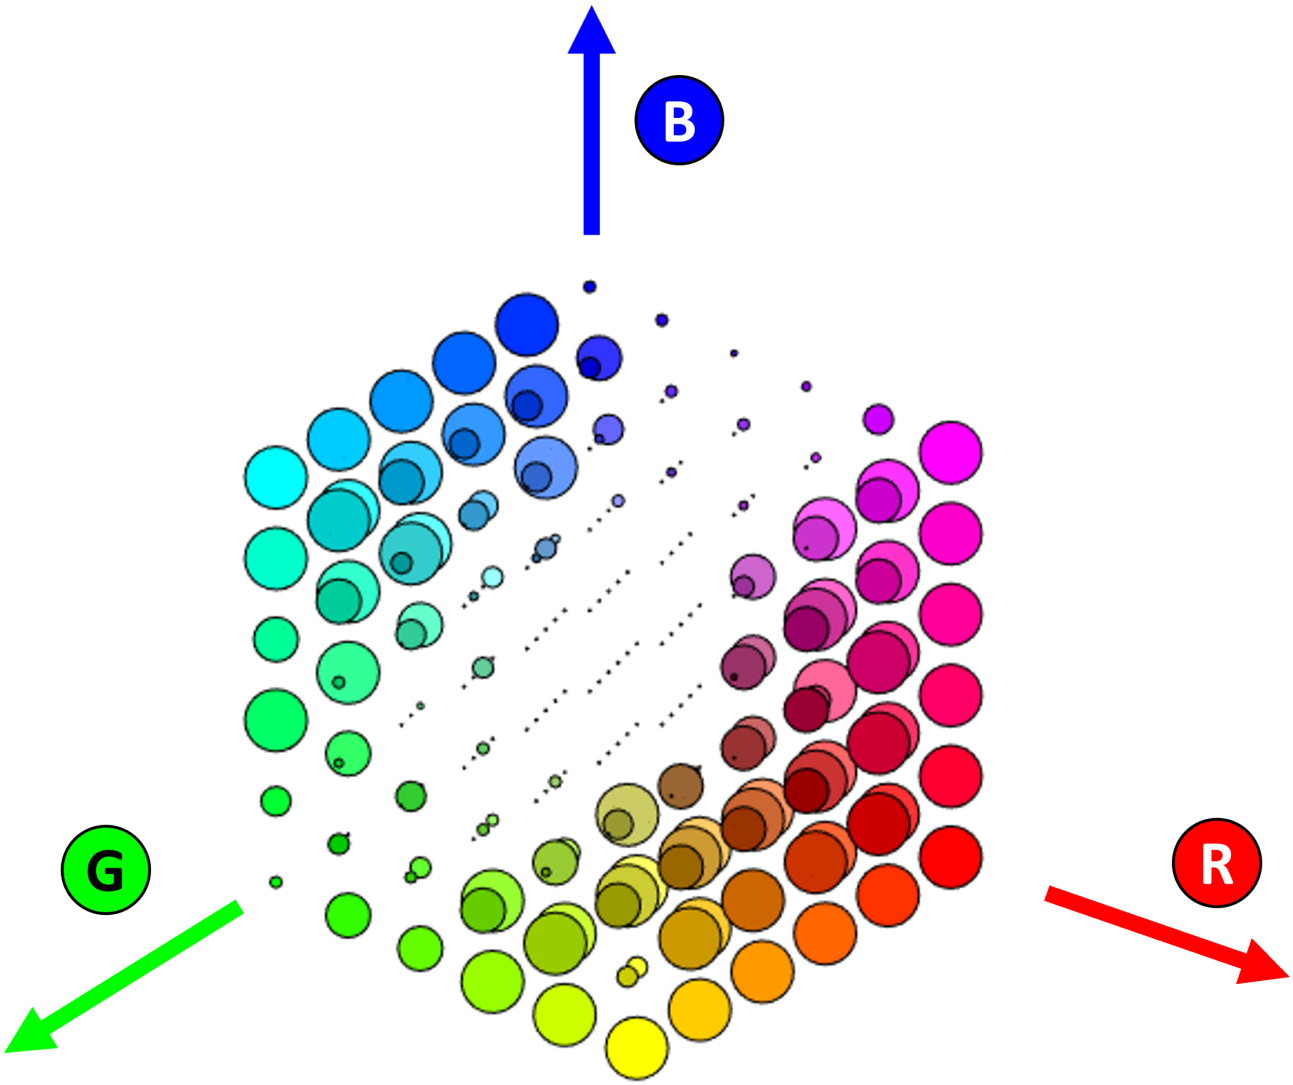
Results

Color Analysis

A Boolean table with the results of pain spot identification was generated with 216 lines (1 for each color) and 11 columns (1 for each scanner). A graphical representation of the table is represented in Figure 4.

Each color is represented by a circle in the 3D color cube, and the size of each circle is proportional to the number of scanners that were able to identify that color (ie, if the area of the identified pain spot was larger than 90% of the printed circle). The maximum circle diameter was set to two-thirds of the spacing between adjacent circles. In this way, it is easy see which colors are best for PDs. As expected, the colors with identical values in RGB triplets (ie, shades of gray, black, and white) were never identified by the software, and colors with low values of SD in RGB triplets (eg, low-saturation colors) were not identified with most devices. The colors that were identified with all devices are located close to the corners of the color cube (ie, high-saturation colors, such as red, cyan, magenta, and yellow).

Figure 4. Representation of the performance of the algorithm in identifying different color circles. The middle diagonal (from white to black where RGB components are equal) and the colors located close to the central diagonal are not identified by the algorithm, while colors such as red, magenta, and yellow are identified by all devices. RGB: red, green, and blue.



Area and Location Analysis

Figure 5 shows the distribution of areas of the pain spots generated artificially and randomly distributed on each of the 5 body charts. The pain spots were divided into 3 categories according to their area in square pixels ($A<50^2$: small; $50^2 \leq A<100^2$: medium; and $A \geq 100^2$: large).

The ICC for pain area was 0.99, with a 95% CI 0.99 - 0.99 ($F_{74,750}$=1.44e+04). In addition, the ICC and CI values for barycenter coordinates were above 0.99 (x-coordinate: $F_{84,930}$=4.55e+05; y-coordinate: $F_{103,843}$=5.12e+05).

Table 2 shows the SEM and minimal detectable change values for each device compared with the theoretical value.

Figure 6A shows the percentage error of pain extent for each device for the 3 categories of pain spot areas. For all devices, the percentage error was below 20% for small, medium, and big pain spots, with lower values associated with bigger areas. A significant negative correlation was observed between percentage of error and spot size (R=−0.237; P=.04; Figure 6B).

Figure 7 shows the percentage error of distance between the theoretical location of the centroid of each pain spot and the location of the centroid of the identified pain spot. The distribution of the distances was always below 5 pixels except for the Armor device with the TurboScan app (11th column).

Figure 5. Representation of the distribution of shapes according to their size. The 3 colors are used to represent the 3 categories that were used for further analysis The image in the legend shows the thresholds used to divide the categories (as square shapes).

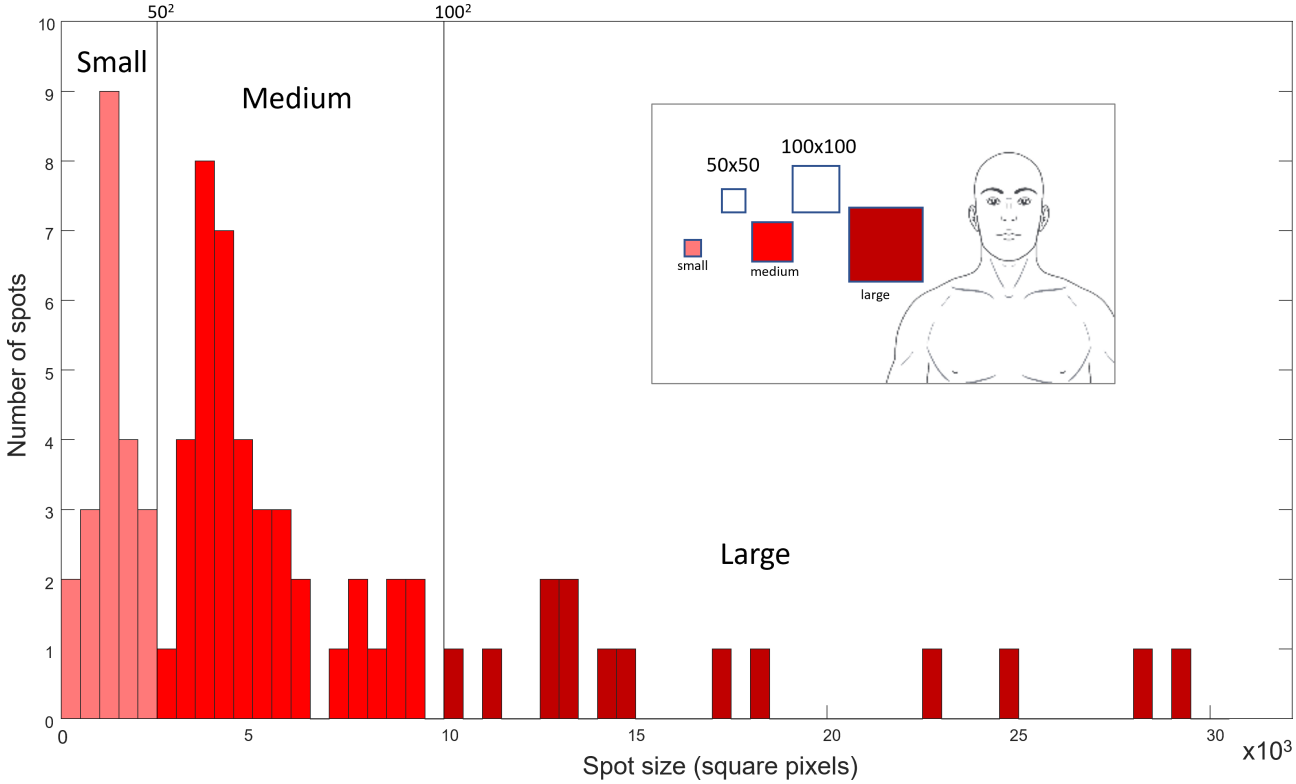


Table . Standard error of measurement and minimal detectable change for the identification of pain area and for the barycenter distance for each device compared with the theoretical value.

Device model	Area SEM[a] (pixels^2)	Area MDC[b] (pixels^2)	Barycenter distance SEM (pixels)	Barycenter distance MDC (pixels)
Sharp MX-4070	262	513	1.5	2.9
Canon Lide 220	348	682	1.5	3.0
HP Envy 4500	219	429	1.5	3.0
iPhone—vFlat	134	262	1.0	2.1
Galaxy S10 lite—vFlat	172	336	1.4	2.6
Armor X—vFlat	182	356	1.3	2.5
Armor X—TapScanner	247	485	2.1	4.2
Armor X—Simple Scan	251	491	2.6	5.1
Armor X—Fast Scanner	287	563	2.4	4.8
Armor X—CamScanner	227	444	2.0	3.8
Armor X—TurboScan	505	989	4.0	7.8

[a]SEM: standard error of measurement.

[b]MDC: minimal detectable change.

Figure 6. (A) Distribution of errors in identifying the pain spot areas expressed in percentages. The 3-color box and whisker plots for each device represent the distribution of area error for each of the 3 categories (small, medium, and large pain spots). (B) Correlation between percentage of error and spot size (the regression line is indicated as a dashed line).

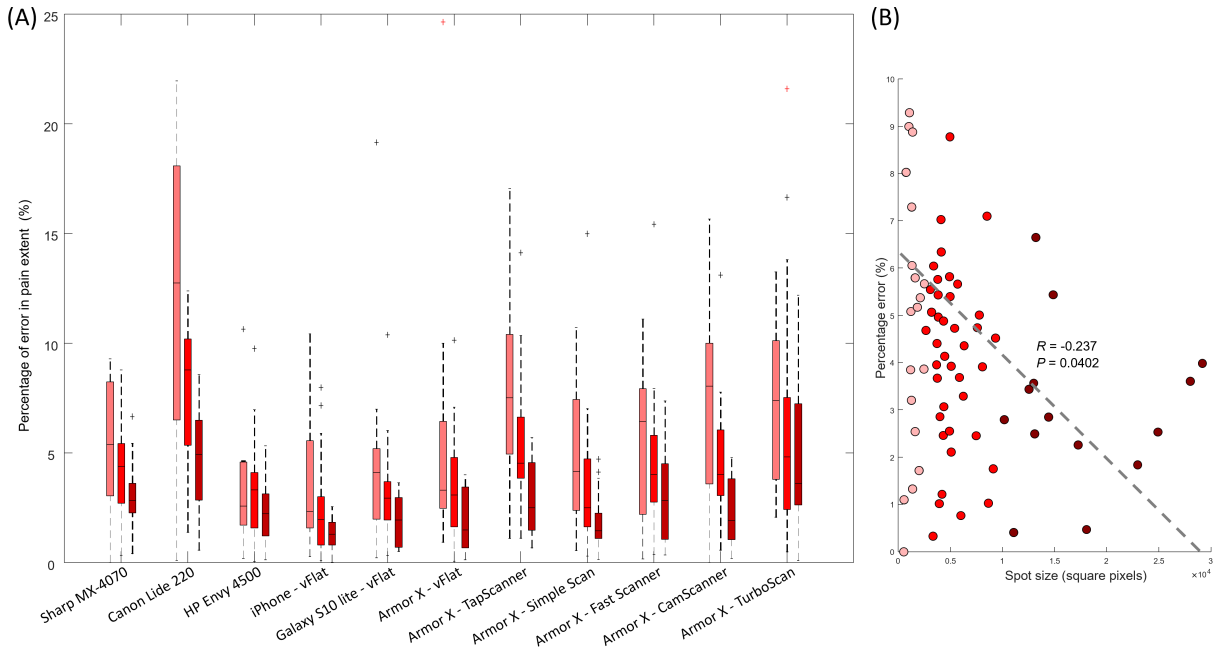

Figure 7. Distribution of errors in the location of the pain spots expressed in pixels. The 3-color box and whisker plots for each device represent the distribution of barycenter distance error for each of the 3 categories (small, medium, and large pain spots). The image of the eye shows the actual dimensions of 5 pixels in the full body chart (paper dimensions: 2048×1536 pixels).

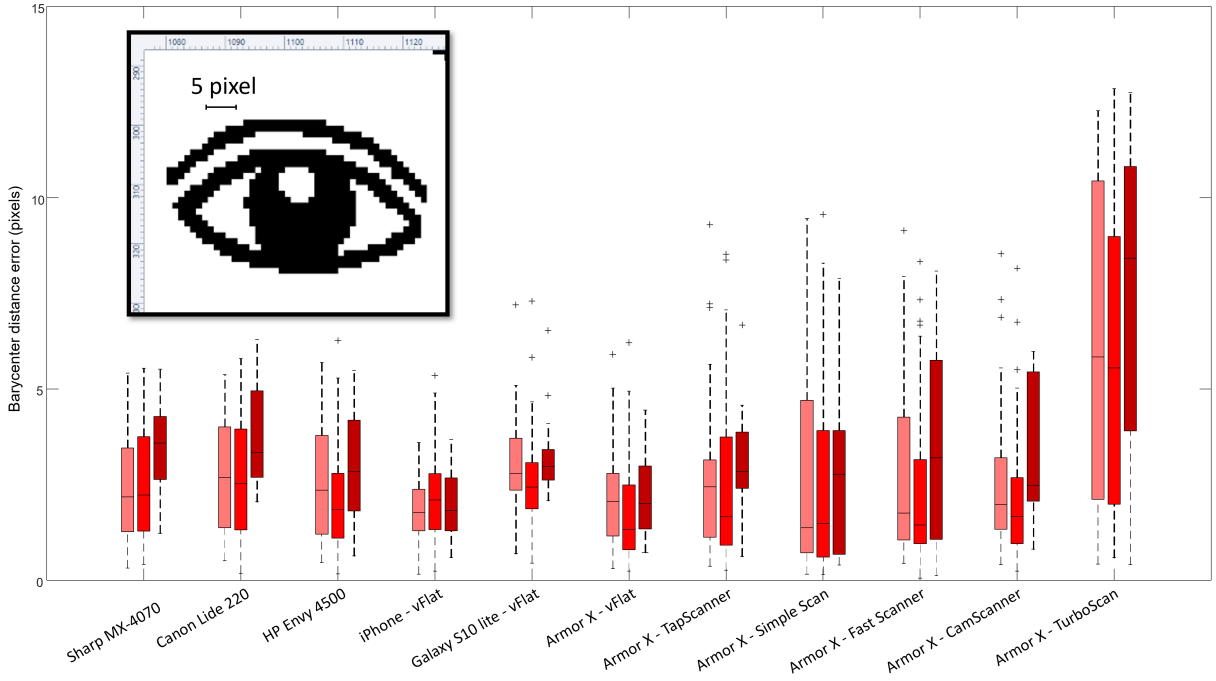

Discussion

Principal Findings

The results of this study showed that the pen-and-paper drawings can be imported and processed with negligible differences using different devices. To our knowledge, there were no other studies focusing on the acquisition of paper pen drawings using mobile devices. Before conducting this study, we were largely using our platform, asking patients to use the red marker because we suspected that blue markers would be mistaken as black. As expected, indeed the red color is the best choice for multiple reasons: the red color is associated with the inflammatory process; thus, it is easy for a patient to visualize their own pain as a red spot (eg, compared with green or blue). Moreover, in shops, markers labeled as “red” are very similar to the theoretical

value of (255, 0, 0), while markers labeled as "green," or "blue" can have different darker or lighter shades.

Surprisingly, in our results, blue and green were identified only with few devices (mostly flatbed scanners). One of the reasons could be the ink of the printer, whose color was slightly different from what was expected. The illumination of the room could also have an impact, since the light emitted by different bulbs or neon could carry different wavelengths in different proportions. The light sensors of cameras and scanners could have different sensitivities to different wavelengths, and probably the red-light sensors have higher sensitivities.

When observing the printed page, we noticed that the blue ink was slightly darker than what we observed on the PC monitor, but it was difficult to objectively evaluate which one was correct, as we did not have a gold standard for each color. In summary, the results confirmed our initial prediction: the red marker is the optimal choice for PDs. However, in cases where the patient does not have a red marker available, we recommend using a flatbed scanner to generate the PDF for import to the platform. This approach helps minimize the bias resulting from external factors such as lights or photo LED sensitivity.

Regarding the accuracy of the pain spot identification, all the devices showed similar performance when using red color. The cheapest flatbed scanner showed larger errors probably due to the distortion of the image. When observing the digital image, we noticed that the proportions were slightly distorted (maybe due to the calibration of the motor or due to friction of the transmission chain). For this reason, the alignment process of the algorithm could not perfectly align the 4 markers in the corner; thus, the pain spot location had larger errors and extensions.

As expected, the smaller pain spots showed larger percentage errors but no differences in the barycenter location error, because of the distortion of pain spots due to the erosion process. The choice of the app for the mobile device had a significant effect on the percentage errors. In particular, the app named V-Flat showed better results than the others (when installed on the cheapest mobile device), leading to results that were comparable with high-rank mobile devices. The V-Flat app includes an algorithm that recognizes the corners of the paper and compensates for the distortions of the camera and even the distortions due to bent paper. For this reason, the results were as good as flatbed professional scanners (<5% of error). In general, the errors in identification of pain extent (<5%) and pain location (<5 pixels) were much lower than the precision of a subject in drawing or identifying their own pain and thus were lower than the minimum clinical significance of PDs [17,37,38].

Limitations

This study has some limitations that may introduce bias into the results. First, the acquisitions made with mobile devices were not conducted under controlled lighting conditions. Although all acquisitions took place during daylight hours without direct sunlight on the paper, variations in the time of day and weather conditions could have affected the colors identified by the devices. In addition, we did not calibrate the "white level" of the mobile phone camera. While some apps offered advanced camera settings for optimizing virtual scanners, we chose to use the default settings to maintain as close to a real-life environment as possible. As a result, we did not test under unusual lighting conditions (eg, candlelight, colored lamps, neon lights).

Another limitation is that we could not directly compare the performance of our platform with other existing methods, since the body charts are specific for each existing app.

Furthermore, we tested only 1 printer to print all the artificial PDs, which introduces potential bias. The colored circles in the first part of the study were positioned within the body chart but in different locations. This variation in placement could impact the results, as colors farther from the center of the paper may experience greater distortion due to misalignment. However, this approach was necessary to avoid printing an excessive number of papers.

The decision of using artificial PDs is due to the fact that we conducted 2 studies in parallel. The first study involved the use of actual PDs generated by humans [36], while in this study, we wanted to investigate different colors in order to investigate all the RGB space. In addition, the location of pain spots in PDs generated by humans depends on the pathology of patients, while in this case, we preferred to have a uniform distribution of pain spots with a priori known sizes and locations. Both studies showed that the platform has excellent results, but in this study, we were able to quantify the error since we knew the theoretical pain spot areas.

The sample size of mobile devices and flatbed scanners is small. However, the objective of the study was not to provide an exhaustive sample of devices but rather to demonstrate that even inexpensive devices are sufficient for accurately acquiring paper PDs.

Similarly, the sample of scan apps is also limited, and some of them are no longer available for free as of manuscript submission. The app market is continuously evolving, with new apps being released regularly. Our intention was to find a selection of free virtual scanners available in the Play Store, and again, our aim was to show that various apps perform similarly.

Conclusions

The system was already tested in real clinical settings and was shown to be easy to implement, easy to use, and well accepted. The acquisition of paper PDs using the proposed platform has been demonstrated to be robust and reliable across a wide range of scanning devices. The accuracy of pain extent and location analysis consistently falls within the error measurement range of PDs. The use of the proposed algorithm will enable the use of PD analysis in various clinical settings.

Authors' Contributions

CC participated in the conceptualization, methodology, software, data curation, and writing—original draft preparation. GL participated in the software and validation. NB led the visualization and investigation. VG participated in the investigation. MD contributed to data curation. EK participated in writing—review and editing. PM did the supervision. Abstract

Background: Mobile health (mHealth) has the potential to radically improve health behaviors and quality of life; however, there are still key gaps in understanding how to optimize mHealth engagement. Most engagement research reports only on system use without consideration of whether the user is reflecting on the content cognitively. Although interactions with mHealth are critical, cognitive investment may also be important for meaningful behavior change. Notably, content that is designed to request too much reflection could result in users' disengagement. Understanding how to strike the balance between response burden and reflection burden has critical implications for achieving effective engagement to impact intended outcomes.

Objective: In this observational study, we sought to understand the interplay between response burden and reflection burden and how they impact mHealth engagement. Specifically, we explored how varying the response and reflection burdens of mHealth content would impact users' text message response rates in an mHealth intervention.

Methods: We recruited support persons of people with diabetes for a randomized controlled trial that evaluated an mHealth intervention for diabetes management. Support person participants assigned to the intervention (n=148) completed a survey and received text messages for 9 months. During the 2-year randomized controlled trial, we sent 4 versions of a weekly, two-way text message that varied in both reflection burden (level of cognitive reflection requested relative to that of other messages) and response burden (level of information requested for the response relative to that of other messages). We quantified engagement by using participant-level response rates. We compared the odds of responding to each text and used Poisson regression to estimate associations between participant characteristics and response rates.

Results: The texts requesting the most reflection had the lowest response rates regardless of response burden (high reflection and low response burdens: median 10%, IQR 0%-40%; high reflection and high response burdens: median 23%, IQR 0%-51%). The response rate was highest for the text requesting the least reflection (low reflection and low response burdens: median 90%, IQR 61%-100%) yet still relatively high for the text requesting medium reflection (medium reflection and low response burdens: median 75%, IQR 38%-96%). Lower odds of responding were associated with higher reflection burden (P<.001). Younger participants and participants who had a lower socioeconomic status had lower response rates to texts with more reflection burden, relative to those of their counterparts (all P values were <.05).

Conclusions: As reflection burden increased, engagement decreased, and we found more disparities in engagement across participants' characteristics. Content encouraging moderate levels of reflection may be ideal for achieving both cognitive investment and system use. Our findings provide insights into mHealth design and the optimization of both engagement and effectiveness.

Introduction

Background

Mobile health (mHealth) is transforming health delivery as a highly convenient and effective approach for supporting individuals with chronic conditions [1-3]. Delivered via phones, tablets, and wearables, mHealth provides education, motivation, monitoring, and other forms of support to improve health behaviors. SMS text messaging is one form of mHealth that is uniquely poised to benefit everyone, including people who are older, are disadvantaged, and are from traditionally minoritized racial or ethnic backgrounds [4-6]. A critical factor influencing mHealth effectiveness is users' engagement or interaction with the technology, which is typically measured via system use [7-9]. Across the mHealth literature, engagement tends to be highly variable [10,11], which has spurred a whole body of research that aims to understand predictors of engagement, including user characteristics and intervention features (eg, intervention duration and frequency of sending content) [10-14]. However, very little research has attended to the type of mHealth content that users are expected to engage with [15] and, more specifically, how the content may be requesting more or less cognitive reflection.

The primary goal in having users engage with mHealth content is health behavior change. With respect to mHealth interventions, there is a hyperfocus on wanting the user to interact with the technology (eg, responding to a text message), with less consideration of whether the user is reflecting on the content cognitively (eg, reflecting on past behavior and planning future behavior) [8]. Although interaction with the technology is a critical measure, there is a growing consensus that cognitive investment is also important for meaningful behavior change in many types of mHealth interventions [16-18]. Notably, content may be designed in a way that represents a low response burden, thereby easily eliciting a response (ie, producing high engagement), but such content may not evoke the necessary cognitive reflection required to change behavior [18]. Alternatively, content that is designed to encourage deeper reflection may overwhelm users, which risks them disengaging completely. Understanding how to strike the balance between response and reflection has critical implications for effective engagement (ie, engagement needed to impact outcomes) [19]. To our knowledge, no studies have explored the association between reflection demands and the degree of interaction with an mHealth tool. Understanding the interplay between reflection burden and response burden will help guide the design of interventions seeking to strike this balance.

Objective

Our team previously developed an mHealth intervention (delivered via text messages and phone calls) called *Family/Friend Activation to Motivate Self-care* (FAMS) [20,21]. FAMS is a diabetes self-management intervention that targets persons with type 2 diabetes and provides the option for persons with diabetes to invite a support person to also receive text messages. We recently evaluated FAMS in a randomized controlled trial (RCT) [22], and during routine monitoring in the first few weeks of the trial, we observed a low response rate to text messages among support persons. Because support persons' engagement with the text messages was an optional component of the intervention, we determined that this was an opportunity to explore how changing the content of these texts might impact response rates without compromising our ability to evaluate FAMS' effects. Over the course of the RCT [22], we used a pragmatic approach to vary both the reflection burden and the response burden of the two-way text messages sent to support persons assigned to the intervention. In this observational study, our primary goal was to explore how these variations would impact users' engagement with text messages, as measured via response rates. We also explored support persons' characteristics that were associated with response rates for each type of text and described the different responses to each text.

Methods

Study Design and Eligibility

This study was conducted as part of the FAMS 2.0 RCT. The trial design, intervention details, and outcomes for persons with diabetes and support persons were published [22-24]. For the trial, dyads comprising a person with diabetes and their support person were randomized to FAMS or a control condition. We recruited persons with diabetes who were receiving care for type 2 diabetes at Vanderbilt University Medical Center primary care clinics. Enrolling persons with diabetes were asked to invite a support person to participate with them and receive text messages; however, support person invitation and enrollment were not required. We defined a *support person* as any family member or friend with whom the person with diabetes would feel comfortable talking about diabetes management and health goals. Eligible support persons were aged ≥18 years, could speak and read English, and had a mobile phone separate from that of the person with diabetes. The only exclusion criterion was the inability to receive and respond to a text after training. For this study, we analyzed data from support persons in dyads that were randomly assigned to the intervention group (FAMS).

Ethical Considerations

The Vanderbilt University Institutional Review Board approved all study procedures (institutional review board number: 200398; approved April 8, 2020), and the trial was registered on ClinicalTrials.gov (trial number: NCT04347291).

Procedure

While enrolling persons with diabetes into the trial, research assistants collected contact information for a potential support person. A research assistant then contacted potential support persons to verify interest and eligibility, obtain verbal informed consent, and ask support persons to complete a baseline survey. Surveys were completed by phone with a research assistant, on the web via an emailed link, or via a mailed paper copy, per participants' preferences. All survey data were stored in REDCap (Research Electronic Data Capture; Vanderbilt University), a secure web-based platform that supports data capture for research studies [25,26]. In addition to collecting data on sociodemographic characteristics, surveys asked support persons to choose the time of day they wanted to receive text

messages. Relevant survey responses were transferred from REDCap to our technology partner, PerfectServe, using an automated application programming interface. PerfectServe used participant information to tailor, schedule, and send text messages to support persons for 9 months. Support persons could earn a total of US $120 for completing all study surveys (through 15 mo for the larger RCT). There was no compensation for receiving or responding to text messages.

The Intervention

Persons with diabetes received daily text message support and monthly coaching sessions, during which they set behavioral diabetes self-management goals (as detailed by Mayberry et al [22]). Support persons received text messages that were designed to increase dialogue about and facilitate their involvement in the diabetes self-management of the persons with diabetes; a one-way message was sent 3 to 4 times per week, and a two-way message (also known as an *interactive text message*) was sent once per week. One-way messages were either a general text message about providing diabetes self-management support or a text message tailored to the identified diabetes goals of the persons with diabetes. Two-way messages asked support persons about how they supported the health of the persons with diabetes. Support persons who replied to the two-way text received an automated response, thanking them for their answer.

Although an individual support person's intervention experience lasted 9 months (36 wk), intervention delivery for the trial lasted 2 years. Over the course of those 2 years, we varied both the response burden (the level of information requested for the response relative to that of other messages) and the reflection burden (the level of cognitive reflection requested relative to that of other messages) of the weekly two-way text messages, which were sent to support persons in 6 fixed periods (ie, waves). The waves coincided with the weeks of the trial; they did not coincide with the weeks of each individual support person's intervention experience. Figure 1 includes the content for each version of the text message, the weeks of the trial when each text was sent (ie, calendar time), and the respective waves. We started the trial (wave 1) by sending a text message that was high in both reflection burden and response burden (*high/high*). In wave 2, we tested a text that was low in both reflection burden and response burden (*low/low*), and then in wave 3, we tested a text that involved medium reflection burden and low response burden (*medium/low*). In wave 4, we retested the *high/high* message to help determine if the point at which the text was sent during the trial impacted engagement. In wave 5, we sought to delineate the relative impacts of reflection burden and response burden; therefore, we tested a text message that was high in reflection burden and low in response burden (*high/low*). Finally, we closed out the trial by retesting the *low/low* text message (wave 6). The decisions about what messages to test were made iteratively based on response rates to the prior message, with the goal of learning how much reflection we could request while still achieving a relatively high response rate.

Figure 1. The four versions of the two-way text message. The content references an example person with diabetes named Tom.

Reflection burden	Response burden	Content	Weeks of trial when each text was sent	Wave
High	High	"This week is done! Reflect on how you supported Tom this week. Reply with what went well or what could go better next week."	1-24; 73-85	1; 4
Low	Low	"Please text back Yes or No. Were you able to support Tom with his health goals this week?"	25-48; 96-113	2; 6
Medium	Low	"How confident do you feel supporting Tom with his health goals? Please provide a rating from 1 to 5 where 1=not so confident and 5=very confident."	49-72	3
High	Low	"Take a minute to think about how you supported Tom this week with his health goals. Consider what went well and what could go better. Reply OK when done."	86-95	5

Of note, each support person only received the versions of the two-way text message that were sent during their 36-week trial participation, with most (120/148, 81.1%) receiving 2 or 3 different versions and no participants receiving the same message in 2 separate waves. Because this analysis used data from support persons only, we refer to them as *participants* henceforth.

Measures

Sociodemographic and Relationship Characteristics

We collected self-reported data on age, gender, race, ethnicity, socioeconomic status (measured based on education [ie, years in school] and annual household income), and health literacy (assessed via the Brief Health Literacy Screen [27]). In addition, we asked whether participants were cohabitating with the

persons with diabetes and the frequency with which they provided diabetes-specific helpful involvement to the persons with diabetes at baseline, as assessed via the Family and Friend Involvement in Adults' Diabetes (FIAD) helpful subscale, support person version [28].

Engagement

We operationalized engagement by using response rate (ie, two-way messages responded to divided by the two-way messages sent, for each participant).

Analyses

Statistical Analysis Overview

All statistical analyses were performed by using R version 4.2.1 (R Foundation for Statistical Computing). We described participant characteristics via means and SDs or via frequencies and percentages, as appropriate. Except for when examining temporality, message waves that included the same version of the two-way text message were grouped together. Because this study was exploratory, we did not perform sample size calculations.

Overall Engagement by Text Message Version

For each version of the text message, we determined the proportion of two-way text messages sent to support persons that received a response by study week (ie, calendar time). We also generated summary statistics (means, medians, and first and third quartiles) for response rates at the participant level; reporting both mean and median provides more detailed information on the distribution of data. If participants withdrew during their intervention experience, we calculated their response rates based on the data available prior to their withdrawal. To account for repeated measures within participants, we used generalized estimating equations with a working independence correlation structure and a logistic link function to compare the odds of responding to two-way text messages across the four versions.

Participant Characteristics and Engagement

We used Poisson regression to estimate associations (as incidence rate ratios) between participant characteristics and text message response rates for each version of the text message. We included the number of two-way messages sent to a participant as an offset term in order to account for variation in the number of messages sent to each participant in a given wave; therefore, the exponentiated coefficients from the Poisson regression model compared response rates on a per-message basis. Participant characteristics included age, race and ethnicity (non-Hispanic White vs minoritized race or ethnicity), gender, education (years), annual household income (≥US $50,000 per year), health literacy (Brief Health Literacy Screen), whether the persons with diabetes and support persons were cohabitating, and self-reported baseline helpful involvement (FIAD). Further, we multiplied participants' age by 10 to allow for easier interpretation of the results. Especially in regression models, it can be difficult to interpret the association between age and an outcome when the change in the outcome is based on a single-year change in age (ie, the coefficients end up being too small). Scaling the age variable in this way allowed us to interpret the findings in a more meaningful way, that is, we compared groups that differed in age by 1 decade rather than 1 year.

For this analysis, we excluded 5 participants who were missing all baseline data. However, missing covariate values were otherwise addressed via multiple imputation by chained equations (M=500 iterations).

Types of Responses

We characterized the responses to each version of the two-way text message. For the *low/low*, *medium/low*, and *high/low* texts, we reported the frequency of responses based on what the respective text requested (eg, "Yes," "No," "1," "2," "3," "4," or " 5"). For the *high/high* text messages, 2 team members reviewed responses and categorized each as being either high effort or low effort. High-effort responses included comments on what went well that week, comments on what could go better next week, or both, and they referred to a diabetes self-management behavior such as diet, exercise, stress management, or communication (eg, "[He] and I got out several times this week walking after work. Our biggest problem is watching portion size when we are eating. Always continue to work on that."). A low-effort response consisted of only a brief phrase that did not reference a diabetes self-management behavior (eg, "Things went well" and "We were on vacation this week") or did mention a behavior but was unclear as to what went well or what could go better next week (eg, "Walking").

Results

Participant Characteristics

In the trial, of the 150 support person participants who were enrolled and randomized to receive the FAMS intervention, 2 withdrew before the intervention started. The remaining 148 were included in the analyses (Table 1). The mean age was 50.3 (SD 14.7) years; 28.4% (42/148) of participants were men, and 33.1% (49/148) reported a minoritized racial or ethnic background. The mean length of education was 14.9 (SD 2.5) years, and 31.1% (46/148) of participants had annual household incomes of <US $50,000. Over half (84/148, 56.8%) were spouses or partners of the persons with diabetes, and 70.3% (104/148) were cohabitating with the persons with diabetes. Further, 9 participants withdrew at some point during the intervention; the analyses below reflect their engagement during the time they participated.

Table . Participant characteristics (N=148).

Characteristic			Value
Age[a] (y), mean (SD)			50.3 (14.7)
Gender [b] , n (%)

[f]FIAD: Family and Friend Involvement in Adults' Diabetes.

[g]5 participants did not have data for the FIAD helpful subscale.

[h]8 participants did not have data about cohabitating with the persons with diabetes.

Overall Engagement by Text Message Type

Figure 2 presents the proportion of two-way text messages that received a response within each week of the trial (ie, by calendar time). Notably, text message response rates for waves 1 and 4 (both were *high/high* message waves) were comparable, as were those for waves 2 and 6 (both were *low/low* message waves). Table 2 includes descriptive statistics for the overall and

participant-level response rates for each version of the two-way text. The median response rates for the *high/high*, *medium/low*, and *low/low* messages were 23% (IQR 0%-51%), 75% (IQR 38%-96%), and 90% (IQR 61%-100%), respectively. When we kept reflection burden high but lowered response burden in the *high/low* message, the median response rate (10%, IQR 0%-40%) was closest to that for the *high/high* message, suggesting that reflection burden was responsible for the lower response rates seen with the *high/high* message.

Figure 2. Text message response rates by week across each wave. Response data were excluded for the first 4 weeks and the last 5 weeks of the trial when <5 individuals were receiving the intervention.

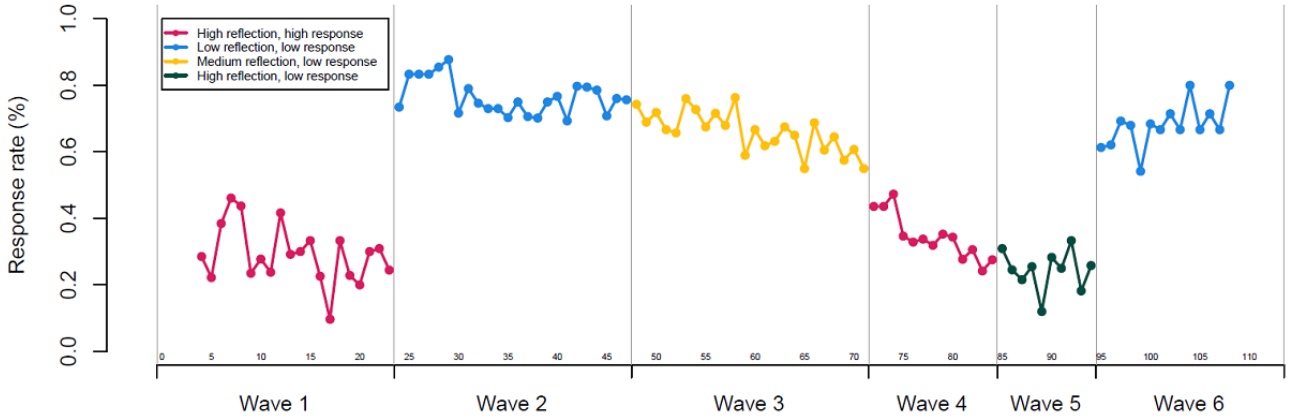

Table . Response rates for each version of the two-way text message.

Reflection burden and response burden	Participants included in analysis, n	Participant-specific response rate	
		%, mean (SD)	%, median (IQR)
High and high	127	33 (33)	23 (0-51)
Low and low	123	74 (32)	90 (61-100)
Medium and low	125	65 (35)	75 (38-96)
High and low	55	26 (32)	10 (0-40)

We also compared the odds of responding to the four versions of the text message (Table 3). When compared to the *high/high* message, the odds of responding to the *low/low* message was 53% (95% CI 42%-65%) higher, the odds of responding to the *medium/low* message was 40% (95% CI 31%-49%) higher, and the odds of responding to the *high/low* message was 7.5% (95% CI 0.7%-14%) lower. All other pairwise comparisons (Table 3) indicated decreasing odds of responding at increasing levels of reflection burden.

Table . Comparison of text message response rates by text message version. Included are odds ratios (ORs) and 95% CIs, along with *P* values.

Comparison		OR (95% CI)	*P* value
Relative to high reflection burden and high response burden			
	Low reflection burden and low response burden	1.53 (1.42-1.65)	<.001
	Medium reflection burden and low response burden	1.40 (1.31-1.49)	<.001
	High reflection burden and low response burden	0.93 (0.86-0.99)	.03
Relative to low reflection burden and low response burden			
	Medium reflection burden and low response burden	0.92 (0.86-0.98)	.01
	High reflection burden and low response burden	0.60 (0.55-0.66)	<.001
Relative to medium reflection burden and low response burden			
	High reflection burden and low response burden	0.66 (0.61-0.72)	<.001

Participant Characteristics Associated With Odds of Responding

Table 4 presents estimated incident rate ratios, along with 95% CIs and *P* values, from multivariate Poisson regression models that were used to identify participant characteristics predictive of response rate. Younger participants, participants who were not cohabitating with the persons with diabetes, and participants who had a lower socioeconomic status had lower response rates to both the *high/high* message and the *medium/low* message compared to those of older participants, participants who were cohabitating, or participants who had a higher socioeconomic status, respectively. The only characteristic associated with response rates for the *low/low* message was gender, such that men had lower response rates. Further, the only characteristic associated with response rates for the *high/low* message was age, such that younger age was associated with lower response rates. Across message versions, younger participants had lower response rates to any message with more burden than the *low/low* message, and participants who were not cohabitating with the persons with diabetes had lower response rates to the higher-burden messages than those of participants who were cohabitating. Race, ethnicity, health literacy, and baseline helpful involvement provided to the person with diabetes did not show patterns indicating the prediction of response rates to any message version.

Table . Participant characteristics predicting text message response rates for each version of the text. Presented are estimated incident rate ratios (IRRs) and 95% CIs, along with *P* values.[a]

Predictor	High reflection/high response		Low reflection/low response		Medium reflection/low response		High reflection/low response	
	IRR (95% CI)	*P* value	IRR (95% CI)	*P* value	IRR (95% CI)	*P* value	IRR (95% CI)	*P* value
Age (y × 10)	1.14 (1.06-1.23)	.004[b]	0.99 (0.95-1.03)	.67	1.08 (1.04-1.14)	.001[b]	1.28 (1.09-1.51)	.002[b]
Race and ethnicity	1.07 (0.85-1.35)	.57	0.96 (0.84-1.09)	.51	0.94 (0.81-1.09)	.40	0.60 (0.36-1.01)	.052
Gender (men)	0.62 (0.49-0.78)	<.001[b]	0.78 (0.68-0.89)	<.001[b]	0.89 (0.78-1.02)	.10	1.28 (0.83-1.98)	.26
Education	0.98 (0.94-1.02)	.34	1.00 (0.98-1.03)	.77	0.96 (0.94-0.99)	.007[b]	0.99 (0.90-1.09)	.87
Income	0.71 (0.57-0.89)	.003[b]	1.05 (0.91-1.21)	.51	1.14 (0.98-1.33)	.10	0.77 (0.46-1.27)	.30
BHLS[c]	1.04 (0.97-1.12)	.30	1.04 (1.00-1.09)	.06	1.02 (0.98-1.06)	.24	1.02 (0.86-1.21)	.80
Cohabitating	1.37 (1.09-1.73)	.007[b]	1.03 (0.90-1.19)	.64	1.21 (1.05-1.40)	.008[b]	1.63 (0.93-2.85)	.09
FIAD[d]	1.05 (0.94-1.17)	.41	1.00 (0.93-1.07)	.99	0.99 (0.93-1.06)	.79	0.90 (0.71-1.14)	.37

[a]A total of 5 support persons without baseline characteristics were excluded from this analysis: 2 were excluded from the models for the *high/high*, *low/low*, and *medium/low* messages; 1 was excluded from the models for the *high/high* and *medium/low* messages; 1 was excluded from the models for the *high/high*, *low/low*, and *high/low* messages; and 1 was excluded from the models for the *low/low* and *medium/low* messages.

Types of Responses

In this section, we report on engagement at the text message level (vs the participant level). For the *high/high* messages, 1429 texts were sent, and 445 responses were received. Further, 13 responses were excluded from the analysis because the content was uninterpretable or was not relevant to the two-way text prompt. The reviewers categorized each response into the high- or low-effort response category, with 98.6% (responses: 426/432) agreement; of the 426 texts agreed upon, 350 (82.2%) were categorized as high-effort responses, and 76 (17.8%) were categorized as low-effort responses. For the *low/low* texts, 1791 texts were sent, and 1341 responses were received; almost all of the responses were "yes" responses (n=1239, 92.4%), while only 97 (7.2%) were "no" responses, and 5 (0.4%) were considered "other" responses. For the *medium/low* texts, 1847 texts were sent, and 1218 responses were received; the most common response was a "5" response (n=681, 55.9%), followed by a "4" response (n=338, 27.8%) and then a "3" response (n=144, 11.8%). Lastly, for the *high/low* texts, 446 texts were sent, and 109 responses were received; most of the responses received were "OK" responses, as requested in the message (n=86, 78.9%).

Discussion

Principal Results

Despite the potential of mHealth to enhance self-management support and quality of life, there are still key gaps in understanding how to optimize mHealth engagement [16,17,19]. Most engagement research reports only on system use without consideration of the cognitive reflection done in the process of

engaging with the content [16,29]. Ideally, we want to encourage reflection that results in meaningful behavior change, but it is unclear how much we can request, with respect to reflection, before users disengage. We varied the reflection and response burdens of two-way text messages to examine how these variations impacted users' engagement, as assessed via response rates. We found, generally, that as the reflection burden of the message increased, participants' engagement decreased. Importantly, when the same version of the text was sent at different points in the trial, participants' engagement was consistent, suggesting that the message itself was key for response rates. The response rates for the *high/low* message were similar to those for the *high/high* message, and this supports reflection burden (vs response burden) being the primary driver of lower engagement. We also found evidence that as the reflection burden of the message increased, there were more disparities in engagement across participant characteristics. This finding helps inform who we may lose with content requiring more from users and thus how to ensure mHealth interventions do not widen existing health disparities.

Research focused on promoting mHealth engagement has proliferated in recent years, with the primary goal of increasing system use [30]. Across such studies, we see evidence that content that is more personalized; uses simpler, nontechnical language; and is empowering results in higher engagement [10,19,31-35]. Less research has compared specific types of content and has rarely tested different types within the same study. An exception is a recent study by Klimis et al [15], wherein they used machine learning to demonstrate that text messages with informative (providing health facts or education) and instructional (providing tips or recommendations) message intents were associated with increased engagement, while notification messages that addressed noneducational matters (eg, welcome and exit messages) were associated with reduced engagement [15]. Our study targeted a two-way message and varied the levels of reflection and response burdens in that message. By adjusting the reflection level specifically, we gained unique insight into how engagement with each message variation may ultimately influence behavior change [17,18]. The main way in which our study differs from others in this area of research is that we looked beyond system use as the sole dimension of mHealth engagement. Our goal was not necessarily to see which message resulted in the highest response rate but rather to determine how much reflection we could request from users and achieve a level of interaction that suggested that they were still invested in the content.

Although our results show generally that engagement decreases with more reflection, the nuances in our findings allow us to provide unique recommendations around mHealth design. For instance, it may be best to alternate through content with different levels of reflection burden. Although users were more likely to respond to content that was lower in reflection burden, nearly all (350/426, 82.2%) of the responses that we received to the high-reflection messages included a high-effort level of reflection. The act of asking people to reflect stimulates internal thoughts that are difficult to measure without a response [36] but may still occur among some persons who do not respond. Alternating content may help promote periodic responding and reflecting throughout an intervention experience. Another option involves using an adaptive intervention to tailor the content based on each person's responsiveness. That is, everyone could start receiving content with a high reflection burden, but if a person's response rate starts to drop, they could then switch to content with a moderate reflection burden. Finally, especially in situations where there is limited flexibility with the mHealth functionality, researchers may consider sending the *medium/low* message to all participants, given that the content encouraged a moderate level of reflection (more than the *low/low* message) yet still yielded a high response rate.

Limitations

Our study has several limitations to acknowledge. For instance, our results are based on an SMS text messaging intervention, which is a specific form of mHealth. It is possible that users would have responded differently if the content was delivered via an app or wearable technology. Importantly, compared to apps and other internet-dependent technologies, SMS text messaging is both lower in cost and more easily accessed, and it tends to have higher rates of engagement [4,37]. In addition, this study recruited persons with diabetes and their support persons from a specific region in Middle Tennessee. We acknowledge that the findings may not be generalizable to other types of individuals who are living in other locations. Relatedly, the content asked about how the support persons supported the health of the persons with diabetes, and engagement may differ when asking about a user's own health; however, the marked differences in engagement across message types support broader applications. Another limitation of our work is that we restricted our assessment of engagement to a behavioral measure (ie, responding to the text) and did not have a way to assess participants' cognitive investment or experience with each version of the text. Based on our analysis of participants' responses to the *high/high* message, it appeared that responders were cognitively engaged, but we were not able to compare cognitive engagement across the other messages. In addition, the sample size for the *high/low* message analysis (n=55) was considerably smaller compared to those for the other message analyses, which was due to testing the *high/low* message during only 1 wave near the end of the trial when fewer participants were enrolled. Relatedly, we did not have the time or a sufficient number of participants toward the end of the trial to test the *medium/low* and *high/low* text messages in a second wave, and we do not know for certain whether engagement with these texts could be impacted by temporality; however, as engagement with the *high/high* and *low/low* texts remained similar across multiple waves, it is unlikely. The ordering of the text messages was variable across participants, and due to the observational nature of this study, we cannot determine the extent that ordering may have impacted results; however, the average response rates and trends across message versions and waves provide general insights on how these variations may impact engagement. Finally, we did not assess the impact of engagement on outcomes, as this fell outside the scope of our study; however, other studies in digital health have examined this association [38,39].

Conclusions

In order for individuals to benefit from mHealth and achieve desired effects on outcomes, engagement with the mHealth tool is needed. Our results help elucidate how truly complex the nature of engagement is. Although our past work and that of others have demonstrated the importance of behaviorally interacting with mHealth interventions [9,31,40,41], this measure represents one piece of a larger puzzle. Engagement may be best conceptualized as including both a behavioral dimension and a cognitive dimension. Balancing these dimensions may be what is ultimately needed to achieve effective engagement for impacting intended outcomes. Our study contributes to a growing body of research that encourages a more nuanced approach to studying engagement that goes beyond measuring system use. We hope that our findings help advance the field of mHealth and inform intervention design, with the goal of optimizing both engagement and effectiveness.

Acknowledgments

This research was funded by the National Institutes of Health (NIH), National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), through grant R01-DK119282. The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH. MKR is funded by the National Center for Advancing Translational Sciences (NIH; grant KL2TR002245).

Authors' Contributions

LAN, AJS, LSM, RAG Jr, and MKR significantly contributed to the conception of the study and planned analyses. LAN wrote the manuscript. AJS analyzed the quantitative data, and RAG Jr oversaw data analyses. LML and SM analyzed responses to the *high/high* message. LSM was the principal investigator of the Family/Friend Activation to Motivate Self-care (FAMS) study. All authors were involved in data interpretation and manuscript revision and approved the final version submitted for publication.

Abstract

Background: In the Dutch National Food Consumption Survey, dietary intake has been assessed since 2003 through 24-hour dietary recalls using the GloboDiet software. A new self-administered smartphone food record app called DitEetIk! was developed for potential use in future surveys.

Objective: This study aims to evaluate the data collected using the DitEetIk! app and its relative validity for food group, energy, and nutrient intake compared with the previous dietary assessment method (GloboDiet 24-hour dietary recalls).

Methods: A total of 300 participants aged 18 to 79 years were recruited from a consumer panel. Participants were asked to keep a record of their consumption using the DitEetIk! app on 3 nonconsecutive days. Trained dietitians conducted a 24-hour dietary recall interview by telephone using the GloboDiet software (International Agency for Research on Cancer) regarding 1 of 3 DitEetIk! recording days. Nutrient intake was calculated using the NEVO database (version 2021/7.0). Relative validity was studied by comparing data from GloboDiet 24-hour dietary recalls and the DitEetIk app for the same day. Participants with implausible records, defined as days with energy intake of <0.6 or >3.0 basal metabolic rate, were excluded from the analyses. For 19 food groups and 29 nutrients, differences in median intake were assessed using the Wilcoxon signed rank test, and Spearman correlation coefficients were calculated. Bland-Altman plots with mean differences and 95% limits of agreement were created for energy intake and the contribution to energy intake from fat, carbohydrates, and protein.

Results: A total of 227 participants completed a combination of a DitEetIk! app recording day and a 24-hour dietary recall interview for the same day. Of this group, 211 participants (n=104, 49.3% men and n=107, 50.7% women) had plausible recording days. Of all recorded food items, 12.8% (114/894) were entered via food barcode scanning, and 18.9% (169/894) were searched at the brand level. For 31% (5/16) of the food groups, the median intake assessed using the DitEetIk! app was >10% lower than that assessed using 24-hour dietary recalls; this was the case for fruit (P=.005), added fats (P=.001), milk and milk products (P=.02), cereal products (P=.01), and sauces (P<.001). This was also the case for 14% (4/29) of the nutrients (all P<.001). Regarding mean intake, differences were generally smaller. Regarding energy intake, the mean difference and 95% limits of agreement were 14 kcal (−1096 to 1124). Spearman correlation coefficients between intake assessed using the DitEetIk! app and 24-hour dietary recalls ranged from 0.48 to 0.88 (median 0.78) for food groups and from 0.58 to 0.90 (median 0.72) for nutrients.

Conclusions: Compared with GloboDiet 24-hour dietary recalls, the DitEetIk! app assessed similar mean energy intake levels but somewhat lower median intake levels for several food groups and nutrients.

Introduction

Background

Many countries conduct national food consumption surveys as these are considered important instruments for prioritizing, developing, and evaluating food policies [1,2]. Food consumption survey data can be used to assess adherence to food-based dietary guidelines and obtain insight into the food consumption patterns of a population. After combination with other data sources such as food composition databases, food contamination occurrence data, and life cycle assessment data, the nutritional adequacy of the diet, dietary exposure assessment to potentially hazardous substances, and the environmental impact of dietary patterns can be assessed [3-5].

The use of national food consumption survey data for multiple purposes requires dietary assessment methods that allow all consumed food items to be reported with detailed characterizations. On the basis of European projects such as the European Food Consumption Survey Method [6] and European Food Consumption Validation [7], the 2014 guidance on the European Union Menu methodology by the European Food Safety Authority prescribes the use of food records for children and 24-hour dietary recalls for adults as dietary assessment methods in European national food consumption surveys [8]. It is advised that trained personnel is employed to administer the recall interviews or conduct a food record completion interview with the participants [8,9]. The requirements of trained personnel and detailed food descriptions, the large number of and continuously changing food items on the market, and the need to handle all possible reported food items make food consumption surveys costly [10]. Moreover, these requirements also pose a burden on the survey participants. It has been suggested that this burden has led to declining and possibly selective participation rates in national food consumption surveys [1].

In the past decades, various tools for self-administered 24-hour dietary recalls or food records have become available [11]. These digital tools have the potential to be less resource intensive. Many users prefer these applications over the traditional methods as they can be used where and when it is convenient [12]. Information and communications technology–based applications also enable the use of user-friendly support functionalities that were not feasible with interviewer-based methods. For example, food package barcode scanning using the camera function of a smartphone [11] combined with a comprehensive branded food database reduces the time burden of searching for a product through a long list of food items. However, without the help of a trained interviewer, it might be challenging for participants to report all food items consumed and describe and quantify them accurately. These developments warrant further exploration of whether interviewer-based dietary assessments in national food consumption surveys can be replaced with self-administered dietary assessments using digital food record applications.

In the Dutch National Food Consumption Survey (DNFCS), dietary intake has been assessed through 24-hour dietary recalls by trained interviewers using the GloboDiet software since 2003 [13-16]. A new food record app for dietary assessment called DitEetIk!, which uses self-administration, was developed for potential use in future national dietary surveys in the Netherlands. A smartphone food record was chosen over a self-administered digital 24-hour dietary recall because of the availability of a branded food database in the Netherlands [17]. Such a database allows for specific food identification and can be used most optimally when keeping a food diary throughout the day on a mobile phone with a camera function for barcode scanning. Moreover, the level of smartphone ownership and use in the Netherlands is high. In 2019, smartphones were present in 89% of Dutch households [18].

Objectives

To assess the suitability of the DitEetIk! app for future surveys, it is important to evaluate its quality and comparative validity against the method currently used in the DNFCS. Therefore, the aim of this study was to evaluate the level of detail regarding the food description obtained in the reported consumption in the DitEetIk! app and determine how well the DitEetIk! app is able to assess the daily intake of food groups, energy, and nutrients in comparison with dietitian-administered 24-hour dietary recalls using the GloboDiet software (International Agency for Research on Cancer) in adults. This study focused on systematic differences at the food group and nutrient levels, with random error being of secondary interest. To study the potential effects of the study design on the 24-hour dietary recall data, we also compared the GloboDiet 24-hour dietary recall data in this study with those of a matched population of the DNFCS 2019 to 2021 [19].

Methods

Recruitment

The intention was to collect data from 200 participants with sufficient variation in gender, age group, and educational level. To account for potential dropouts and invalid food recording data, 300 participants were recruited. Participants from a consumer panel of Kantar Netherlands were invited via email to take part in the study. Information regarding the privacy policy of the DitEetIk! app was provided. The sociodemographic characteristics of the panel members were known. Potential participants were eligible if they were aged between 18 and 79 years; were not institutionalized; did not participate in the DNFCS 2019 to 2021 [19] or the Eetmeter study [20]; did not use tube or parental feeding; and were able to use the DitEetIk! app on their smartphone, which had to run on the Android operating system version 7 or higher.

Ethical Considerations

The Medical Research Ethics Committee of Utrecht University evaluated that the study was not subject to the Medical Research Involving Human Subjects Act of the Netherlands (dossier 21/686). All study participants provided written informed consent. After completion of the study, participants received an incentive bonus (NIPOints to be exchanged for a gift card or coupon).

DitEetIk! App

Objective of the DitEetIk! App

In the Dutch language, "Dit eet ik" means "This is what I eat." The DitEetIk! app was developed specifically for the objectives of the DNFCS. The food description had to be specific enough to provide insights into the intake of nutrients, the exposure to chemicals relevant from a food safety point of view, and the environmental impact of the diet of the Dutch general population aged 1 to 79 years.

Development Process

The DitEetIk! app was developed using an agile approach. Various usability tests and focus group sessions were part of this process. The development period lasted approximately 3 years, with a team of app builders, data managers, dietitians, and nutritionists. Technical development was conducted by Dienst ICT Uitvoering in collaboration with National Institute for Public Health and the Environment for functional development and formative evaluation. Both are Dutch governmental organizations. Safety and General Data Protection Regulation issues were considered in the app development. The DitEetIk! app does not collect information that makes the participant identifiable. The user interface of the app is in Dutch (B1 level).

App Availability, Registration, and Instruction

Version 1.0 of the DitEetIk! app was developed for Android smartphones and is available on the Google Play store. Using the DitEetIk! app, a person can keep a food record for specific days upon invitation (ie, the DitEetIk! app can be used only after entering a participant number with matching gender and age). An instruction movie can be viewed at any time after registration. Moreover, to support participants, context-specific information and relevant sections of the instruction movie are available on each screen. Participants were instructed to record all food and drinks consumed from getting up one day to getting up the next day.

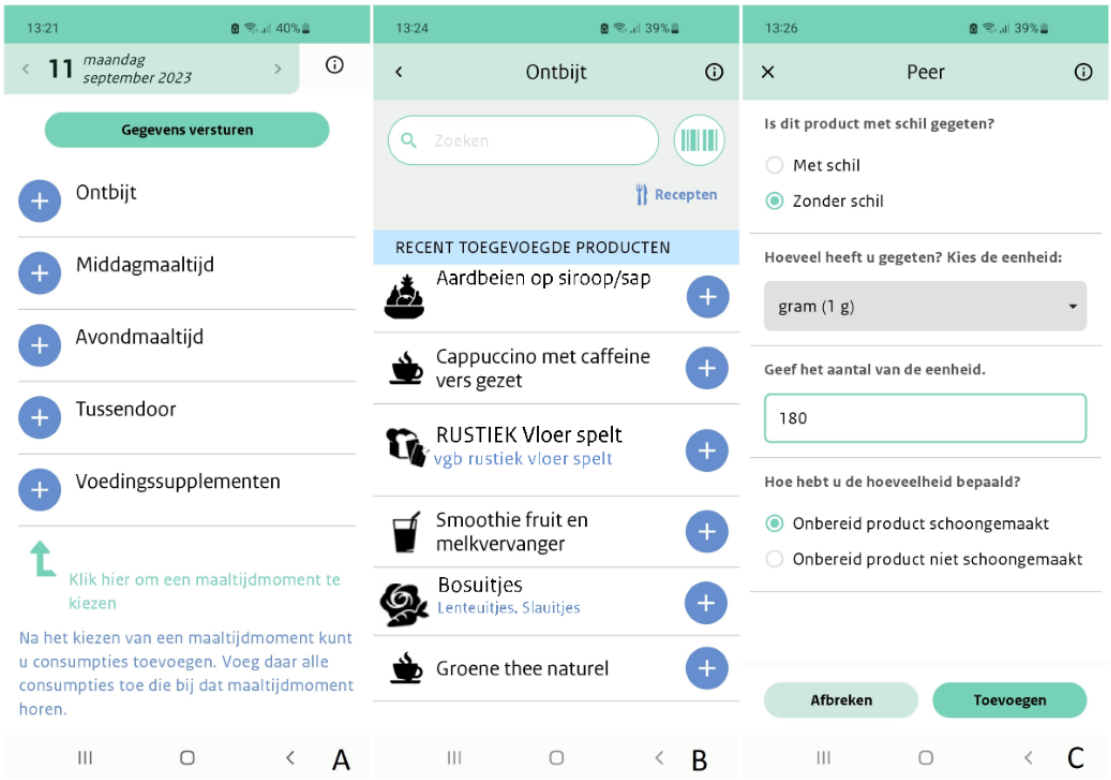
Push Notifications and Feedback

At several moments—before, during, and after the specified day—push notification messages are sent via the DitEetIk! app to the participants to help remind them of food recording and submission of the food record. The DitEetIk! app does not provide instant feedback to the participants regarding their food consumption as, for dietary monitoring, it is important not to influence the participants.

Main Menu

Food recording is performed via a main menu where 4 eating occasions can be selected (ie, breakfast, midday meal, evening meal, and in between meals). If applicable, dietary supplements can be filled out separately (Figure 1A). After choosing breakfast, midday meal, or evening meal as eating occasions, the time and place of consumption need to be registered; for the occasion "in between meals," time and place of consumption (eg, home or restaurant) are asked every time a food item is selected, whereas for dietary supplements, information regarding time and place of consumption is not asked for.

Figure 1. Screenshots of the DitEetIk! app depicting (A) eating occasions, (B) recently added products, and (C) food-specific follow-up questions.



Food Recording

The DitEetIk! app food list in this study included 140,781 food items, of which 3432 (2.44%) were generic and the rest were a selection of branded food items from the Dutch-branded food database Dutch-branded food database (Levensmiddelendatabank [LEDA]; download date: October 27, 2021) [17]. The selection consisted of 70.89% (137,349/193,742) of the branded food items in the LEDA database that were matched to a generic product. Generic food items can be found through text searching. Branded food items can be found by scanning the barcode or, for predefined food groups, by selecting the brand and specific branded product once a generic food item is chosen. If the scanned food items are not included in the LEDA database or are not matched to generic products, they are not recognized in the app, and the participant has to record their food via text search. Once a product is selected and added to an eating occasion, the food item can also be found via "recently added products" and can be selected again (Figure 1B). A recipe feature is available it allows participants to create mixed dishes indicating quantities of foods that were used for the prepared dish as a whole or save frequently consumed combinations of foods. Commonly used mixed dishes are also available as prepared generic food items.

Follow-Up Questions for Each Food Item

After a food item is chosen or scanned, food-specific follow-up questions are asked regarding the preparation method, consumption with or without skin or peel, and quantity consumed (Figure 1C). In case a preparation method with fat (eg, frying or deep-frying) is chosen, the participant is asked to specify the type of fat used. The follow-up questions are defined at the generic food item level. For this reason, each branded food item is linked to a comparable generic food item. Consumed amounts can be indicated via various options that always include the weight in grams or volume in milliliters and often the number or fraction of household measures, natural units, or commercial units. For user-defined recipes, the fraction of the total recipe can be indicated as the consumed portion.

Data Submission and Output

When all consumptions for a day have been recorded, the participant can submit the food record. Upon submission, questions regarding completeness are asked, as well as whether the day was special or not regarding consumption. The data collected using the DitEetIk! app can be downloaded as CSV files that include information on eating occasions with time, place, and registered food items and the answers to the follow-up questions for each consumption.

Study Design and Data Collection

Data were collected in the spring of 2022. Participants were asked to record all food, drinks, and dietary supplements consumed on 3 nonconsecutive days on the DitEetIk! app. The days were assigned by the DitEetIk! app in such a way that all days of the week were covered proportionally at the group level and that there were at least 7 days between each recording day. The day before each registration day, the participants received a push notification message on their smartphones. At the individual level, any combination of days could occur. In case the participant indicated that the day was not convenient for recording or did not record any food items, a replacement recording day was assigned automatically. This could be done maximally 3 times; thereafter, no new days were assigned, and the participant was excluded from further participation.

After 1 of the 3 DitEetIk! app recording days, participants were contacted by a trained dietitian for a 24-hour dietary recall interview by telephone. For the 24-hour dietary recall interviews, it was allowed to make an appointment with the participant; for practical reasons, they were not unannounced. The 24-hour dietary recalls were administered using the Dutch version of the GloboDiet software (version 2021-09-24). This software, which was previously called EPIC-Soft, has been described in detail elsewhere [16]. Briefly, the interview started by composing a quick list in which the participant was asked to roughly list all consumed food and drinks for 7 potential eating occasions with time and place of consumption. Food items were recalled starting from getting up in the morning until getting up the following day. In the second step, the interviewer specified each food item on the quick list using a series of follow-up questions applicable to that food item, for example, asking about preparation methods and, if relevant, the type of fat used. Mixed dishes could be entered as new individual recipes or as (adjustments of) standard recipes, which the software disaggregated into ingredients. Dietary supplements were explicitly asked about. Consumed amounts of the food items could be quantified in several ways: by means of quantities as shown in photos in a picture booklet with a series of 61 food photographs. or in household measures, units, and standard portions; by weight or volume; and by the proportion of a total recipe. Bread shapes were used to estimate the quantity of spreads. At various points, quality control of the data was incorporated into the GloboDiet software, for example, checks on missing quantities, probing questions on often forgotten food items, and checks on total intake of energy and macronutrients.

After the 3 food records were completed, the perceived usability of the DitEetIk! app was evaluated by the participants through a web-based questionnaire, the System Usability Scale (SUS) [21]. This is a widely used questionnaire for the evaluation of electronic devices and systems, including smartphone apps. It consists of 10 statements with response options on a 5-point Likert scale ranging from *strongly disagree* (1) to *strongly agree* (5). There are 5 positive statements alternated with 5 negative statements. The originally English-worded items were translated into Dutch, and the word “system” was replaced with “application” to make the questions more specific to the device.

Data Handling

For the DitEetIk! app data, intake per food item per day was calculated by multiplying the weight of the chosen portion or serving by the number of portions. If applicable, food density (in the case of estimates in household measures or milliliters), an edible fraction (in the case of the inedible part), weight change because of food preparation (amount estimated as unprepared food), and percentage of fat absorption were applied to the calculation of the amount of food in grams per day in its consumed state. Similar calculations were performed using the GloboDiet software for the 24-hour dietary recalls [16]. All food items reported in the GloboDiet 24-hour dietary recalls and the DitEetIk! app were categorized into the food groups mentioned in the Wheel of Five Dutch food-based dietary guidelines [22,23]. Subsequently, consumption of food groups per person per day was calculated.

For both GloboDiet and DitEetIk! data, intake of energy and nutrients per person per day was calculated by multiplying the consumed amount of food by the nutrient level per gram of food and adding the nutrient intake of all food items consumed in a day. Information on food composition was obtained from the NEVO database (version 2021/7.0) [24]. Dietary supplements were not considered in the calculation of nutrient intake.

All extremely high values in energy, nutrient, and food group intake in the 24-hour dietary recalls were evaluated using the same methodology as in the DNFCS [15]. The food items that contributed the most to the high intake values were checked for obvious errors. None of the extreme intake values were judged as unlikely.

The equations developed by Henry [25] were applied to calculate the estimated basal metabolic rate (BMR) using height and weight information provided by the participants in the DitEetIk! app. The average ratio of energy intake to BMR was calculated, as well as the percentage of extreme energy reporters (ie, those participants with a ratio of <0.6 or >3.0). Any day with such an implausible extreme of energy intake in the DitEetIk! app was excluded from further analyses.

Assessment of the Effect of Study Design on the GloboDiet 24-Hour Dietary Recall Results

The GloboDiet 24-hour dietary recall interview was always conducted after the recording in the DitEetIk! app. This might have influenced the results because of potential memory or learning effects [26]. The extent to which this occurred was estimated by comparing the results of the GloboDiet 24-hour dietary recalls in this study with the findings among participants in the DNFCS 2019 to 2021, in which 24-hour dietary recalls were collected using the same software. We only used the first GloboDiet 24-hour dietary recall interviews of these participants. Each participant in the DitEetIk! app evaluation study was matched with a participant in the DNFCS 2019 to 2021 based on characteristics associated with dietary intake, that is, age (5-year classes), gender, weight (10-kg classes), and educational level (3 classes). This provided matches for 86.3% (182/211) of the participants. For those without a match, the matching characteristics were relaxed, starting with educational level (28 matches) followed by age (1 match). For participants in the evaluation study with multiple possible matches in the DNFCS 2019 to 2021, a person with the same or the closest height was chosen (182 matches).

Statistical Analysis

For the analyses, only DitEetIk! data for the day that was recalled using the GloboDiet software were used. Frequency analyses were conducted to describe the population of DitEetIk! app users and the matched participants of the DNFCS 2019 to 2021 in terms of sociodemographic characteristics. For the items of the SUS and the total SUS score, means and SDs were calculated.

The medians, SDs, and IQRs of the food group, energy, and nutrient consumption assessed using both methods were calculated. Owing to skewed distributions, the nonparametric Wilcoxon signed rank test was used to test whether differences between the DitEetIk! app and the 24-hour dietary recalls for

food group and nutrient intake were symmetrical around 0. Differences were considered relevant if the median intake was >10% of the 24-hour dietary recall value. Only food groups for which the 75th percentile was >0 were reported. The analyses were repeatedly stratified by educational level (3 classes) and BMI (3 classes).

In addition, the number of consumers and median intake for consumers only were calculated for each food group for each method. The McNemar test was used to test whether being a consumer per food group differed significantly between both methods. In addition, the Wilcoxon signed rank test was used to test whether the distribution of food group consumption only differed systematically by method. Spearman rank correlation coefficients were calculated for food group consumption and also energy and nutrient intake assessed using both methods.

Bland-Altman plots were constructed for the intake of energy and energy percentage derived from fat, protein, and carbohydrates, plotting the difference in intake assessed using both methods against the mean intake for each participant. The derived 95% limits of agreement [27] were presented to provide information on the variation in individual relative validity.

To assess any design effects, a nonparametric Wilcoxon signed rank test was used to test whether there was a systematic difference between the 24-hour dietary recalls in the relative validity study and the DNFCS 2019 to 2021 regarding the intake of energy, nutrients, and food groups.

All statistical analyses were conducted using SAS (version 9.4; SAS Institute Inc). *P* values of <.05 were considered statistically significant, and 2-sided statistical tests were performed.

Results

Study Population Characteristics

Of the 3418 contacted people, 443 (12.96%) were willing to participate (Figure 2). A total of 300 people were invited to start the study based on their ability to use an Android smartphone and their sociodemographic characteristics. Of the 300 invited individuals, 227 (75.7%) completed a combination of a DitEetIk! app recording day and a 24-hour dietary recall interview for the same day. In total, 7% (16/227) of the participants were excluded because of an implausible ratio of energy intake to BMR of <0.6 or >3.0, resulting in 211 participants included in the analyses.

Approximately half (107/211, 50.7%) of the participants were women (Table 1). The study population consisted of more participants with a middle and higher educational level (81/211, 38.4% and 93/211, 44.1%, respectively) than those with a lower educational level (37/211, 17.5%). Of the 211 participants, 129 (61.1%) had a BMI of ≥25 kg/m^2. Fewer people in the highest age category of 60 to 79 years participated in the study (58/211, 27.5%) than people in the 2 lower age categories (76/211, 36% and 77/211, 36.5%). The 211 participants included in the DitEetIk! app study were matched with 211 participants of the DNFCS 2019 to 2021. They had similar distributions in terms of gender, age, educational level, and BMI.

Of the 211 participants, 207 (98.1%) completed 3 DitEetIk! app recording days. Most GloboDiet 24-hour dietary recall interviews were for the first or second DitEetIk! app recording day (78/211, 37% and 84/211, 39.8%, respectively). Most of the participants started recording their food consumption on the DitEetIk! app in the morning (105/211, 49.8%) or afternoon (61/211, 28.9%) and ended their recording the same day in the evening (95/211, 45%) or the next day in the morning (82/211, 38.9%). The time between starting and ending the food recording using the DitEetIk! app was between 8 and 20 hours for 46% (97/211) of the participants, whereas it took >20 hours for 33.2% (70/211) of the participants and <8 hours for 20.9% (44/211) of the participants (Multimedia Appendix 1).

Food identification for recording was performed via text searching of the food items at the generic level for 23.6% (211/894) of the products and choosing previously selected food items (175/894, 19.6%). Branded food items were recorded via text searching (169/894, 18.9%) and barcode scanning (114/894, 12.8%). The option to make an individual recipe was used for 1.8% (16/894) of the products, associated food items (fats and oils for frying and milk or sugar in tea or coffee) were used for 16.4% (147/894) of the products, and supplements were used for 6.9% (62/894) of the products. Without considering previously selected food items, branded food items were recorded 39.4% (283/719) of times (Multimedia Appendix 2).

The SUS questionnaire was used to evaluate the system usability of the DitEetIk! app. The questionnaire was completed by 98.1% (207/211) of the included participants. The mean score per question ranged from 1.7 (SD 0.8) to 3.7 (SD 0.9). The mean overall score of the SUS was 66.6 (SD 15.1).

Figure 2. Participant recruitment and selection flow. A plausible recording day was a recording day with a ratio of energy intake over BMR between 0.6 and 3.0. BMR: basal metabolic rate; EI: energy intake.

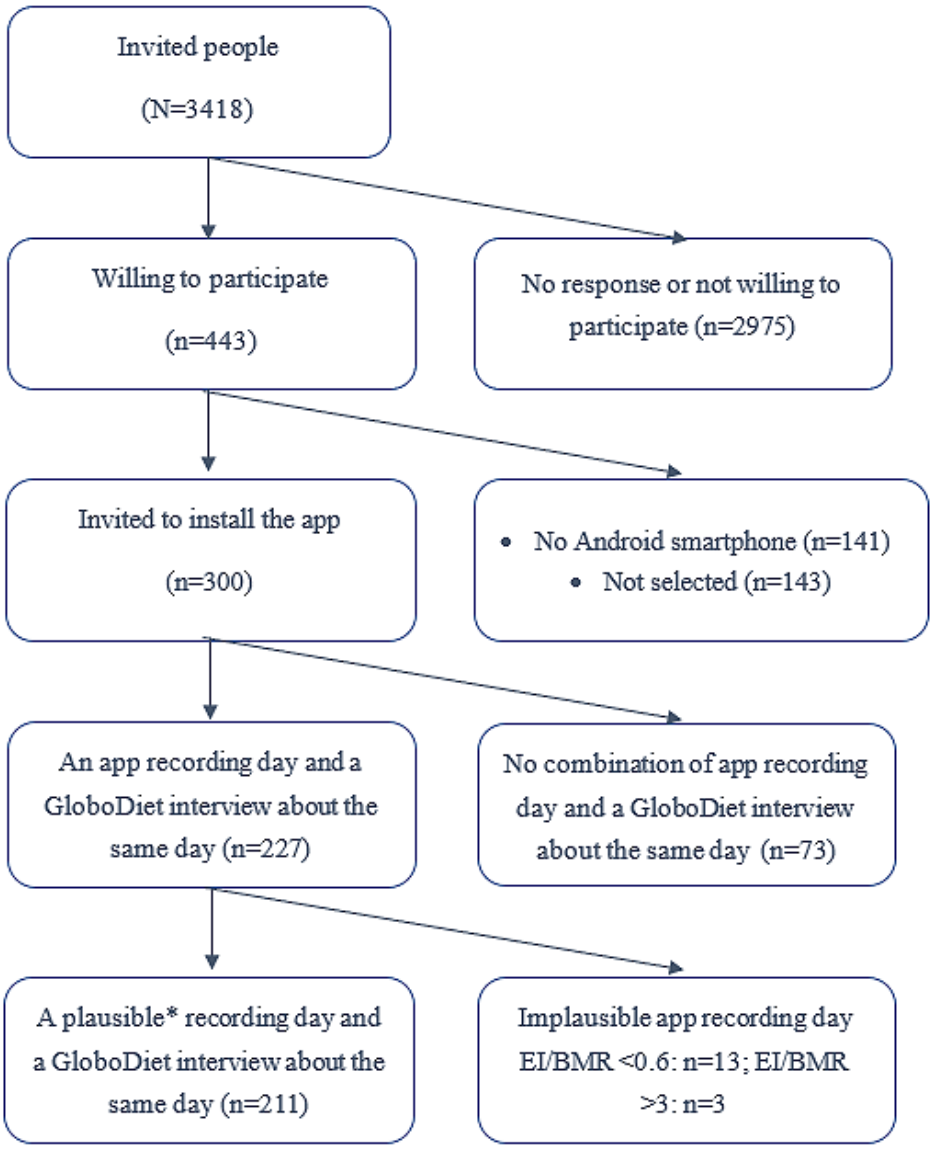


Table 1. Characteristics of the 211 participants in the DitEetIk! app study and matched participants from the Dutch National Food Consumption Survey (DNFCS) 2019 to 2021.

Characteristic	Evaluation study (n=211), n (%)	DNFCS 2019-2021 (n=211), n (%)
Gender		
Men	104 (49.3)	104 (49.3)
Women	107 (50.7)	107 (50.7)
Age category (y)		
18-39	76 (36)	75 (35.5)
40-59	77 (36.5)	78 (37)

[b]Middle educational level: intermediate vocational education or higher secondary education.

[c]High educational level: higher vocational education and university.

Relative Validity for Food Groups

For 44% (7/16) of the food groups, no statistically significant differences between the median intake of food groups assessed using the DitEetIk! app food record and the 24-hour dietary recall were observed (Table 2). No statistically significant differences were observed for the median consumption of vegetables (*P*=.13), meat (*P*=.10), eggs (*P*=.44), nuts (*P*=.73), bread (*P*=.95), potatoes (*P*=.96), and snacks (*P*=.41).

Statistically significant differences of >10% between the 2 methods were observed for the median consumption of fruit (83 vs 130 g/d; *P*=.005), added fats (12 vs 17 g/d; *P*=.001), milk and milk products (219 vs 252 g/d; *P*=0.02), cereal products (6 vs 20 g/d; *P*=.01), and sauces (2 vs 22 g/d; *P*<.001). For all food groups except "Other," the DitEetIk! app assessed a lower median consumption and, therefore, relatively underestimated the consumption of food groups compared with the 24-hour dietary recalls. However, when looking at the mean rather than the median, for 7 food groups, higher values were observed in the DitEetIk! app. Spearman correlation coefficients ranged from 0.50 for the food group "Other" to 0.88 for the food groups *Potatoes*, *Sandwich spreads*, and *Snacks*. The median correlation coefficient was 0.78.

A significant difference in the number of consumers between the 2 methods was observed for the food groups *Fruit* (*P*=.002), *Added fats* (*P*=.02), *Cereal products* (*P*=.03), *Sauces* (*P*<.001), and *Other products* (*P*<.001; Table 3). This list includes 4 of the 5 food groups for which differences in median intake for all participants were statistically significant and of >10%. Focusing on the 5 food groups, the median intake of consumers differed significantly for *Added fats* and *Sauces* (median 15 and 24 grams per day in the DitEetIk! app vs 20 and 45 grams per day in the GloboDiet 24-hour dietary recalls; *P*=.06 and *P*=.004) but not for *Fruit*, *Milk and milk products*, and *Cereal products*, whereas for the food groups *Fish* (90 vs 115 g/d), *Cheese* (36 vs 45 g/d), *Sandwich spreads* (26 vs 20 g/d), and *Soups* (188 vs 50 g/d), significant differences of >10% were also observed in the median intake of consumers only.

Within the strata of educational level (3 classes), a few significant differences that were ≥10% for the median were observed for food groups (Multimedia Appendix 1). For sauces (low educational level *P*=.02; middle educational level *P*=.006; high educational level *P*<.001), the differences were consistent across the 3 educational levels. For milk and milk products, only those with a high educational level had a significantly lower median in the DitEetIk! app compared with the GloboDiet 24-hour dietary recalls (*P*=.01). Within the strata of BMI (3 levels), more differences were observed, but there was no consistent pattern in which differences were generally smaller or larger for persons in one of the BMI classes (Multimedia Appendix 2).

Table 2. The mean, SD, median, and IQR of consumption of food groups[a] as assessed using the DitEetIk! app and 24-hour dietary recalls for the same day and their correlation for the 211 participants with plausible energy intakes.

[d]N/A: not applicable.

Relative Validity for Nutrients

For 41% (12/29) of the nutrients, the median intake assessed using the DitEetIk! app and the 24-hour dietary recalls did not differ significantly (Table 4). Statistically significant differences of >10% between the 2 methods were observed for the median intake of vitamin A (453 vs 515 µg retinol activity equivalents/d; *P*<.001), folate (equivalents; 241 vs 269 µg/d; *P*<.001), vitamin D (1.8 vs 2.1 µg/d; *P*<.001), and vitamin E (9.7 vs 11.7 mg/d; *P*<.001). For 8 nutrients, significant differences were between 5% and 10%, and for 5 nutrients, they were <5%. With the exceptions of mono- and disaccharides and magnesium, in all cases of statistically significant differences, the DitEetIk! app had lower values than the 24-hour dietary recalls. Spearman correlation coefficients between intake assessed using the DitEetIk! app and the 24-hour dietary recalls ranged from 0.55 for sodium to 0.9 for alcohol, with a median correlation coefficient of 0.72.

Compared with the expected energy intake, the mean underreporting using the DitEetIk! app was 19.9% (0.316/1.59; calculated as [measured-expected physical activity level]/[expected physical activity level]) versus 20.1% (0.321/1.59) using the 24-hour dietary recalls. At the individual level, 20.4% (43/211) of the participants could be considered to be underreporting and 0.5% (1/211) of the participants could be considered to be overreporting energy intake using the DitEetIk! app. For the 24-hour dietary recalls, 18% (38/211) of the participants could be considered to be underreporting, and none were overreporting.

Figure 3 shows the Bland-Altman plots for energy intake and for fat, carbohydrates, and protein expressed as a percentage of energy intake. The mean differences and 95% limits of agreement were 14 (−1096 to 1124) for energy in kilocalories, −2.6 (−16.2 to 11) for energy percentage derived from fat, 2.5 (−10.9 to 16) for energy percentage derived from carbohydrates, and −7.5 (−7.5 to 7.4) for energy percentage derived from protein.

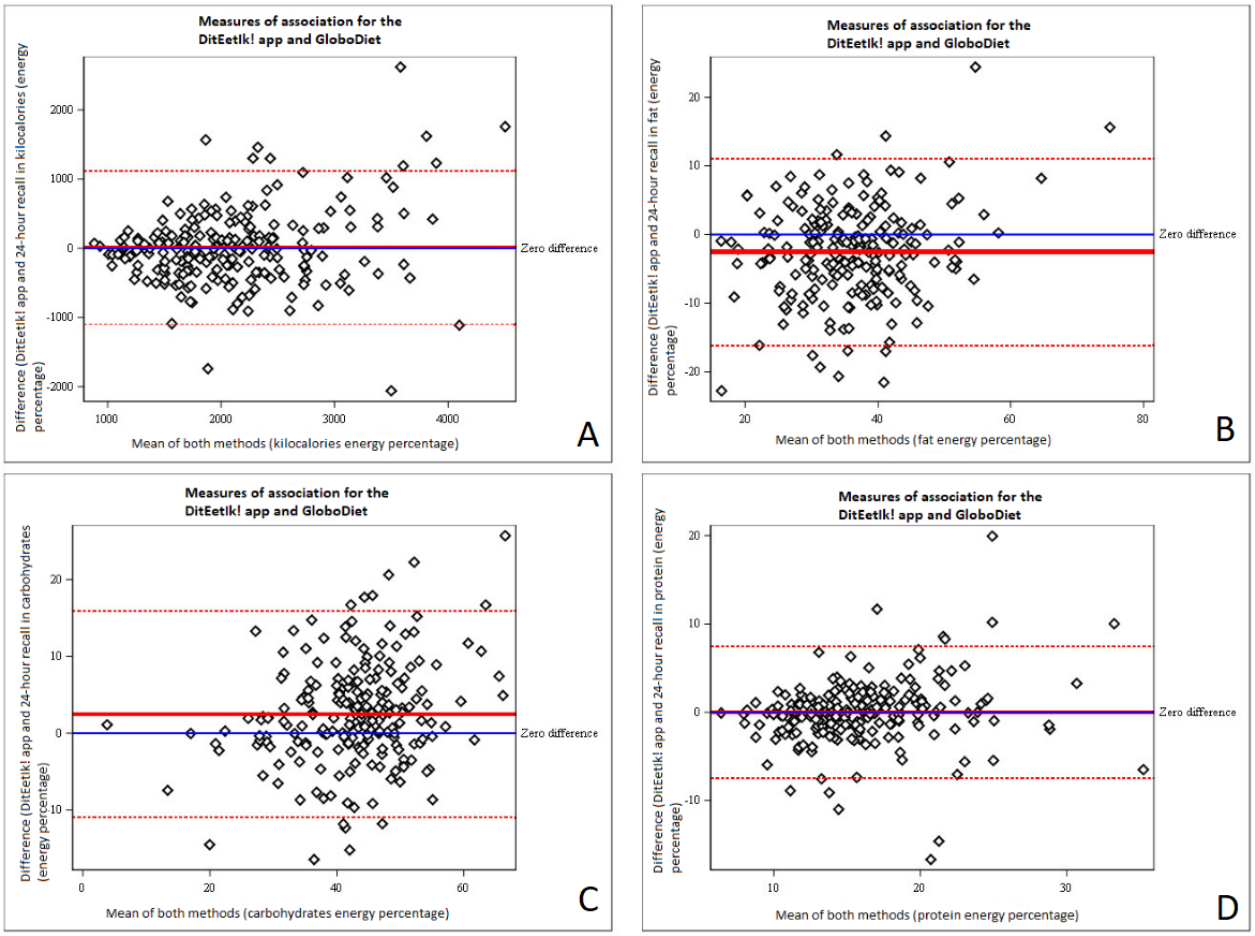
Figure 3. Bland-Altman plot assessed using the DitEetIk! app and GloboDiet (GD) 24-hour dietary recalls (n=211). (A) Results for energy intake, (B) results for fat (energy percentage), (C) results for carbohydrates (energy percentage), and (D) results for protein (energy percentage).



Evaluation of the GloboDiet 24-Hour Dietary Recall Data

For almost all food groups, the consumption of participants in the DitEetIk! app evaluation study, assessed using the GloboDiet 24-hour dietary recall, and the consumption of matched participants selected from the DNFCS 2019 to 2021 did not differ significantly (Table 5). Statistically significant differences of >10% in median intake between the 2 methods were only observed for the consumption of milk and milk products (median 252 grams per day in the DitEetIk! app vs 282 grams per day in the GloboDiet 24-hour dietary recalls; *P*=.03) and bread (median 132 grams per day vs 105 grams per day; *P*=.03).

For all nutrients except vitamin B3, the intake of participants in the evaluation study, assessed using the GloboDiet 24-hour dietary recalls, and the intake of the matched participants selected from the DNFCS 2019 to 2021 did not differ significantly (Table 6).

Table 5. Comparison of consumption of food groups assessed using the GloboDiet 24-hour dietary recalls in the DitEetIk! app evaluation study and the first interview in the Dutch National Food Consumption Survey (DNFCS) 2019 to 2021 for a matched group of participants (n=211).

[a]Wilcoxon signed rank test (normal approximation) of the differences between intake assessed using the GloboDiet 24-hour dietary recalls in the DitEetIk! app evaluation study and the first interview with adults in the DNFCS 2019 to 2021.

[b]RAE: retinol activity equivalents.

[c]Sodium and iodine from food only.

Discussion

Principal Findings

Compared with GloboDiet 24-hour dietary recalls, the DitEetIk! app assessed similar mean levels of energy intake but somewhat lower median levels of intake for several food groups and nutrients. Differences were of >10% for fruit; added fats; cereal products; sauces; and vitamins A, D, and E and folate. Of all logged food items and beverages, most were selected via text searching, whereas the scanning functionality was used for approximately one-seventh of the food products.

Incomplete recording of consumed food items in the DitEetIk! app seems to have occurred for various food groups, such as fruit, added fats, cereal products, and sauces. During the GloboDiet 24-hour dietary recall, the trained interviewer specifically probes for easily forgotten food items [28], which

may explain this difference. Similarly, other studies evaluating mobile food record apps based on text searching reported food omissions, particularly of condiment food items [29]. In a study using wearable camera images as a reference, it was observed that the most forgotten food groups in the Australian Eat and Track app were savory sauces and condiments, vegetables, confectionery, fruit and dairy, and alternatives [30]. There are various options to stimulate complete recording. According to a review of smartphone dietary assessment tools, the most common feature to do so was to allow participants to review the records and make adjustments if information was missing or false [31]. This feature was also built into the DitEetIk! app; before submitting the food recording for one day, participants were shown an overview of reported food items and were asked whether this was complete. In addition, incorporating (more) probing questions for frequently omitted food items into DitEetIk! app could be a way to remind a participant to report such food items. This could be probing questions either linked to other food items (eg, salad dressing in the case of salads) or linked to eating occasions (eg, fruit in between meals). Alternatively, sending prompts when an eating moment is expected or when the DitEetIk! app has not been used for a certain period or allowing participants to explicitly state that they did not consume anything at a given eating occasion are also approaches with the potential to improve completeness [32].

In contrast to the results for median intake, for some food groups and nutrients, the mean intake was higher in the DitEetIk! app than in the 24-hour dietary recalls. For the food groups *Vegetables*, *Meat*, *Bread*, and *Potatoes*, this was caused by higher amounts recorded in the DitEetIk! app than those indicated in the 24-hour dietary recalls. Choosing unlikely high portion sizes in the DitEetIk! app was possible without a warning message in case the amount eaten was indicated in units rather than grams, whereas in the GloboDiet 24-hour dietary recalls, all indicated portions were converted into grams and checked against set improbable maximum values, and if needed, the interviewer was prompted to check with the participant whether the answer was correct [28]. A similar functionality could be considered for inclusion in the DitEetIk! app.

Of all logged food and beverages, most were selected via text searching. In the feedback given by participants in the remark field of the DitEetIk! app, they mentioned that finding the correct food item on the list was a challenging task. This disadvantage of extensive food item lists was also described in a systematic review [33]. This was probably the reason why the average SUS score for the DitEetIk! app was just below 70, the threshold that is generally considered “good” [34]. Only 12.8% (114/894) of all logged food items and drinks were scanned. This percentage was lower than expected based on experiences in a project in which approximately 50% of the food items were scanned using a commercial smartphone food record (personal communication by MO). The availability of branded food items in the DitEetIk! app was still limited, and these did not include food items from some supermarket chains or that were not matched to the generic food composition database. This may have affected the use of the scanning option. One could understand that participants stopped scanning barcodes after some failed attempts. Therefore, including more branded food items in the DitEetIk! app is highly recommended. In addition, a crowdsourcing function could be incorporated whereby users can contribute information on missing products, such as that developed for the FoodSwitch app [35]. The collected food product information can then be added to the database to ensure that the DitEetIk! app is supported by actual and complete product information. If more food items are scanned, food recording will probably be perceived as easier.

As described previously, based on the main findings, several options for improvement via additional DitEetIk! app functionalities can be formulated. However, one should also be careful not to burden participants with too frequent notifications, reminders, and prompts [33]. More insight on the impact of different features used in smartphone-based dietary assessment tools and the characteristics of these features on the respondents’ willingness and ability to record intake reliably and on the validity of the recorded dietary data is needed [31].

Strengths and Limitations

This study is one of the few food record validation studies (Zhang et al [29]) that report results for a rather comprehensive list of food groups and nutrients in a group of >200 men and women of various ages. An important limitation is that relative rather than objective validity was studied. Therefore, lower and higher values compared with GloboDiet 24-hour dietary recall values cannot be interpreted as underestimation or overestimation. However, the results on energy misreporting were included, which are not dependent on the subjective reporting of dietary intake. In the future, follow-up validation with doubly labeled water and excretion of nitrogen, potassium, and sodium in 24-hour urine is recommended. Another limitation is the large number of statistical tests that were conducted, which may have led to chance findings. Moreover, the study did not follow a crossover design, which might have caused a potential memory or learning effect in the 24-hour dietary recall data. However, comparing these data with those from the DNFCS 2019 to 2021 gave no indication that this occurred. People with a lower education and of higher age were included in the study population but were underrepresented. We cannot conclude whether the relative validity is similar for these population subgroups. This study did not focus on the potential selection bias of including only participants who had an Android smartphone. Such an evaluation is also important for use in a national food consumption survey. Potentially, developing an iOS version of the DitEetIk! app and offering an interview option to persons without a smartphone needs to be considered. In this study, the DitEetIk! app was described according to the recommendations of Eldridge et al [11], and the validity study was reported according to the guidance provided by Kirkpatrick et al [26].

Comparison With Prior Work

Although many different smartphone-based dietary assessment tools exist, only a few validation studies have been conducted. Burrows et al [36] concluded that their validity seems to be comparable with that of more traditional dietary assessment methods and that energy intake is often underreported. In a

review from 2013 to 2019, Zhang et al [29] identified 14 smartphone-based food records that were not image based. In the meta-analyses based on 11 tools, all of them underestimated energy intake, with a pooled effect of approximately −200 kcal and limits of agreement of 1918 kcal. The results for the DitEetIk! app fit with this picture, with a below-average mean underestimation and similar limits of agreement for energy intake. The relative validity results were also in line with those of Eetmeter, another Dutch app, although the food groups for which underestimation occurred partly differed [20]. Unlike the DitEetIk! app, Eetmeter shows energy and nutrient values for logged food items, which might influence reporting.

Conclusions

Compared with GloboDiet 24-hour dietary recalls, the DitEetIk! app assessed somewhat lower levels of intake for several food groups and nutrients. Therefore, adding functionalities to the DitEetIk! app that stimulate more complete food recording is important before using the app in national food consumption surveys. In addition, it is advisable to develop a functionality to warn participants when entering extremely large consumption amounts. Less participant burden and more detailed information about consumed food items can be obtained by stimulating the use of barcode scanning.

Acknowledgments

This study as well as the development of the DitEetIk! app was funded by the Dutch Ministry of Health, Welfare, and Sport. The authors would like to thank Dr Maarten Schipper for providing statistical advice and Dr Steffen Bruns, Henny Brants, and Marjolein de Jong for critically reviewing the manuscript.

Abstract

Background: Despite its importance to women's reproductive health and its impact on women's daily lives, the menstrual cycle, its regulation, and its impact on health remain poorly understood. As conventional clinical trials rely on infrequent in-person assessments, digital studies with wearable devices enable the collection of longitudinal subjective and objective measures.

Objective: The study aims to explore the technical feasibility of collecting combined wearable and digital questionnaire data and its potential for gaining biological insights into the menstrual cycle.

Methods: This prospective observational cohort study was conducted online over 12 weeks. A total of 42 cisgender women were recruited by their local gynecologist in Berlin, Germany, and given a Fitbit Inspire 2 device and access to a study app with digital questionnaires. Statistical analysis included descriptive statistics on user behavior and retention, as well as a comparative analysis of symptoms from the digital questionnaires with metrics from the sensor devices at different phases of the menstrual cycle.

Results: The average time spent in the study was 63.3 (SD 33.0) days with 9 of the 42 individuals dropping out within 2 weeks of the start of the study. We collected partial data from 114 ovulatory cycles, encompassing 33 participants, and obtained complete data from a total of 50 cycles. Participants reported a total of 2468 symptoms in the daily questionnaires administered during the luteal phase and menses. Despite difficulties with data completeness, the combined questionnaire and sensor data collection was technically feasible and provided interesting biological insights. We observed an increased heart rate in the mid and end luteal phase compared with menses and participants with severe premenstrual syndrome walked substantially fewer steps (average daily steps 10,283, SD 6277) during the luteal phase and menses compared with participants with no or low premenstrual syndrome (mean 11,694, SD 6458).

Conclusions: We demonstrate the feasibility of using an app-based approach to collect combined wearable device and questionnaire data on menstrual cycles. Dropouts in the early weeks of the study indicated that engagement efforts would need to be improved for larger studies. Despite the challenges of collecting wearable data on consecutive days, the data collected provided valuable biological insights, suggesting that the use of questionnaires in conjunction with wearable data may provide a more complete understanding of the menstrual cycle and its impact on daily life. The biological findings should motivate further research into understanding the relationship between the menstrual cycle and objective physiological measurements from sensor devices.

women's health; menstrual cycle; premenstrual syndrome; PMS; mobile app; wearable device; sensor data; digital health

Introduction

An estimated 56% to 93% of women across the world experience recurrent painful periods [1-5]. Menstrual pain is debilitating for many women and has a major impact on their health-related quality of life [6-11]. One condition that can cause painful menstruation is endometriosis, which affects 10% to 15% of women of reproductive age [12]. In addition to severe pain, intermenstrual bleeding, painful periods (dysmenorrhea), painful intercourse (dyspareunia), painful bowel movements (dyschezia), and painful urination (dysuria), endometriosis can cause infertility, increase psychological distress, and can affect sexuality and relationships [12,13]. Despite its debilitating nature, it still takes around 6 to 8 years from symptom onset to diagnosis [14,15]. The gold standard for diagnosis is still laparoscopy, which is not only risky but also expensive. With the rise of gender equality movements, clinical research into menstrual health has slowly gained more attention in recent years, with researchers emphasizing the importance of timely diagnosis and treatment of menstrual cycle–related concerns and disorders [16]. Each individual has a different baseline of subjective pain experience and the availability of sufficient baseline data can enable a shift toward precision medicine in menstrual health [17]. Frequent and continuous data collection can provide an understanding of symptom variability, which is likely to be an important contributor to variability in treatment response [17]. However, traditional clinical trials to date have relied on infrequent in-person assessments and subjective retrospective data, failing to capture the daily changes in physical and mental well-being that occur over the course of the menstrual cycle [18,19]. In this regard, commercially available menstrual tracker apps offer new opportunities for research. Women can continuously track their menstrual health in digital diaries, with self-learning algorithms continuously improving predictions and educational content empowering users to increase their knowledge about menstrual health [20-22]. As a complement to subjective digital questionnaires, commercially available wearable technology can provide an easy way to collect continuous and objective real-world health data for women's health research purposes. In the example of endometriosis, the combined collection of subjective data from digital diaries and objective wearable devices could help distinguish between "normal" menstrual pain and pain associated with endometriosis, potentially speeding up the diagnosis process and avoiding unnecessary invasive tests.

Previous research, albeit with small sample sizes, has already shown that the collection of sensor data such as step count, heart rate, and sleep duration combined with self-reported menstrual cycle data can uncover interesting correlations and advance knowledge about menstrual health [23-26]. For example, wearables are already increasingly being used to evaluate alternative contraceptive methods and to predict the fertility window [26-29]. Interesting findings from previous research using wearables include an observed lower distal skin temperature (as measured with an Oura ring) during ovulation, as well as higher heart rate in the ovulatory, mid, and late luteal phases [24,25]. While previous studies show a potential effect of physical activity on the menstrual cycle and vice versa [30-32], none of them used wearable devices for daily activity tracking during the menstrual cycle. Similarly, there is a lack of studies using wearable data to analyze sleep behavior during the menstrual cycle. Current scientific knowledge on changes in sleep behavior across the menstrual cycle is conflicting, with some studies finding a decrease in subjective and objective sleep quality during the premenstrual phase and menses [33-36], while other studies did not find such correlations [24,37]. The ongoing Apple Women's Health Study [27], a mobile app–based longitudinal cohort study that includes both survey and sensor-based data, has not yet published results related to sensor data.

Combining subjective data from women's health questionnaires with objective sensor data from wearables can not only facilitate cycle tracking for the everyday consumer but also allow researchers and participants alike, to gain a deeper insight into the clinical changes during the menstrual cycle. Commercially available wrist-worn sensor devices, such as the Fitbit Inspire 2 device, are thereby not only much more affordable than research-grade sensor devices, but can be nearly as accurate [38,39]. However, real-world data collection studies conducted exclusively in the home can present difficulties in terms of retention and adherence to the study protocol [19,40]. To explore the feasibility of consistently collecting wearable and questionnaire data across multiple menstrual cycles, we conducted a 12-week feasibility study with 42 participants. Using the Fitbit Inspire 2 device and digital questionnaires within the Data4Life study app, our primary objective was to refine methods for collecting authentic menstrual cycle data in a real-world setting. This included assessing participant retention rates and gathering usability feedback on their engagement with wearable devices and digital questionnaires. In addition, our study explored potential clinical correlations between wearable and questionnaire data, with the aim of uncovering potential correlations with key parameters of the menstrual cycle.

Methods

Study Design

This digital prospective cohort study was conducted mainly online with enrollment between December 2021 and April 2022. This study was called the Feasibility Study of Menstrual Cycles With Fitbit Device (FEMFIT). Participants were recruited by their local gynecologist at a practice in Berlin, Germany. The owner of the practice, who is also a coauthor of this study (MH), received financial incentives for recruiting participants. During recruitment, participants received a token to access the FEMFIT study in the study app. During account creation, participants provided digital informed consent to share their data for research. All participants received a free Fitbit Inspire 2 (Fitbit International Limited) as an incentive after completing the study. Participants were asked to wear the device at all times throughout the study period of 3 menstrual cycles or 12 weeks. Dropout was defined as individuals who did not provide data for more than 14 days. This cut-off was deliberately set to manage participant dropout while ensuring the inclusion of data from individuals with shorter menstrual cycles.

The primary outcome variables of this study centered on assessing the feasibility of continuous menstrual cycle data collection using the Fitbit Inspire 2 device and digital questionnaires. Specifically, we focused on participant retention rates and usability feedback regarding engagement with these tools. In addition, secondary outcome variables included exploring potential clinical correlations between the collected wearable and questionnaire data and key menstrual cycle parameters.

Data Collection: Digital Questionnaires and Wearable Data

Prior to enrollment, participants completed a paper questionnaire to assess their digital literacy [41] (Multimedia Appendix 1).

Digital questionnaires (Multimedia Appendix 1; Figure S2 in Multimedia Appendix 2) were accessible within the app at varying intervals, with email notifications reminding participants of new questions. Email notifications reminded participants of newly available questions. At enrollment, participants provided demographic information and were asked for clinical information with a focus on women's health, including preexisting conditions, use of hormonal contraception, cycle regularity, and the first day of the last menses (Multimedia Appendix 1). After enrollment, weekly questionnaires focused on monitoring the duration of wearable device use duration and assessing mental and physical well-being (Multimedia Appendix 1). Notably, the specific results of the mental and physical well-being assessments are not presented in this publication. Triggered by the first day of their last menstrual cycle, from day 13 to day 5 of their menstrual cycle, participants were asked about the 12 typical symptoms of premenstrual syndrome (PMS): seclusion, irritability, swelling, anger, weight gain, joint pain, headache, confusion, dejection, bloating, anxiety, and tenderness [42]; participants were also asked about the severity of their bleeding. If a new menstrual cycle had begun, the first day of bleeding triggered the new cadence for all future questionnaires. Data from these daily questionnaires were used for correlation with the wearable data collected simultaneously.

In addition to the digital questionnaires, the Fitbit device recorded 3 parameters daily: average resting heart rate, total steps, and total sleep time. For this study, average resting heart rate was rounded to the nearest 5 beats per minute, sleep time was rounded to the nearest 10 minutes, and step count was rounded to the nearest 100 steps. This generalization was made to protect the anonymity of participants when analyzing deidentified donation records in this small feasibility study.

Definitions

The relevant phases of the menstrual cycle were defined as follows: the menses phase (MP; days 1 to 5), the ovulation day (OD; day 1 of the next MP minus 14) [43], the follicular phase (day 1 of MP to OD minus 1), the luteal phase (OD plus 1 to the menses), and the midluteal phase (OD plus 3 to OD plus 9).

In our analysis of PMS, only PMS symptoms from the days after OD to the end of MP were considered. Severe PMS was defined as a symptom severity rating of 3, equivalent to severe, on the visual analog scale. Participants were included in the severe PMS group if they reported severe PMS symptoms in at least 2 cycles. Participants were included in the no or low PMS group if they never reported PMS symptom severity higher than 1 on a severity scale from 0 to 3.

Data Storage and Wearable Data Integration

The nonprofit organization Data4Life provided the research infrastructure (study application, data storage, and analysis platform) for this study. All research data was stored in Data4Life's secure research environment on servers in Germany. Data4Life is certified by the German Federal Office for Information Security (BSI). For participants who allowed the use of cookies, we were able to analyze user behavior using the General Data Protection Regulation–compliant business analytics tool Matomo (Matomo; data stored in Europe only). In the web app, after entering their study token and providing digital study consent, participants were asked to connect to Fitbit to allow access to their wearable data via the Fitbit web application programming interface (API) [44]. After completing the OAuth 2.0 Authorization Code Grant Flow [45], the API refresh token was stored in end-to-end encrypted form for subsequent use for the duration of their participation in the study or until they withdrew their consent. This allowed the study's wearable parameters to be retrieved client-side via the respective activity and sleep endpoints, and stored in end-to-end encrypted form as Fast Healthcare Interoperability Resources Standard for Trial Use, version 3, [46] observation records each time participants logged into the web app to complete their questionnaires. As the API returns time series data over a few days, data gaps between donations were filled by comparing previously stored records with the data points returned by the API.

Statistical Analysis

All analyses were performed on the Data4Life analytics platform on a jupyterhub notebook running Python (version 3.10.4), using *pandas* (version 1.4.2), *matplotlib* (version 3.5.2), *seaborn* (version 0.11.2), and *numpy* (version 1.22.4). Descriptive statistics were used to report details of the study cohort, retention, and adherence measures. Continuous values were reported as mean with SD or median with IQR; categorical values were reported as numbers with percentages. For comparative analyses of clinical outcomes, we used the Mann-Whitney test [47] for nonnormally distributed data and the 2-tailed *t* test [48] for normally distributed data.

Ethical Considerations

The study was approved by the ethics committee of the Berlin Chamber of Physicians (Eth-11/22). Registration was open for people aged 18 years and older. All participants provided digital informed consent for study participation. Participation was voluntary. Participants were allowed to keep the Fitbit Inspire 2 device after the study ended. Email and password were required to log in to the study app as well as two-factor authentication via phone. Participants could access all study content through a web app on both desktop and mobile devices. All study data was end-to-end encrypted and pseudonymized. Only authorized researchers were provided access to the data on the Data4Life analytics platform. Data was stored exclusively on Data4Life data centers in Germany. Based on IT-Grundschutz

(ISO 27001), Data4Life is certified by the German Federal Office for Information Security (BSI).

Results

Study Setting and Participants

This feasibility study of combined wearable and questionnaire data collection on the menstrual cycle was conducted online with self-reporting of questionnaire data in a study app accompanied by the collection of wrist-worn sensor data from Fitbit Inspire 2 devices. A total of 42 cisgender women were recruited from December 2021 to April 2022 at a gynecological practice in Berlin and agreed to provide menstrual cycle data for 12 weeks (Figure 1).

One participant never requested a wearable device and therefore dropped out of the study before creating an account in the study app. Three participants never donated any questionnaire or wearable data (Figure S1 in Multimedia Appendix 2), leaving data from 38 participants who started to donate data in the study app. Of these, a total of 5 participants withdrew from the study within the first 2 weeks of study entry, 3 of whom never donated any wearable data, leaving valuable data from 33 participants for further analysis. Active participants (n=33) were on average 24.2 (SD 3.0) years old and predominantly identified as female, with 1 individual identifying as diverse (Table 1). Five participants (15.1%) reported preexisting mental health problems (Table 1). In terms of women's health issues, 2 (6.1%) participants reported a history of chlamydia infection and 1 person (3%) reported a history of human papillomavirus infection. At enrollment, the median time since the last menstruation was 17 (IQR 12-26) days.

Figure 1. Feasibility Study of Menstrual Cycles With Fitbit Device (FEMFIT) study concept. The FEMFIT study on collecting combined wearable and questionnaire data on the menstrual cycle was carried out online. Self-reporting of questionnaire data in a study app was accompanied by the collection of wrist-worn sensor data from Fitbit Inspire 2 devices. Weekly questionnaires asked about physical and mental well-being. From day 13 to day 5 of the menstrual cycle, participants answered daily questionnaires on bleeding severity and PMS symptoms. PMS: premenstrual syndrome.

[a]HPV: human papillomavirus.

High Degree of Digital Literacy of Study Participants

Of the 42 people initially recruited, 25 (59.5%) people reported that they had never worn a wearable device before. Of those who had experience wearing a sensor device, 5 had worn an Apple Watch, and other devices worn included Fitbit (n=2), Garmin (n=1), Samsung (n=1), and Denver (n=1). The majority of participants (26/42, 61.9%) regularly used apps on their smartphones to track their food intake, physical activity, or menstrual cycle. The most commonly used menstrual cycle tracking apps were Flo (9/26, 34.6%) and Clue (4/26, 15.3%). At the start of the study, a standardized digital literacy questionnaire [41] showed that the participants were highly digitally literate with an average score of 37.1 (SD 3.1) out of 48.

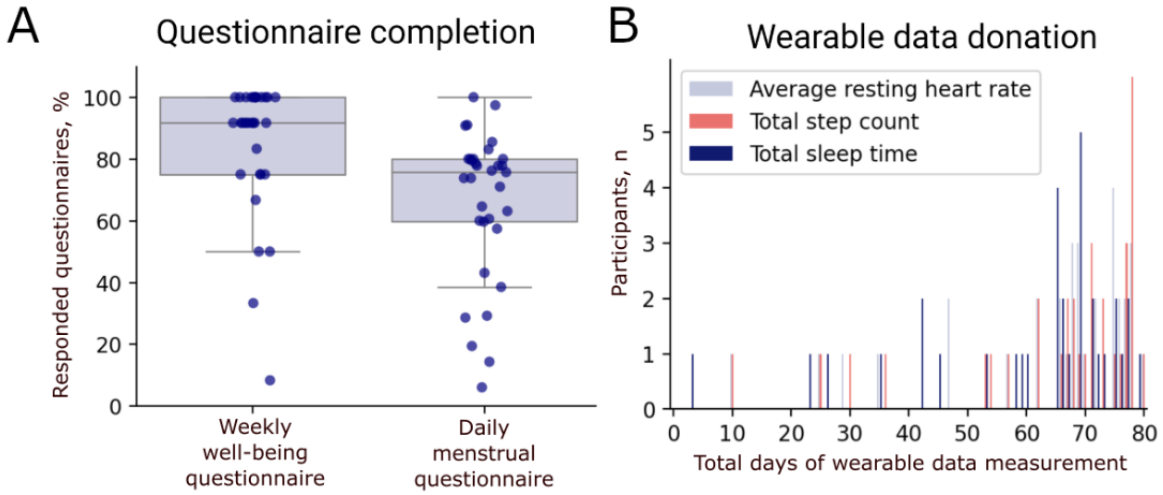
Increased User Engagement After Early Dropouts

Across all 41 participants who enrolled in the study and logged into the study app, the mean time spent in the study (measured from enrollment to last weekly or daily questionnaire delivery) was 63.3 (SD 33.0) days The reported reasons for not completing the study were too great a time commitment (n=1), a high technical barrier (n=2), and technical difficulties that made it impossible to complete the study (n=3).

Among participants who remained in the study for more than 14 days (n=33), questionnaire completion rates were high. The weekly physical and mental well-being questionnaires were completed on average 10.2 times (SD 2.6) out of 12, while 69.7% (n=23) of active participants completed at least 11 of the 12 weekly questionnaires. An average of 65.8% (SD 24.1%) of all questionnaires on menstrual bleeding and PMS symptoms, which were asked daily from day 13 to day 5 of the menstrual cycle, were completed (Figure 2A). Overall, 66.7% (n=22) of participants reported starting dates of at least 3 menstrual cycles, with a median cycle length of 28.0 days (IQR 24-31), and we collected data from a total of 50 complete ovulatory cycles. In general, logins to our study app occurred mostly after email notifications (Figure S3 in Multimedia Appendix 2), suggesting that frequent study reminders may increase retention.

The average number of days wearable data were provided was 65.2 (SD 17.0) days for step count, 64.2 (SD 17.1) days for heart rate, and 60.5 (SD 17.8) days for sleep time (Figure 2B). There were difficulties in collecting continuous wearable data over the entire study period, particularly for sleep time. None of the 33 active participants provided consecutive wearable data over the entire study period. The average number of consecutive days of data donation was 36.4 (SD 25.6) days for sleep time, 38.6 (SD 31.4) days for heart rate, and 52.6 (SD 28.3) days for step count. Wearable data was provided consecutively for at least 50 days by 11 participants and for more than 70 days by 3 participants. In the weekly study questionnaire, participants reported that they were wearing the device continuously for an average of 9 (SD 2.9) weeks out of 12. When participants reported that they did not wear the device continuously, off-times were stated to be longer than 3 hours per day.

Figure 2. Participant engagement. (A) Questionnaire completion rates of weekly and daily questionnaires. Questionnaires on physical and mental well-being were filled out once per week, whereas questions on premenstrual symptoms and bleeding severity were filled out daily from day 13 to day 5 of the menstrual cycle. The box plots show the median and IQR, with whiskers reflecting minimum and maximum values for outliers. Dots represent all data points. (B) Bar plot visualizing the total days of wearable data donation during the study period per participant. Bars are color-coded by the parameter assessed using the Fitbit Inspire 2 wearable device.



Fitbit Device and Study App Supported Subjective Health Monitoring

At the end of the study, 22 participants completed questions about their study experience. Most participants reported that the Fitbit device was very easy to use (n=22; mean rating 1.6, SD 0.6; 1=very easy, 5=very challenging) and did not interfere with their daily life (n=22; mean rating 1.2, SD 2; 1=very comfortable, 5=very disturbing). One person found wearing the Fitbit device at night very uncomfortable, whereas overall it was not perceived to be bothersome at night (n=22; mean rating 2.2, SD 1).

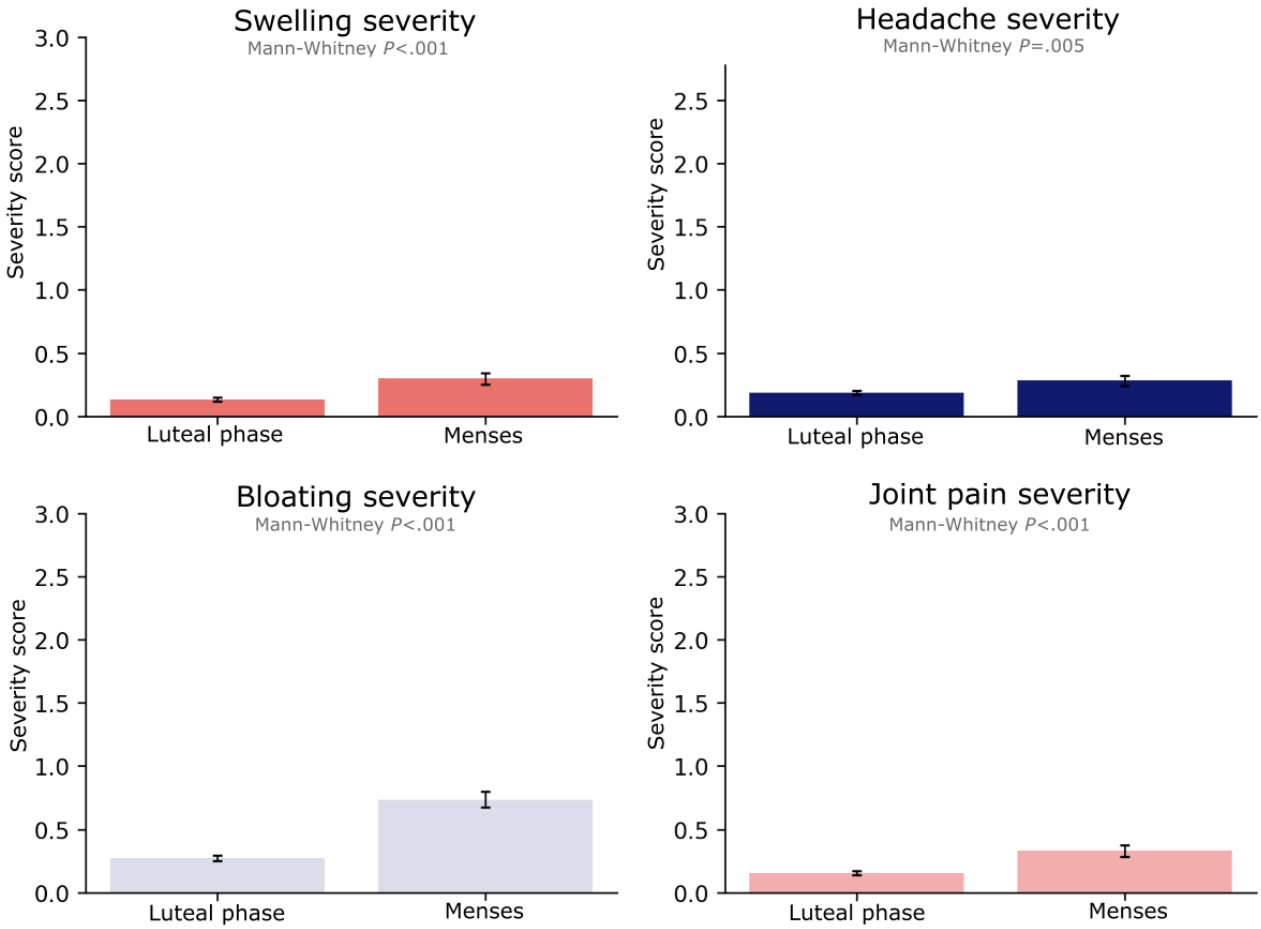
The majority of participants completing the end-of-study questionnaire (13/22, 59%) stated that wearing the device increased their physical activity over the study period. Step count data from all participants over the study period thereby showed an average step count of 9987 (SD 3856) steps per day in the last 2 weeks of study participation compared with an average of 9301 (SD 4076) steps per day in the first 2 weeks of study participation, but this observation was not significant. Overall, participants did not feel that the sensor tracking changed their sleep behavior (13/22, 59%). Five participants reported that wearing the device and answering the questionnaires made them feel stressed, while 9 participants reported that wearing the Fitbit device made them feel more in control. For 15 participants (67.9%), the study helped them to better associate symptoms such as mood swings, headaches, and pelvic pain with a particular phase of their menstrual cycle. Overall, the study seemed to improve participants' health awareness, and 21 of the 22 participants who completed the final questionnaire said they would take part in a similar study again.

Digital Symptom Questionnaires Revealed Patterns of PMS Symptoms Across the Menstrual Cycle

PMS-related symptoms and their severity on a scale of 0 to 3 were only assessed on potential PMS days during the luteal phase and menses. The majority of participants (22/33, 66.7%) reported severe PMS symptoms on at least 1 day of the menstrual cycle for at least 2 cycles. Severe PMS was reported by 18.2% (n=6) of participants in at most one of the cycles recorded in our study, and only 15.2% (n=5) did not experience any severe PMS symptoms during the study period.

In terms of mental health, dejection (average score 0.5, SD 0.9) and seclusion (average score 0.3, SD 0.7) were among the most commonly reported symptoms during the menses. The data suggested a notable impact on participants' mental health during the menses, with higher severity of seclusion (Mann-Whitney P=.03), dejection (Mann-Whitney P=.02), and irritability (Mann-Whitney P=.01) reported during the menses compared with the luteal phase (Figure S4 in Multimedia Appendix 2). Reported levels of anxiety, confusion, anger, and tenderness did not differ substantially between the luteal phase and menses (Figure S4 in Multimedia Appendix 2). In contrast to mental health symptoms, reported physical symptoms during menses were more severe. Participants experienced a significantly higher severity of bloating during the menses (mean 0.7, SD 1.1) compared with the luteal phase (mean 0.3, SD 0.7; Mann-Whitney P<.001; Figure 3). Similarly, the swelling was reported to be more severe during the menses (mean 0.3, SD 0.8; luteal phase: mean 0.1, SD 0.5; Mann-Whitney P<.001). In addition, participants reported more severe headaches during the menses compared with the luteal phase (mean 0.38, SD 0.7; luteal phase: mean 0.2, SD 0.67; Mann-Whitney P=.005) and more bothersome joint pain during the menses (mean 0.3, SD 0.8; luteal phase: mean 0.2, SD 0.5; Mann-Whitney P<.001). In terms of reported weight gain, there was a trend toward increased weight gain during the menses, although this increase did not reach statistical significance (Figure S4 in Multimedia Appendix 2).

Figure 3. Symptom severity over the menstrual cycle. Bar plots show the mean rating for symptom severity on a scale from 0 to 3 (0=no symptoms to 3=very strong symptom severity). Error bars are the SE. Mann-Whitney *P* values comparing groups are shown for each plot.



Combined Questionnaire and Wearable Data Delivered Interesting Insights Into the Menstrual Cycle

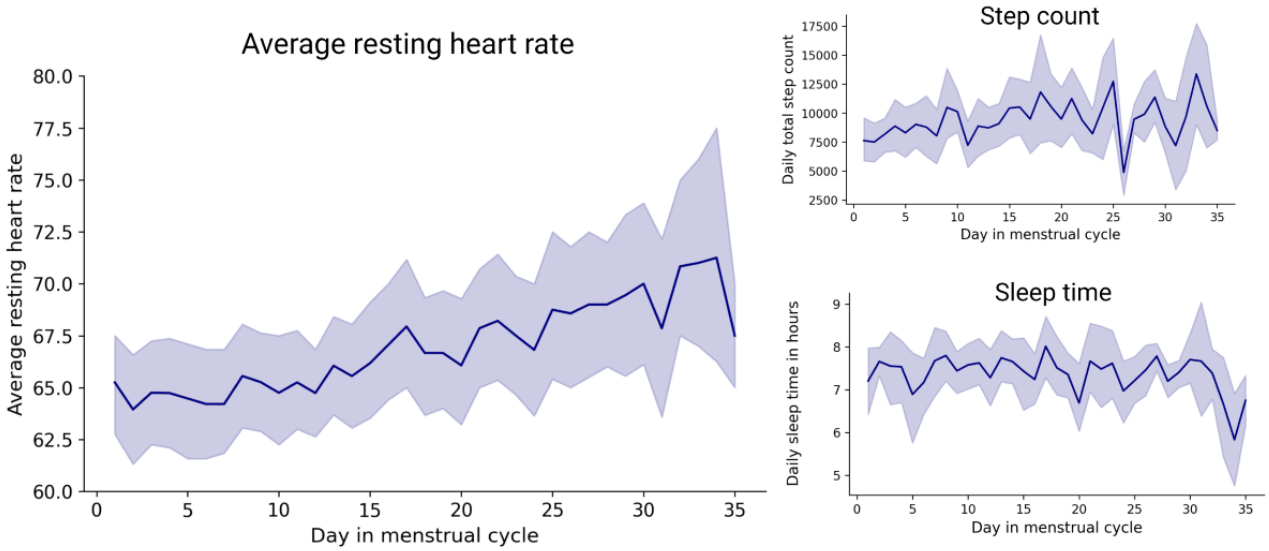
Participants provided a total of 23,424 symptom reports, with a total of 2468 symptoms reported in the daily questionnaires, which were administered during the luteal phase and menses. Heart rate sensor data was collected on a total of 2118 days, step count on 2153 days, and sleep time on 1996 days.

The average resting heart rate over the entire study period was 66.7 (SD 6.7). Participants slept an average of 7.3 (SD 1.6) hours while wearing the Fitbit device. With an average of 10,184 (SD 6120) steps per day, the FEMFIT cohort was quite physically active, with some participants walking >20,000 steps per day (153 days from 21 participants recorded with >20,000 steps; Figure S5 in Multimedia Appendix 2). When examining correlations between sensor data and questionnaire data on the menstrual cycle, we observed that mean resting heart rate appeared to be highest in the mid and late luteal phases relative to the time between menses and ovulation (Mann-Whitney $P<.001$; Figure 4, Figure S6 in Multimedia Appendix 2). We did not observe any significant differences in the change in step count (Mann-Whitney $P=.72$) or sleep time (Mann-Whitney $P=.58$) between the follicular and luteal phases (Figure 4).

In an exploratory analysis of the wearable data across participants with different PMS severity, participants with severe PMS (n=22) walked significantly fewer steps (mean daily steps10,283, SD 6277) during the luteal phase and menses compared with participants with no or low PMS (n=5; mean 11,694, SD 6458; Mann-Whitney $P<.001$). There was no significant difference in sleep duration (Mann-Whitney $P=.18$) or heart rate with PMS severity (Mann-Whitney $P=.72$).

To investigate whether hormonal contraception had an effect on step count, sleep time, or heart rate, we compared 4 participants using hormonal contraception with 29 participants not using hormonal contraception. Participants on hormonal contraception appeared to be less active (mean step count 7400, SD 4433; no hormonal contraception: mean 9800, SD 6203; Mann-Whitney $P<.001$). The average daily resting heart rate was significantly higher in the hormonal contraceptive group (mean 68.2, SD 7.7 vs mean 66.6, SD 6.6; Mann-Whitney $P<.001$). There was no difference in sleep behavior between the 2 groups.

Figure 4. Physical parameters measured by wearable devices over the menstrual cycle. Progression of daily average resting heart rate, step count, and sleep time over the menstrual cycle across all active study participants. Only cycles with a maximum length of 35 days were included. The dark lines show the mean and the shadowed lines show the 95% CI. The average resting heart rate was highest in the mid and late luteal phase relative to the time from menses to ovulation (Mann-Whitney $P<.001$); no significant difference was seen for sleep time or step count.



Discussion

Principal Findings

To date, only a few studies have assessed the menstrual cycle using both objective wearable and subjective questionnaire data [23,27,29,49,50]. Previous research has demonstrated potential effects of physical activity on the menstrual cycle and vice versa [30-32]. However, none of these studies used wearable devices to monitor daily activity levels, and there is a gap in studies using wearable data to examine sleep patterns across the menstrual cycle. Recognizing that participant retention is a significant challenge in digital cohort studies [19,40], our feasibility study was designed to primarily assess the effectiveness of study participation and adherence to the study protocol, highlighting challenges and opportunities for future large-scale studies in women's health. Secondarily, we focused on potential biological outcomes.

Our cohort was a group of young, mostly digitally literate, cisgender women with regular cycle lengths. Overall, retention was good among participants who remained in the study beyond the second week. The observed dropout rate of 21.4% (n=9) within the first 2 weeks of the study is consistent with rates reported in other digital cohort studies [51,52], and the overall median retention of 81.0 days was remarkably high [52]. Nevertheless, these dropouts may have introduced selection bias. Among the 5 dropouts who provided demographic data, we did not identify any discernible demographic patterns in relation to retention. The mean age of the dropouts was 24.8 (SD 3.2) years, which was not significantly different from the rest of the cohort. None of the dropouts had preexisting medical conditions and only 1 reported menstrual irregularity. In future large-scale studies, it would be advisable to collect demographic information directly at recruitment (in our case when the wearable device was distributed) to ensure comprehensive data on dropouts. This may contribute to a better understanding of the potential retention patterns and help to address selection bias. Among those who dropped out early, technical barriers were the most commonly reported problem. Although our study team provided access to technical support, future studies could potentially reduce dropout rates by further reducing barriers to accessing technical support or by conducting active outreach. The young age of participants, such as our cohort, is also known to be associated with lower retention [19,52]. Targeted engagement strategies such as increased outreach and communication with younger participants could counteract this [19]. For large-scale studies, continuous monitoring of data donations in an ongoing study can facilitate real-time strategies such as increased outreach to engage inactive participants, reduce dropouts, and ensure data completeness [19]. In 2 similar studies using sensor devices to investigate physiology surrounding the menstrual cycle [23,25], retention was generally not an issue, but retention efforts were not further highlighted in the publications.

In addition to the potential bias introduced by study dropouts, ensuring high data completeness is critical for investigating temporal patterns in menstrual cycles. Similar to our study, Maijala et al [23] reported issues with continuous data contribution across consecutive days. In particular, issues related to participant retention and data completeness could potentially undermine the integrity of the results. In our study, this was particularly challenging for sleep data. To mitigate these concerns, several strategies can be considered for future research. The comfort of wearable devices should be a priority in study design, as some participants in our study found the devices too uncomfortable. Data completeness may be further increased if a clear purpose for data collection is visible to participants, for example, having the clinical condition of interest in the study [52,53]. As this was a feasibility study without a specific disease focus, we expect retention and data completeness to be higher when applying a similar study setting

to a clinical condition with a high disease burden, such as endometriosis [54]. Recruitment strategies should also be tailored to improve data completeness. Although participants in our study were highly digitally literate, the vast majority had never worn a wearable device before. Recruiting participants who already have a sensor device and are accustomed to wearing it on a daily basis may increase data completeness. However, such targeted recruitment would introduce additional bias, as sensor devices are mostly owned by individuals from high-income households [55]. Although some participants in our study felt stressed by wearing the sensor devices, positive prior experience with wearing sensor devices as a selection criterion for study participation may further increase data completeness. In our study, participants received the wearable device as a free gift at the start of the study, and the incentive was not dependent on their questionnaire completion rate or the duration of wearing the device. Future studies may benefit from offering incentives upon successful completion of the entire study, thereby encouraging full participation [52,56]. Increasing compensation beyond just the Fitbit device could further improve retention [52]. In terms of questionnaire data completeness, it may be beneficial to reduce the number of daily questions. In our study, completion rates for daily questionnaires were lower than for weekly questionnaires, and 1 of the 9 people who dropped out within the first 2 weeks reported that the study was too time-consuming. These strategies can potentially help to improve participant retention and ensure more comprehensive and reliable data.

Despite challenges related to data completeness, our study successfully demonstrated the technical feasibility and value of combining wearable and questionnaire data. The information derived from the digital questionnaires helped to map the sensor data to the respective day of the menstrual cycle and to correlate the objective physiological data with the subjectively reported symptom data from the study app, leading to interesting biological insights. The average resting heart rate measured by wrist-worn wearable sensors changed over the course of the menstrual cycle, with an increase in the mid and late luteal phases compared with the menses. This observation supports the findings of a larger study by Shilaih et al [25], where the pulse rate measured using laboratory standard photoplethysmography technology showed a peak in the midluteal phase. Another study with a smaller sample size similarly found increased heart rate (measured during sleep) in the mid and late luteal phases compared with menses and ovulation [24]. In our feasibility study, we also found that people with more severe PMS symptoms had lower daily step counts. Due to the observational nature of our study, we cannot establish causality. This finding may suggest that individuals with more severe PMS symptoms may exercise less due to the impact of the symptoms on their physical activity. Alternatively, this finding may be consistent with the existing literature, where increased physical activity has been found to reduce PMS symptoms [57-62]. In attempting to fill the research gap regarding sleep patterns across the menstrual cycle, we did not make any notable discoveries when comparing sleep duration between different phases of the menstrual cycle, across PMS severity, or when comparing individuals using hormonal contraception with those who did not. It is worth noting that there were more issues with data completeness for sleep data compared with daytime data, highlighting the need for improved retention strategies to motivate participants to wear the devices consistently at night. Although of very small sample size, the observed differences in heart rate and physical activity in participants using hormonal contraception (n=4) also provided an interesting starting point for future investigation. These observations show that sensor devices may offer a great opportunity to study physical changes over the menstrual cycle and suggest that further investigation on a larger scale may be valuable. Overall, it is important to interpret the biological findings of this feasibility study with caution, given the limitations of the small sample size and issues with data completeness.

Limitations

Apart from the interesting results of this feasibility study, this study has several limitations that should be taken into account when interpreting the findings.

First, the study was conducted as a feasibility study with a small sample size. Any biological interpretations made from such a small sample size must be taken with caution and merely represent an interesting starting point for future large-scale research. Our cohort was also not representative, recruited from only 1 recruitment site, and lacked ethnic diversity.

We further had limitations in data accuracy. The amount of wearable data we collected was limited to 3 aggregated parameters, which severely limited our ability for quality filtering. As we did not collect continuous wearable data throughout the day, but rather one aggregated data point for each measurement of interest, we had no objective insight into how long the device was worn each day and relied only on subjective reporting of wear time in the weekly questionnaires. Not wearing the device consistently or correctly could have resulted in inaccurate data.

Furthermore, the study relied on self-reported questionnaire data, which may introduce reporting bias and errors in data collection. In addition, the wrist-worn wearable device used in our study may not be as accurate as research-grade devices in tracking changes in physiological parameters related to the menstrual cycle. One must consider potential confounding factors that may affect the measurement accuracy of the sensor devices such as body sweat and unusual movements [63].

Regarding the medical accuracy of possible correlations between wearable data and specific phases of the menstrual cycle, the design of our study only allowed the day of ovulation to be estimated based on the total cycle length. In future studies, additional at-home ovulation tests could ensure greater accuracy in assessing the different phases of the menstrual cycle [25].

Conclusions

In conclusion, this study demonstrated that an app-based approach to collecting combined wearable and questionnaire data on the menstrual cycle is technically feasible and provides interesting biological insights. Study participants had a high level of digital literacy, which may have supported adherence to the study protocol. With 9 of 42 participants dropping out

within the first 2 weeks, engagement efforts at baseline would need to be improved in future, larger studies to ensure long-term adherence to the study protocol. To further improve the quality and applicability of such large-scale studies, challenges with data completeness need to be addressed. This could include using more frequent reminders for study participation, using more user-friendly wearable technology, or providing incentives to encourage participants to maintain consistent data contributions over the entire study. Although the sample size was small, we discovered an increase in average resting heart rate over the menstrual cycle and found differences in step count by PMS symptom severity in our cohort. Ultimately, using digital studies to research the menstrual cycle can be feasible and has the potential to improve our understanding of women's health and inform the development of personalized health care approaches.

Acknowledgments

The authors want to thank all feasibility study of menstrual cycles with Fitbit device (FEMFIT) participants for their contribution to women's health research. The authors further want to acknowledge the work and dedication of all Data4Life employees working on this project. The authors especially want to thank the business intelligence (BI) and analytics team for helping with all inquiries concerning BI data and the development team for the technical implementation of the study. This study was fully funded by the Data4Life gGmbH.

The data sets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

MF and CR initiated the study and wrote the study protocol. ALL conducted all data analysis on wearable and questionnaire data. IK supported data analysis. JR set up wearable data collection from Fitbit devices. RLB and MH recruited participants and handed out pre- and poststudy questionnaires. RLB evaluated the questionnaire responses to surveys conducted before and after the study. ALL wrote the first version of the manuscript. All authors have contributed to writing the manuscript.

Conflicts of Interest

ALL, IK, JR, CR, and MF worked for Data4Life, the company that developed the study and study app as well as the underlying research infrastructure. RLB declares no competing interests. MH received financial incentives from Data4Life for recruiting participants for this study.

Abstract

Background: Chronic pain affects approximately 30% of the general population, severely degrades quality of life and professional life, and leads to additional health care costs. Moreover, the medical follow-up of patients with chronic pain remains complex and provides only fragmentary data on painful daily experiences. This situation makes the management of patients with chronic pain less than optimal and may partly explain the lack of effectiveness of current therapies. Real-life monitoring of subjective and objective markers of chronic pain using mobile health (mHealth) programs could better characterize patients, chronic pain, pain medications, and daily impact to help medical management.

Objective: This cohort study aimed to assess the ability of our mHealth tool (eDOL) to collect extensive real-life medical data from chronic pain patients after 1 year of use. The data collected in this way would provide new epidemiological and pathophysiological data on chronic pain.

Methods: A French national cohort of patients with chronic pain treated at 18 pain clinics has been established and followed up using mHealth tools. This cohort makes it possible to collect the determinants and repercussions of chronic pain and their evolutions in a real-life context, taking into account all environmental events likely to influence chronic pain. The patients were asked to complete several questionnaires, body schemes, and weekly meters, and were able to interact with a chatbot and use educational modules on chronic pain. Physicians could monitor their patients' progress in real time via an online platform.

Results: The cohort study included 1427 patients and analyzed 1178 patients. The eDOL tool was able to collect various sociodemographic data; specific data for characterizing pain disorders, including body scheme; data on comorbidities related to chronic pain and its psychological and overall impact on patients' quality of life; data on drug and nondrug therapeutics and their

benefit-to-risk ratio; and medical or treatment history. Among the patients completing weekly meters, 49.4% (497/1007) continued to complete them after 3 months of follow-up, and the proportion stabilized at 39.3% (108/275) after 12 months of follow-up. Overall, despite a fairly high attrition rate over the follow-up period, the eDOL tool collected extensive data. This amount of data will increase over time and provide a significant volume of health data of interest for future research involving the epidemiology, care pathways, trajectories, medical management, sociodemographic characteristics, and other aspects of patients with chronic pain.

Conclusions: This work demonstrates that the mHealth tool eDOL is able to generate a considerable volume of data concerning the determinants and repercussions of chronic pain and their evolutions in a real-life context. The eDOL tool can incorporate numerous parameters to ensure the detailed characterization of patients with chronic pain for future research and pain management.

Trial Registration: ClinicalTrials.gov NCT04880096; https://clinicaltrials.gov/ct2/show/NCT04880096

KEYWORDS

mHealth; mobile health; eHealth; self-monitoring; chronic pain; observational study

Introduction

Chronic pain affects approximately 30% of the general adult population [1,2] and was one of the top 5 leading causes of years lived with disability in 2016 [3], especially among older people [4]. Moreover, 60% of people with chronic pain are less able or unable to work, and 20% report having lost their job as a result [5]. The overall cost of chronic pain is estimated to be approximately €441 billion (US $468 billion) in Europe and US $560 to $635 billion in the United States [6-8]. At the same time, the market for analgesic drugs represented approximately US $68 billion in 2016, and an increase from 2% to 5% was forecast for 2021, with a further 5% increase by 2025 [9]. Unfortunately, available analgesics often have limited efficacy, with undesirable effects and without any real pharmacological innovation [10], despite prolific basic research [11].

One of the solutions could be based on better patient characterization to offer physicians decision aids in the management and initial choice of treatment for chronic pain. A preliminary step that would make it possible to identify patient trajectories and factors capable of predicting treatment success. This characterization should cover the entire biopsychosocial field. It should also include a temporal dimension, with real-life monitoring of different parameters, and subjective and objective markers of chronic pain. Indeed, the current assessment of patients with chronic pain provides only fragmentary data on their daily pain experiences due to memory bias [12]. This monitoring strategy is currently being developed by several research teams [13-18]. It is also necessary to make the patient an active participant in their own care, with the goal of improving compliance and adherence. Indeed, evidence suggests that the self-management of chronic diseases reduces hospitalizations, the use of emergency services, and overall care management [19,20].

The use of innovative digital technologies (eHealth) appears to be a solution. eHealth can improve the characterization and monitoring of pain symptoms, and the management of pain and associated comorbidities [21-23]. eHealth can also offer remote interventions without the difficulties inherent in long-distance travel or regular visits to the general practitioner or specialist [24]. Thus, recent publications have highlighted the urgent need to develop, assess, and use validated eHealth programs for chronic pain [13,14,18,25-31]. eHealth technologies encompass a wide range of diverse tools, offering potential applicability for chronic conditions [32,33]. These technologies can be categorized into 6 types: virtual visits, electronic health records, digital therapeutics, artificial intelligence and machine learning, wearable monitors, and mobile health (mHealth) apps [32]. This last category can vary in its content, which can generally be grouped into 3 objectives: education, monitoring, and treatment (often including self-management strategies), sometimes with a combination of these objectives [34]. However, there are many obstacles in putting this management into practice and monitoring it via digital tools, including the lack of training of patients in the management of their pathology and the use of digital tools, the lack of interest or training of some physicians for this new management integrating new digital technologies, the lack of integration of these digital strategies in medical management, the over-medicalization of pain that can result from the use of these digital tools, and the lack of time and information in health care structures [35].

Change is therefore necessary to integrate digital technology in the management of chronic diseases, including pain [36]. Among digital tools, mHealth offers significant opportunities for patients to foster communication with their practitioners or other patients (ie, through forums). mHealth offers distraction strategies, provides information and therapeutic education, promotes self-expression, improves access to health care, and facilitates social support. Moreover, mHealth can provide patients with greater convenience and more regular access to information about their conditions compared to traditional care. Although many studies have examined the use of innovative mHealth to assist in the management of chronic diseases, less attention has been paid to chronic pain [37]. However, the context is favorable, with growing interest from health agencies and funding organizations for these solutions. Moreover, in France, patient demand was evidenced by the results of a survey on compliance conducted in early 2017 by the French Institute of Public Opinion. The results showed a strong demand by patients for the development of digital tools for the self-management of their chronic diseases.

In response to this situation, the Analgesia Institute (Clermont-Ferrand, France) has recently created an mHealth

tool (called eDOL) for data collection and monitoring of chronic pain and its impacts on patient well-being. Following a feasibility study on the use and acceptability of eDOL Version 1 [38] and the implementation of Version 2, we provide in this article an overview of eDOL's ability to retrieve a significant amount of medical data of interest for physicians and researchers on the subject of chronic pain. This study was carried out after more than a year of existence of the eDOL national cohort, and it included more than 1000 patients. This study did not assess the impact of the eDOL tool on patients' medical management or on patients' pain symptoms and their consequences.

Methods

Ethical Considerations

The study was approved by the research ethics committee (Comité de Protection des Personnes Ouest II Angers; reference number: 2020-A02027-32) and the French Data Protection Authority (Commission Nationale de l'Informatique et des Libertés [CNIL]; n° 921059). The study has been registered at ClinicalTrials.gov (NCT04880096). The study was conducted in accordance with French laws and regulations on research on human beings and data protection, and in accordance with the Declaration of Helsinki [39].

Data Collection

Data were collected and managed using the eDOL tool (mobile app + web platform) developed by Bepatient (Paris, France) and hosted by Avenir Télématique (Villeneuve-d'Ascq, France). In accordance with the provisions relating to the confidentiality of information concerning, in particular, the people who took part in the research and the results obtained [40], individuals with direct access took all the necessary precautions to ensure the confidentiality of the information relating to the participants. These persons and the investigators themselves are subject to professional secrecy [41]. All data collected and transmitted to the sponsor (University Hospital of Clermont-Ferrand, France) were anonymized, and each patient had an individual numerical code. The head of research ensured that each patient was informed of which data were collected and that they did not object to their use or disclosure. Answers to questionnaires and medical data were transmitted in spreadsheet format (Excel 2013; Microsoft Corporation). All anonymized data were accessible to the biostatisticians (BD and BP), coordinator (ND), and project manager (NK). Only the investigators could access their patients' personal data to identify them. A dashboard linking patients' identities and individual numerical codes was available only on the investigators' professional interface on the eDOL web platform. The final database, which was used for statistical analyses, included only individual numerical codes to preserve anonymity.

Data Entry and Processing

To manage data processing, a data warehouse has been set up in the Laboratory of Informatics, Modelling and Optimization of the Systems (LIMOS) Mixed Unit of Research (UMR 6158) (Clermont Auvergne University, France).

This warehouse has made it possible to retrieve the anonymized data collected by BePatient regularly and automatically. The data were retrieved via a secure application programming interface (API). Files were saved and read to extract the data. These data were then cleaned according to a set of rules to remove erroneous data (patient input errors), integrate them into a database, and provide an interface to view and export the cohort data.

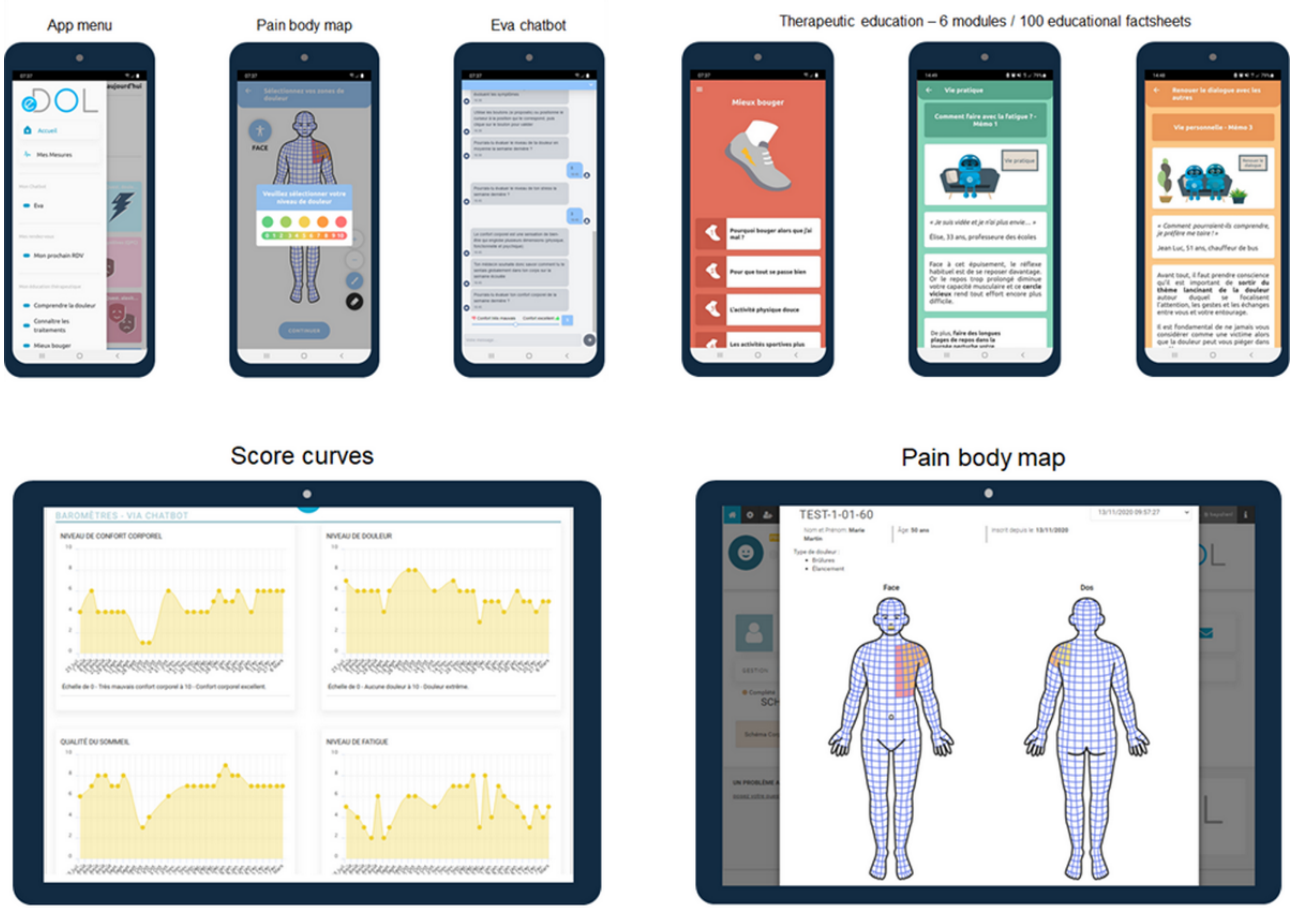
Study Design and Population

This cohort study provides a snapshot after 1 year of a national cohort of patients with chronic pain using the eDOL app. The characterization and real-life monitoring of patients from 18 pain clinics and follow-up by 80 investigators in France took place between September 14, 2021, and January 31, 2023. The study was offered to all physicians and allied health professionals in the investigating centers. Participation in the study was offered to patients with chronic pain, who were owners and regular users of a smartphone and who were followed up in a pain clinic. All adult (≥18 years old) patients able to read and understand French and provide consent to integrate the cohort study were included. Participants were free to withdraw their consent at any time by informing the sponsor. Each patient had access to the information document (paper or electronic) detailing the purpose, content, and conduct of the cohort. If they agreed to participate, they were asked to download the eDOL app and complete questionnaires using the eDOL app. The URL to access this app was sent by email from physicians to their patients. After downloading the app and creating their profiles, patients could accept the general terms and conditions of use and confirm that they agree to the use of their medical data in this study. Each patient made only 1 initial study visit during which the physician introduced the study to them, checked their eligibility, explained the eDOL tool, and gave them a brief training document on how to use the eDOL app. Participants completed several questionnaires and assessments over a period of 1 month (initial patient characterization) and then repeatedly (or not) quarterly, half-yearly, and yearly depending on the questionnaire. Throughout the duration of the study, physicians saw their patients at several follow-up visits (optional), according to the patient's health pathway, after the inclusion visit.

eDOL Digital Tool

eDOL is a digital health tool used for data collection and monitoring related to pain and its impacts on patient well-being. It comprises 3 main components: a smartphone app for patients, a web interface for health care professionals (Figure 1), and a data repository for researchers. The tool provides various features and modules to support patients in managing their chronic pain while allowing physicians to access and monitor real-time data for clinical and therapeutic purposes.

Figure 1. Interface of eDOL Version 2. Screenshots of the various modules of the eDOL smartphone app for patients (top) and the eDOL web interface for clinicians (bottom).



Patient Mobile App

The app allows patients to regularly input data regarding their pain and its effects and to access educational content. Patients were invited to complete various contents, but none of them were compulsory.

Questionnaires

Patients complete questionnaires and assessments on a regular basis. These questionnaires cover general aspects, specific chronic pain symptoms, and associated comorbidities. They are filled systematically at different intervals, such as once only, quarterly, half-yearly, or yearly. Some questionnaires address specific types of chronic pain. For a detailed list of all the questionnaires used, refer to the previous publication by Kerckhove et al [38].

Weekly Meters

The app facilitates the real-life monitoring of various parameters related to pathology. Patients can assess the evolution of their pain and its impacts using an 11-point numeric rating scale (from 0 to 10) for intensity assessment in different areas, such as pain, stress and anxiety, fatigue, sleep, morale, and bodily comfort.

Body Map

Each month, patients can use a body map to select and indicate the painful areas on their body, assigning corresponding intensity levels. The map provides front and back views (Figure 1).

Chatbot

Patients can download a chatbot (conversational agent called Eva) to integrate it into the app. The Eva chatbot has been developed in collaboration with the company Aliae (Metz, France) and with a medical group of the Analgesia Institute. The chatbot prompts participants to complete their meters on a weekly basis.

Educational Modules

The app offers educational modules that cover therapeutic education on pain and its broader aspects. These modules consist of informative sheets with images for better comprehension. They have been developed with the assistance of a group of physicians working in various pain clinics. Each module starts with a “What you need to know” section, defining the chapter’s scope, followed by educational sheets comprising an image corresponding to the subsection, a short testimonial or quote, an explanatory text, and a personalized image with a concluding statement. Modules include understanding pain, understanding treatments, moving better, improving fatigue and sleep, functioning in daily life, and managing emotions.

In the event of technical problems or questions regarding the app or the completion of questionnaires or meters, participants could refer to contact details provided via an email, and for each investigator center, a clinical research assistant was available by phone.

Web Interface for Health Care Professionals

The eDOL web platform enables health care professionals to access real-life patient data (questionnaire scores and graphical presentation of weekly meters) and input consultation data (clinical examinations, treatments, etc). The platform features an ergonomic dashboard with tabs for management (patient medical records), health measures (graphical display of weekly assessments), and questionnaires (all completed with scores and answers).

Big Data Repository for Researchers

The development of eDOL V2 involved the creation of a data repository in collaboration with the LIMOS. The data repository interfaces directly with eDOL V2 and automatically collects patient cohort data (via the app) and data from health care professionals (via the web platform) on a weekly basis. The transferred data are anonymized to comply with the French data protection authority for analysis purposes. Information on the data contained in the database is available to investigators on request. In the event of a clinical study requiring eDOL data, a written request describing the study must first be sent to the data controller (Analgesia Institute). The Analgesia Institute's Scientific Committee will assess the relevance of the project before giving its approval.

Study Outcomes

The primary objective of this study was to describe the tool's ability to retrieve a large amount of longitudinal medical data and its relevance to cohort patient follow-up.

The secondary objectives were to assess the characterization of participating patients, pain disorders, pain medications, and related comorbidities, and evaluate the acceptability of the eDOL app with a satisfaction survey (based on the Patient Satisfaction Questionnaire Short Form [42] and the Client Satisfaction Questionnaire [43,44]) for patients (10 questions). The satisfaction survey (in French language) was sent to each included patient via the eDOL tool. Response options for each question ranged from 0 (strongly disagree with the statement) to 10 (strongly agree with the statement). The questionnaire/weekly meter completion rate and center participation (inclusion rate) were also calculated.

As an exploratory study, the profile of patients adhering to the eDOL program was analyzed.

Statistics

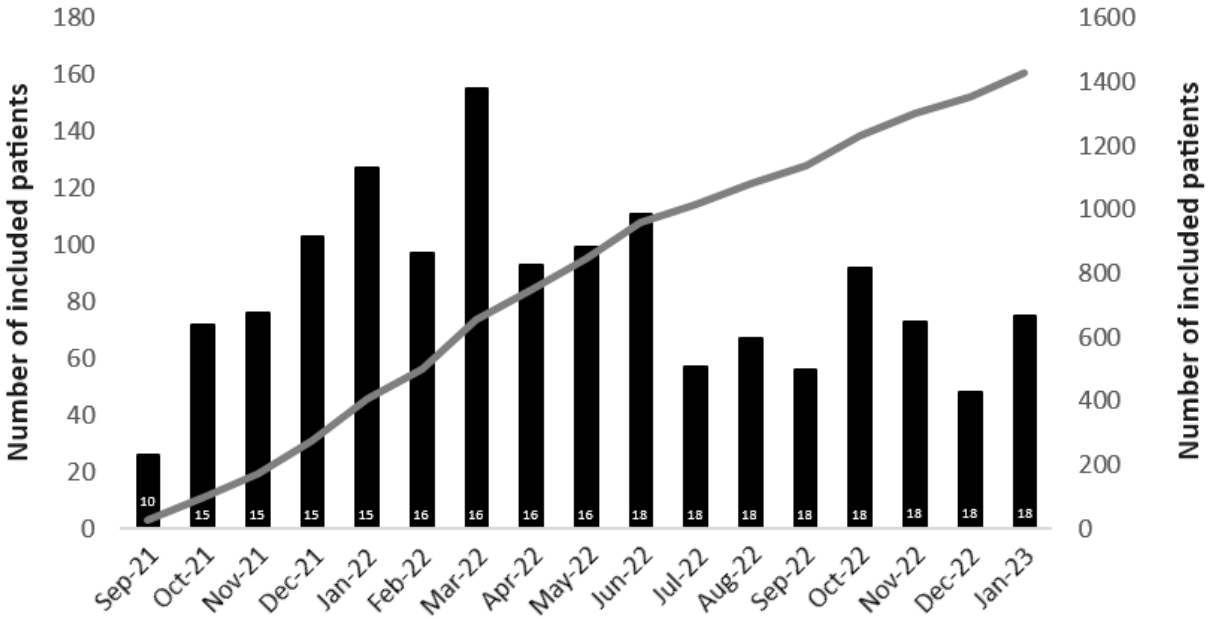
Patients have been described according to the following variables: compliance with eligibility criteria, epidemiological characteristics, and clinical and treatment characteristics. Categorical data are expressed as numbers and associated percentages, and continuous data are expressed as means with standard deviations or medians (25th-75th percentiles), according to the statistical distribution. The assumption of normality was studied using the Shapiro-Wilk test. Comparisons according to observance were conducted using the chi-square test or Fisher's exact test for binary variables, whereas comparisons concerning quantitative variables were performed using ANOVA or the Kruskal-Wallis test. When appropriate (omnibus P value <.05), a post-hoc test for 2×2 multiple comparisons was applied: Tukey-Kramer test after ANOVA or Dunn test after the Kruskal-Wallis test. Different analyses were carried out according to the level of use (compliance) of the eDOL app, which was defined by quartiles of percentage weekly meters completed during follow-up (Q1: <5%, Q2: <50%, and Q3: >50%). Statistical analyses were performed using Stata software (Version 15; StataCorp). All tests were 2-sided, with an α level set at 5% for statistical significance.

Results

Generalities

All the 18 pain clinics participating in the study included at least one patient. The median rate of inclusion per center was 5.5 patients/month, and an average of 84.5 (SD 31.9) patients were consistently included every month (Figure 2). During the study period, from September 14, 2021, to January 31, 2023, 1427 patients were included.

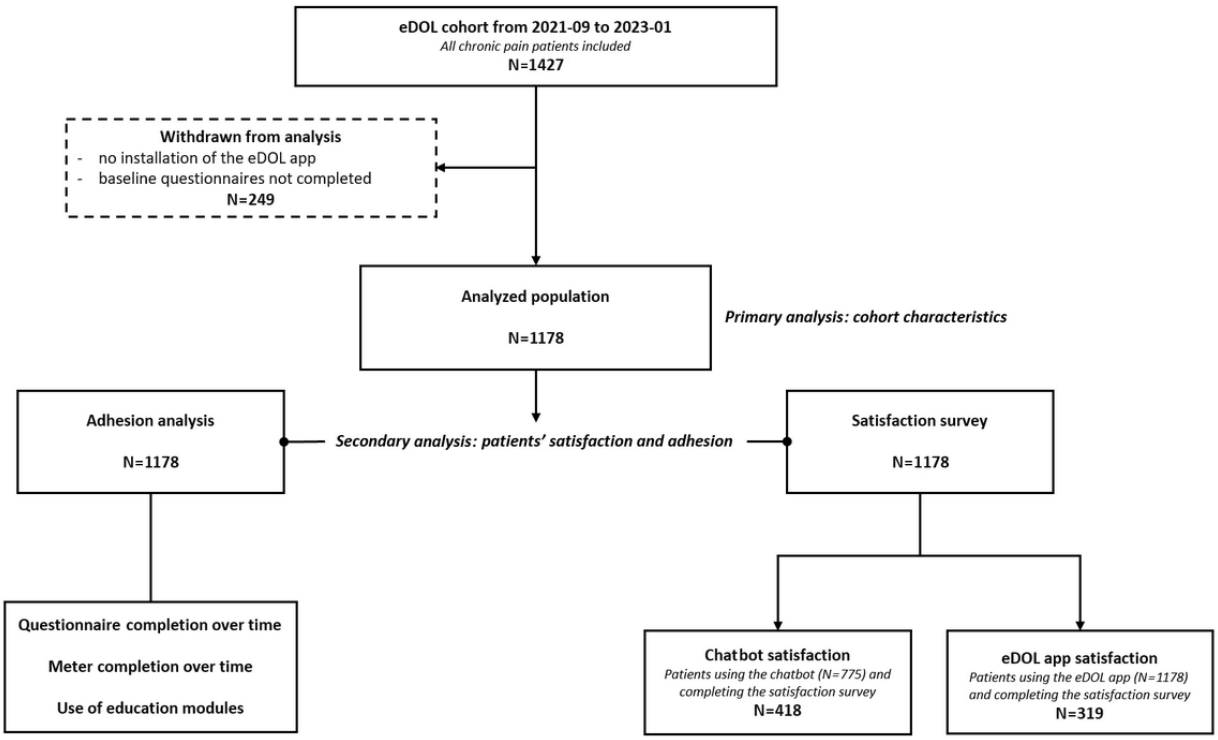
Figure 2. Recruitment rate by month and cumulative frequency. Rate of patient recruitment in the eDOL study is represented in terms of patient frequency/month (histogram) and cumulative frequency (curve). The numbers at the bottom of the histogram bars represent the number of active investigator centers.



Collected Data

Of the 1427 patients included in the study, 249 (17.4%) were not analyzable (no installation of the eDOL app or no completion of the baseline sociodemographic questionnaire). Thus, data from 1178 patients were analyzed (Figure 3). At the time of data recovery (February 1, 2023), 23.3% (275/1178) of patients had ≥12 months of follow-up, 30.1% (355/1178) had ≥9 to <12 months of follow-up, 20.5% (242/1178) had ≥6 to <9 months of follow-up, 11.5% (135/1178) had ≥3 to <6 months of follow-up, and 14.3% (168/1178) had <3 months of follow-up. The median follow-up time for patients in the cohort was 9.3 (IQR 9.1-9.5) months. eDOL's functionalities enable it to retrieve a large and varied range of biopsychosocial data (Multimedia Appendix 1). Below is a detailed overview of the sociodemographic and medical data collected, which allowed us to precisely characterize our cohort population.

Figure 3. Study flowchart. Graphical representation of the various stages in patient recruitment and analysis.



At baseline, participating patients were mostly middle-aged (median 49.0, IQR 48.3-49.7 years), women (937/1178, 79.5%), in a relationship (759/1178, 64.4%), with children (635/1178, 53.9%), nonsmoking (805/1096, 73.4%), with a university degree (581/1178, 49.3%), and in professional activity (732/1178, 62.1%), and a significant number were considered to be in a precarious state (468/980, 47.8%). Among patients in professional activity, 34.1% (250/732) were on sick leave due to their chronic pain (Multimedia Appendix 2 and Multimedia Appendix 3).

Most patients (906/1034, 87.6%) had moderate to severe pain (>5/10), of which 26.0% (236/906) had a high chronic pain interference score (called "high impact chronic pain" [45]). Moreover, 25.1% (296/1178) had at least two different types of chronic pain. Most patients (492/1178, 41.8%) had nociplastic pain, and the duration was longer than 5 years in more than 50% (601/1178, 51.0%) of patients. Most participants (667/1178, 56.6%) were at the beginning of their course in the pain clinic (≤6 months), with a median of 5.0 (IQR 3.0-7.0) months prior to inclusion.

Several patients (481/1094, 44.0%) described their chronic pain as permanent during both day and night (with painful paroxysms every day) and as inducing frequent nocturnal awakenings (995/1094, 90.9%) (Multimedia Appendix 3 and Multimedia Appendix 4). Moreover, body schemes were recovered for 73.1% (861/1178) of patients. Among these patients, 94.0% (809/861) had at least two different pain locations. The dorsolumbar, hypogastric, and cervical regions were the most frequent in terms of pain location, with over 40.0% (344/861) of patients affected (Multimedia Appendix 5).

The eDOL tool also enabled us to collect data on comorbidities related to chronic pain and its psychological and overall impact on patients' quality of life. High numbers of patients were considered to have kinesiophobia (753/1029, 73.2%), alexithymia (591/1038, 56.9%), degraded quality of life (599/1025, 58.5%), catastrophism (448/1056, 42.4%), and a possible cognitive disorder (774/1008, 76.8%). More than 60% (640/1033, 62.0%) of patients had impaired sleep, and 44.7% (457/1023) and 26.8% (274/1023) had proven anxiety and depressive disorders, respectively (Multimedia Appendix 3 and Multimedia Appendix 6).

With regard to analgesic treatments, 2643 treatments were prescribed for 839 patients (71.2%), with 64.8% (763/1178) of patients using nondrug analgesic treatments, including transdermal electroneurostimulation (480/763, 62.9%) and physical techniques such as physiotherapy (352/763, 41.6%) (Multimedia Appendix 3 and Multimedia Appendix 7). Interestingly, 23.3% (275/1178) of patients were not receiving treatment (pharmacological or nonpharmacological) for their pain at the time of inclusion. The drugs used by the patients were mainly antidepressants (369/839, 44.0%), followed by paracetamol (363/839, 43.2%), opioids (358/839, 42.7%), and antiepileptics (224/839, 26.7%). The therapeutic benefit was assessed by clinicians for 1407 prescribed treatments, and opioids and antidepressants had the best medical benefit (1282/1407, 91.1% of treatments were rated as very good or good) (Multimedia Appendix 8). In the same way, clinicians were able to report on treatment adverse events (AEs) and patient compliance. A total of 289 AEs were reported, and antidepressants and anticonvulsants were the most likely causes (73/289, 25.4% and 66/289, 23.0% of AEs, respectively) (Multimedia Appendix 8). Compliance was assessed by clinicians for 1192 prescribed treatments, and in 97.1% (1158/1192) of cases, compliance was very good or good.

Lastly, the eDOL tool enabled clinicians to record patients' medical history. A large majority of patients (981/1178, 83.3%) had at least one medical history (Multimedia Appendix 9). Among these patients, 60.9% (597/981) declared a traumatic life history (mainly death, accident, and divorce), 35.3% (346/981) reported a history of violence (mainly physical and psychological), 43.3% (425/981) reported a psychiatric history (mainly anxiety and depression), 37.9% (372/981) reported addictive behaviors (mainly tobacco), and 82.2% (806/981) reported ongoing illnesses (mainly rheumatologic, digestive, and neurological).

Real-Life and Longitudinal Data Collected

As previously reported, 82.6% (1178/1427) of included patients effectively used the eDOL tool in their daily life. On average, each questionnaire was completed by 86.7% (SD 2.0%) of participants at inclusion. Among the questionnaires repeated every 3 (2 questionnaires) or 6 months (7 questionnaires), this percentage decreased over time to 60.8% (SD 0.1%) at the 3-month follow-up, 42.8% (SD 3.6%) at the 6-month follow-up, 32.1% (SD 0.1%) at the 9-month follow-up, and 23.6% (SD 2.5%) at the 12-month follow-up (Multimedia Appendix 10).

The completion rate of the weekly assessments for the real-life monitoring of the different meters (pain, moral, anxiety, fatigue, sleep, bodily comfort, and physical activity) was 75.1% (885/1178) at patient inclusion. Among the 1007 patients with at least 3 months of follow-up, the completion rate decreased over the course of follow-up to 49.4% (497/1007) after 3 months of follow-up and then stabilized at 39.3% (108/275) for patients with at least 12 months of follow-up (Multimedia Appendix 10). An acceptable meter completion rate was defined as at least 50% completion of all theoretical meters over the follow-up period (1 meter/week). Univariate analysis was performed to characterize patients according to their percentage of weekly meter completion (<5%, ≥5% to <50%, and ≥50%). Univariate analysis showed very little difference between compliant and noncompliant patients. In fact, women and patients with an intermediate profession or no activity appeared to be slightly more compliant. Age, level of education, family situation, and alcohol or tobacco consumption had no impact on compliance. Surprisingly, the same observation was noted for pain characteristics. It was found that the length of time the pain had been present, the frequency or duration of painful paroxysms, the pain intensity and interference, and the presence of nocturnal awakenings or difficulty in falling asleep did not interact with patient compliance. There was no difference in the inclusion scores for the various questionnaires, depending on the level of compliance of patients. Finally, analysis of the type of pain and treatments received showed no difference between patients irrespective of their level of compliance.

The eDOL tool also includes educational modules on chronic pain and its repercussions. These modules were freely available to the patients but were not compulsory. Overall, 16.3% (192/1178) of patients viewed at least one educational module. The educational modules were viewed in their entirety by around 65.2% (minimum: 44.6%, maximum: 85.5%, according to the educational module) of patients who opened them. The most frequently viewed educational module was the one on "improving fatigue and sleep." Conversely, the educational module on "living with pain" was the least viewed (Table 1).

Table 1. Educational module use.

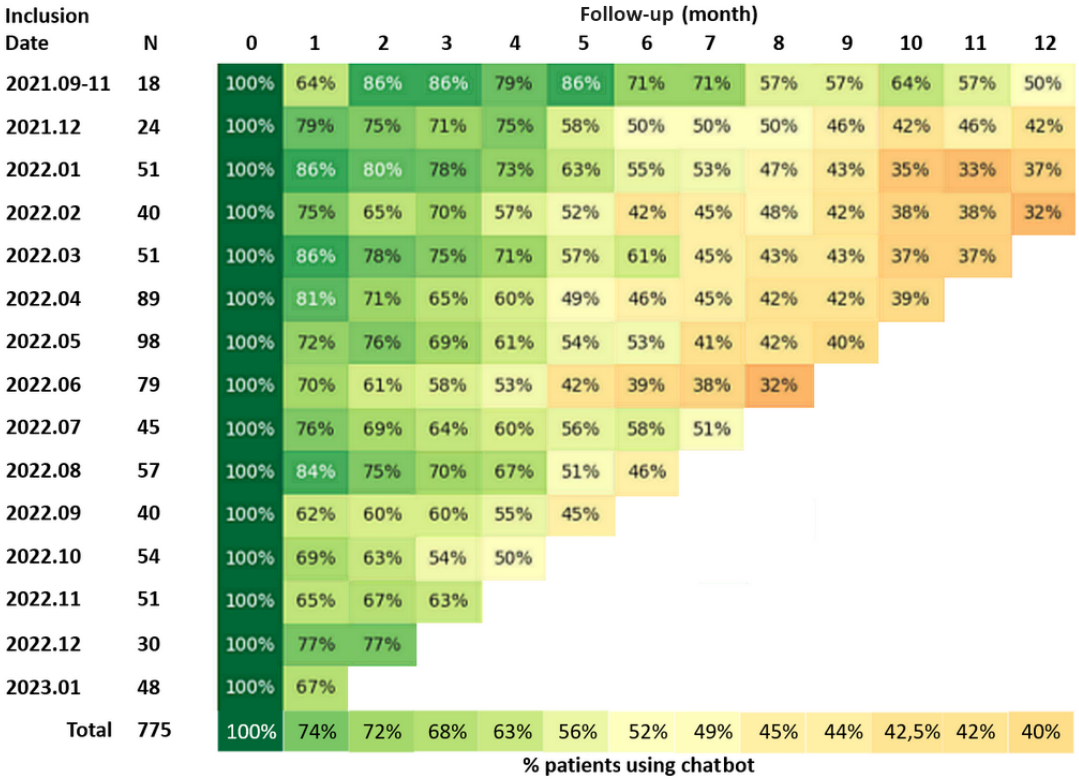
Educational module	Patients opening the module (N=1178), n (%)	Patients viewing the entire module (N=1178), n (%)
Understanding pain	188 (16.0)	118 (10.0)
Knowing about treatments	181 (15.4)	129 (10.9)
Moving better	173 (14.7)	148 (12.6)
Improving fatigue and sleep	369 (31.3)	272 (23.1)
Living with pain	159 (13.5)	71 (6.0)
Managing emotions	209 (17.7)	111 (9.4)

Satisfaction With the Use of the eDOL Tool

The satisfaction questionnaire was filled in by 27.1% (319/1178) of patients at the end of the study. These patients had similar characteristics to all the patients in the cohort (average age 49.4 years; 258/319, 80.1% female; 213/319, 66.9% with pain for more than 5 years; and 137/319, 42.8% with nociplastic pain). The median acceptability score was 7.2/10 (95% CI 6.9-7.7), with only 7.2% (23/319) of patients providing a rating less than 5/10. Moreover, 83.4% (267/319) of patients who responded wanted to participate in the further development of the eDOL tool. The items with the lowest scores were "I enjoy my exchanges with the Eva chatbot and I think it's a tool that can assist me on a daily basis" (mean 6.0, SD 3.1), "I think the Eva chatbot is a relevant tool for collecting my meters every week" (mean 6.7, SD 2.8), and "I believe that the information I have entered in eDOL enables my doctor to better understand my pain and improve its management" (mean 6.9, SD 2.6) (Multimedia Appendix 11).

The interest of adding a chatbot in the eDOL tool was also assessed. Among the 1178 participating patients, 775 (65.8%) downloaded the chatbot, and among these, all 775 (100%) used the chatbot at inclusion. This percentage halved (403/775, 52.0%) at the 6-month follow-up and appeared to stabilize at 40.0% (310/775) at the 12-month follow-up (Figure 4). The use of the chatbot allowed us to recover 9456 weekly meters and 12,300 conversations. With regard to satisfaction, of the 775 patients, 418 (53.9%) responded to the questionnaire, and among these patients, 230 (55.0%) had a satisfaction score of at least 7/10, which corresponds to high satisfaction, and only 35 (8.4%) had a score below 5/10, which corresponds to low satisfaction. The main positive points of the chatbot indicated by the participants were "easy to use," "responsive," "moral support," "converse with a positive message," and "availability." Conversely, the main difficulties related to the use of the chatbot indicated by the participants were "forgetfulness of use," "answers sometimes not adapted," and "repetitive."

Figure 4. Chatbot use over time. Visual representation of chatbot use among the 775 patients who downloaded the chatbot. Patients were classified according to their month of inclusion, and chatbot use (at least one conversation in the month) was assessed for each month of follow-up. A darker green color represents a higher utilization rate, and a darker red color represents a lower utilization rate.



Discussion

Principal Findings

This study presents the most extensive cohort of patients using an mHealth follow-up app and living with chronic pain, irrespective of the type of pain, worldwide. Indeed, studies in the literature on the use of an mHealth app in a cohort of patients have mainly focused on specific types of pain conditions, predominantly osteoarthritis and chronic low back pain [34]. Most studies have concentrated on digital interventions directed toward the patient-provider interface [46], which makes comparisons with the available literature challenging. This is also due to the typically shorter duration of such studies.

In this cohort study, 82.6% (1178/1427) of eligible patients consented to use the eDOL tool, and among them, about 86.7% (1021/1178) of participants used the eDOL app to complete different questionnaires during the initial phase. Thus, the rate is in line with the rate identified in our previous feasibility study (89.3%) [38] and the rate reported in the study by Stoppok et al [47] wherein 85.5% of participants expressed a willingness to use the app for more than a month when surveyed beforehand. Nevertheless, attrition appears to be high in internet interventions for chronic pain [48], and this has been reflected in our study, with about 60% (167/275, 60.7%) loss of users (according to weekly meter filling) among patients with at least 12 months of follow-up. A comprehensive American study [49] involving a large sample revealed that over half of the participants discontinued participation within the first week. Attrition is not solely confined to mHealth, and a systematic review of longitudinal studies on chronic spinal pain identified attrition as the most significant risk of bias [50]. Notably, attrition rates varied widely across these longitudinal studies, with a rate of 63% after 12 months in a study assessing pain after intensive care unit discharge [51] and 83% after 12 months in a study assessing pain self-management (chronic musculoskeletal pain and comorbid depression) [52]. Moreover, in the longitudinal study conducted by Bicego et al [53], attrition rates varied within the range of 11% to 22% 1 year after treatment.

With the loss of patient adherence over time, it is necessary to include a huge number of patients (inclusion of a minimum of 5000 patients is planned in the eDOL cohort) to have enough longitudinal data available. Despite this, the eDOL tool is already making it possible to collect a significant volume of data to characterize patients experiencing chronic pain, and it opens the door to future clinical studies to better understand the biopsychosocial aspect of chronic pain, the therapeutic management (drug or nondrug) implemented, the patient's care pathway (type of consultation, frequency of consultation, medical wandering, etc), and the cost of management (treatment prescriptions, consultations, work stoppage, etc). All these possibilities make the eDOL cohort an enormous potential source of data on chronic pain that is available to clinicians and researchers.

Limitations and Difficulties Encountered

The main limitation of our study was the attrition rate described previously. This attrition could influence the results of patient satisfaction with the eDOL tool, as only 30% responded to the

satisfaction questionnaire. However, it is difficult to know whether the patients who did not respond were dissatisfied, or simply forgot or did not feel like answering the questionnaire despite their effective satisfaction, especially since compliant patients and those who responded to the satisfaction questionnaire had similar characteristics to all the patients in the cohort. In our study, the chatbot was an attempt to add a social role to this tool in order to establish a good therapeutic alliance, as recommended for promoting engagement and reducing attrition in digital interventions [54]. However, its algorithms were trained in the United States, which might make it impersonal and irrelevant for the French population, which are characteristics identified as barriers to the use of such tools [55]. The lack of use of the chatbot could also be explained by patients' lack of interest in "chatting" with a robot, as such a robot has shown several limitations in its exchanges. One solution would be to replace it with a chat or message involving health care staff, who have already shown an interest in adhering to the digital tool [56]. However, this strategy inevitably requires additional time for caregivers to respond to patients' expectations, and such time is rarely available in view of caregivers' current workloads in pain clinics. An additional possibility is to add a forum for patient users to exchange information with each other. This strategy has been proven to be beneficial [31].

Educational modules have been integrated into the eDOL app to make it more informative for patients and thus increase their adherence. Nonetheless, patients made very little use of them. Their low use can be partially explained by the fact that the modules were not available on the homepage but were present on a dedicated page of the menu. Another explanation is that patients only received 2 smartphone notifications informing them of the existence of these modules in the app. We can hypothesize that patients might have had difficulties in finding them.

Additionally, in the absence of compulsory follow-up visits in the eDOL protocol, patient visits to the pain clinics were those scheduled as part of their usual care pathway (ie, not focused on the app itself); thus, some patients had visits 3, 6, or even 12 months apart. This may have acted as a hindrance to user engagement, as noted in telemedicine interventions [57]. Furthermore, although the use of an app and a mobile phone appears to be widely preferred over other interface options to access pain-related resources among individuals living with chronic pain, less than 60% of them expressed a desire to use online pain management tools permanently, according to a German survey [47]. This finding could also explain the significant attrition commonly observed in mHealth interventions.

Various strategies are available to mitigate this adherence issue observed within this study, including reducing the number of questionnaires and the number of questions per questionnaire, simplifying navigation (user experience/user interface design), adding activities to help patients manage their symptoms (therapeutic education for sleep, mindfulness for stress, positive psychology for morale, etc), ensuring greater involvement of the care team, etc. Our research team has already taken steps to mitigate attrition rates in the ongoing novel version of the eDOL tool (Version 3; since November 2023) by reducing the number of questionnaires, replacing some questionnaires with shorter ones (PROMIS [Patient-Reported Outcomes Measurement Information System] questionnaires), enhancing user experience by designing a new interface, and deactivating the chatbot. Additionally, the reminders to complete meters, body schemes, or questionnaires were changed into notifications instead of emails as patients did not solely rely on their phones to read their emails. The limited interaction with educational modules suggests that there is an opportunity to enhance user engagement and accessibility features within the app. The new design should facilitate increased engagement with therapeutic education activities by making them more prominently visible. Additional activities are currently being prepared and will be incorporated into the new version soon. Finally, to limit missing medical data, the new version of eDOL enables us to link our data with the national databases of the French health insurance system. This linkage will make it possible to obtain data on all the care received by patients in our cohort, including treatment reimbursements, doses and quantities of treatments prescribed, hospitalizations or consultations, sick leave benefits, etc. This linkage will also enable us to carry out medicoeconomic studies on the cost of chronic pain management.

The second limitation pertains to the representativeness of the sample in this cohort regarding the general population living with chronic pain. The participants in this study were recruited exclusively from pain clinics; however, only 3% of people living with chronic pain benefit from this type of health care setting in France. The vast majority seek assistance in primary care settings or in other specialized services such as rheumatology, neurology, and oncology. Nonetheless, the characteristics of the patients included in the eDOL cohort demonstrate resemblances to people living with chronic pain in Europe in terms of various factors such as age, pain intensity, duration of pain, and comorbidities [2,58-60]. These data reveal a higher proportion of women, which is not surprising as this difference in prevalence is well documented in the literature [61-63]. This female-to-male ratio is also observed in remote research studies utilizing mobile apps (median 56.9%) [49]. However, as in our feasibility study [38], this ratio is exacerbated in our cohort, reaching nearly 8/2. There are other examples of digital health studies showing a similar gender distribution [64-66].

A selection bias was evident, primarily due to the prerequisite of smartphone utilization, which inherently excludes individuals who lack access to or proficiency with this technology. This criterion could potentially result in the exclusion of older patients or patients with a more precarious status. Lastly, another limitation could be measurement bias, a phenomenon commonly encountered in observational studies [67]. It can emerge from factors such as recall period, selective recall, social desirability, or approach to sampling. Within our study, the recall period emerged as the primary potential source of risk. Given that all the inquiries focused on the present moment or, at the most, events occurring within the preceding 1 to 2 weeks, the likelihood of recall bias can be considered marginal.

Conclusion

Overall, the eDOL tool collected a large volume of medical and biopsychosocial data from 1178 patients over a short period of just over 1 year. The quantity of data collected demonstrated the effectiveness and interest of the eDOL tool with regard to the collection of medical data for research and for caregivers. This interest will continue to grow as more patients are included in the cohort, enabling clinical studies to be carried out on eDOL data to assess care pathways, management costs, patient trajectories, patient profiles, benefits or risks of treatments, and other aspects.

Abstract

Background: People with chronic pain experience variability in their trajectories of pain severity. Previous studies have explored pain trajectories by clustering sparse data; however, to understand daily pain variability, there is a need to identify clusters of weekly trajectories using daily pain data. Between-week variability can be explored by quantifying the week-to-week movement between these clusters. We propose that future work can use clusters of pain severity in a forecasting model for short-term (eg, daily fluctuations) and longer-term (eg, weekly patterns) variability. Specifically, future work can use clusters of weekly trajectories to predict between-cluster movement and within-cluster variability in pain severity.

Objective: This study aims to understand clusters of common weekly patterns as a first stage in developing a pain-forecasting model.

Methods: Data from a population-based mobile health study were used to compile weekly pain trajectories (n=21,919) that were then clustered using a k-medoids algorithm. Sensitivity analyses tested the impact of assumptions related to the ordinal and longitudinal structure of the data. The characteristics of people within clusters were examined, and a transition analysis was conducted to understand the movement of people between consecutive weekly clusters.

Results: Four clusters were identified representing trajectories of *no or low pain* (1714/21,919, 7.82%), *mild pain* (8246/21,919, 37.62%), *moderate pain* (8376/21,919, 38.21%), and *severe pain* (3583/21,919, 16.35%). Sensitivity analyses confirmed the 4-cluster solution, and the resulting clusters were similar to those in the main analysis, with at least 85% of the trajectories belonging to the same cluster as in the main analysis. Male participants spent longer (participant mean 7.9, 95% bootstrap CI 6%-9.9%) in the *no or low pain* cluster than female participants (participant mean 6.5, 95% bootstrap CI 5.7%-7.3%). Younger people (aged 17-24 y) spent longer (participant mean 28.3, 95% bootstrap CI 19.3%-38.5%) in the *severe pain* cluster than older people (aged 65-86 y; participant mean 9.8, 95% bootstrap CI 7.7%-12.3%). People with fibromyalgia (participant mean 31.5, 95% bootstrap CI 28.5%-34.4%) and neuropathic pain (participant mean 31.1, 95% bootstrap CI 27.3%-34.9%) spent longer in the *severe pain* cluster than those with other conditions, and people with rheumatoid arthritis spent longer (participant mean 7.8, 95% bootstrap CI 6.1%-9.6%) in the *no or low pain* cluster than those with other conditions. There were 12,267 pairs of consecutive weeks that contributed to the transition analysis. The empirical percentage remaining in the same cluster across consecutive weeks was 65.96% (8091/12,267). When movement between clusters occurred, the highest percentage of movement was to an adjacent cluster.

Conclusions: The clusters of pain severity identified in this study provide a parsimonious description of the weekly experiences of people with chronic pain. These clusters could be used for future study of between-cluster movement and within-cluster variability to develop accurate and stakeholder-informed pain-forecasting tools.

Introduction

Background

Chronic pain (ie, pain lasting ≥3 months) is a common symptom of many long-term health conditions [1,2] and is associated with poor quality of life, poor health outcomes, and low participation in work and social activities [3,4]. There is substantial day-to-day variability in the severity of pain experienced [5,6], and people with chronic pain report that this variability leads to feelings of frustration and uncertainty about future pain [7,8]. Studies have identified associations between pain variability and response to treatment [9] as well as lower quality of life [10,11]. However, pain variability remains underestimated by researchers [12].

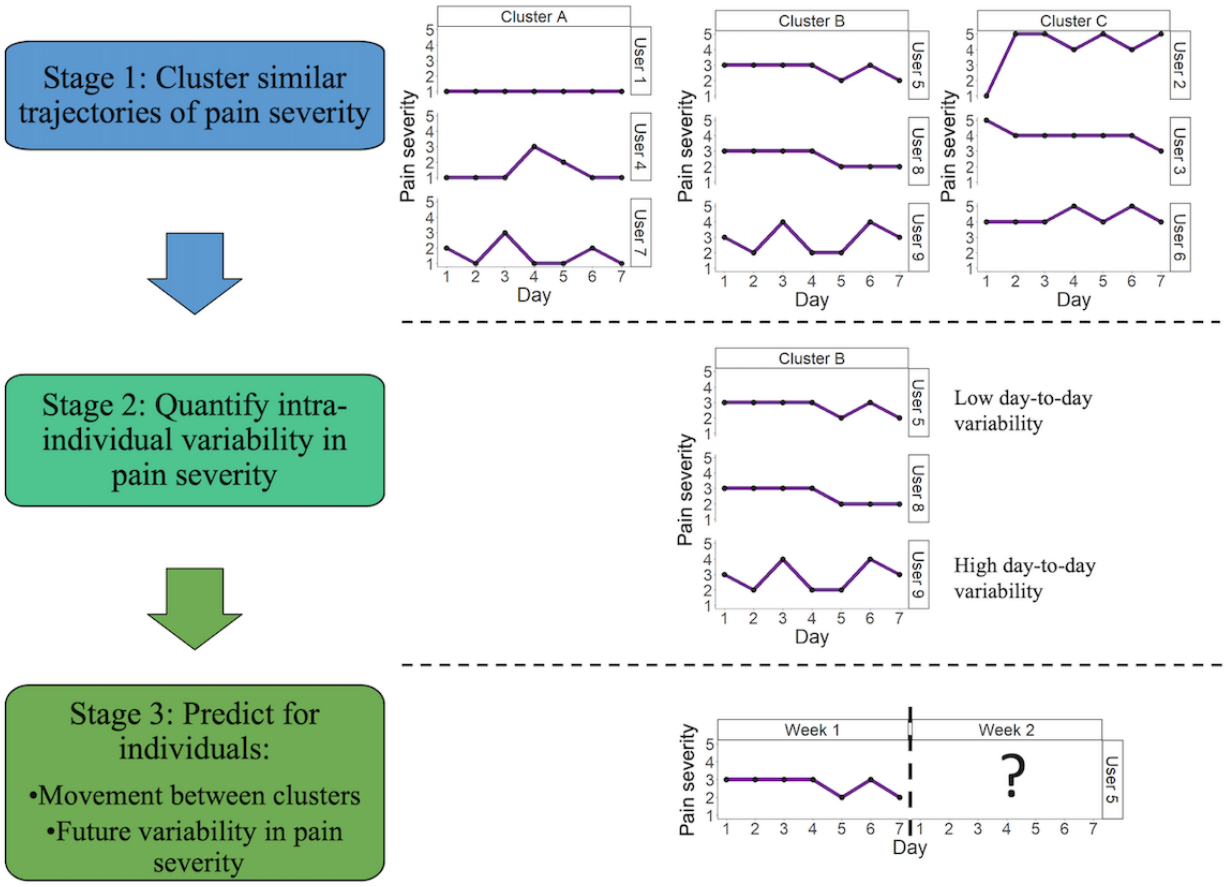
One way to explore pain variability is to cluster common pain trajectories and quantify movement between clusters. Previous studies have identified patterns of pain severity by clustering pain trajectories among individuals with chronic pain. These studies have often used sparse data on pain severity collected once per week [13], once per month [14], or less frequently [15]. These studies inform our understanding of longer-term experiences of chronic pain but not the day-to-day experience of pain severity that is important to patients. There is a need to extend this knowledge of pain clusters to within-week pain trajectories. Recent advances in mobile health (mHealth) methods that support the collection of data in the patients' own environments [16,17], often using their own devices (eg, smartphones and tablets) [18], offer the opportunity to capture daily pain severity data.

It is also possible to explore movement between clusters of pain data; for example, Rahman et al [19] used changes between pain severity scores (not necessarily day-to-day changes) to identify 2 clusters of low pain volatility and high pain volatility. The authors then predicted movement between these clusters at 6-month intervals. However, there is a need to explore movement between clusters on a shorter time frame.

Once identified, weekly pain trajectories could be forecast. People living with chronic pain have reported that a pain forecast would reduce unpredictability and could be used to support planning daily activities, such as shopping, chores, and social participation [20,21]. In a research prioritization study, 75% of the respondents to a survey said they would use a pain forecast and prioritized a model that predicted daily fluctuations (ie, relatively short-term variability) and pain flares (patterns across multiple days) [20].

We propose 3 stages to develop a pain forecast (Figure 1). Stage 1 identifies common weekly trajectories of pain severity using cluster analyses. Stage 2 investigates day-to-day variability in trajectories of pain severity for individuals within each cluster. These first 2 stages provide a better understanding of an individual's pain experiences. Stage 3 predicts for an individual their movement between clusters of pain severity across consecutive weeks and future within-cluster day-to-day variability. This study focuses on the first of these stages: clustering trajectories of pain severity. Understanding clusters of weekly trajectories is an important stage in this forecasting model to identify group-level associations that may be masked by population-level analysis.

Figure 1. Three stages to build a pain forecast using data from a mobile health study. Data used in this figure are for illustrative purposes only (to provide an example of how data may be used in the pipeline of developing a pain forecast). First, data are clustered to identify common trajectories of weekly pain severity. Second, the remaining variability is explored for each trajectory within a cluster. The process is repeated for each cluster. Third, movement between clusters on consecutive weeks and the amount of day-to-day variability are predicted for an individual. The process is repeated for each individual.



Once daily pain severity data are collected, there are several challenges to overcome in clustering these data for use in a pain-forecasting model. First, patient-generated health data are often collected on an ordinal scale. However, equal intervals between responses cannot be assumed, and using metric models to analyze ordinal data can lead to errors [22]. Second, data collected are longitudinal, and algorithms used for clustering should respect this longitudinal feature of the data. Third, clusters of pain severity that will be used in a pain-forecasting model should be interpretable to end users. To address these challenges, it is necessary to identify and use a suitable method for clustering patient-generated health data. Any assumptions made about the data should be tested in sensitivity analyses to ensure robustness. Observing substantial movement between clusters would suggest the feasibility of forecasting cluster movement in future work. Therefore, understanding the characteristics of individuals who contribute to different clusters and how these individuals move between clusters over time will aid end-user interpretability.

Objectives

The aim of this study was to understand pain severity clusters in people living with chronic pain. The specific objectives were to (1) use a suitable algorithm to identify the optimum number of clusters of pain trajectories, (2) conduct sensitivity analyses to test assumptions made when clustering data, (3) examine the characteristics of people within clusters, and (4) describe the movement of people between different clusters over time.

Methods

Data Source

This study is a secondary analysis of a population-based mHealth study, Cloudy with a Chance of Pain [16,23,24]. Study participants were recruited between January 2016 and January 2017 through advertisements on television, radio, and social media. Data collection ended in April 2017, with participants able to contribute data for between 0 and 15 months. The inclusion criteria were as follows: participants with chronic pain, aged ≥17 years, living in the United Kingdom, and owning an Android or iOS smartphone. Participants downloaded a co-designed mobile phone app; gave electronic consent; and provided demographic information, including their sex (male or female), year of birth (entered as free text), and pain conditions (selected from a list of predefined responses, eg, rheumatoid arthritis and fibromyalgia). Daily reports of 10 variables were collected, including pain severity. Participants were asked "How severe was your pain today?" They responded by selecting *no pain* (score=1), *mild pain* (score=2), *moderate pain* (score=3), *severe pain* (score=4), or *very severe pain* (score=5). Daily reports of other variables included mood, fatigue, and physical activity, but these were not included in

this secondary analysis. Data were collected locally on the smartphone, transferred to an external server where they were anonymized, and then returned to the researchers in anonymized form. Daily data could be contributed for a maximum of 15 months, with participants requested to track symptoms for 6 months. In total, 10,584 people downloaded the app and recorded their demographic information and at least 1 record of pain severity. Of the 10,584 participants, 8554 (80.82%) were female, with a mean age of 51 (SD 12.5) years. On average, these participants contributed pain severity data on 76 days (10,067/10,584, 95.12% of the participants contributed data on between 1 and 359 days). Previous analysis of these data classified participants as *highly engaged* (865/6370, 13.58%), *moderately engaged* (1384/6370, 21.73%), *less engaged* (2503/6370, 39.4%), and *tourists* (1618/6370, 25.4%) [24].

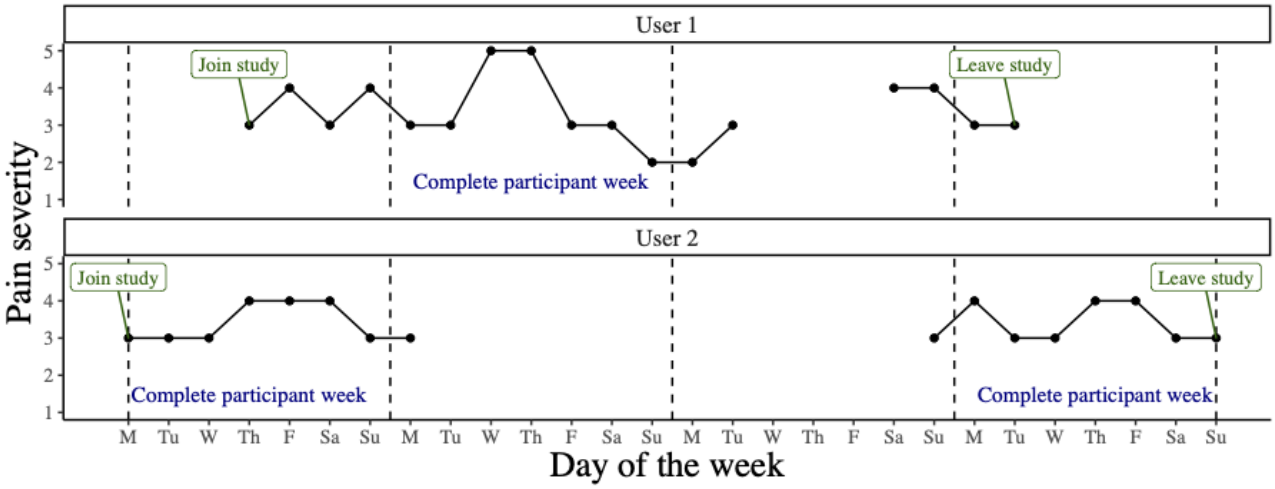
Ethical Considerations

Ethics approval for the Cloudy with a Chance of Pain mHealth study was obtained from the University of Manchester Research Ethics Committee (ethics/15522) and from the National Health Service Integrated Research Application System (23/NW/0716). Participants were required to provide electronic consent for study inclusion. Anonymized data were received by the research team. Further ethics approval was not required for the secondary analysis described in this study.

Data Preparation

For this study, weekly trajectories of pain severity data were used. To align data across multiple respondents, trajectories beginning on a Monday were identified. This alignment introduced a structure to the data based on the work week to mitigate the impact of individuals entering the study at different times and to deal with day-of-the-week effects. A complete participant week was defined as complete pain severity data contributed by a single participant during a single calendar week (Monday-Sunday; Figure 2). Pain severity data from a complete participant week were included in the analysis if (1) the participant had joined the study on or before the Monday, (2) the participant had remained in the study on or after the following Sunday, and (3) the participant had provided complete pain severity data (ie, 1 pain severity score on each of the 7 days). Multiple complete participant weeks could be included in the analysis for each participant (up to 64 weeks due to the length of the study).

Figure 2. Example selections of complete trajectory weeks for 2 participants. The participants join and leave the study at different times. One complete participant week from user 1 is included in the analysis. Two complete participant weeks from user 2 are included in the analysis.



Statistical Methods

Identifying the Optimal Number of Clusters

Previous studies have used a range of methods to cluster pain severity, including k-means clustering [25,26], hierarchical cluster analysis [27], growth mixture modeling [28-31], latent class growth analysis [13-15,32,33], multilevel latent class analysis [34], and group-based trajectory analysis [35-40]. Different approaches have different strengths and kinds of assumptions; for example, some may assume that clusters are internally homogeneous, while others may assume that the data overall follow a particular (eg, linear) form, are continuous, or are similar. In fact, clustering of ordinal and longitudinal data using a model that explicitly represents these features in a computationally inexpensive way remains a major unsolved methodological challenge. In this study, we chose a method that does not make strong assumptions about the form or generating mechanism of the data or the within-cluster variance and maintains the assumption that the data are ordinal in nature while having excellent computational performance and convergence properties. However, the assumption about the longitudinal nature of the data is relaxed.

To identify the optimal number of clusters, data were summarized in feature vectors, compared using the Manhattan (ℓ_1) distance measure, and clustered using an adaptation of the k-medoids algorithm, detailed herein. The feature vectors were 7D, with entries representing the pain severity data on each of the 7 days in a complete participant week. Using the data directly in this way ensured that feature vectors remained interpretable. The differences between feature vectors were found by calculating the Manhattan distance through entry-wise summation of absolute differences to respect the ordinal nature of the outcome variable. The implementation of the k-medoids algorithm used to cluster the feature vectors can be derived as follows. A k-medoids algorithm randomly assigns user-defined k feature vectors to be the cluster centers (or medoids) and then

iteratively (1) assigns each feature vector to the closest medoid and (2) recalculates the medoid of the clusters. The term *medoid* refers to the use of actual data points as the centers for the clusters [41]. Such use of observed data as centers for the clusters prevents outputs such as "pain severity of 3.2" that might arise if means are used and that are uninterpretable and erroneously assume an interval scale. To implement the k-medoids algorithm, the Clustering Large Applications (CLARA) program was used, which was specifically designed to be used with large data sets to reduce overall computation time [42,43].

A k-medoids algorithm requires a user-defined value for the number of clusters (k) in the data [41]. The implementation of the CLARA program was therefore repeated for values of k from 1 to 20. The output of the algorithm can be sensitive to the random feature vectors selected as the medoids in the first stage of the algorithm. The algorithm was therefore repeated 20 times, once for each value of k. At each iteration, the remaining variance within each cluster was calculated as the within-cluster sum of squares (WSS). The WSS calculates the total remaining distance between pairs of feature vectors in the same cluster. For each value of k, the iteration that returns the smallest value of WSS is selected and reported on a plot.

The optimal number of clusters was then selected using 3 criteria. First, from the plot of k against WSS, the optimal number of clusters was chosen visually using the elbow method [44]. While ideally a formal trade-off would be made between model complexity and goodness of fit, there is no clear method to use. Existing methods (eg, information criteria, silhouette method, and gap statistic) can suggest different numbers of clusters [45], possibly due to underpenalizing the complexity of data sets of the size used in this study. Therefore, the less formal elbow method allows us to be more explicit in the judgments we make to resolve the absence of an unambiguous method for learning cluster numbers from data. Second, clusters were required to contain 5% of the trajectories, similar to previous studies [13,36,46-49]. Third, cluster solutions were examined for clinical interpretability. For this measure, candidate solutions were examined to ensure meaningful differences between the cluster medoids. Furthermore, the distribution of the demographic data of participants contributing trajectories to each cluster were examined to ensure that the results reflected expected distributions.

Sensitivity Analyses

Overview

Three sensitivity analyses were conducted to test assumptions made in the main analysis, with the methodology behind choosing these being to modify assumptions made about the data and to see whether the broad conclusions were robust. Robust conclusions would be indicative of a strong model-independent signal in the data, even if modified assumptions led to a less interpretable output. The main analysis assumed that data were on an ordered scale but relaxed the assumption that the data were longitudinal.

Sensitivity Analysis 1

The first sensitivity analysis maintained the longitudinal nature of the data but implicitly assumed that the outcome variable was on a continuous scale. Feature vectors were compared using the Euclidean distance, which erroneously assumes regular intervals between values on the pain severity scale. However, the use of the Euclidean distance permits the use of the *KmL* package, which specifically clusters longitudinal data [50]. The *KmL* package is an adaptation of the k-means algorithm. The k-means algorithm is similar to k-medoids, but the center of each cluster is calculated using the mean of the feature vectors assigned to the cluster. The use of the *KmL* package, instead of the CLARA program, and the resulting use of mean trajectories rather than medoid trajectories were the only adaptions to this sensitivity analysis. The feature vectors, the 20 repetitions of the algorithm for each value of k, and the use of the elbow method to select k remained unchanged.

Sensitivity Analysis 2

The second sensitivity analysis relaxed assumptions about the longitudinal nature as well as the ordinal nature of the outcome variable. In this sensitivity analysis, the data were not assumed to be longitudinal, and the outcome variable was assumed to be unordered categorical data. A different feature vector was used that converted ordinal pain severity values into dummy variables using one-hot encoding. In this encoding, there were 35 binary categories, each representing a unique day and pain severity category. The feature was recorded as *1* if the pain severity score was seen on that day and *0* otherwise. In this way, 7 of the features were recorded as *1* for each complete participant week. The feature vectors were compared using the Jaccard distance, typically used for such vectors of binary data. The cluster analysis was then conducted using the CLARA program in the same manner as described in the main analysis.

Sensitivity Analysis 3

The third sensitivity analysis challenged the definition of a Monday-to-Sunday week when defining complete participant weeks. Instead, the following analysis was conducted for each day (*D*) in the week. Complete participant weeks were selected from the original data for each participant when there were pain severity data for each day in the *D*-to-*D*+6 week (eg, Wednesday-Tuesday week). On each new data set corresponding to a different *D*, clustering was conducted using the CLARA program at each value of k between 1 and 20, as described in the main analysis. Due to the adapted complete participant weeks, individuals may have contributed different numbers of weeks to the sensitivity analysis.

Calculations for Each Sensitivity Analysis

For each sensitivity analysis, the optimal number of clusters was calculated. Similar numbers and descriptions of the clusters would provide evidence that the conclusions from the main analysis are robust. Furthermore, for each cluster in the main analysis, the proportion of trajectories allocated to the same cluster in each sensitivity analysis was calculated. A high proportion would further suggest that the results are robust to the assumptions made by using the Manhattan distance and k-medoids algorithm in the main analysis.

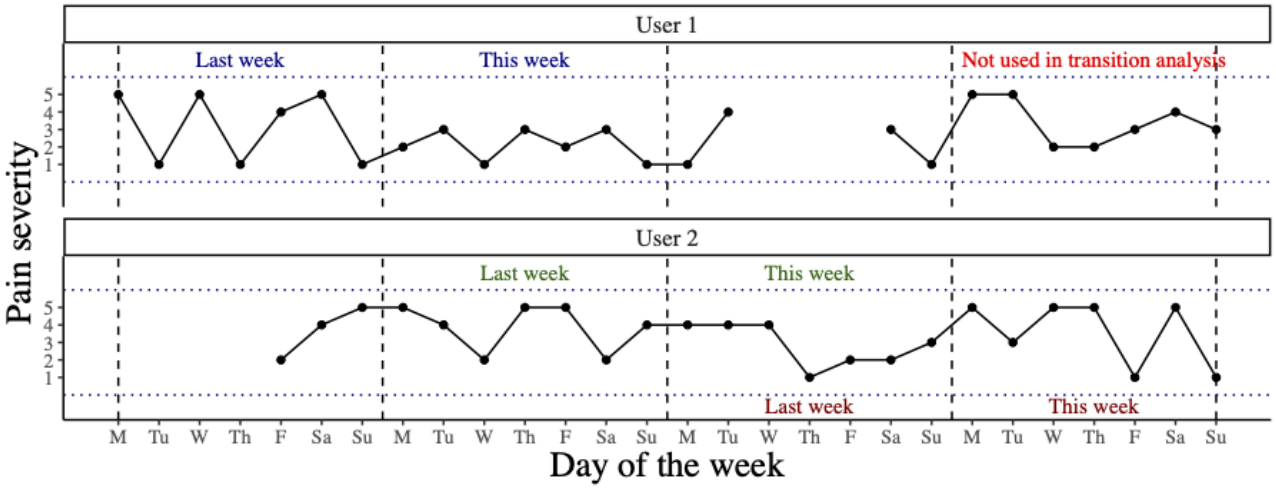
Description of Clusters

Information about the trajectories assigned to each of the clusters in the optimal solution was summarized. First, the number of trajectories assigned to each cluster was reported. Second, the clusters were visualized with a spaghetti plot of individual trajectories and the medoid of each cluster. Finally, the average proportion of time spent in each cluster by each participant was calculated. This information was summarized by calculating the mean proportion of time spent in each cluster across demographics (ie, age, sex, and chronic pain condition or conditions).

Transition Between Clusters

For the optimal solution of clusters in the main analysis, the transition of individuals between clusters on consecutive weeks was examined. To do this, a subset of the total data was used. Complete participant weeks (*this week*) were retained if the participant had also contributed a complete participant week in the directly preceding week (*last week*). A trajectory could be labeled as both *this week* and *last week* if there were both preceding and succeeding weeks for the individual (Figure 3). The demographic data of participants included in this transition analysis were compared to those included in the main analysis.

Figure 3. Example data from 2 participants highlighting how their data are used to examine transitions between clusters. User 1 provided data in 3 complete participant weeks. The first 2 are consecutive and therefore are used in the transition analysis. The final complete participant week is not used. User 2 provided 3 complete participant weeks. All three are used in the transition analysis. The middle week is labeled as both this week and last week in different pairings.



Each trajectory was assigned a cluster in the CLARA program of the k-medoids cluster algorithm. The transition probabilities were then calculated as follows. For all trajectories in each cluster *last week*, the percentage of trajectories that transitioned to each cluster *this week* were calculated. The resulting percentages are reported in a transition matrix.

Data were analyzed in R (version 4.1.2; R Foundation for Statistical Computing). The reporting of the analysis followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [51].

Results

Data Source

There were 2807 participants who contributed 21,919 participant weeks of data to this analysis. The participants' mean age was 51.2 (SD 12.8) years, and 83.11% (2333/2807) were female. Table 1 reports the number of participants by age, sex, chronic pain condition, and the average number of participant weeks contributed to the analysis by members of the subgroup. Overall, older participants contributed a greater number of participant weeks than younger participants. Male participants contributed slightly more (8.1) participant weeks than female participants (7.7). Participants with osteoarthritis (9.1) and unspecific arthritis (9.0) contributed the highest number of participant weeks, and participants with chronic headache (6.0) contributed the fewest participant weeks. Comorbid conditions are described in Tables S1 and S2 in Multimedia Appendix 1.

Table 1. Demographic information of the participants who contributed to the analysis and the average number of participant weeks contributed by each subgroup (n=2807).

Demographic information	Participants, n (%)	Weekly trajectories contributed by participants, mean (SD)
Age group (y)		
17-24	67 (2.39)	5.2 (8.6)
25-34	255 (9.08)	5.6 (7.1)
35-44	508 (18.1)	6.8 (9.0)
45-54	755 (26.9)	7.5 (9.1)
55-64	788 (28.07)	8.6 (9.7)

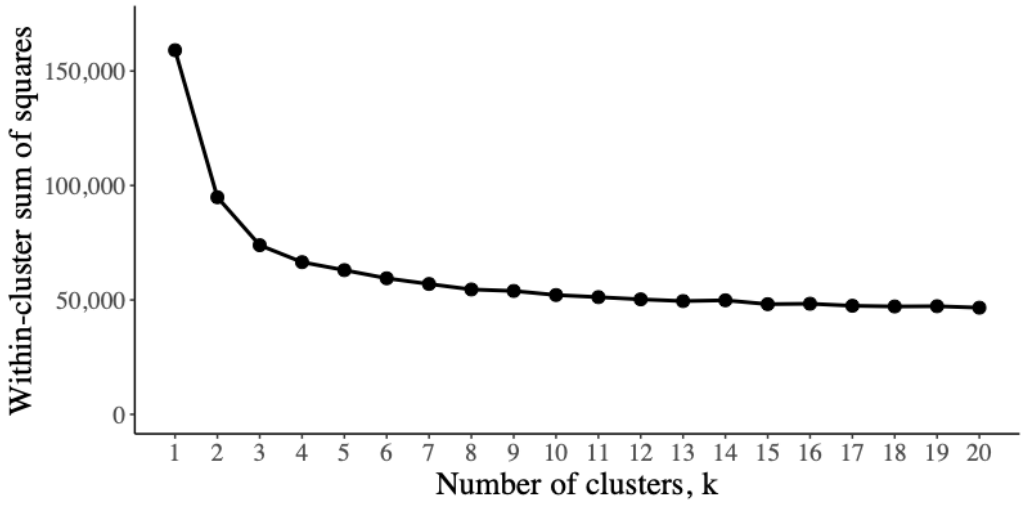
Identifying the Optimal Number of Clusters

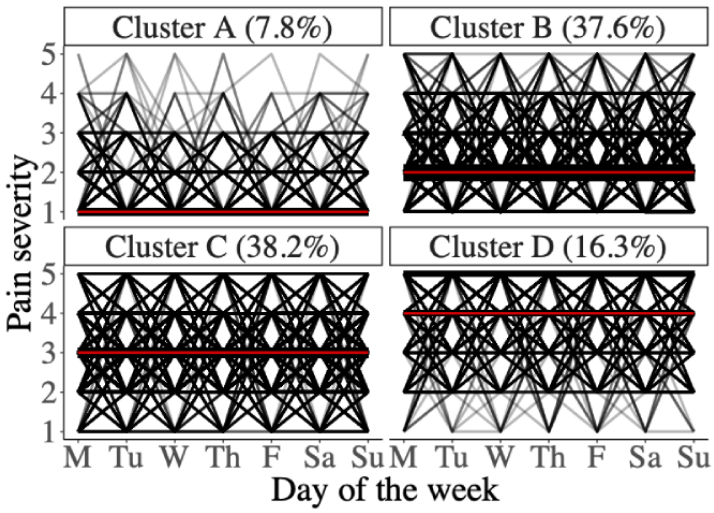
The results of the CLARA algorithm are shown herein. Figure 4 reports the remaining variability within clusters as the WSS at each value of k. There is an elbow at k=4, suggesting that most of the observed variability can be explained by a solution with 4 clusters, with diminishing returns for including further clusters in the solution. Four clusters reduced the WSS from 159,100 to 66,507; therefore, the clustering algorithm describes 58.2% of the variability in the data. Each cluster contained >5% of the pain trajectories. Therefore, 4 clusters provide an appropriate choice for these data.

Figure 4. Unexplained variability across different cluster (k) solutions. The within-cluster sum of squares indicates the remaining variance within clusters. An elbow at k=4 suggests an appropriate solution, with diminishing returns for the inclusion of further clusters.



The trajectories in each cluster are shown in the spaghetti plot in Figure 5. Trajectories are weighted such that thicker lines represent a higher number of trajectories following the path. The red line represents the medoid of the k-medoids algorithm. The clusters can be named by examining the medoid: A=*no or low pain*, B=*mild pain*, C=*moderate pain*, and D=*severe pain*. Of the 21,919 trajectories, cluster A contained 1714 (7.82%), cluster B contained 8246 (37.62%), cluster C contained 8376 (38.2%), and cluster D contained 3583 (16.35%).

Figure 5. Weighted spaghetti plot of trajectories assigned to each cluster. The weight (and transparency) of each path represents the number of trajectories following that path. The red line represents the medoid of the cluster. Cluster A=no or low pain, cluster B=mild pain, cluster C=moderate pain, and cluster D=severe pain. The percentage of trajectories assigned to each cluster is shown.

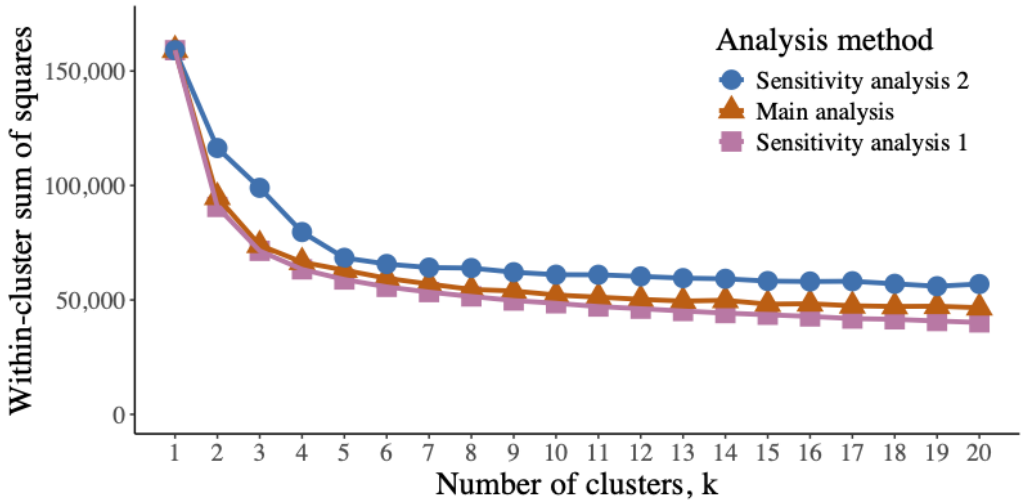


Sensitivity Analyses

Sensitivity Analysis 1 (KmL Algorithm and Euclidean Distance)

Full results are presented in Multimedia Appendix 2. The plot visualizing WSS against k for this analysis is similar to that of the main analysis and has an elbow at k=4 (Figure 6). The optimal 4-cluster solution describes 60% of the observed variability. The descriptions of the spaghetti plots (ie, cluster A=*no or low pain*, cluster B=mild pain, cluster C=*moderate pain*, and cluster D=*severe pain*) are the same as those in the main analysis, despite the use of a mean rather than a medoid to describe the average trajectory in each cluster. Of the 21,919 trajectories, 18,895 (86.2%) were assigned to the same cluster as in the main analysis, indicating similar results. Clusters B and C remain the largest clusters (8484/21,919, 38.71% and 8001/21,919, 36.5% trajectories, respectively), although cluster A is larger in this sensitivity analysis than in the main analysis (2493/21,919, 11.37% vs 1714/21,919, 7.82%).

Figure 6. Unexplained variability across different cluster (k) solutions for the main analysis and 2 sensitivity analyses. In the main analysis and sensitivity analysis 1, there is an elbow at k=4. In sensitivity analysis 2, there is an elbow at k=5.



Sensitivity Analysis 2 (CLARA Algorithm and Jaccard Distance)

Full results are presented in Multimedia Appendix 2. The plot of k against WSS for this analysis has an elbow at k=5 (Figure 6). However, 1 cluster contained 990 (4.52%) of the 21,919 trajectories in the 5-cluster solution, which did not meet the criteria for cluster sizes >5%, and therefore a 4-cluster solution remained optimal in this analysis. A 4-cluster solution describes 50% of the variability. Spaghetti plots of the 4-cluster solution show the same descriptions as those in the main analysis. In total, 20,197 (92.14%) of the 21,919 trajectories were assigned to the same cluster as in the main analysis.

Sensitivity Analysis 3 (Day of the Week)

Full results are presented in Multimedia Appendix 3. Each plot of WSS against k suggested an optimal solution at k=4. The proportions of trajectories assigned to each cluster in each 4-cluster solution are similar to those in the main analysis. The proportions in cluster A ranged between 7.72% (1717/22,255) and 7.9% (1769/22,404), cluster B between 37.49% (8273/22,067) and 37.71% (8393/22,255), cluster C between 38.04% (8523/22,404) and 38.43% (8481/22,067), and cluster D between 16.19% (3614/22,320) and 16.42% (3679/22,404). These results show that the main analysis is robust to the day of the week on which the trajectories begin.

Description of Clusters

The average proportions of time spent in different clusters across different characteristics (age, sex, and condition) are summarized in Table 2. The participants in the oldest age bracket (65-86 y) spent less time (mean 9.8, 95% bootstrap CI 7.7%-12.2%) in the *severe pain* cluster than those in the youngest age bracket (17-24 y; mean 28.3, 95% bootstrap CI 19%-38%). Female participants spent more time in the *severe pain* cluster (mean 18, 95% bootstrap CI 16.6%-19.3%) than male participants (mean 12.3, 95% bootstrap CI 10%-14.7%) and less time in the *lowest pain* cluster (female participants: mean 6.5, 95% bootstrap CI 5.8%-7.3%); male participants: mean 7.9, 95% bootstrap CI 6.1%-10%). Participants with fibromyalgia and neuropathic pain spent the most time in the *severe pain* cluster (mean 31.5, 95% bootstrap CI 28.8%-34.5%) and (mean 31.1, 95% bootstrap CI 27.2%-35.1%, respectively). Participants with rheumatoid arthritis spent the most time in the *lowest pain* cluster (mean 7.8, 95% bootstrap CI 6%-9.6%).

Table 2. Percentage of time spent in each cluster by baseline characteristic (for each characteristic, the average percentage of time spent in each cluster by members of the characteristic is reported).

	Time spent in cluster A (%), mean (95% CI)	Time spent in cluster B (%), mean (95% CI)	Time spent in cluster C (%), mean (95% CI)	Time spent in cluster D (%), mean (95% CI)
All	6.7 (6.0-7.5)	36.8 (35.4-38.2)	39.4 (38.0-40.9)	17.0 (15.9-18.2)

Male	7.9 (6.1-10.0)	42.5 (39.1-46.1)	37.2 (34.0-40.5)	12.3 (10.0-14.7)
Chronic pain condition[a]				
Rheumatoid arthritis	7.8 (6.0-9.6)	38.9 (35.7-42.0)	39.5 (36.5-42.5)	13.8 (11.5-16.2)
Osteoarthritis	5.4 (4.4-6.5)	34.7 (32.5-37.0)	42.6 (40.2-44.9)	17.2 (15.2-19.3)
Spondyloarthropathy	4.1 (2.5-6.1)	31.8 (27.5-36.2)	43.5 (38.9-47.9)	20.6 (16.3-25.0)
Gout	6.1 (2.4-10.4)	33.0 (25.5-40.1)	41.6 (34.2-48.9)	19.3 (12.9-26.2)
Unspecific arthritis	6.3 (5.2-7.5)	39.0 (36.6-41.3)	38.5 (36.3-40.7)	16.2 (14.3-18.2)
Fibromyalgia	1.7 (1.0-2.4)	19.1 (17.0-21.3)	47.7 (45.0-50.5)	31.5 (28.8-34.5)
Chronic headache	5.1 (3.1-7.4)	28.7 (24.6-33.2)	40.3 (35.9-44.7)	25.9 (21.5-30.4)
Neuropathic pain	3.3 (2.0-4.7)	23.6 (20.4-27.0)	42.0 (38.4-45.8)	31.1 (27.2-35.1)
Other or no medical diagnosis	6.7 (6.0-7.5)	36.8 (35.4-38.2)	39.4 (38.0-40.8)	17.0 (15.8-18.3)

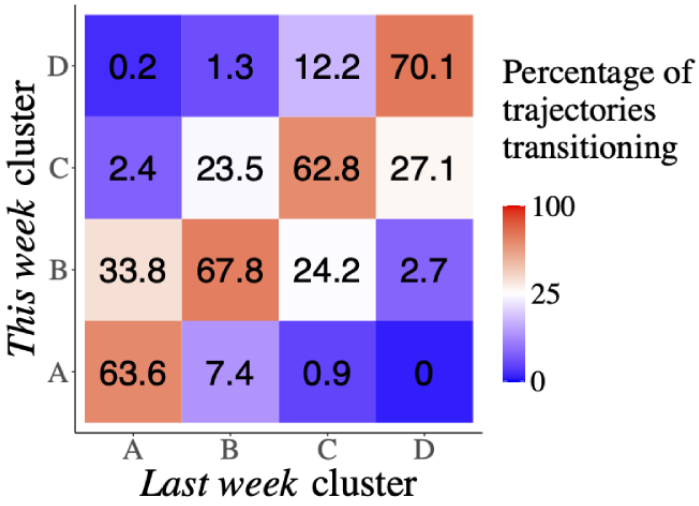
[a]Percentages exceed 100% because participants could report multiple chronic pain conditions.

Transition Between Clusters

There were 12,267 pairs of participant weeks from 1761 participants used in the transition analysis. The demographic data are compared to those in the main analysis in Multimedia Appendix 4. In general, a slightly higher proportion of older adults contributed to the transition analysis compared to the cluster analysis; for example, of the 2807 participants in the main analysis, 434 (15.46%) were aged 65 to 86 years, but of the 1761 participants in the transition analysis, 300 (17.04%) were older adults. There are no other differences in the demographics of participants contributing to the main analysis and the transition analysis.

The percentages of consecutive trajectories transitioning between clusters are shown in Figure 7. For each cluster, the highest percentages of trajectories in consecutive weeks remain in the same cluster, with the percentage values ranging between 62.76% (2948/4697) and 70.14% (1466/2090). On average, 65.96% (8091/12,267) of the trajectories remain in the same cluster. When individuals move between clusters, it is most frequently to an adjacent cluster. There is a very small percentage of consecutive weeks displaying movement between clusters ≥2 levels away.

Figure 7. Transition matrix of movement between clusters on consecutive weeks. For membership in each cluster for last week, the percentage of membership in each cluster for this week is shown. Random movement between clusters would suggest that each combination has a transition percentage of 25%. Blue squares represent transitions that have a higher-than-random percentage (>25%). Red squares represent transitions that have a lower-than-random percentage (<25%). A white square would have exactly the random percentage (25%).



Discussion

Principal Findings

This study identified and described clusters of weekly trajectories of pain severity in a large population-based mHealth study to address 4 objectives in turn. First, we reported that 4 clusters (A=*no or low pain*, B=*mild pain*, C=*moderate pain*, and D=*severe pain*) represented an optimal clustering solution for these data. In this solution, clusters B and C contained the greatest number of weekly pain trajectories.

Second, we conducted sensitivity analyses to identify whether the conclusions made about the first objective were robust to modified assumptions around the structure of the data. Two sensitivity analyses were conducted when the outcome variable was assumed to be (1) continuous and longitudinal and (2) categorical and not longitudinal. These analyses found that 4 clusters remained a suitable conclusion. A third sensitivity analysis found no differences in the clusters of trajectories starting on different days of the week.

Third, younger people and female participants contributed a greater number of trajectories to the *severe pain* cluster than older people and male participants, respectively. Participants with fibromyalgia and neuropathic pain contributed more trajectories to the *severe pain* cluster than those with other pain conditions, whereas participants with rheumatoid arthritis contributed more trajectories to the *no or low pain* cluster than those with other pain conditions.

Fourth, we examined transitions between clusters and found that 65.96% (8091/12,267) of the consecutive trajectories contributed to the same cluster. However, there was clear evidence of between-cluster movement with 34.04% (4176/12,267) of the consecutive trajectories assigned to different clusters. Between-cluster movement was most likely to a neighboring cluster; for example, moving from cluster 1 to cluster 2 was more common than moving from cluster 1 to cluster 3. This analysis demonstrates that overall, individuals tend to experience similar patterns of pain severity from week to week, although there are substantial experiences of increases or decreases in pain severity, thereby reflecting the lived experience of people with chronic pain having variability in symptoms and noting how pain can fluctuate between weeks.

People with chronic pain have highlighted a need to describe and predict the variability in the severity of their pain. Through clustering, this study has described 4 common experiences of pain severity, accounting for two-thirds of the observed variability. However, trajectories within each cluster are not homogeneous, and there remains within-cluster variation. To

better describe the individual weekly pain experience, future work should explore the remaining variability within clusters.

Comparison With Prior Work

Many studies have identified clusters of pain trajectories among individuals living with chronic pain. Some have focused on participants with 1 chronic pain condition, such as osteoarthritis [15,36-39,52-58], low back pain [13,14,27,59-65], other back pain [25,32,49,66], neck or shoulder pain [33,61,67,68], leg pain [29], knee pain [69], or foot pain [70], whereas others have identified clusters among a broader population, such as those with musculoskeletal pain [26,31,47,71,72] or general pain [48,73-75]. Clusters in these studies were described by the severity of pain (eg, *no pain*, *very low pain*, *mild pain*, *moderate pain*, *high pain*, and *severe pain*), the level of change in pain severity (eg, *persistent*, *ongoing*, *episodic*, *worsening*, *recovering*, and *fluctuating*), or a combination of these features.

These previous studies have often considered only sparse data, with relatively large time intervals between consecutive data points. Of those gathering data for at least 1 year (n=27 studies), data were collected >2 times in only 2 studies [13,67]. In these 2 studies, data were collected weekly for 1 year to explore the course of specific pain conditions (neck pain and low back pain). Kongsted et al [13] used 12 models to identify between 5 and 12 clusters in each model. Clusters were described by the severity of pain (eg, *moderate* and *severe*) and also by the temporal features of the trajectories (eg, *episodic*, *recovery*, and *ongoing*). Pico-Espinosa et al [67] identified 6 clusters of pain described as *small improvement*, *moderate improvement*, *persistent*, *large improvement*, *slightly fluctuating*, and *highly fluctuating*. The clusters identified in our analysis were described by the severity of pain, similar to clusters in studies with sparse data. Our clusters were unlikely to identify long-term disease development, as with trajectories over longer periods.

Similar to our study, some previous studies have used methods from the k-means and k-medoids family of algorithms. Knecht et al [25] used the *KmL* package to identify 2 clusters in *responders* and *nonresponders* groups. Weng et al [76] used a k-median algorithm to identify 4 clusters of pain severity: *slightly rise*, *completely drop*, *sudden rise*, and *steady group*. Both these studies identified trajectories with changing pain severity, while our study identified trajectories of weekly pain where the medoid was stable across the week.

In all aforementioned studies, the experiences of individuals were described by a single trajectory across the full duration of follow-up, whereas our study examined week-to-week transition between clusters. Kongsted et al [77] have previously examined week-to-week pain severity across a year, using predefined clusters. The authors identified that 41% and 21% of the respondents in 2 different data sets had stable pain over a year, defined as pain within 1 point of the mean pain value on an 11-point numerical rating scale. The remaining pain trajectories were classified as having a single episode of pain, being *episodic* or *fluctuating*. The transitions identified in our study suggest stability between 65.96% (8091/12,267) of the consecutive weeks. However, some individuals in our study may experience the other longer-term descriptions outlined by Kongsted et al [77]; for example, an individual might not transition out of a cluster for most of the year; yet they might experience only 1 episode. Future studies should further examine the movement between different pain states and identify the drivers of these transitions.

Strengths and Limitations

A number of strengths and limitations of this study should be considered. First, a strength was that participants could contribute daily data for up to 64 weeks. This frequent and granular data collection, enabled by mHealth, overcame limitations of sparse data collection in previous studies (as identified by Beukenhorst et al [78]). As a result, this study was able to analyze the weekly trajectories contributed by participants, determining common pain patterns among a population with chronic pain at a more granular scale than previously investigated.

Second, the analysis presented in this paper modeled weekly pain trajectories rather than individual people. In contrast to studies that assign each individual to a single cluster across the whole follow-up, individuals were able to transition between different pain clusters over time as their pain experience changed, and their condition developed. These transitions were observed in 34.04% (4176/12,267) of the consecutive weeks, and this flexibility can be used in future work to explore the mechanisms driving movement between clusters.

Third, assumptions about the ordinal and longitudinal form of the data were modified in sensitivity analyses. A 4-cluster solution was most suitable for each analysis, indicating a strong model-independent signal in the data and a more robust conclusion regarding the most suitable number of clusters. Furthermore, the assignment of trajectories to each cluster were similar in each analysis (at least 86% similarity), indicating further stability in the results. There were benefits to the use of both the k-medoids algorithm and the longitudinal adaptation of the k-means algorithm used in this analysis. First, neither of these methods requires parametric assumptions about the form of the data [50]. Second, no prior assumptions, including the shape of the trajectory, are required by the algorithms [79]. Therefore, this data-driven approach made limited assumptions about the form of the data.

There were also limitations to the study. The data used in this study were from a population-based study that represented the UK population. Cloudy with a Chance of Pain recruited participants from all UK postcodes, although male participants and those in the age brackets 17 to 34 years and ≥75 years were underrepresented in the study population [24]. Despite being a smaller population, older people and male participants contributed more trajectories on average and were more likely to contribute trajectories to a *less severe pain* category. As these clusters will be used in the development of a pain-forecasting model, clusters should be generalizable to the population with chronic pain, and there remains the possibility that different pain clusters and between-cluster transitions could be realized among those who contributed to the study did and those who did not. Although it is unlikely that our large study population would display pain clusters and transitions different from those of the population with chronic pain that would use a smartphone

tracking app, it remains a possibility that should be explored in future studies.

This analysis further selected participants by the requirement to provide a week of complete pain severity data, thus excluding missing data. There are reasons that data might be missing not at random, including missing due to severe pain, missing due to low pain severity, and missing due to stable pain, that result in repetitive score input and thus disengagement. The transition analysis also further selected participants by requiring 2 weeks of complete pain severity data. However, the age, sex, and chronic pain conditions of respondents in the main analysis and transition analysis (Multimedia Appendix 4) were similar to those in the full-study population (see the first supplementary in the study by Dixon et al [16]), suggesting that the included participants were representative of the study population.

There were limitations in the method used for clustering. First, the absence of parametric assumptions in either the k-medoids algorithm or the *KmL* package resulted in goodness-of-fit measures being inappropriate [79]. Therefore, the elbow method was used to select the optimum number of clusters. However, the use of the elbow method introduces subjectivity. Second, both the k-medoids algorithm and the *KmL* package require random starting values for the cluster centers, which can add volatility to the results. This volatility was mitigated by repeating the algorithms 20 times each and selecting the solution with the lowest remaining variability within clusters.

Conclusions

Previous research has highlighted a need to better understand pain variability experienced by individuals with chronic pain [20]. Feelings of uncertainty among people with chronic pain have led them to want to better understand the pain that they may experience in the future. Clustering weekly pain trajectories offers a first step to better understanding common experiences of pain severity. Once these common experiences are better described, they can be used in future work to predict movement between clusters.

There are limited methods available for clustering pain severity that respect the ordinal and longitudinal nature of patient-generated health data in a computationally inexpensive manner. The clustering method and subsequent sensitivity analyses presented in this paper suggest that the use of k-medoids is robust to assumptions about the data structure.

This study identified 4 distinct patterns of weekly pain severity: *no or low pain*, *mild pain*, *moderate pain*, and *severe pain*. These can be used to describe the short-term pain experiences of people with chronic pain. Future work is required to identify how these clusters can be used in a pain-forecasting model. First, there remains individual variability within clusters of pain severity. Participants in patient and public involvement studies have identified that fluctuations in pain severity should be forecast, and therefore within-cluster variability should be quantified to further understand the weekly pain experience of individuals. Second, the transition of individuals between clusters should be explored to identify the drivers of movement between pain clusters on an individual level. The clusters identified in this study and in future work to understand within-cluster variability and the drivers of movement between clusters will enable a future pain-forecasting model.

Acknowledgments

This study was supported by the Centre for Epidemiology Versus Arthritis (21755). Cloudy with a Chance of Pain was funded by Versus Arthritis (21225), with additional support from the Centre for Epidemiology Versus Arthritis (21755 and 20380). TH received funding from the Royal Society (INF/R2/180067) and the Alan Turing Institute for Data Science and Artificial Intelligence. The funders of the study had no role in study design, data interpretation, writing of the manuscript, or the decision to submit for publication.

Abstract

Background: SMS text messages through mobile phones are a common means of interpersonal communication. SMS text message surveys are gaining traction in health care and research due to their feasibility and patient acceptability. However, challenges arise in implementing SMS text message surveys, especially when targeting marginalized populations, because of barriers to accessing phones and data as well as communication difficulties. In primary care, traditional surveys (paper-based and online) often face low response rates that are particularly pronounced among disadvantaged groups due to financial limitations, language barriers, and time constraints.

Objective: This study aimed to investigate the potential of SMS text message–based patient recruitment and surveys within general practices situated in lower socioeconomic areas. This study was nested within the Reducing Alcohol-Harm in General Practice project that aimed to reduce alcohol-related harm through screening in Australian general practice.

Methods: This study follows a 2-step SMS text message data collection process. An initial SMS text message with an online survey link was sent to patients, followed by subsequent surveys every 3 months for consenting participants. Interviews were conducted with the local primary health network organization staff, the participating practice staff, and the clinicians. The qualitative data were analyzed using constructs from the Consolidated Framework for Implementation Research.

Results: Out of 6 general practices, 4 were able to send SMS text messages to their patients. The initial SMS text message was sent to 8333 patients and 702 responses (8.2%) were received, most of which were not from a low-income group. This low initial response was in contrast to the improved response rate to the ongoing 3-month SMS text message surveys (55/107, 51.4% at 3 months; 29/67, 43.3% at 6 months; and 44/102, 43.1% at 9 months). We interviewed 4 general practitioners, 4 nurses, and 4 administrative staff from 5 of the different practices. Qualitative data uncovered barriers to engaging marginalized groups including limited smartphone access, limited financial capacity (telephone, internet, and Wi-Fi credit), language barriers, literacy issues,

mental health conditions, and physical limitations such as manual dexterity and vision issues. Practice managers and clinicians suggested strategies to overcome these barriers, including using paper-based surveys in trusted spaces, offering assistance during survey completion, and offering honoraria to support participation.

Conclusions: While SMS text message surveys for primary care research may be useful for the broader population, additional efforts are required to ensure the representation and involvement of marginalized groups. More intensive methods such as in-person data collection may be more appropriate to capture the voice of low-income groups in primary care research.

Introduction

Mobile phone ownership in countries with advanced economies is almost universal [1,2], and most phone users regularly send text messages through an SMS. [3] An SMS text message is one of the most frequently used channels of interpersonal mobile communication that enables real-time exchange of alphanumeric messages, commonly in packages of up to 160 characters [4], and may be delivered manually or through an automated system.

SMS text messages have been used for clinical and research purposes with promising results in terms of patient feasibility and acceptability. While the standard route for collecting patient data in health research has traditionally been paper-based surveys [5], SMS text message methods may offer equivalent, if not higher, response rates than paper-based methods [6,7], and patients express a preference for SMS text message–based surveys over paper-based alternatives [8], including in low-income settings [9]. When information from multiple time points is requested (as in the case of daily or weekly surveys), SMS text message–based methods may offer a greater chance of obtaining more reliable, complete data, as recall bias can be minimized [6]. In addition, SMS text messaging may assist in collecting data on stigmatized topics, with some evidence suggesting that participants are more likely to disclose issues, such as mental health and substance use information, when asked by non–paper-based methods (eg, SMS text message and internet surveys), rather than face-to-face interviews [10,11].

Surveys of patients in primary care often have low response rates, and this rate is even lower among disadvantaged groups [12]. This reduced participation in research occurs for a variety of reasons, including financial barriers to participation, language barriers, and lack of discretionary time [12]. A recent case study conducted in Australia found that SMS text message surveys of Arabic-literate participants recruited through a community group were successful in data collection while recognizing difficulties with translating materials into readily understandable Arabic resources [13].

Digital inclusion is an important consideration for improving research participation [14]. Digital technologies have been highlighted as a potential option for low-cost, scalable solutions for survey participation that could allow adequate representation of participants from disadvantaged groups. There is variation in access to digital technology through device type, and disadvantaged communities may find the internet most accessible through mobile phones [15]. A recent Australian study of surveys conducted with a culturally and linguistically diverse group using SMS text messages recommended further research on using SMS text messaging surveys with people from low-income groups [13]. There continue to be disparities in smartphone ownership, limited access to data or Wi-Fi, and language barriers that can impede participation in digital health initiatives [16]. While SMS text messaging surveys appear to be an attractive option for research data collection, more research is needed to determine if this would allow equitable participation to achieve digital inclusion [16].

We aimed to explore the use of SMS text messaging for recruitment and data collection in general practice research with a focus on patients who are socioeconomically disadvantaged.

Methods

Ethics Approval

The study was approved by the Monash University Human Research Ethics Committee (22865). Participants provided informed consent to participate. Data were deidentified.

Recruitment

This substudy was nested within an implementation trial of the REACH (Reducing Alcohol-Harm in General Practice) project [17,18]. The overall objective of the study was to explore the feasibility and acceptability of a tool kit to support the use of alcohol brief interventions in general practice. This paper focuses exclusively on the use of SMS text messages to collect data from patients through general practice.

This study was set in Melbourne, Australia. Within Australia, 83.6% of the population is estimated to visit a general practitioner (GP) at least once a year [19], and smartphone ownership is estimated to be 91% [20]. The general practices were located within the state of Victoria, which is Australia's second-largest jurisdiction by population. To be eligible for this study, the general practice had to be situated in a lower socioeconomic area [18]. There were 6 general practices located in lower income communities that participated in the REACH trial and were recruited for the implementation trial through the local primary health network (PHN) [18]. PHNs are

independent, primarily federally funded organizations across Australia that support primary health care providers, including general practices and commission services based on local unmet needs. They are similar in function to other primary care commissioning bodies in the United Kingdom and Canada [21].

SMS Text Message Data Collection

Each practice had its own process for sending the initial SMS text message, details of which are outlined in the Results section. Practices were paid an honorarium of US $658 (US $1=Aus $1.52) to cover some of the costs associated with sending the SMS text messages, including administrative time. The research program manager and PHN staff were also available to discuss any issues the practice had with sending SMS text messages and followed up practices that were having technological difficulties. This approach meant that the research team did not have access to patient names or phone numbers at any time.

There were 2 main steps to the SMS text message surveys. For the first step, a staff member in each practice was asked to send an SMS text message to all current patients aged 18 years or older through an SMS text message blast (where an SMS text message is sent out to a large group of numbers at one time). This initial email contained a link to an online Qualtrics survey (Textbox 1). Patients needed a smartphone to accept the SMS text message as well as mobile data or access to a Wi-Fi connection to complete the survey online. All surveys were in English.

Textbox 1. Initial SMS text messages sent to patients by their general practice.

"Hello, you are receiving this message as you recently visited <<Practice Name>>. We and Monash University are inviting you to complete a survey on alcohol and your health through <<Survey link>>. The survey is confidential, voluntary, and will help us improve the service we deliver to you. Thanks!"

To include patients who attended during the implementation of the REACH project, patients were eligible to complete the online survey if they had visited the general practice within the past 3 months. At the end of the online survey, patients could elect to give their details (name and mobile phone number) for further SMS text message surveys to be sent 3, 6, and 9 months to capture data about their alcohol use and whether they had recently consulted with their GP (Multimedia Appendix 1). We did not have formal checks to assess the authenticity of responses or remove duplicates within Qualtrics. However, the recruitment process (direct SMS text message from the patients' GP clinic) and lack of an incentive to provide multiple responses make it unlikely that we had bot-generated or multiple responses.

The second step involved 2-way SMS text message surveys sent to patients who submitted their details in the online Qualtrics survey that was then downloaded and stored in a password-protected secure drive. In a 2-way SMS text message survey, it is only possible to ask closed questions that can be answered with a number (Textbox 2). The 2-way SMS survey had 5 questions in total and each question had 5 possible responses that were indicated by the patient selecting a number between 1 and 5. It should be noted that patients did not have any contact with the research team between the 3-month, 2-way SMS text message surveys.

Textbox 2. Two-way SMS text message surveys were sent to patients from the research team who agreed to receive the surveys in Step 1.

Hello! This is the REACH team.

Thank you for agreeing to take part in our survey when you last visited your doctor. Text STOP to opt-out of this survey (Note–the respondent answers the SMS with the number that corresponds to their answer)

- Q1 How often do you have a drink containing alcohol?
  - Never (1)
  - Monthly or less (2)
  - Two to four times a month (3)
  - Two to three times a week (4)
  - Four or more times a week (5)
- Skip To: Q4 If the answer is (1), Never
- Q2 How many standard drinks do you have on a typical day when you are drinking?
  - One or two (1)
  - Three or four (2)
  - Five or six (3)
  - Seven to nine (4)
  - Ten or more (5)
- Q3 How often do you have six or more standard drinks on one occasion?
  - Never (1)
  - Less than monthly (2)
  - Monthly (3)
  - Weekly (4)
  - Daily or almost daily (5)
  - Q4 Have you spoken with your GP in the last 3 months?
  - No (1)
  - Yes, and we spoke about alcohol (2)
  - Yes, but we didn't talk about alcohol (3)
  - I can't remember (4)
- Q5 Which of the following describes you?
  - I'm drinking within safe limits (1)
  - I plan to cut down in the next 3 months (2)
  - I want to cut down but haven't decided when (3)
  - I should cut down but really don't want to (4)
  - I don't want to cut down (5)

Interviews and Qualitative Analysis

Toward the end of the REACH trial (May to August 2021), JA, an experienced qualitative research fellow, interviewed PHN staff, clinicians, and practice staff at each of the general practices about their experience of participating in the REACH project, including the SMS text message substudy reported here. JA is a qualitative researcher and an allied health clinician, with more than a decade of experience in primary care research. All staff and clinicians of the practices who were involved with REACH were invited to participate. Data collection concluded when the authors had interviewed participants from each practice and had sufficient data to explain the process of implementation.

The semistructured interview guide included questions about the benefits and barriers of using SMS text messages to communicate with patients. The interviews were conducted remotely due to COVID-19 restrictions (phone or videoconference), and lasted from 18 to 60 minutes, with most approximately 30 minutes. They were audio-recorded and professionally transcribed. The excerpts of the interviews

pertaining to SMS text messages were used in the analysis of this specific study. The elements related to SMS text messages were coded inductively using NVivo software (version 14, QSR International) and then organized according to constructs from the Consolidated Framework for Implementation Research (CFIR) [22] codebook to understand the findings in relationship to implementation factors, both in the inner and outer contexts of the practices.

JA verified the transcripts and coded the data, and a subset of investigators formed an analysis team who met regularly (JA, ES, SN, TL, NG, and CB) to discuss findings based on the CFIR factors.

Results

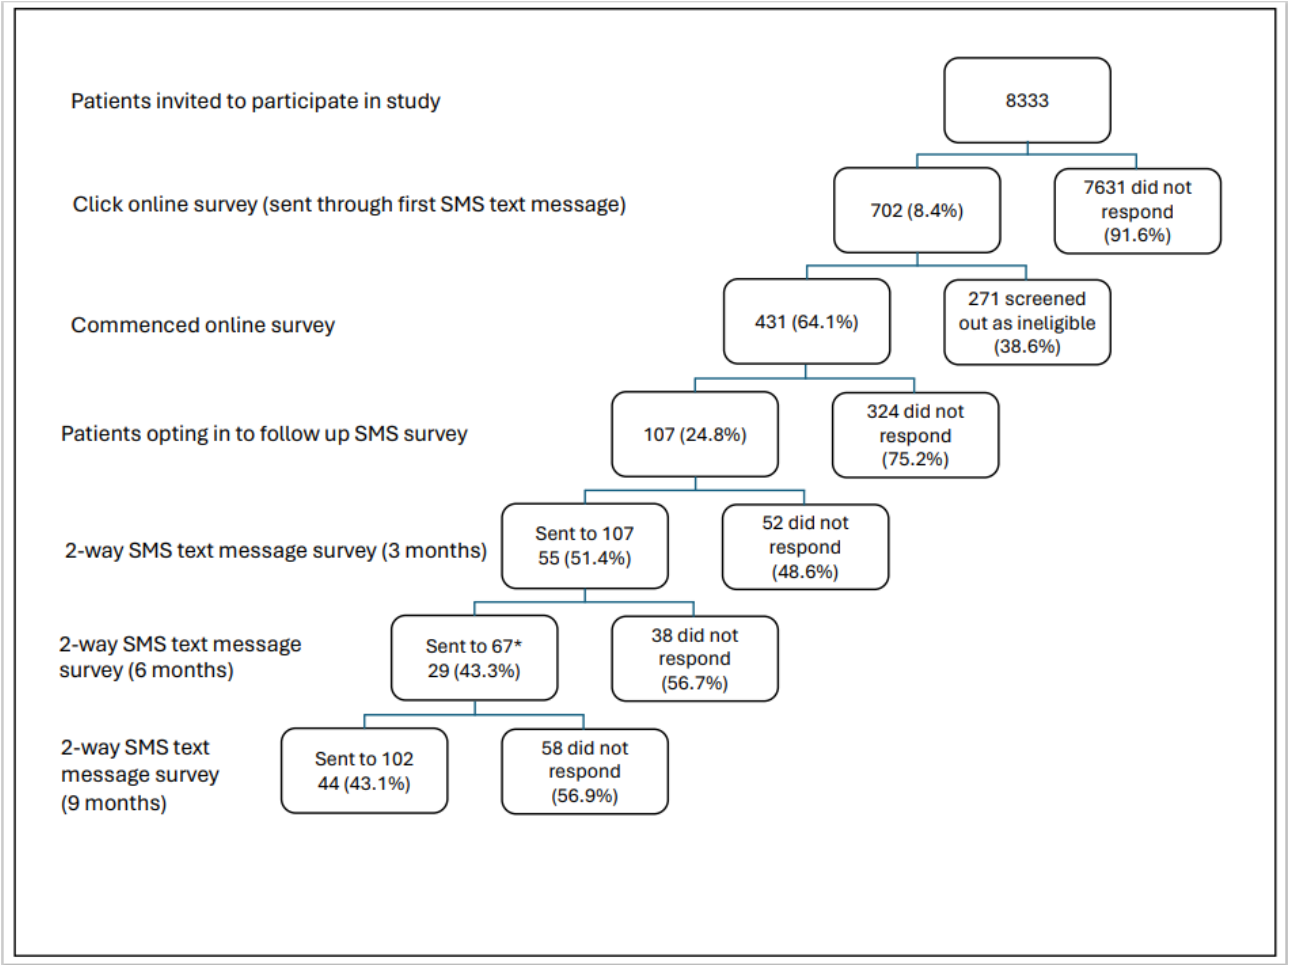
Overview

The practices involved in the REACH project were all located in lower socioeconomic areas and most practices estimated that more than 50% of their patients lived in low-income households [18]. Only 4 of the 6 participating practices were able to send the initial survey link by SMS text message to their patient cohort. One practice reported that IT problems meant they were not able to send SMS text messages to their patients at all, and they did not use SMS text messages to communicate with their patient group. A second practice felt that the SMS text message was inappropriate as their patient group was highly culturally and linguistically diverse. The practice preferred a poster in their waiting room with a QR code for the online survey and then they could assist patients to complete the survey or explain the survey, as needed. However, no patients from this practice completed the survey through the QR code.

Each of the 4 general practices that were able to send SMS text messages to their patients had very different internal processes and thus ended up sending the SMS text message to vastly different numbers of patients. One practice could send the SMS text message to each current patient's mobile number in their system, and a total of 5286 SMS text messages were sent, with 506 commencing the survey (9.6%). Another practice could only send the SMS text message to patients attending on the actual day due to an IT system issue, so they sent it to 500 patients over 3 days with 8 responses (1.6%). The third practice had software that did not allow any past patients to be contacted (usually not seen within 2 years). This practice sent an SMS text message to 2500 patients with 172 initial responses (6.9%). The final practice required patients to give their specific consent to receive the SMS text message, so they asked patients as they presented to the practice and only sent it to those who agreed, with a total of 50 sent across 2 days with 16 responses (32%).

Figure 1 shows the overall response rate at each step of the SMS text message study. In total, 8333 SMS text messages were sent by the practices, and 702 (8.4%) of SMS text messages received a response. To record a response, the patient had to click on the online link for the survey. This would require the mobile phone number for the patient on record to be current, and the mobile phone to have data or Wi-Fi to enable a response if they did click on the external link.

Figure 1. Number of SMS text messages sent and response rate at each step of the SMS survey. *The 6-month 2-way SMS text message was sent to 67 participants; 40 participants only received the 2-way SMS survey at 3 and 9 months.



A total of 431 patients completed at least some of the online surveys with a majority of the survey respondents being women, aged 45 years or older, and were not from a low-income group (Table 1).

Of the 431 survey respondents, 107 (24.8%) agreed to receive an SMS text message survey every 3 months. For the second step of the study using 2-way SMS text messages, the response rate improved to approximately 50% (216/431) for each survey (Figure 1).

Table 1. Respondents in the online survey. The survey link was sent through an initial SMS text message from the general practice (n=431).

Demographics	Participants, n (%)
Age (years; n=340)	
18-24	15 (4.4)
25-34	27 (7.9)
35-44	50 (14.7)
45-54	86 (25.3)
55-64	70 (20.6)
65-74	74 (21.8)
75-84	16 (4.7)
85 or older	2 (0.6)
Gender (n=340)	
Woman	227 (66.8)
Man	105 (30.9)
Nonbinary or third gender	3 (0.9)
Prefer to self-describe as transgender male or nonbinary trans	4 (1.2)
Prefer not to answer	1 (0.3)
Low-income status (n=335; multiple choices possible)	
Unemployed and looking for work	17 (5.1)
Receive a government pension	50 (14.9)
Health care cardholder	16 (4.8)
Live in a low-income household	8 (2.4)
None of these apply to me	236 (70.4)
Prefer not to say	8 (2.4)
Do you have a chronic disease? (n=344)	
Yes	141 (41.0)
No	195 (56.7)
Prefer not to say	8 (2.3)
Did you talk to your doctor or nurse about your alcohol intake during your last visit? (n=377)	
Yes	58 (15.4)
No	303 (80.4)
Do not recall	15 (4.0)
Prefer not to say	1 (0.3)
How often do you have a drink containing alcohol? (n=344)	
Never	60 (17.4)
Monthly or less	77 (22.4)
2-4 times a month	138 (40.1)
4 times a week or more	69 (20.1)

Qualitative Findings

We interviewed 12 representatives from the 5 practices. At least 2 staff members were interviewed from each practice. Our sample included 4 GPs, 4 practice nurses (PNs), and 4 administrative staff members, including PMs. Table 2 summarizes the demographic and professional characteristics of participants.

A total of 7 PHN staff were interviewed, detailed in Table 3.

Table 2. Interviewees from each of the 5 general practices.

Practice	Professional background
1	
Participant 1	General practitioner
Participant 2	Practice manager
Participant 3	Practice nurse
2	
Participant 1	General practitioner
Participant 2	Practice nurse
Participant 3	CEO
3	
Participant 1	General practitioner
Participant 2	Administrative staff member
4	
Participant 1	General practitioner
Participant 2	Practice nurse
5	
Participant 1	Practice manager
Participant 2	Nurse/care coordinator

Table 3. Interviewees from the primary health networks.

Number	Staff role
1	Practice relationship manager
2	Practice relationship manager
3	Continuous quality improvement program officer
4	Project coordinator
5	Continuous quality improvement program officer
6	Continuous quality improvement program officer
7	Manager

In the interviews, the PMs and clinicians gave details about their experience of using SMS text messages in their own practice. PHN staff described any issues that came up with practices they supported that were relevant to the SMS substudy. Qualitative results are organized with reference to CFIR, to assist in understanding factors that affected the implementation, both internal and external, of the practices (Textbox 3).

Textbox 3. Findings from qualitative data mapped to the Consolidated Framework for Implementation Research constructs.

Outer setting

- Needs and resources of the patient population, including language, tech ability, Wi-Fi access
- Competing demands from external policy, including those related to the COVID-19 vaccination roll-out

Inner setting

- Size of the general practice
- Networks and communication between team members
- Implementation climate
- Readiness for implementation of the SMS text message surveys

Characteristics of individuals

- Individual attitudes toward the SMS text message surveys

Innovation characteristics

- Complexity of the SMS text message process
- Relative advantage compared with usual ways of communicating with patients
- Cost-effective
- Modern forms of communication

Outer Setting

Needs and Resources of Those Served by the Organization

Patient demographics came up often during interviews with clinicians and practice staff, including language spoken, age, cultural background, and mental health status. Concerns about patient literacy were reported, especially by staff at clinics serving more diverse communities:

> *I think from the patient's perspective, there were some struggling, because we have 80% non-English speaking people here, so I think they struggled with the text messages.* [P1GP]

For patients whose primary language was other than English, it was common that they were neither able to read words written in their primary language, nor English.

> *…they're not translated at all, even the SMS messages we were able to send out to the patients, we didn't use them because it would just be them ringing us up saying, "We received a text message and we don't know what it is." So, it was just too much work, so we didn't go ahead with that either.* [P1PM]

Patient characteristics also came up in relation to the patient population served at one of the practices, which included people with dual diagnoses of complex mental illness and alcohol and other drug addictions. It was thought by the PM that patients in this practice would not respond to SMS text messages and that they would not have the technical skills to adapt to new systems.

> *not everyone is tech-savvy. I have to say, some of my patients still have the flip-flop phones, not smartphones. So if we send - it definitely can receive a text message, but it's not adaptable to QR codes, to links, those things…So for us, a good old paper that they can take and read and not print out I think is still the best…* [P5PM]

If patients did have a suitable phone, they may not have a phone plan with data or access to Wi-Fi. Practices did not report providing free access to Wi-Fi for patients within their practice. Low phone credit could also make returning an SMS text message survey problematic.

The age of patients also came up as a relevant factor for 2 of the practices (P4 and P5):

> *For some, the younger ones prefer technological things, like SMS, QR codes. But the older ones prefer something to read that's actually printed. Yeah. It's a good thing that either way, you'll be available for that.* [P5PM]

External Policy and Incentives

External policy and incentives is a broad CFIR construct that is related here to the inclusion of policy and regulations from the governmental level or external mandates. Given the timing of the study, one practice was rolling out the COVID-19 vaccination at the direction of the government at the same time they were trying to troubleshoot IT issues and did not have the resources to participate (from PHN2).

Inner Setting

Structural Characteristics

The most prominent structural characteristic mentioned by participants was the size of one of the clinics. Its small size, having only 1 GP, meant that they had not set up the SMS text message component of the clinical software.

> *We don't have a big amount to do, if you know what I mean. So, it's just something that we never really*

> *set up, because we didn't really need to use it. Like, when we go through our recalls, I just give it to reception and they just call each patient individually.* [P4PN]

Networks and Communication

Another practice found that networks and communication within the practice were not strong enough to maintain a "whole of team" approach. They were not, therefore, able to keep the SMS text message process in their institutional memory.

> *one of the other girls was involved, like organising the SMS' to be sent out, but she's actually left the clinic to take on another job.* [P2PN]

Implementation Climate

Here we examined the capacity for change of the practices. In total, 2 practices had work processes that lacked compatibility with the innovation. As 1 (PN) put it, their "IT guy" provided an "ongoing battle" to get it set up. (P4PN) The other practice noted that their clinical software was not compatible with what the study asked of them (P5PM).

Readiness for Implementation

Readiness for implementation refers to "tangible and immediate indicators of organizational commitment to its decision to implement an innovation." The level of resources that an organization allocates to implementation is an indication of readiness. The CFIR subcode "available resources" came up in the data through a discussion of cost. In total, 1 PHN participant noted that the use of SMS text messages costs more than email and might have been a barrier to practices participating in this substudy.

> *"sometimes they're not too keen on doing huge campaigns on SMS, because it actually costs them money to send the information. Whereas, via email would have been better, but it's just difficult to pull that sort of information from the clinical software systems."* [PHN1]

Characteristics of Individuals

An individual stage of change refers to an individual attitudes toward innovation. In total, 1 PHN participant noted that GPs are sometimes hesitant about change.

> *But a lot of them can be a bit hesitant to sending patients out anything, How will that look? Am I targeting my patients? They're a bit anxious.* [PHN6]

Innovation Characteristics

In total, 1 PHN worker noted that one of the practices found the complexity of the intervention a bit more than they were used to and it made participation difficult:

> *I did have a practice that was struggling a little bit with – because there was the SMS surveys to send out. So I had a practice that was – they weren't very used to using that sort of system. They just did phone recalls and reminders to patients, not SMS.*

A total of 2 "Innovation Characteristics" were found to drive participation, including relative advantage and another way of understanding cost. In total, 1 practice in particular understood the SMS text message substudy offered them a couple of advantages over their usual practice. First, the SMS text message approach was thought to be "proactive and opportunistic," enabling them to use a flexible approach to engage their "really passive" patients (P5PM). Second, the study was thought to provide improved access, giving the practice another alternative to offer patients:

> *I could give you this, I could send this to you via email. I can send it to you by text. So that adds to what we can do, what we can provide.* [P5PM]

For 1 PHN worker, the SMS study was a more modern and cost-effective approach to communicating with their patients:

> *I think they realised that it's another way of communicating with the patients that they really should have been using for a long time. So that's been quite a good benefit for that practice certainly, just getting them on board with a more modern way of working with their patients.* [PHN1]

Suggestions for Future Implementation

Practice managers and clinicians had several suggestions for how researchers could more successfully engage with patients who are from disadvantaged groups. These included preferentially using paper-based surveys that were administered at a place that patients already knew and trusted; having researchers available to assist patients in completing surveys if literacy, manual dexterity, or vision was a problem; and vouchers for patients who complete surveys (suggested US $6.6 [US $1=Aus $1.52]).

Discussion

Principal Findings

We found that sending an SMS text message through general practice did not lead to a high response rate from patients, but a 2-way SMS text message survey to patients who had answered the first SMS text message had a higher response rate. Our approach did not capture participants from more marginalized groups due to constraints related to technology and human factors.

We used 2 processes to explore the use of SMS text messages for data collection in general practice research (1) an SMS text message from the patient's own general practice that contained an external link to an online survey and (2) a 2-way SMS survey that was sent from the research team to patients who agreed to be contacted. We found most general practices experienced technical constraints in sending SMS text messages, such as limited software infrastructure. A researcher needed to be proactive in communicating with the clinic's professional and administrative staff to adapt each clinic's unique practice processes to the SMS text message survey procedure. We also used a poster in the waiting room of one practice at the practice's request; however, no patients used this QR code and it did not prove to be a practical strategy in this culturally and linguistically diverse patient group.

Only a small number of participants clicked the external link to the online survey within the initial SMS text message, but it was a comparable percentage to primary care surveys in general [12]. The ongoing 2-way SMS text message surveys were more successful as the patients had agreed to be contacted again and were able to answer questions within the SMS text message environment. Response rates remained over 50% for the 3-month SMS text messages, with no additional contact from the research team or the general practice.

CFIR provided a structure to tease out characteristics that influenced the successful uptake of the SMS text message study from the qualitative data [22]. The most relevant outer setting factors that impacted participation included the needs and resources of the patient populations, notably English language proficiency, age, and 1 practice, which worked primarily with addiction. The data further indicates that size, teamwork, and capacity for change all influenced the uptake of the SMS text message study.

While SMS text message surveys are an attractive option for primary care research, there are constraints to consider. These include a restriction in the type of questions that can be asked due to the limits of SMS text message length and closed question format. Furthermore, SMS text messages are unlikely to capture socioeconomically disadvantaged populations who have barriers, including phone infrastructure and hesitancy around unknown contact numbers. With a recent increase in SMS text message use in scams, this hesitance may increase in the future [23]. Researchers should also be aware that practices are likely to have their own policies or software limitations in sending SMS text messages to patients, and this is likely to influence recruitment and response rates, as seen in this study.

Comparison With Previous Work

The lower response rate in our study is still in line with the international literature where response rates for SMS text message data collection vary considerably, from 12.5% to 100%, with the lowest uptake (12.5%) in a drug and alcohol clinic [24], while response rates beyond 90% were seen a decade ago in general practice, especially when youth were involved [25-27]. A patient's willingness is likely dependent on a number of factors, including familiarity with texting, relationship with the individual recruiting them, health-related motivation or interest in research, and the presence of incentives [28]. Most longitudinal SMS text message surveys also see response rates typically decline, by an estimated 2%-13%, over the duration of the study, which is comparable to our study's decline of 8% from baseline to the 9-month follow-up [24,29-31]. In studies where participants did not respond to an initial SMS text message, high responsiveness was seen after reminder messages were sent [5,32]. Other studies have called participants who did not respond to prompts, which was an effective method of retaining participants in the study, although this does increase the research staff's time and requires consent for contact by phone call [8].

We kept our 2-way SMS text message survey as short as possible to improve response and completion rates [10]. Among patients who ceased surveys before completion or stated they would not be willing to complete a future text survey, a commonly cited reason was that the initial survey had too many questions [29,33]. More than half (52%) of patients in a Singaporean study stated they preferred surveys with 1-10 questions, and only 12% stated they would be willing to complete an SMS survey with more than 30 questions [29]. In 1 study, participants were asked what they would consider an acceptable number of SMS text messages to receive in 1 week from researchers, with a mean response of 4 (SD 3.7) [24], while most participants in another study felt 2 SMS text message questions per day was sufficient [9].

This study included about one-third of participants from a low-income group. The digital divide recognizes easier digital health access for the more advantaged patients [34], and patients have reported the cost of texting as a reason not to participate in an SMS text message trial [24]. The type of phone a patient uses may also influence completion, with patients who use smartphones more likely to complete SMS text message surveys than those using older, more basic phones [33]. With these recognized barriers, this study also highlighted the additional research effort that should be afforded to capture data from the most marginalized patients.

Limitations

A key limitation of this study is the absence of qualitative data from patients about their experience of SMS text message surveys. Although clinicians and PMs could draw on their broader experience, they may have made some assumptions about patient preferences that we could not verify with patients themselves. Our low response rate, while a finding in itself, limited what we were able to learn about SMS text message surveys in lower income populations. We used the general practice as a trusted source to deliver the initial SMS text message, with the assumption that this would increase the response rate, but this did not appear to facilitate SMS text message responses. We are also unable to report if SMS text messages were actually received, which may artificially lower the response rate. For example, this could occur if the patient had changed their phone number since they were last at the practice. Our quantitative data could not make direct comparisons with those from other groups, and further work is required to determine if other strategies may make SMS text message survey work feasible in lower income primary care populations.

Conclusions

While SMS text message survey methods offer a low-intensity option for research data collection, a general SMS text message survey is unlikely to capture participants from more marginalized groups. When recruiting patients through general practice, researchers need to consider the different practice protocols that may be in place for contacting patients by SMS text message as this greatly influences the potential of the method. To promote research participation from the most socially disadvantaged groups, paper-based, or researcher-facilitated surveys undertaken at a trusted location may yield more responses.

Abstract

Background: SMS text messaging- and internet-based self-reporting systems can supplement existing vaccine safety surveillance systems, but real-world participation patterns have not been assessed at scale.

Objective: This study aimed to describe the participation rates of a new SMS text messaging- and internet-based self-reporting system called the Kaiser Permanente Side Effect Monitor (KPSEM) within a large integrated health care system.

Methods: We conducted a prospective cohort study of Kaiser Permanente Southern California (KPSC) patients receiving a COVID-19 vaccination from April 23, 2021, to July 31, 2023. Patients received invitations through flyers, SMS text messages, emails, or patient health care portals. After consenting, patients received regular surveys to assess adverse events up to 5 weeks after each dose. Linkage with medical records provided demographic and clinical data. In this study, we describe KPSEM participation rates, defined as providing consent and completing at least 1 survey within 35 days of COVID-19 vaccination.

Results: Approximately, 8% (164,636/2,091,975) of all vaccinated patients provided consent and completed at least 1 survey within 35 days. The lowest participation rates were observed for parents of children aged 12-17 years (1349/152,928, 0.9% participation rate), and the highest participation was observed among older adults aged 61-70 years (39,844/329,487, 12.1%). Persons of non-Hispanic White race were more likely to participate compared with other races and ethnicities (13.1% vs 3.9%-7.5%, respectively; $P<.001$). In addition, patients residing in areas with a higher neighborhood deprivation index were less likely to participate (5.1%, 16,503/323,122 vs 10.8%, 38,084/352,939 in the highest vs lowest deprivation quintiles, respectively; $P<.001$). Invitations through the individual's Kaiser Permanente health care portal account and by SMS text message were associated with the highest participation rate (19.2%, 70,248/366,377 and 10.5%, 96,169/914,793, respectively), followed by email (19,464/396,912, 4.9%) and then QR codes on flyers (25,882/2,091,975, 1.2%). SMS text messaging–based surveys demonstrated the highest sustained daily response rates compared with internet-based surveys.

Conclusions: This real-world prospective study demonstrated that a novel digital vaccine safety self-reporting system implemented through an integrated health care system can achieve high participation rates. Linkage with participants' electronic health records is another unique benefit of this surveillance system. We also identified lower participation among selected vulnerable populations, which may have implications when interpreting data collected from similar digital systems.

Introduction

Globally, there has been a rapid adoption of digital technologies, partly due to widespread access to mobile phones [1]. Mobile health (mHealth) has the power to revolutionize health care delivery and monitoring systems. Due to their ability to collect real-time self-reported symptom data from a large number of patients, mHealth systems have proven particularly useful in post licensure vaccine monitoring surveillance [2,3]. However, the broader applicability and significance of mHealth extends across multiple clinical domains, including chronic disease management, mental health support, and preventative care [4-7], underscoring the need to ensure their equitable implementation.

Despite this clear need, digital health care tools have been criticized for the underrepresentation of selected population groups, such as persons of different races or ethnicities or older age [8]. This phenomenon, known as the "digital divide" [9], impacts the generalizability of findings and risks exacerbating existing barriers to health care and health disparities [10,11]. Furthermore, in addition to enhancing equity, understanding and accounting for major drivers of participation also has important implications when interpreting data collected from mHealth systems. Without accounting for these systemic biases, epidemiological associations could be substantially altered, as demonstrated previously [12]. However, previous studies have lacked data with enough granularity within a closed system to identify population-level participation patterns.

These studies include several smartphone-based reporting systems for postvaccine reporting of adverse events (AEs) following immunizations [13-17]. However, since most systems rely on voluntary app-based smartphone enrollment, uptake has generally been low (often under 5% of vaccinated individuals) [3,18-22], contributing to a lack of representativeness. In addition, none of these studies have linked self-reported symptom data with individual-level electronic health record (EHR) data, limiting their ability to contextualize demographic or clinical information against that of the total vaccinated population and to validate clinical diagnoses. Evaluating participation in a similar digital system implemented across a large integrated health care system will improve the interpretation of data collected from SMS text messaging- and internet-based self-reporting systems and can inform the design of future systems. In January 2021, Kaiser Permanente Southern California (KPSC) developed the Kaiser Permanente Side Effect Monitor (KPSEM), a digital survey tool that allows patients to report on potential adverse events following COVID-19 vaccination. In this study, we aimed to assess KPSEM participation by demographic and clinical characteristics within a large integrated health care system.

Methods

Study Population

This prospective cohort study of all patients receiving COVID-19 vaccinations through KPSC from April 23, 2021, through July 31, 2023, monitored self-reported adverse events and solicited symptoms following vaccination.

Data Collection

Patients receiving COVID-19 vaccinations at a KPSC facility could join the system online by scanning a QR code available on study flyers and posters using their smartphone devices. Except for SMS text messages, all study recruitment and communication materials in this study were branded with standard Kaiser Permanente institutional affiliations, including the study flyer, emails, and portal messages. Patients who did not sign up on the day of vaccination received an invitation by SMS text message, email, or a notification through their online Kaiser Permanente health care portal account. This included patients with Kaiser Permanente membership who were vaccinated by an external provider and identified through insurance claims databases and other integrated sources. Parents or guardians provided consent and submitted responses on behalf of their child under 18 years of age or their legal dependent. Initially, the Kaiser Permanente health care portal message center and SMS text message invitations were prioritized over email if patients had online accounts and valid contact information on file since these channels were found to result in higher participation rates during a pilot study (unpublished data). However, in December 2021, all health care portal communication was stopped due to concern of it interfering with care delivery messages, and SMS text messages became the prioritized channel of communication for initial invites. During the consent procedure, participants were asked whether they would prefer to complete the survey exclusively by SMS text message rather than online. After providing consent, patients were sent surveys inquiring about solicited AEs and symptoms at regular intervals according to their preferred contact method for up to 5 weeks after each dose; daily for the first week, alternate days for the second week, then weekly for 3 additional weeks. Survey wording and timing of survey questions are provided in Tables S1 and S2 in Multimedia Appendix 1. Upon receipt of additional vaccine doses, the survey cycle was restarted. Participants could actively withdraw from the survey at any point and would not be recontacted for subsequent doses. Survey information was subsequently combined with EHR data for access to patients' demographic and clinical data across all care settings. Surveys were also made available in Spanish according to a patient's on-file preference.

Statistical Analysis

Selected characteristics were described among all patients who received a COVID-19 vaccination at KPSC over the study period

and among those opting to participate in KPSEM. Participation was defined as completing at least 1 survey within 35 days of their vaccination. Selected clinical and demographic characteristics of interest included age, sex, race or ethnicity, socioeconomic status, and the presence of chronic comorbidities within 1 year before the date of first vaccination within the study period. Prespecified *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) diagnosis codes were used to define comorbidities (Tables S3 and S4 in Multimedia Appendix 1). The neighborhood deprivation index (NDI) was used as an indicator of community-level socioeconomic status [23]. Race or ethnicity was categorized using mutually exclusive self-determined categories of non-Hispanic race (White, Black, or Asian), ethnicity (Hispanic), other (not within race or ethnicity groupings), or unknown race or ethnicity. Differences in survey participation statistics, survey reminder preferences (ie, SMS text message, email, or Kaiser Permanente portal message reminders), and self-reported solicited AEs and symptoms were described across selected demographic and clinical characteristics. Similarly, differences in participation (response rates and withdrawal rates over time) were described by separate recruitment and reminder channels, irrespective of demographic and clinical characteristics. Participant characteristics were compared using the chi-square test. All analyses were done with SAS Enterprise Guide statistical software (version 7.1) and R (version 4.3.0, R Foundation for Statistical Computing). Results were reported according to the updated CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines [24] and the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) [25].

Ethical Considerations

All study activities were reviewed by the Centers for Disease Control and Prevention (CDC) and completed in accordance with applicable Federal law and CDC policy. In addition, the study protocol was reviewed and approved by the KPSC institutional review board, which waived the requirement for informed consent (#12769).

Results

Study Population and Recruitment

Among 2,091,975 patients who were vaccinated between April 23, 2021, and July 31, 2023 (Table 1), 164,636 (7.9%) enrolled in the KPSEM system and completed at least 1 survey in the 35 days following the first dose of COVID-19 vaccination they received within the study period. This included patients who were vaccinated at KPSC facilities and KPSC members who received vaccination at non-KPSC facilities. Passive recruitment methods through patients scanning QR codes on flyers and posters at the time of vaccination enrolled only a small proportion of all vaccinated individuals (25,882/2,092,824, 1.2%; Figure 1 and Table S4 in Multimedia Appendix 1). Among persons contacted through their Kaiser Permanente health care portal account, 19.2% (70,248/366,377) joined and submitted at least 1 survey following their vaccination. Hence, this method was the most successful recruitment channel. SMS text message invitations resulted in a participation rate of 10.5% (96,169/914,793). Email invitations resulted in the lowest participation rate compared with the other active invitation channels (4.9%, 19,464/396,912). Among all individuals who received at least 1 digital invitation across all vaccine doses, participation was 13.1% (181,462/1,382,095; Table S4 in Multimedia Appendix 1).

[a]Participation rate was calculated as: Participants with at least 1 documented report through KPSEM within 35 days following receipt of vaccination ÷ total vaccinated population × 100.

[b]COVID-19 vaccine dose is defined as a documented dose received within the defined study period, regardless of patient history of previous doses.

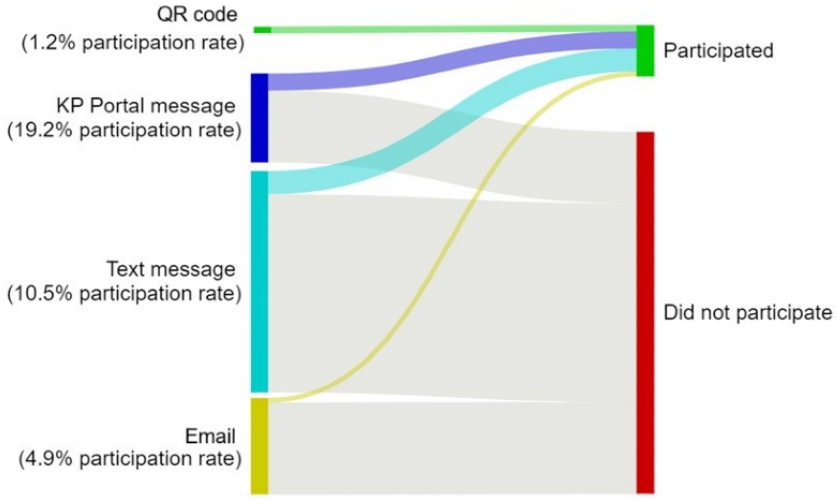
[c]Differences in participation rate were compared across demographic characteristics using the chi-square test for heterogeneity.

[d]KP: Kaiser Permanente.

[e]KP membership is defined as enrollment at least 1 year before vaccination and for 35 days following vaccination.

[f]Neighborhood Deprivation Index (NDI) was defined as the latest available NDI before COVID-19 vaccination.

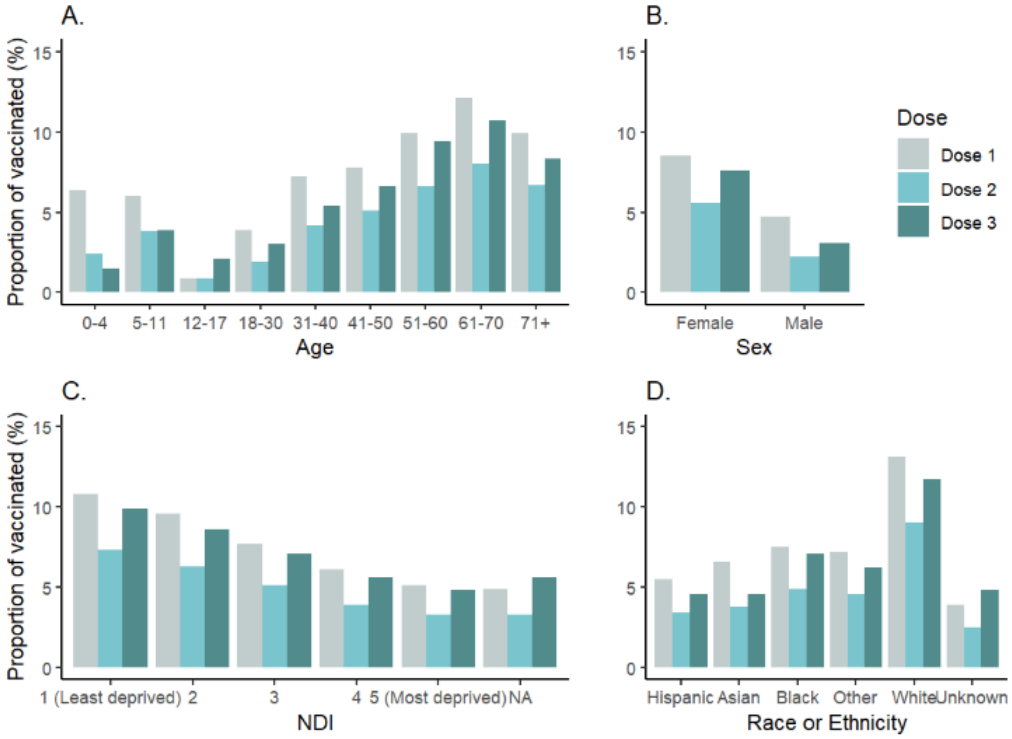
Figure 1. Participation rate by invitation channel among patients receiving a COVID-19 vaccination from April 23, 2021, to July 31, 2023. The participation rate was defined as follows: at least 1 documented report through Kaiser Permanente Side Effect Monitor within 35 days following receipt of vaccination ÷ total invited population × 100. KP: Kaiser Permanente.



Patterns of Participation

Females (102,445/1,135,626, 9%) were more likely to participate than males (62,191/956,349, 6.5%, *P*<.001; Table 1). Parents or guardians joining on behalf of their children demonstrated higher participation rates for younger children aged 0-4 years (2266/35,594, 6.4%) and 5-11 years (8001/133,418, 6%) than parents or guardians of children aged 12-17 years (1349/152,928, 0.9%; Figure 2). Low participation rates were also observed for young adults aged 18-30 years (10,599/274,968, 3.9%). The age group with the highest participation rates was adults aged 61-70 years (39,844/329,487, 12.1%). Participation also varied systematically by race or ethnicity and NDI; persons of non-Hispanic White race were more likely to participate compared with other races or ethnicities (13.1% vs 3.9%-7.5%, respectively, *P*<.001). Patients residing in areas with a higher NDI were less likely to participate (5.1%, 16,503/323,122 vs 10.8%, 38,084/352,939, in the highest vs lowest deprivation quintiles, respectively, *P*<.001). Overall, regardless of demographics, participation decreased for the second dose following dose 1 and then increased following the third dose (Figure 2).

Figure 2. Participation rate by dose and demographic characteristics among patients receiving a COVID-19 vaccination from April 23, 2021, to July 31, 2023. Participation rate was defined as follows: participants with at least 1 documented report through Kaiser Permanente Side Effect Monitor within 35 days following receipt of vaccination/total vaccinated population x 100. NDI: Neighborhood Deprivation Index.

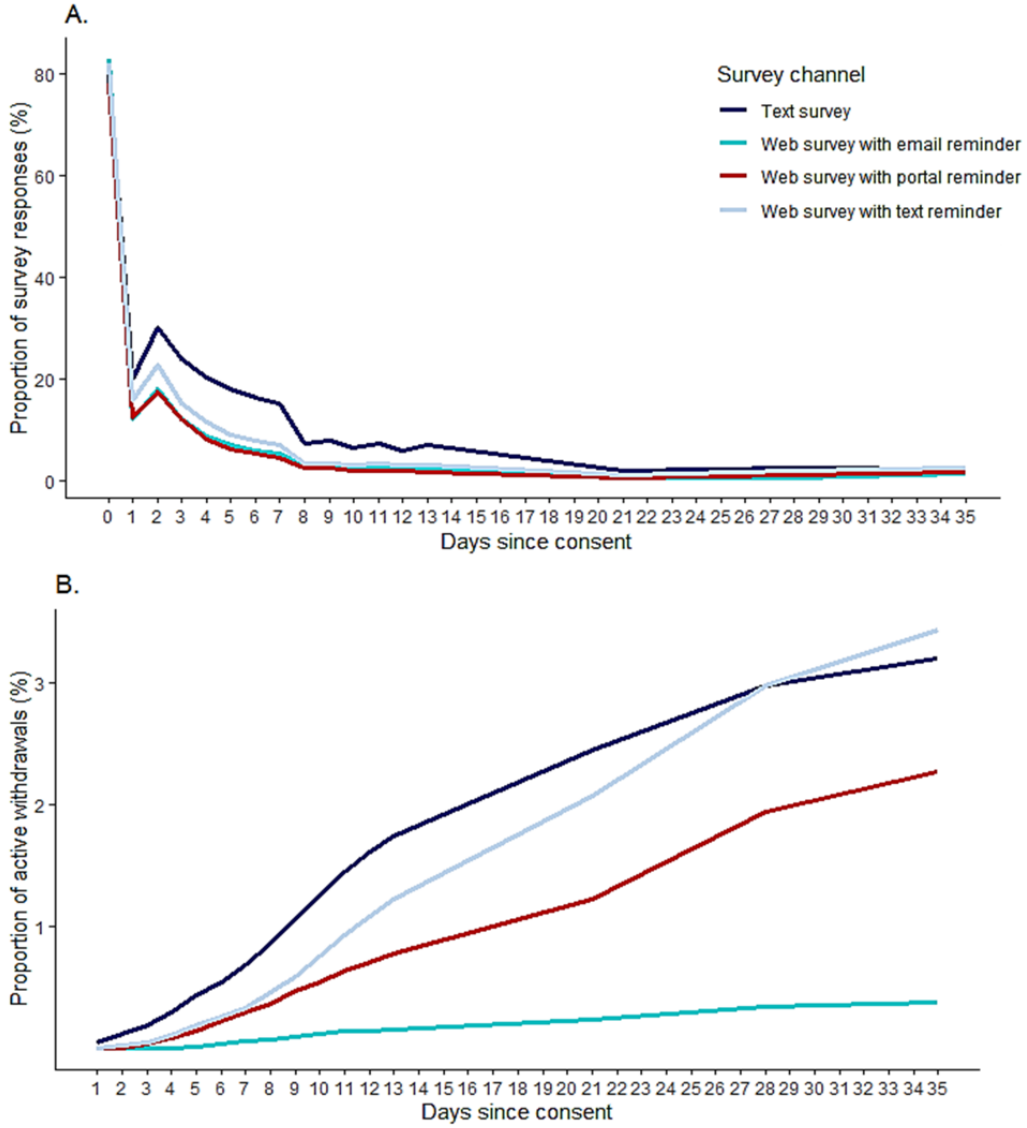


Survey response rates dropped during the first week of survey notifications, from over 80% of participants across all invite channels on the day of consent (day 0) to below 30% of all enrolled participants on day 2 of the survey (Figure 3A). After

the second day of the survey, the response rates consistently dropped through approximately week 3 of the survey and remained low until week 5 (<5% of enrolled participants). However, the sustained response rates differed by survey reminder channel, notably, SMS text message prompts and SMS text message surveys achieved consistently higher sustained responses compared with the other survey channels over 5 weeks. During the 35-day follow-up period, a cumulative proportion of around 3% of study participants withdrew from the study among those who were receiving SMS text message reminder notifications (Figure 3B). Withdrawals were less frequent over the same period among persons who opted to receive notifications through their Kaiser Permanente health care portal account (approximately 2%), and active withdrawals were lowest among persons receiving email reminders (<1%), although email reminders also had the lowest daily response rates (Figure 3A).

Initial reactions (local, systemic, and additional symptoms) were reported more frequently among persons who responded to multiple surveys during the 35-day follow-up period compared with participants who only responded to a single survey (Table S5 in Multimedia Appendix 1), as was the proportion reporting seeking medical care for symptoms; however, initial reports of reactions or solicited symptoms did not affect the likelihood of participation after subsequent vaccine doses (Table S6 in Multimedia Appendix 1).

Figure 3. Rate of survey response (A) and active withdrawals (B) by day since consent and survey channel among Kaiser Permanente Side Effect Monitor participants receiving a COVID-19 vaccination from April 23, 2021, to July 31, 2023. Participation was defined as at least 1 documented report through Kaiser Permanente Side Effect Monitor within 35 days following receipt of COVID-19 vaccination.



Discussion

Principal Findings

Overall, these findings provide evidence for the feasibility of a digital self-reporting system as a timely, flexible, and scalable supplement to existing vaccine safety surveillance systems. We observed a high participation rate among vaccinated patients compared with other digital reporting systems deployed to a general US population. However, we also observed differences in participation across neighborhood-level socioeconomic characteristics and race or ethnicity, suggesting the existence of barriers to participation in these systems. If self-reporting

digital health systems are to be used at scale, outreach efforts must be optimized to ensure that they accurately represent the underlying population. These findings also provide valuable information to improve the design of future digital self-reporting systems and to improve the interpretation and validity of the data collected through such systems.

There could be several reasons for the high participation rate of 30% observed in this study when compared with other digital vaccine safety self-reporting systems such as V-safe (CDC), which enrolled approximately 1-2% of all vaccinees in the United States during the national COVID-19 vaccination program [26]. First, owing to the integrated health care system setting (rather than a federal entity), our system may have had enhanced trust among participants [27,28]. An increase in awareness of the system by staff and patients could have also contributed to enhanced participation since a conscious effort was made to publicize the system through staff awareness sessions and internal communication platforms. Furthermore, recruitment invitations were sent to patients following receipt of multiple vaccine doses, further increasing their awareness of the system and the likelihood of participating with each new dose. In addition, by leveraging the expertise of trained digital teams, our system had many unique features designed to enhance survey usability and acceptance, such as the ability for enrollees to select their preferred survey methods (ie, SMS text message or internet-based surveys) and survey reminder preferences which may have improved participation and survey retention rates. Indeed, we observed that users had a strong preference for SMS text message surveys compared with other channels, and SMS text messages were associated with higher sustained survey response rates over 5 weeks. SMS text messages have proven to be an effective communication method to enhance trust and awareness of vaccine safety previously [29]. Furthermore, the preference for SMS text messaging–based systems over smartphone apps or targeted emails has been noted elsewhere [3,22], and most app-based reporting systems have demonstrated much lower participation rates compared with this study [3,18-20,22]. Previous work with patient usability surveys has identified barriers specifically related to smartphone apps, including lack of device memory, the need for software updates, and the additional time required to download apps [22]. Hence, not requiring a smartphone to participate in our system likely contributed to our observed high participation rates.

Akin to this study, other studies assessing the uptake of self-reporting systems for vaccine safety have identified the highest rates of participation among middle-aged adults and females [3,13,18-21,30]. In addition, we observed significant differences in participation by other demographic and socioeconomic characteristics not as well studied, most notably by NDI, where there was a clear inverse association between community-level socioeconomic deprivation and survey participation. Although general health care disparities predate the pandemic, they have been observed across many aspects of COVID-19–related care, including testing, vaccination, and severe outcomes, even in settings with no direct consumer health care costs such as prepaid insurance premiums [31]. As observed in this study, these disparities are also known to exist with respect to digital self-reporting systems [32]. However, although this area is less studied, encouragingly there is some evidence for reduced disparities for telehealth tools compared with in-person care [33]. The reasons underlying the observed disparities in digital system participation are unknown, but some have suggested that data literacy plays an important role [34]. Future research would benefit from understanding the barriers to participation in digital self-reporting systems, including eliminating gaps in digital literacy that could exacerbate health inequities.

As well as informing approaches for improved participation and potential targeted efforts for equitable uptake of future digital self-reporting systems, this study provides important insights that will aid in the interpretation of large-scale analysis using such data. This has not been feasible at scale previously due to the need for complete EHR data. For example, we identified that persons with immunocompromising conditions were more likely than the general vaccinated population to enroll in the system and, hence, may be overrepresented in similar studies. This is important when interpreting data from similar self-reporting vaccine safety monitoring systems since immunocompromised individuals may systematically differ with respect to reactions following vaccination [35]. In addition, most previous work has relied on enrollees inputting their demographic details and clinical information, which may adversely impact enrollment, reduce survey completion rates, and introduce data entry errors. In addition, one-third of smartphone-based vaccine safety app users in Germany reported that they found entering vaccination details difficult, often not knowing the vaccine's name [19]. This exposure misclassification issue was also associated with certain patient demographics, such as advanced age, hence introducing systematic bias. Furthermore, another important finding from this study was that participation appeared to be slightly higher following a third vaccine dose compared with the second dose across most population subgroups studied. This could have been due to selection bias since third doses were not enforced to the same extent as the primary vaccine series, and hence they were more likely to be received by so-called "early adopters" or older or multimorbid populations, both of which are more likely to take part in research projects.

Data from previous self-reporting vaccine safety systems could be biased by the propensity of persons who have experienced reactions or AEs to be more motivated to engage in self-reporting studies. Interestingly, in this study, individuals who answered multiple surveys within 35 days following receipt of a vaccine were more likely to report local or systemic reactions on their initial report after the same dose and were also more likely to report seeking medical care for their reactions compared with participants who only answered the survey once. Therefore, reactions themselves may be a motivating factor underlying sustained survey participation and hence may lead to overestimations of symptom duration [36]. In contrast, while it was true that certain groups of participants were more likely to enroll after receipt of multiple vaccine doses in this study (parents of young children, persons of white race, etc.), baseline symptom reports did not differ greatly between persons who took part after only 1 dose compared with participation after multiple doses. Hence, we found no evidence that reporting

reactogenicity to a previous vaccine dose influences participation after a subsequent vaccine dose. To date, no studies have investigated this phenomenon due to the need to access EHR for complete follow-up of a vaccinated cohort after multiple doses.

Public Health Implications and Future Directions

Overall, our study findings demonstrated the ability of an SMS text messaging- and internet-based self-reporting system to complement other existing vaccine safety surveillance systems. The findings can also inform the future design of similar digital systems that seek to optimize the direct involvement of the public as empowered stakeholders in scientific research [37]. Furthermore, the population sociodemographic of persons likely to participate in such systems will inform the interpretation of future clinical studies using similar tools. Given the rapid expansion of digital health technology, understanding the potential for biased outputs should remain a priority for health care researchers [34].

Limitations

There are some potential limitations to this study. First, the digital system was designed to operate almost entirely remotely, hence providing a real-world pragmatic overview of the scalability and uptake of our digital system. Consequently, patient usability was not formally assessed in a representative sample of users. However, previous studies incorporating usability surveys have generally lacked representativeness and were conducted among a small sample of participants due to feasibility constraints [22]. Second, although the long study period was a particular strength of this analysis, heightened media attention during the introduction of COVID-19 vaccines likely increased public awareness and possibly influenced participation during earlier months of the vaccine roll-out compared with later months. This could have explained the higher participation rate observed for older persons since they were eligible for vaccination earlier or among those invited through their Kaiser Permanente health care message center compared with other invitation channels because this contact route was halted after November 2021.

Conclusion

In this study, an SMS text messaging- and internet-based self-reporting vaccine safety system enabled reactions to be reported by vaccinees in real time within a large and diverse managed care population. Hence, these findings demonstrated the feasibility of digital systems as timely and scalable methods that could supplement existing vaccine safety surveillance platforms. Our findings also emphasized the importance of implementing such a system through a trusted health care system for higher participation rates and potential clinical follow-up. However, we observed lower participation among selected vulnerable populations, demonstrating the existence of barriers to participation in digital reporting tools. If self-reporting digital tools are to be used in public health, their reach must be optimized to ensure that their implementation is equitable.

Acknowledgments

This study was funded by the US Centers for Disease Control and Prevention but was solely conducted at Kaiser Permanente Southern California. The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention (CDC). Abstract

Background: Although at the base of the pyramid-shaped organization of the Rwandan health system, community health workers (CHWs) are central to the community-based management of disease outbreaks.

Objective: This mixed methods study aimed to explore the feasibility, acceptability, satisfaction, and challenges of a mobile health (mHealth) tool for community-based COVID-19 screening in Rwanda.

Methods: Two urban (Gasabo and Nyarugenge) and 2 rural (Rusizi and Kirehe) districts in Rwanda participated in the project (smartphone app for COVID-19 screening). A mixed methods approach was used to inform the feasibility (awareness and expectation), acceptability (use and perceived benefits), satisfaction, and challenges of the mHealth intervention. At the end of the project, CHWs were asked to complete a quantitative questionnaire on the use of and satisfaction with the app. Then, in-depth interviews and focus group discussions were organized with CHWs. A content analysis was performed on the transcripts.

Results: Overall, 383 CHWs were recruited and trained; 378 CHWs participated in the study. The mean age of CHWs was 36.7 (SD 6.6) to 45.3 (SD 9.9) years and most were women (237/378, 62.7%). More than 7000 people were registered with the use of the app and 20% were referred to a local COVID-19 testing facility. According to CHW reporting, the median number of people screened by each CHW ranged from 152 (IQR 70-276) for Nyarugenge to 24 (IQR 16-90) for Rusizi. COVID-19 positivity rates were higher in urban than rural districts: more than half of the CHWs in Gasabo reported a confirmed positive case versus only 2.4% for Kirehe and 15.4% for Rusizi. Despite the app being a novel tool, CHWs were well aware of the use of such a tool and had appropriate expectations. Acceptability and satisfaction were very high, with differences between urban and rural districts. Satisfaction was higher in Nyarugenge (72.8/100) and Gasabo (80.7/100) than in Kirehe (61.6/100) and Rusizi (64.5/100). More than 80% of the CHWs were willing to continue using the e-ASCov app, with the exception of CHWs in Kirehe (56.7%). The app was perceived as a tool to generate information on COVID-19, inform on the status of the pandemic, and help curb the spread of the pandemic in Rwanda. CHWs were satisfied with the app at all stages of its implementation in their districts.

Conclusions: In this proof-of-concept study, a smartphone app for screening COVID-19 was useful as an mHealth tool to be used by CHWs, with the potential to increase health system efficiency in an epidemic context. The context should be analyzed for generalization on a country-wide scale, both in case of an epidemic and to take into account certain conditions at the community level. Information is needed on the conditions of generalization and transferability of this type of app to other health conditions so that CHWs can be given their full place in a pyramidal health system.

Introduction

Since December 2019, the appearance of a new strain of coronavirus (SARS-Cov-2) has been at the origin of the current COVID-19 pandemic [1]. In Africa, the first case of COVID-19 was reported on February 14, 2020, in Egypt and on February 27, 2020, in Nigeria, sub-Saharan Africa. With lockdowns, curfews, closures of public places and businesses, and the suspension of international flights, the continent's public health leaders tried to contain the epidemic. Rwanda was greatly affected by the COVID-19 pandemic, with initially a majority of imported cases.

The Rwandan government, through the Ministry of Health and the Rwanda Biomedical Center, a national agency for developing and implementing public health programs, developed a nationwide plan to deal with the COVID-19 epidemic [2]. This action plan aimed to improve Rwanda's ability to prevent, rapidly diagnose, and effectively respond to the COVID-19 epidemic and was structured around prevention and management. Prevention activities were mainly based on epidemiological surveillance, human resources, patient transfer, hygiene reinforcement, social mobilization and coordination, and monitoring activities [3]. A multisectoral rapid response team was activated at central and local levels to respond to the pandemic [4].

The pyramidal organization of the Rwandan health system gives an important place to community health workers (CHWs) at the base of the pyramid. Rwanda has an important network of CHWs throughout the country. Their role is essential in the field of primary health care. These CHWs are the essential link between the population and the health care system at the community level. The activation of this network and the provision of simple and ergonomic tools for epidemic surveillance were seen as an effective and efficient way to combat this epidemic.

The experience of the Ebola epidemic in 3 sub-Saharan African countries (Guinea, Liberia, and Sierra Leone) showed that CHWs played a key role in controlling the epidemic, but it also highlighted the need to involve CHWs very early in the epidemic response to ensure optimal effectiveness [5,6]. Some health actors believed that with this COVID-19 pandemic, CHWs were more than ever indispensable in addressing the disease [7]. However, formal evidence was needed. Although long-term solutions to the pandemic would be based on the rollout of vaccines and effective treatments, digital technologies remained crucial in terms of detection during the pandemic.

In light of its strategic objectives to leverage opportunities and innovations of communication technology and essentially drive the transformation of Rwanda to a knowledge-based economy, Rwanda has embraced innovative technologies as part of the COVID-19 early case detection response [8]. In this regard, the Rwanda Biomedical Center and its partners (CIC de Nancy, and Institut Pasteur, Paris, France) launched the e-ASCov project (Utilisation des outils numériques par les agents de santé communautaire dans la stratégie d'endiguement et d'atténuation de l'épidémie de Covid-19 au Rwanda–une recherche-action). This project aimed to assess the involvement of CHWs and the use of digital tools (mobile health [mHealth] smartphone app) in managing the COVID-19 pandemic in Rwanda in 2020.

This study aimed to assess the feasibility (awareness and expectations), acceptability (use and perceived benefits), satisfaction, and challenges of an mHealth tool for community-based COVID-19 screening in Rwanda.

Methods

The e-ASCov Project

The e-ASCov project is an action-research project that enrolled, trained, and equipped CHWs in 4 administrative districts in Rwanda: 2 urban (Nyarugenge and Gasabo) and 2 rural (Rusizi and Kirehe). CHWs were equipped with a smartphone app (e-ASCov app) to detect and triage suspected COVID-19 cases at the community level and to propose referral to the health care system for appropriate management. A total of 400 CHWs were selected (100 per district) based on 2 criteria: age <50 years and availability and proficiency in the use of a smartphone. The project was carried out from November 2020 to December 2021. Phase 1 of the project emphasized training and equipping CHWs with the e-ASCov app, and facilitating them to use the app in their day-to-day activities. Phase 2 emphasized an evaluation of the implementation of the e-ASCov app for the management of the COVID-19 pandemic. A parallel mixed (quantitative and qualitative) method was used to highlight the implementation of the e-ASCov app for managing COVID-19 at the community level.

Ethical Considerations

This project was approved by the Rwanda National Ethics Committee (number 752/RNEC/2020) as well as the Rwanda

CHW Technical Working Group. The target population consisted of CHWs trained in the use of digital tools (e-ASCov app) for managing the COVID-19 pandemic. Informed consent was required from all participants before using the app, and they had the ability to opt out without any consequence. All data collected were anonymized and without the possibility of participant identification. No compensation was given to participants.

Data Collection

Quantitative Data

All CHWs were asked to complete a questionnaire at the end of the intervention (use of the e-ASCov app by CHWs). The questionnaire covered sociodemographic characteristics (sex, age, educational attainment, occupation, marital status, etc), the description of the intervention (number of persons screened, persons referred, confirmed cases), and satisfaction with the e-ASCov app. Satisfaction was measured on a 5-point Likert scale (very satisfied, satisfied, undecided/neutral, unsatisfied, very unsatisfied) that addressed the following dimensions: quality of training, availability of equipment, internet connectivity, simplicity/use of the tool, time needed to complete one record, getting technical assistance, delivery of service to clients, and continued use of the tool.

Qualitative Data

In-depth interviews (IDIs) and focus group discussions (FGDs) were conducted: 2 FGDs with CHWs and 2 with clients of CHWs per district (4 FGDs per district). Each FGD consisted of 8 participants, for a total of 64 CHWs and 64 clients. For the IDIs, a purposive sampling strategy was used to recruit key members of staff (who were not directly involved in using the app in the field) from the following 3 categories: COVID-19 taskforce members, data managers at central and district levels, and CHW supervisors at central and district levels. Qualitative data management and analysis involved verbatim transcription of interviews, translation, and thematic analysis. Interviews were conducted in Kinyarwanda, transcribed using Microsoft Word, and translated into English. The transcripts were cross-checked for quality by 2 analysts who compared audio records and scripts in Kinyarwanda, then with the English translation, considering what was directly said by the respondent. Each individual transcript was used for analysis.

Data Analysis

Qualitative and quantitative data were analyzed to address the question of feasibility (awareness and expectations), acceptability (use and perceived benefits), satisfaction, and challenges.

Quantitative Data

Sociodemographic characteristics are described with mean and SD for continuous and number (percentage) for categorical variables. We compared characteristics according to districts of participants by Student *t* test or chi-square test as applicable. Then we compared the number of persons screened with or without e-ASCov, persons referred to the district hospital, and confirmed cases by the district of the CHWs. A satisfaction score was calculated and normalized on a scale from 0 to 100 (highest satisfaction) for each dimension, and a global satisfaction score was calculated.

Qualitative Data

An inductive thematic analysis approach was used to analyze qualitative data in the following 6 areas: familiarization, coding (each code described the idea or the feeling expressed in the specific part of the text under the topic of discussion), generating themes and subthemes (ideas and patterns that came up repeatedly), reviewing themes, defining and naming themes, and writing up [9]. The analysis was conducted with Dedoose software (version 9.0.18), a web-based cross-platform for qualitative analysis and mixed methods research.

Results

Sample Characteristics

Of the 400 CWHs recruited, 378 CWHs completed the quantitative questionnaires (Gasabo region: n=93; Kirehe: n=97; Nyarugenge: n=90; Rusizi: n=98). The mean age of CHWs ranged from 36.7 (SD 6.6) to 45.3 (SD 9.9) years (Table 1). CHWs were mostly women (237/378, 62.7%) with primary or secondary educational attainment. CHWs were mostly unemployed in the districts of Gasabo (52/93, 55.9%) and Kirehe (71/97, 73.2%), whereas those from the 2 other districts were mostly employed (Nyarugenge: 53/90, 58.9%; Rusizi: 79/98, 80.6%). Most were experienced CHWs, with a mean number of years of experience of 7.3 to 10.1.

The IDIs involved 19 respondents: 5 CHW supervisors (2 at the central level and 3 at the district level), 5 CHWs from the COVID-19 taskforce (2 at the central level, 3 at the district level), 3 data managers from the district hospitals, 2 director generals of the hospitals, and 4 clinical directors at the district level. The FGDs involved 64 CHWs from all 4 districts included in this study.

[b]TVET: technical vocation education training.

[c]MCHC: maternal and child health coordinator.

[d]CEHO: community and environmental health officer.

Awareness of and Expectations for the e-ASCov App

Most respondents were aware of the e-ASCov app and believed that it was used to provide information on COVID-19. These respondents were located predominantly in urban districts (Nyarugenge and Gasabo).

> *e-ASCov is the application which is used by the community health workers to help people who are suspected of COVID-19 symptoms* [COVID-19 Taskforce, central level]

The CHWs, especially the respondents with the opportunity to use the app, considered it a tool to generate information on COVID-19.

> *Those who gave us training, they explained to us how to write a report on COVID-19 using forms for identified clients; after filling the forms, we could take them to the health center. That is how we worked* [CHW, Kirehe District, FGD]

> *About knowledge on e-ASCOv, I can tell you that we do not have any because the only training we received was on how to use the forms.* [CHW, Kirehe District]

The respondents expected the app to help inform on the status of the pandemic and help with community outreach on COVID-19. Even though some CHWs were not aware of the app and did not have any expectations, a number of them were expecting the e-ASCov app to help curb the spread of COVID-19. They also expected it to support an extension of the service to home-based care, provide support to cases, and improve CHWs knowledge and the app to be used by all CHWs.

> *What we have expected and still expect with current results is that the use of technology has impacted well in curbing the spread of COVID-19* [COVID-19 Taskforce, district level]

> *What we all expect is that the app contributes [to] the continuous fight against COVID-19, like getting information on time* [CHW supervisor, central level]

> *As I said, what we were expecting is to find out the status of the pandemic, and other measures that could be taken to prevent it because there is no other way to use it without the technology* [district director of health]

The CHWs' expectations were mostly that the app would provide an update on the status of the pandemic in their area. They thought that the detection of COVID-19 cases would lead to a decrease in the magnitude of the pandemic. In addition, some CHWs emphasized the app's contribution to early diagnosis and treatment and the opportunity to screen other health commodities as in their routine community-based health services. Some clients also considered that screening with the technology would reduce the burden of COVID-19.

> *What we expected was the results of using this application in helping Rwandans during the pandemic. We can say, like follow-up of the infected people before they get complications for them to receive early medical management, for the health system at central level to get information on time and all the people with the disease to be managed on time. I think that was what we expected and the results have been seen* [CHW, Gasabo District, FDG]

> *We expected to provide early and quick information if someone was having the signs and symptoms for the healthcare providers to provide early and timely care. Another thing that this application helped … and we expected … was data storage in a trusted way as we are moving from analogue to a digital world* [CHW, Nyarugenge District, FDG]

Use and Perceived Benefits of the App

According to CHW reporting, the median number of people screened by each CHW ranged from 152 (IQR 70-276) for Nyarugenge to 24 (IQR 16-90) for Rusizi (Table 2). Of these, few were referred to a health center for diagnostic confirmation, between 1 and 5 per CHW. In total, 48.4% and 47.4% of the CHWs sent more than 5 people screened to the health centers in Gasabo and Kirehe, respectively. Positivity rates were higher in urban than rural districts. For example, more than half of the CHWs in Gasabo reported a confirmed positive case, whereas this rate was only 23.7% for Kirehe and 15.4% for Rusizi. Only 2 CHWs from Gasabo declared a case of death.

A high number of respondents considered that the most perceived benefit of using the e-ASCOV app was the enhancement of information sharing about COVID-19, followed by timely decision-making and quick dissemination of information.

> *The first thing, information got to be known so fast and this helps to make measures* [district director of health]

> *The way of using e-ASCOV or technology in delivering services and information about COVID-19 pandemic is used to know information about the pandemic earlier, so that the information can reach … the decision makers, and the patients may get treated in a quick way because technology might be quick than the ordinary ways in delivering information.* [CHW supervisor, central level]

Some of the respondents believed that using e-ASCov app would benefit quick data retrieval and decision-making. Respondents also shared that the e-ASCov app would benefit in avoiding COVID-19 infection spread by enhancing information storage because it was paperless and time-saving.

> *The benefits that I have seen in our application that we visited every household and asked the questions in the application and found that he was seriously sick at home but did not know the symptoms of COVID-19 and I immediately advised the client to go to the health center and accompanied the client and treat him right away; that is the benefit I have seen.* [CHW from Gasabo District]

Satisfaction With and Challenges of the App

The satisfaction of CHWs is presented in Table 3. Overall satisfaction was higher in Nyarugenge (72.8/100) and Gasabo (80.7/100) than Kirehe (61.6/100) and Rusizi (64.5/100). More than 80% of CHWs were satisfied with the training offered before deployment of the app in all districts. In terms of availability of tools and internet connection, satisfaction was lower in rural than urban districts. More than 80% of the CHWs were willing to continue using the app, with the exception of CHWs in Kirehe (56.7%).

Table . Satisfaction (very satisfied/satisfied) of community health workers according to district.

[a]*P* value of χ^2 test for qualitative variables or Student *t* test for quantitative variables.

[b]Not applicable.

Most of the respondents stated that the main challenges were poor internet access or a poor network, CHWs having a low level of operational knowledge, lack of access to smartphones, and the shortage of equipment. Challenges were the lack of CHWs' incentive and internet fees, use of a personal cell phone, low number of trained CHWs, limited access to electricity by CHWs, incompatibility of the app with CHWs' cell phones, inability to use the app, inability to edit and correct an error, older CHWs feeling excluded, and the inability to retrieve information. The CHWs viewed the lack of smartphones as a factor that impeded reporting via the e-ASCov app. The poor internet connectivity was also highlighted by most of the CHWs as a limiting factor for better access.

Discussion

Principal Findings

This project confirmed the central position of CHWs in an effective strategy to deal with a pandemic such as COVID-19 in a pyramidal health system such as Rwanda's. By including 2 districts, 2 rural and 2 urban, we were able to show that this type of system was possible in the health systems of countries where CHWs play a predominant role. Qualitative and quantitative results were consistent, and there was enthusiasm for the e-ASCov app. The smooth organization of the CHW network and its fully integrated nature into the Rwandan health system ensured that the app was easily deployed. In an epidemic context, CHWs were able to use this app as a screening and prevention tool to stem the spread of the epidemic in each district. The CHWs were able to use the app for screening suspected cases at the community level and were largely satisfied. However, there were some slight differences, particularly between urban and rural districts. Therefore, the conditions of implementation and transferability of such an app on a national scale need to be investigated in a broader context.

Comparison With Prior Studies

This type of tool has been used in the African context for other diseases [10,11]. Although the use of the app was good in all districts, it was easier in urban than rural districts. This difference, beyond the organization of the CHW system in participating districts, seems to be linked to the level of education and CHWs' experience in implementing this type of action. Indeed, in the urban districts, three-quarters of the CHWs had a level of education higher than primary school, whereas in the rural districts, the opposite was true. In addition, the smoothness of the internet connection in urban districts was also identified as a facilitating factor in the use of the app. Duclos et al [12] stated that mHealth implementation in rural health districts is expected to present considerable challenges, including technological barriers, organizational challenges, gender issues, confidentiality concerns, and unplanned aftereffects.

The successful implementation of the e-ASCov app at the community level opens up several possibilities. This type of app could be used in an epidemic context and in community-based monitoring of certain chronic diseases or maternal and child health [13]. The Rwanda CHW program was established in 1995. It aimed to strengthen essential maternal and child health care services through the education of pregnant women, health promotion and risk behavior reduction, follow-up, and linkages with health services. Rwanda has more than 50,000 CHWs (4 per village) with an organization of 3 CHWs (3 different dedicated functions) for each 100 to 150 households. One CHW is in charge of maternal and child health (identifying pregnant women, accompanying the regular monitoring of the pregnancy, and ensuring that the delivery takes place in a health facility). Two CHWs are responsible for referral and integrated community-based management of diseases (assessment, classification, and treatment) such as diarrheal diseases, pneumonia, malaria, and malnutrition in children younger than 5 years; provision of community-based contraceptives; directly observed treatment surveillance for tuberculosis; and prevention of noncommunicable diseases. The fourth CHW is specifically responsible for the hygiene of the village population. This organization allows for the use of connected tools for screening and monitoring several other diseases.

Although the implementation and experience of CHWs seem to support the good acceptability and feasibility of this type of tool, a positive perception of the population receiving the intervention is also important. This perception should be ensured by raising the awareness of the population, especially in rural areas, to improve their literacy in relation to digital health tools. For e-ASCov, part of the population was not sufficiently informed of the use of e-ASCov app. Those who were aware of it stated that the system provides useful information about COVID-19.

> *According to that technology of e-ASCOV, they did not use it. I think they were not even having it. I agree with what others have said...* [client, Kirehe District, FGD]

Limitations

The first limitation is that the e-ASCov project was implemented in only 4 of the country's 30 districts, which may restrict confidence in a full generalization of results. To minimize representation bias, we selected the 4 districts according to their rural or urban character and their geographical location. The 2 urban districts are located in the capital, where most of the cases of COVID-19 were identified (imported cases). The 2 other rural districts were located at the 2 extremities of the country: Rusizi in the western region bordering the Democratic Republic of Congo and Kirehe in the eastern region bordering Tanzania. Another limitation was the significant spread of the epidemic throughout the country, so the use of this type of app was less effective and less appropriate. Indeed, when the prevalence of the disease becomes very large and the strategy is to learn to live with the virus, community-based screening becomes less relevant. However, beyond COVID-19, the e-ASCov project reinforces the idea that digital tools such as smartphone apps can be of great use in community health. Despite these limitations, the e-ASCov project is one of the first projects to include more than 400 CHWs who were trained to use the app and who screened several thousand potential cases over a year. The results of this study have led the country's health authorities to consider rolling out the app nationwide.

Conclusion

Findings from this study show proof of concept that the use of mHealth tools by CHWs can enhance their participation and contribution to an effective and resilient health system in low- and middle-income countries. A study is needed of the generalization and transferability conditions of this type of app to other health conditions to enable CHWs to be given their full place in a pyramidal health system.

Acknowledgments

Many people worked together selflessly and enthusiastically for the success of the e-ASCov project. The e-ASCov project group warmly acknowledges the community health workers, members of the Rwanda Biomedical Centre, and members of the Rinda Ubuzima Association who contributed to the project. We especially thank Florian Le Goff from Kelindi, a French start-up, for the contextualization of the digital tool. The e-ASCov project was funded by the French Agency for Research on AIDS and Viral Hepatitis (ANRS-MIE) and the Embassy of France in Kigali (Rwanda).

Abstract

Background: The COVID-19 pandemic accelerated the need to understand citizen acceptance of health surveillance technologies such as contact tracing (CT) apps. Indeed, the success of these apps required widespread public acceptance and the alleviation of concerns about privacy, surveillance, and trust.

Objective: This study aims to examine the factors that foster a sense of trust and a perception of privacy in CT apps. Our study also investigates how trust and perceived privacy influence citizens' willingness to adopt, disclose personal data, and continue to use these apps.

Methods: Drawing on privacy calculus and procedural fairness theories, we developed a model of the antecedents and behavioral intentions related to trust and privacy perceptions. We used structural equation modeling to test our hypotheses on a data set collected at 2 time points (before and after the launch of a national CT app). The sample consisted of 405 Irish residents.

Results: Trust in CT apps was positively influenced by propensity to trust technology (β=.074; *P*=.006), perceived need for surveillance (β=.119; *P*<.001), and perceptions of government motives (β=.671; *P*<.001) and negatively influenced by perceived invasion (β=−.224; *P*<.001). Perceived privacy was positively influenced by trust (β=.466; *P*<.001) and perceived control (β=.451; *P*<.001) and negatively influenced by perceived invasion (β=−.165; *P*<.001). Prelaunch intentions toward adoption were influenced by trust (β=.590; *P*<.001) and perceived privacy (β=.247; *P*<.001). Prelaunch intentions to disclose personal data to the app were also influenced by trust (β=.215; *P*<.001) and perceived privacy (β=.208; *P*<.001) as well as adoption intentions before the launch (β=.550; *P*<.001). However, postlaunch intentions to use the app were directly influenced by prelaunch intentions (β=.530; *P*<.001), but trust and perceived privacy only had an indirect influence. Finally, with regard to intentions to disclose after the launch, use intentions after the launch (β=.665; *P*<.001) and trust (β=.215; *P*<.001) had a direct influence, but perceived privacy only had an indirect influence. The proposed model explained 74.4% of variance in trust, 91% of variance in perceived privacy, 66.6% of variance in prelaunch adoption intentions, 45.9% of variance in postlaunch use intentions, and 83.9% and 79.4% of variance in willingness to disclose before the launch and after the launch, respectively.

Conclusions: Positive perceptions of trust and privacy can be fostered through clear communication regarding the need and motives for CT apps, the level of control citizens maintain, and measures to limit invasive data practice. By engendering these positive beliefs before launch and reinforcing them after launch, citizens may be more likely to accept and use CT apps. These insights are important for the launch of future apps and technologies that require mass acceptance and information disclosure.

Introduction

Background

The outbreak of COVID-19 and the ensuing global pandemic resulted in many governments undertaking digital government transformation [1] through the introduction of public health surveillance technologies including contact tracing (CT) apps [2,3]. As a result, and unlike previous health emergencies, governments had access to an unprecedented volume, variety, and velocity of location and health data [4]. The use of such data for epidemiological surveillance can aid in decision support, accelerate case identification, interrupt community transmission, and enable public health communication [5]. Notwithstanding these benefits, the pace at which these apps have been implemented and the level of surveillance they enable have raised ethical concerns [6] and fears around privacy and public trust [7].

The success of CT apps is dependent on uptake by large populations [8], and privacy-related concerns have been positioned as a critical barrier facing government-introduced CT apps [9]. Government-introduced CT apps differ from surveillance technologies and mobile health (mHealth) apps, as they combine both location-based data and electronic personal health information (ePHI). Both these contexts, in themselves, raise significant privacy concerns, particularly with respect to potential secondary use and government intrusion [10]. Thus, the COVID-19 pandemic presents a unique empirical context to explore citizens' perceptions of health surveillance using mobile apps that capture both location-based data and ePHI. Government-introduced CT apps constitute a new public health context. Although there is an established literature based on traditional CT, digital CT is an innovation that can only be fully explored during pandemics, and thus research opportunities are limited. Given the novel context for individuals and public health agencies, where the former engage with new or unfamiliar trust referents, it is particularly critical to explore how individuals marry competing beliefs about surveillance, trust, and government motives for introducing these technologies and how these beliefs influence their behavioral responses. Extant literature has demonstrated the importance of trust in the government in influencing CT adoption [11,12] and perceptions of CT technologies [13] and shown that privacy concerns represent a barrier to adoption [9].

Prior Work

This study builds upon important extant research focusing on the acceptance of CT apps to delve further into the role of privacy and trust and addresses 3 gaps in the literature. First, existing studies support the importance of trust in driving the acceptance of CT apps, but the approach to measuring trust and the trust referent under examination varies. For example, studies have found that high trust in the national government, the health care system, and science positively impacted willingness to use CT apps in Switzerland [14]. A US-based study found that trust in COVID-19 information positively influenced citizens' comfort with and acceptance of CT [8]. In this study, our emphasis is on technology-related trust, as opposed to trust in an individual or organization. Specifically, we examined trust perceptions regarding a specific technology, namely a CT app. In addition, we investigated the perceptual factors that shape trust, namely perceptions of government motivations, need for surveillance, and propensity to trust technology (PTTT).

Second, studies have investigated the influence of privacy on CT adoption, with many studies finding that privacy concerns reduce intentions toward adopt CT apps [11,14]. Several studies conclude that privacy represents a barrier to the success of CT apps, with respondents in several countries citing privacy concerns as a reason for not installing apps [9] or conversely, those with low privacy concerns are more likely to use CT apps [12]. However, the influence of privacy concerns on CT adoption intentions was weak in another study [15]. Although privacy concerns are the most common proxy for measuring privacy across many contexts, the negative connotation and failure to directly capture privacy suggest the need for more precise operationalization [16]. Thus, we focus on perceived privacy defined as "an individual's self-assessed state in which external agents have limited access to information about him or her" [16]. In this study, perceived privacy refers to a citizen's belief in the level of privacy afforded by the CT app. Perceived privacy influenced intentions toward CT apps in a recent Brazilian study, thus supporting its use [17]. To further our understanding of perceived privacy, this study investigated the role of trust, perceived control, and perceived intrusion in shaping citizens' perceptions of privacy.

Third, many CT studies are cross-sectional in nature, with the exception of a small number of longitudinal studies [12]. In addition, the literature focuses largely on whether citizens adopt CT apps or engage in behaviors recommended by CT apps such as staying at home [14,18]. This study broadens our understanding of citizens' acceptance of CT apps by examining 2 variables related to acceptance, namely intention to adopt or continue using the app and willingness to disclose personal information. These acceptance variables are measured before and after the app launch, thereby deepening our understanding of how privacy and trust influence intentions toward and use of CT apps.

We argue that understanding the determinants of success of CT apps is critical not only for future digital CT but also for other contexts that require rapid digital technology adoption by the population [19]. This paper proceeds with an overview of the hypothesized relationships and our research context. Our methodology, data analysis, and results are presented in the following sections. The *Discussion* section outlines the implications of this study. The paper concludes with the limitations and avenues for future research.

Theory

Overview

Privacy Calculus Theory (PCT) posits that before engaging in a behavior such as adopting a new technology or disclosing personal information, individuals will conduct a cognitive comparison of the costs and benefits associated with this behavior [20]. Individuals are likely to engage in the behavior for as long as the benefits outweigh the costs [20]. Thus, PCT has direct comparisons with the concept of calculus-based trust,

which underpins trust decisions when engaging with new or unfamiliar trust referents [21]. PCT has been operationalized in many contexts using a variety of belief-based variables that can be grouped into confidence beliefs and risk or privacy beliefs. An extension of PCT that holds considerable promise for understanding privacy and trust in the context of CT apps is the inclusion of the procedural fairness theory. Procedural fairness refers to an individual's perception that a particular activity is conducted fairly [22]. In the context of information privacy, fairness refers to the perception that personal data are collected and used fairly. Culnan and Armstrong [22] proposed that perceptions of procedural fairness can help citizens to "strike a balance between the competing forces of privacy and information use." Individuals' perceptions of the fairness of an organization's data collection and use practices can influence their decision-making related to technology use and information disclosure [23]. In this study, we investigated the drivers of trust and privacy through the procedural fairness lens, which suggests the importance of factors related to the legitimacy of data collection (ie, the need for government surveillance and perceptions of the government's motive for the app), the costs to the citizen (ie, perceived intrusion), and the level of autonomy and input citizens are afforded (ie, perceived control). Furthermore, the wider literature on fairness and trust suggests that individual differences in citizens' PTTT are likely to play an important role alongside procedural fairness perceptions in trust [24], particularly given the unfamiliar referent of the CT app. In addition, the theory of reasoned action (TRA) allows us to consider the influence of these perceptions on behavioral outcomes. The TRA argues that individuals' behaviors are determined by their beliefs, attitudes, and intentions [25]. We propose that individuals will express positive intentions toward downloading the app and disclosing information if they believe that the app demonstrates fairness.

Hypotheses

Trust is an important factor in the success of CT apps as demonstrated in recent studies [14]. Indeed, trust allows individuals to overcome concerns about uncertainty and fosters a willingness to engage in trust-related behaviors, such as disclosing information and engaging with technology [26]. In this study, our emphasis is on technology-related trust, which refers to individuals' beliefs that the technology in question will perform as expected [27]. Trust perceptions refer to the extent to which the CT app will consistently deliver the proposed services and act in citizens' best interest.

A significant body of theoretical work suggests that variables related to trust propensity are important drivers of trust perceptions [28], particularly in new and unfamiliar trust referents [29]. PTTT refers to a general tendency that is not specific to one trustee or situation but focuses on individuals' willingness to depend on technology across different contexts and technologies [27]. We propose that, in the current context, PTTT will positively influence trust in CT apps.

- *Hypothesis 1a: PTTT will have a positive association with trust in the app.*

Surveillance programs are often introduced following large-scale events such as terrorist attacks [30]. Given the public health emergency caused by the COVID-19 pandemic, the importance of surveillance technologies, such as CT apps, is clear. The link between surveillance and trust has long attracted discussion with Dutton et al [31], highlighting the existence of *trust tension* between the government's need to collect surveillance data and citizens' concerns about the excessive use of this information. They assert that developing trust is imperative for resolving this tension. As CT apps require the surveillance of large groups of people [32], citizens must understand the need for government surveillance in the general sense to build trust in a CT app. Need for government surveillance refers to individuals' perceptions that the government requires authority to access personal information using web-based means [33].

- *Hypothesis 1b: need for surveillance will have a positive association with trust in the app.*

Procedural fairness theory suggests that if individuals believe that the government's motivations to introduce the app are rooted in good intentions, such as reducing virus transmission, they will express higher trust in the app to perform consistently and with their best interests in mind. Indeed, a perception of benevolent motives is at the heart of theories regarding trustworthiness [28], and perceptions of trustworthiness at the government level are likely to trickle down to influence trust in related referents [34]. Accordingly, we posit that government motive will engender trust in the app.

- *Hypothesis 1c: government motive will have a positive association with trust in the app.*

Government surveillance technologies can garner negative opinions, which may lead individuals to alter their behaviors. Perceived intrusion is described as a "harmful incursion into the personal information space" [35]. This relates to procedural justice and individuals' perceptions of whether data are collected fairly in the CT app. Government surveillance technologies can be viewed as intrusive, but not all intrusions are considered harmful [35]. For example, the CT app may be viewed as intrusive, but as data are collected to reduce virus transmission, some individuals may not view this as harmful. Thus, only if individuals believe that the intrusiveness of the app is harmful to them, then their trust in the app is likely to be reduced.

- *Hypothesis 1d: perceived intrusion will have a negative association with trust in the app.*

Studies have asserted that privacy concerns represent a barrier to the success of CT apps [14,36]. However, there is a lack of research examining *if* citizens are likely to accept CT apps when they perceive that they provide some level of privacy. As perceived privacy refers to a perception that access to personal information by external agents is limited, the relevance of perceived intrusion as a privacy cost resulting from the use of an app is apparent. Indeed, the potential of CT apps to violate citizens' privacy has been raised [36]. Thus, if individuals believe that the app is intrusive in a harmful manner in their informational space, they are less likely to believe that the app affords them privacy.

- *Hypothesis 2a: perceived intrusion will have a negative association with perceived privacy.*

Perceived control is described as individuals' perceptions of their ability to control their personal information [37]. If individuals perceive that they maintain control over their information when transacting with a technology, they are more likely to feel comfortable that the technology will not act in a harmful manner [37], strengthening their perception of privacy in that context. A recent study supports the positive association between perceived control and perceived privacy of CT apps in Brazil [17]. We proposed that if individuals believe that they maintain control in the app, they will express higher levels of perceived privacy.

- *Hypothesis 2b: perceived control will have a positive association with perceived privacy.*

Finally, we argue that from a theoretical perspective, trust in the app will act as an uncertainty-reducing mechanism [38,39] and a heuristic that allows citizens to form privacy perceptions. Specifically, if citizens believe that the app will perform consistently and with their best interests in mind when using personal information, they will believe that the app provides some degree of privacy. This uncertainty reduction provides a foundation for facilitating other judgments of a technological artifact. Thus, trust in the app may influence perceptions of privacy.

- *Hypothesis 2c: trust in the app will have a positive association with perceived privacy.*

The success of CT apps is largely dependent on a critical mass of people downloading [40] and disclosing personal information. Thus, we draw on the TRA to consider 2 context-critical dependent variables: adoption intention and willingness to disclose personal information. Before the app launch, these variables were behavioral intentions. Adoption intention is described as an individual's internal subjective judgment of the probability that they will perform the behavior in question [25]. The willingness to disclose information is based on an individual's willingness to provide personal information when using the app [33]. Trust has repeatedly been identified as a driver of behavioral intentions across a range of contexts, including the acceptance of e-government technologies [41] and surveillance [30]. Indeed, behavioral operationalizations of trust often use behavioral intentions related to disclosure and reliance [42]. Empirical evidence suggests that perceived privacy influences intentions toward the use and data disclosure in general CT apps [17]. Although our study focuses on the privacy perception of a government-led CT app as opposed to general CT apps, we argue for similar effects. Finally, if individuals express high intentions toward downloading the app, we argue that they will be more willing to disclose personal information, as it is crucial to the app's functionality.

- *H3a-b: trust in the app before the launch (a) and perceived privacy (b) will have a positive association with adoption intentions before the launch.*
- *H4a-c: trust in the app before the launch (a), perceived privacy (b), and adoption intentions before the launch (c) will have a positive association with disclosure intentions before the launch.*

There have been calls for research to understand the perceptions of a technology before and after the launch [43]. In the context of CT apps, it is important to explore how both perceptions of privacy and trust influence individuals' behavioral intentions after launch. Thus, we examined both intentions after the launch. As some individuals may have already downloaded the app, adoption intentions are represented by future use intentions, which encompasses intentions to continue use among app users and intentions to adopt in the future among nonusers. TRA asserts that intentions will lead to behavior [44]. In other words, individuals' intentions to download the app before the launch will be positively related to their use intentions after the launch. We draw on the TRA to posit effects similar to those hypothesized for before the launch. We argue that trust perceptions regarding the app and perceived privacy will positively impact use intentions after the launch.

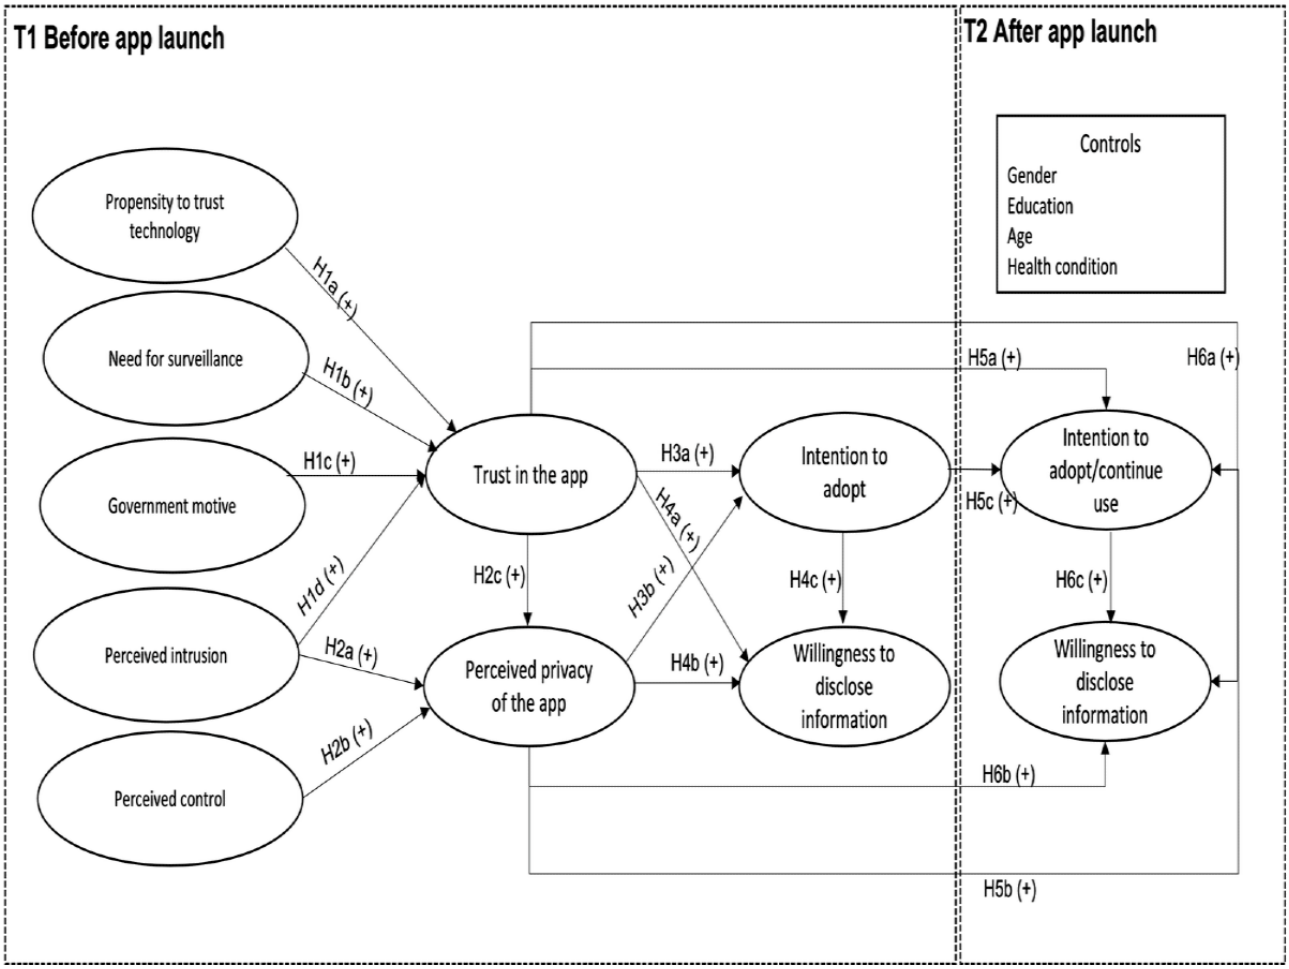
- *H5a-b: trust in the app (a) and perceived privacy (b) will have a positive association with intentions to use after the launch.*
- *H5c: adoption intentions before the launch will have a positive association with intentions to use after the launch.*

The influence of trust and privacy on the willingness to disclose a specific surveillance technology after the launch has not been explored. Again, we leverage the TRA intention-behavior link and our hypotheses before the launch and argue that trust and perceived privacy will positively impact willingness to disclose personal information after the launch. Finally, as was the case before the launch, we argue that if individuals express high intentions toward using the app after the launch, they will be more willing to disclose personal information.

- *H6a-b: trust in the app (a) and perceived privacy (b) will have a positive association with disclosure intentions after the launch.*
- *H6c: intentions to use after the launch will have a positive association with disclosure intentions after the launch.*

The hypotheses are depicted in Figure 1.

Figure 1. Research model.



Methods

Study Context

On July 6, 2020, the COVID Tracker app was launched in Ireland. COVID Tracker has 3 main features. CT uses Bluetooth and anonymous ID numbers to log phones within close contact for more than 15 minutes. It downloads the anonymous ID numbers of people who have tested positive and provides an alert if the user has been in close contact with those ID numbers. Check-in allows users to check for symptoms and seek health advice. The updates provide an overview of the daily COVID-19 figures. Within 48 hours of launch, 1 million people had downloaded the app [45]. By November 2021, the COVID Tracker app had over 1.7 million active users, representing 67% to 76% of the total possible Irish users [46].

Instrument Development

We used existing scales when developing our instrument with minor wording amendments to adapt the items to the context. We provide the full list of items in Table S1 in Multimedia Appendix 1. The survey at T1 included general constructs related to PTTT, the need for government surveillance, and situationally framed constructs related to the proposed app, namely government motive for introducing the app, trust in the app, perceived surveillance in the app, perceived control in the app, and perceived privacy in the app. The dependent variables included intention to download the app on launch and willingness to disclose personal information to use the app. At T2, the emphasis was on future behavioral intentions, namely the use of the app and information disclosure. At T2, we asked participants if they had downloaded the app, and app users' intentions to continue to use the app were examined and nonusers' intentions to download the app in the future were examined. These intentions were combined as use intentions for analysis. Willingness to disclose personal information to the app was examined across both users and nonusers of the app. In addition, gender, age, and education were used as the control variables. Respondents were asked if they had any health condition that left them particularly susceptible to COVID-19. This was also a control variable. Both surveys were piloted and tested among a small panel of survey design experiments, and several wording amendments were made. Respondents were asked to answer demographic and health questions first, followed by general perceptual constructs and control variables, the order of which was randomized. In the third section, participants were presented with a neutrally framed description of the proposed national CT app at T1, and a description of the launched app was presented at T2. The final section examined perceptions of the app, behavioral intentions, and willingness to disclose personal data, the order of which was randomized.

Ethical Considerations

Ethics approval was obtained from the university's research ethics committee before the launch of the survey (DCUREC/2020/096).

Recruitment

Qualtrics (Qualtrics International Inc) was used to host and administer the survey using their panel services. An attention check was included to screen for unengaged responses. A total of 1109 complete responses were received at T1 and were recontacted at T2. After 2 follow-up invitations, 405 responses were received at T2, achieving a response rate of 36.5%. Responses at T1 and T2 were, on average, 77 days apart. Incomplete responses and responses failing the attention check were removed using Qualtrics. The sample characteristics are illustrated in Table 1, along with the population characteristics as per the latest census at the time of data collection. Overall, the sample demographics were similar to the population characteristics of Ireland, as reported in the last census, and included respondents from the 26 counties within the country. Of the 405 respondents in T2, 202 had downloaded the app and 203 had not yet downloaded the app.

Table 1. Sample and population characteristics (N=405).

	Sample, n (%)	Population (%)[a,b]
Gender		
Man	180 (44.4)	49
Woman	225 (55.6)	51
Rather not say	0 (0)	N/A[c]
Age group (years)		
18-24	13 (3.2)	11
25-44	124 (30.6)	39
45-64	173 (42.7)	32

Doctorate degree	14 (3.5)	1

[a]Population figures are based on data provided by the Irish Central Statistics Office in the latest population census at the time of data collection (ie, 2016).

[b]Employment and education figures include all people aged ≥15 years living in Ireland in 2016, whereas our sample only includes people aged ≥18 years.

[c]N/A: not applicable.

Results

Reliability and Validity Testing

Data analysis was performed using IBM AMOS (version 25.0). The proposed model comprising 11 constructs was examined using Confirmatory Factor Analysis with further detail provided in Table S2 in Multimedia Appendix 1. In total, 3 items were dropped from the PTTT because of their low loadings. The model indicated a good fit: c_{min}/df=1.805, comparative fit index=0.980, root mean square error of approximation=0.045, and standardized root mean squared residual=0.034. A test of equal specific bias was conducted to examine potential common method bias among the data [47]. This test demonstrated an unevenly distributed bias; thus, the specific bias construct was

retained for causal analysis to control for any effects because of method [48]. The validity and reliability of all the constructs were explored. Convergent validity was assessed by calculating the average variance extracted (AVE). As all the variables had AVE scores above 0.500, convergent validity was achieved [49]. Discriminant validity was tested by comparing the square root of the AVE with the interconstruct correlations. As the square root of AVE was higher than the interconstruct correlations, discriminant validity was achieved, as shown by the italicized diagonal values in Table 2. Reliability was assessed by calculating composite reliability for each construct. With composite reliability scores above 0.700, all constructs were reliable [50]. Further details on the validity testing are provided in the supplementary appendices available on the web.

Table 2. Validity and reliability statistics.

	Composite reliability	Average variance extracted	1	2	3	4	5	6	7	8	9	10	11
Need for Surveillance	0.868	0.526	*0.725* [a]	—[b]	—	—	—	—	—	—	—	—	—
Propensity to trust technology	0.870	0.626	0.183[c]	*0.791*	—	—	—	—	—	—	—	—	—
Perceived control	0.967	0.879	0.329[d]	0.210[d]	*0.938*	—	—	—	—	—	—	—	—
Willingness to disclose information (T1)	0.983	0.966	0.378[d]	0.271[d]	0.682[d]	*0.983*	—	—	—	—	—	—	—
Intention to adopt (T1)	0.990	0.970	0.342[d]	0.270[d]	0.666[d]	0.872[d]	*0.985*	—	—	—	—	—	—
Perceived intrusion	0.932	0.820	−0.181[e]	−0.109[e]	−0.471[d]	−0.508[d]	−0.397[d]	*0.906*	—	—	—	—	—
Trust in App	0.916	0.786	0.365[d]	0.336[d]	0.702[d]	0.814[d]	0.784[d]	−0.491[d]	*0.886*	—	—	—	—
Perceived Privacy in App	0.962	0.895	0.371[d]	0.259[d]	0.852[d]	0.801[d]	0.753[d]	−0.603[d]	0.852[d]	*0.946*	—	—	—
Intention to adopt or use (T2)	0.991	0.973	0.234[d]	0.167[e]	0.500[d]	0.612[d]	0.658[d]	−0.347[d]	0.574[d]	0.548[d]	*0.986*	—	—
Willingness to disclose information (T2)	0.985	0.970	0.309[d]	0.241[d]	0.537[d]	0.678[d]	0.666[d]	−0.401[d]	0.686[d]	0.646[d]	0.844[d]	*0.985*	—
Government motive	0.971	0.894	0.246[d]	0.332[d]	0.550[d]	0.682[d]	0.654[d]	−0.378[d]	0.799[d]	0.658[d]	0.494[d]	0.575[d]	*0.946*

[a]As the square root of AVE was higher than the interconstruct correlations, discriminant validity was achieved, as shown by the italicized values.

[c]Significance at 10% level.

[d]Significance at 1% level.

[e]Significance at 5% level.

Hypotheses Testing

The causal model was tested using Structural Equation Modeling in AMOS. The model indicated a good fit c_{min}/df=2.835, comparative fit index=0.985, root mean square error of approximation=0.067, and standardized root mean squared residual=0.021. H1a-d focused on the antecedents of trust in the app. H1a proposed a positive relationship between PTTT and trust. The data revealed a positive, significant relationship supporting hypothesis 1a (β=.074; *P*=.006). Hypothesis 1b posited that the perceived need for government surveillance would positively influence trust. This was also supported (hypothesis 1b: β=.119; *P*<.001). H1c posited that government motive would be positively related to trust. The data supported the hypothesis (hypothesis 1c: β=.671; *P*<.001). The negative relationship between perceived intrusion and trust was supported (hypothesis 1d: β=−.224; *P*<.001). The following set of hypotheses examined the antecedents of perceived privacy. Hypothesis 2a proposed a negative association between perceived intrusion and perceived privacy. These data supported hypothesis 2a (β=−.165; *P*<.001). We hypothesized that perceived control and trust would be positively related to perceived privacy. Both relationships were supported (hypothesis 2b: β=.451; *P*<.001; H2c: β=.466; *P*<.001).

In terms of T1 behavioral intentions, it was posited that perceived privacy and trust would positively influence the intention to adopt. Both relationships were supported (hypothesis 3a: β=.247; *P*<.001; hypothesis 3b: β=.590; *P*<.001). H4a-c proposed that trust, perceived privacy, and adoption intentions would positively influence willingness to disclose personal information. The data revealed that trust (β=.215; *P*<.001), perceived privacy (β=.208; *P*<.001), and adoption intentions (β=.550; *P*<.001) each positively influenced willingness to disclose. In terms of T2 behavioral intentions, hypothesis 5a to 5c proposed that trust, perceived privacy, and adoption intentions (T1) would all influence use intentions (T2). Both trust (β=.124; *P*=.15) and perceived privacy (β=.042; *P*=.60) had a positive but nonsignificant influence on intentions. T1 adoption intentions significantly influenced use intentions

supporting hypothesis 5c (β=.530; *P*<.001). Finally, trust, perceived privacy, and use intentions at T2 were proposed to positively influence the willingness to disclose at T2. Perceived privacy (β=.042; *P*=.40) had a nonsignificant influence, whereas trust and use intentions had significant relationships supporting hypothesis 6a and hypothesis 6c (hypothesis 6a: β=.250; *P*<.001; H6c: β=.655; *P*<.001). In terms of control variables, COVID-19 vulnerable illness had a significant negative effect on individuals' willingness to disclose at T1 (β=−.043; *P*=.009), and education had a positive effect on T2 use intentions (β=.075; *P*=.04).

The model explains 74.4% of variance in trust, 91% of variance in perceived privacy, 66.6% of variance in T1 adoption intentions, 45.9% of variance in T2 adoption intentions, and 83.9% and 79.4% of variance in willingness to disclose at T1 and T2. Bootstrapping using 2000 samples and a confidence level of 90% was conducted in AMOS to explore the indirect effects. The findings revealed that perceived privacy had a significant influence on T2 adoption intentions (β=.131; *P*=.001) and willingness to disclose at T2 (β=.127; *P*=.04). Similarly, trust had a significant influence on intention to download (β=.394; *P*<.001) and willingness to disclose at T2 (β=.386; *P*<.001). Further detail is provided in Table S3 in Multimedia Appendix 1.

Discussion

Principal Findings

This study focuses on understanding how citizens' beliefs shape their perceptions of privacy and trust to influence their acceptance of a CT app for COVID-19. Our study found that trust in the app was positively influenced by the PTTT, perceived government motive, and perceived need for government surveillance, whereas perceived intrusion had a negative influence. Perceived privacy was positively shaped by perceptions of control and trust and negatively shaped by perceived invasion. The study examined citizens' acceptance of CT app at 2 time intervals. Before launch, the intention to adopt the app was positively influenced by trust and perceived privacy, and willingness to disclose personal information to the app was influenced by adoption intentions, trust, and perceived privacy. However, postlaunch use intentions were influenced only by prelaunch adoption intentions, whereas willingness to disclose personal information was influenced by trust and postlaunch use intentions but not by perceived privacy. Although the insignificant results may suggest that perceived privacy is only important before launch, and the influence of trust on use intentions diminishes over time, post hoc bootstrapping analysis revealed that both perceived privacy and trust had significant indirect relationships with use intentions and willingness to disclose information at T2. This suggests that both perceptions play a role in influencing behavioral intentions before and after the launch.

Contributions

Studies have shown that trust and privacy are important factors in the success of health surveillance technologies such as CT apps [11]. Our study leverages the procedural fairness theory to understand how citizens' perceptions of trust and privacy emerge in the context of a CT app. This context is interesting, as the technology in question was introduced by the national government and backed by several organizations with the app's potential benefits extending to the public at large. Therefore, it is important to look beyond the role of a single organization in driving perceptions of fairness to consider a broader set of antecedents that drive perceptions of trust and privacy in this context. Indeed, as research has shown the importance of trust and privacy in the success of mHealth and health technologies introduced by health care organizations and indeed national health systems [51], our study contributes to the broader health technology literature.

The first contribution of our study is the deeper understanding of how trust is formed in this context. Lack of trust in the government has been identified as a barrier to CT app adoption [18]. Thus, it is important to provide governments and public health organizations with insights into how trust in CT can be fostered [8]. Our findings bolster assertions regarding the important role of fairness perceptions and suggest that citizens' trust perceptions regarding the app are formed based on their beliefs about the legitimacy of data collection, perceived autonomy, and perceived costs. Legitimacy is represented by citizens' perceptions of the need for government surveillance and perceptions of the government's motive for introducing the app, autonomy is captured by perceptions of control over one's information in the app, and perceived costs to the individual relate to perceptions of personal intrusion.

The second contribution of our study is the investigation of how perceptions of privacy are formed. Many studies have highlighted the negative impact of privacy concerns on CT adoption [11,52-54]. However, we argue that privacy can be seen as a factor driving adoption if citizens believe that apps can afford them with some level of privacy. Our findings demonstrate that citizens' privacy perceptions are shaped by trust in the app, which encompasses legitimacy perceptions and their perception of control offered by the app, and are negatively influenced by perceptions of intrusion. By highlighting the importance of fairness perceptions and elucidating the role of several perceptual factors at the governmental level (need for surveillance and government motives) and the app level (perceived intrusion and perceived control), which have been sparingly studied to date, our study advances our understanding of how privacy perceptions are developed in this context.

Understanding the factors driving CT app acceptance is paramount for future outbreaks [8]. The third contribution relates to understanding how citizens form intentions toward CT apps at different stages of the implementation process. Our study provides support for the influence of perceived privacy on individuals' intentions to adopt an app and willingness to disclose personal information before launch and support for an indirect influence over time on future use and willingness to disclose data. This finding supports many studies that found that privacy concerns negatively impacted adoption intentions toward mHealth [51]. In the context of a national CT app, if individuals perceive that the app offers a sufficient state of privacy, they will express positive intentions toward adoption and information disclosure before and after the app launch. Put

simply, perceived privacy can have a sustained positive influence on behavioral intentions.

Trust has been widely studied within the privacy and other domains to understand individuals' intentions to disclose information [42]. Trust in the app was found to influence individuals' adoption and disclosure intentions before launch, indirectly influencing use intentions after launch and directly influencing disclosure intentions after launch. These findings suggest that the influence of initial trust perceptions prevails over time and may operate as a heuristic for interacting with the app on an ongoing basis. The stability of trust perceptions and their ongoing influence are a relatively nascent topic, although some theorists have suggested the possibility of trust as a heuristic [55]. Our research provides empirical evidence for this phenomenon and offers further support for claims that initial trust perceptions might be relatively robust and long acting [56].

Implications for Practice

The findings of this study have several practical implications. First, the trust tension between public good and the intrusiveness of surveillance technologies has led researchers to emphasize the importance of effective trust-building strategies when introducing surveillance programs [31]. Indeed, citizens in the United States and Germany have expressed concerns regarding possible surveillance stemming from CT apps [9]. Our study shows that citizens' perceptions of trust and privacy can be influenced by fairness perceptions based on their beliefs regarding the need for surveillance and the government's motives for introducing surveillance technologies, the perceived control they are offered over their personal information and negatively influenced by their perceptions of the intrusiveness of these technologies. Thus, governments should focus on transparency in their public health surveillance efforts, including the involvement of data protection authorities and civil liberties advocates throughout the project life cycle, potentially through a privacy advisory committee [57]. This transparency should be extended to communication with citizens on the need and purpose of a technology while stressing the control they have over their personal information. Our research suggests that early communications that shape first impressions are particularly important. Such practices not only comply with data protection laws, such as the EU (European Union) General Data Protection Regulation, but also foster a sense of trust and ultimately influence the use of technology.

Second, our findings highlight the positive influence of privacy perceptions on adoption and disclosure. Thus, we argue that privacy should not be viewed as a barrier to new technologies, such as mHealth or CT apps, but rather as an important consideration throughout the design, implementation, and postlaunch stages. Designers should ensure compliance with the regulatory requirements for consent and control. Governments and other organizations charged with introducing new technologies should ensure that they clearly communicate their compliance with regulations and the considerations of individuals' personal data. Given that CT apps provide data on the location, copresence, and potentially ePHI of not only the focal person but also others that they have been in contact with, the principles of both necessity and proportionality would appear to be key. As per Ienca and Vayena [4], data collection must (1) be proportional to the seriousness of the public health threat, (2) be limited to what is necessary to achieve a specific public health objective, and (3) be scientifically justified. Policy makers and public health decision makers need to consider what communication and control mechanisms can be introduced to (1) build trust with the public and (2) repair trust, if necessary. This includes declaring what data will be collected and used while the app is live and by whom, confirming that data have been deleted, when no longer relevant (as is the case with COVID-19 data) or once the app is no longer required.

Third, in the context of technologies that require mass acceptance and willingness to share personal data, the focus cannot be placed solely on the number of downloads but must account for actual use and disclosure behaviors. Individuals' intentions to download CT apps influence their willingness to disclose personal information both before and after launch. Once they have downloaded the app, it is critical that decision makers encourage use and that the widespread use of the app is linked, through public communication, to successful intervention strategies so that the benefits to the individual and society are reinforced.

Limitations and Directions for Future Research

This study has several limitations. First, other factors may influence privacy and trust perceptions or moderate the relationships between trust and privacy and adoption. Although it is not possible to consider all potential antecedents and intervening variables, it would be interesting to explore the role of other prominent perceptions, such as perceived sensitivity, as these apps require users to disclose identifying information, health information, and location information, all of which are arguably sensitive. Second, although our study considers 2 important technology use outcomes, before and after the launch, this approach has limitations. First, the collection of data from the same respondents at multiple time points inevitably led to a drop in responses. Although we sent repeated invitations during the second phase of data collection, the final sample that completed both surveys was smaller. Although this is commonplace within this approach and our sample characteristics are similar to the broader population of Ireland, we acknowledge that a large sample would be ideal and stress the importance of considering the sample size when drawing inferences from our study. Second, our 2 time points did not allow us to take full advantage of the potential to model longitudinal change trajectories over time. Further work is needed to incorporate time more fully into our understanding of how privacy and trust influence adoption and use behaviors.

Third, our study relies on individuals' self-reported adoption and disclosure intentions. This approach is commonplace in the privacy and technology adoption literature streams, and it would not have been possible to study actual behaviors. However, we must acknowledge that intentions are not always matched with behaviors and that information disclosure is not always accurate or true. In other settings, it may be more feasible to collect more objective behavioral data, and we would encourage researchers to do so, particularly in settings where widespread adoption is

required for success. In addition, studies may go beyond our focus to understand disclosure behaviors at a deeper level and examine privacy-protective behaviors, such as withholding information or falsifying information. These protective behaviors are potentially dangerous in contexts such as CT apps because of the reliance on accurate data to track virus transmission.

Finally, our study explores a public health surveillance context where the focal person volunteers to participate and therefore has notice of the surveillance, control of their data and gives explicit consent. There are several conditions under which public health surveillance, including name reporting, may be undertaken without notice or explicit patient consent with well-established justifications in public health ethics, science, and law [58]. Even in the context of COVID-19, digital CT has not always been voluntary. In China, there is evidence of digital CT without notice or consent [59]. Furthermore, even when the focal person has notice and gives consent, contacts of the focal person have not given explicit consent. Although the primary focal person is subject to direct active surveillance, the secondary focal person is subject to passive indirect surveillance. In addition to the ethical issues that such practices raise, particularly where there is coordination and data exchange between private firms and the government [60], testing the theoretical framework developed in this study in this new context may provide a fruitful avenue of research. Similarly, aggregated anonymous spatiotemporal data sourced from commercial providers have been used as proxies for human movement and social interaction and as indicators of the effectiveness of social distancing interventions [61]. Although these data are currently anonymous, governments have already mandated access to identifiable data on the basis that the public interest overrides privacy rights [62]. This context may provide interesting insights and further extend our understanding of the limits of consumer acceptance of governmental health surveillance.

Conclusions

The COVID-19 pandemic was the first time governments implemented large-scale digital CT. Its success as a public health intervention depended on rapid technology adoption by a significant proportion of the population. Here, surveillance is active, and the target of government surveillance through COVID-19 digital CT apps is an active participant in sharing data with the government on their personal health status, their location, and often their social network. The opportunity to study such an empirical context is not only rare but also the time frame for research is limited. Understanding the formation of individuals' perceptions of trust and privacy in this context and how these perceptions influence their acceptance of digital CT apps is critical not only for informing the design of future digital CT initiatives but also for other situations that require rapid digital technology adoption by a significant proportion of society. If governments wish to leverage the power of digital technologies to control future public health threats, we recommend 3 principles to guide the design of both their surveillance initiatives and communications with the public—necessity, transparency, and proportionality—before and after the launch.

Abstract

Background: As smart speakers become more popular, there have been an increasing number of studies on how they may benefit older adults or how older adults perceive them. Despite the increasing ownership rates of smart speakers among older adults, studies that examine their integration and the long-term use in older adults' daily practices are scarce.

Objective: This study aims to uncover the integration of smart speakers into the daily practices of older adults over the long term, contributing to an in-depth understanding of maintained technology use among this demographic.

Methods: To achieve these objectives, the study interviewed 20 older adults who had been using smart speakers for over 6 months. These semistructured interviews enabled participants to share their insights and experiences regarding the maintained use of smart speakers in the long term.

Results: We identified 4 dimensions of the long-term use of smart speakers among older adults, including functional integration, spatial integration, cognitive integration, and semantic integration. For the functional integration of smart speakers, the study reported different types of use, including entertainment, information collection, medication reminders, companionship, environment modification, and emergency calls. For the spatial integration of smart speakers, the study showed older adults' agency in defining, changing, and reshaping daily practices through the spatial organization of smart speakers. For the cognitive integration of smart speakers, the findings showed the cognitive processes involved in adapting to and incorporating smart speakers into daily habits and routines. For the semantic integration of smart speakers, the findings revealed that older adults' enjoyable user experience and strong bonds with the device contributed to their acceptance of occasional functional errors. Finally, the study proposed several suggestions for designers and developers to better design smart speakers that promote maintainable use behaviors among older adults.

Conclusions: On the basis of the findings, this study highlighted the importance of understanding how older adults use smart speakers and the practices through which they integrate them into their daily routines. The findings suggest that smart speakers can provide significant benefits for older adults, including increased convenience and improved quality of life. However, to promote maintainable use behaviors, designers and developers should consider more about the technology use contexts and the specific needs and preferences of older adults when designing these devices.

KEYWORDS

smart speaker; private home; older adults; long-term use; daily practices; smart speakers

Introduction

Along with the advancement of speech technology and artificial intelligence, smart speakers such as Google Home and Amazon Echo are becoming integral to households [1]. Equipped with smart voice assistants such as Google Assistant and Amazon Alexa, these devices respond to voice commands, facilitating activities like playing music, answering questions, setting reminders, and controlling smart home appliances. Their speech input and output features enhance accessibility, especially for individuals with limited mobility and vision [2,3].

In the realm of health care, the adoption of smart speakers has opened avenues for significant advancements, akin to the transformative impact of mobile phones. These devices present unique advantages for health research in out-of-hospital environments, offering opportunities for chronic disease management, passive identification of medical emergencies, detection of behavioral and cognitive changes, and remote monitoring of respiratory diseases impacting public health [4,5]. A range of successful pilot studies has demonstrated the positive impact of smart speakers on users requiring social care, and adults with learning differences, showcasing potential cost savings and improved well-being [6,7].

Despite the potential benefits, scholars have highlighted a notable gap in knowledge concerning older adults' experiences with smart speakers in long-term use, which poses challenges to assessing the long-term impact and implications of these devices on the well-being and quality of life of older adults. Specifically, while research has explored smart speaker use among various demographics, such as low-income populations [8,9], people with disabilities [10,11], parents [12,13], and children [14], studies specifically focusing on the older adult demographic remain relatively scarce [3,15]. Among the limited studies, the majority of the existing literature concentrates on the design of smart speakers for later life, encompassing discussions on effective conversational cues [16], privacy concerns [17], and the anthropomorphism of speakers [18]. Other studies have assessed the feasibility and usability of smart speakers for promoting active aging [19,20], investigated older adults' first impressions of smart speakers [19,21], and identified influential factors regarding older adults' attitudes toward smart speakers [22]. The most recent studies emphasized there is a missing knowledge about older adults' experiences with smart speakers in long-term use. This knowledge gap hinders the development of tailored interventions and policies to maximize the benefits of smart speakers for this demographic, ensuring their inclusion in the digital revolution and promoting healthy aging in the digital era [23-25]. Consequently, there is a pressing need for comprehensive exploration into older adults' long-term experiences with smart speakers, emphasizing their perceptions, attitudes, and the evolving nature of their interactions with this technology.

This study aims to understand how older adults routinely use smart speakers and integrate them into their daily lives. The outcomes can add to the emerging body of literature for a more comprehensive understanding of older adults' use of smart speakers in the long term. We conducted semistructured interviews with 20 older adults who used the smart speaker for over half a year, to answer the following research questions: "How does the use of smart speakers integrate into older adults' daily practices?" and "What design considerations can be generated from the long-term use of smart speakers by older adults?"

In summary, our study embarks on an exploration into the long-term experiences of older adults with smart speakers, filling a notable gap in the existing knowledge. While previous research has delved into aspects such as conversational cues, the feasibility of smart speakers for active aging, and the before-and-after adoption changes or the broader impact, the focus on the nuanced, day-to-day interactions of older adults with these devices over an extended period is a novel dimension that sets our study apart [26]. By unraveling the complexities and diverse experiences during older adults' long-term engagement with smart speaker technology, we aim to contribute not only to the effective design of age-friendly devices but also to the broader discourse on the role of technology in promoting well-being among older populations.

Methods

Study Design

A qualitative research study was conducted to investigate the experiences of older adults' long-term use of smart speakers in daily practices. Semistructured interviews were used to facilitate an in-depth exploration of older adults' experiences, even when the study involved a relatively small number of participants [27,28]. The study adhered to the guidelines and reporting standards outlined in the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist for qualitative studies [29].

Ethical Considerations

Ethical approval for the research was obtained from the research ethics committee of the Shanghai Jiao Tong University (H2022335I). Informed consent was obtained from all participants.

Participants and Recruitment

The research was conducted in Shanghai, China. To ensure diverse perspectives, participants were recruited from 2 distinct communities of older people—one situated in a bustling urban environment and the other in a rural area on the outskirts of the city. In the urban community, the researchers partnered with a community coordinator who had established relationships with older adults. In the rural community, the research team collaborated with the head of the older people's community, who was responsible for arranging community activities. The coordinator and the community head served as a liaison between the research team and the two communities to help in identifying suitable candidates.

The specific criteria for participant inclusion in the study remained consistent across both communities, requiring individuals to be aged 60 years or older and to have a minimum of 6 months of experience using a smart speaker in their homes. The time limit served to ensure that current practices of using

smart speakers were represented and to improve the reliability of experience recollection. Therefore, to be included in the study, participants needed to be aged 60 years or older and have had at least 6 months of experience using a smart speaker in their homes. Community members were thus excluded if they did not meet the age requirement, or had less than 6 months of experience with a smart speaker.

During the recruitment process, the research team first contacted the community coordinator or the community head, who shared the information about this research with all the members of the community. The older adults who met the inclusion criteria and showed their interest in participating in the study were recruited. The snowball approach was then used to identify more older adults using smart speakers for more than 6 months. Those who met the inclusion criteria were recruited as participants. The participants were compensated with gift cards (valued at around US $9) for interview participation. Ultimately, 20 older adults were recruited (Table 1). The sample size is in line with the recommendations by Guest et al [30] and Hennink et al [31], who pointed out that empirical data reached saturation within 20 interviews. Other qualitative literature about older adults' use of technology used a similar number of participants [24,32].

Table 1. Demographics of participants.

Label	Sex	Age (years)	Years of experience[a]	Technical proficiency[b]	Used smart speaker
OA1[c]	Female	72	2	Intermediate	Brand A
OA2	Female	66	0.5	Intermediate	Brand A
OA3	Female	69	1	Novice	Brand A
OA4	Female	71	1	Novice	Brand A
OA5	Male	73	3	Novice	Brand B
OA6	Male	67	2.5	Novice	Brand B
OA7	Male	68	0.5	Intermediate	Brand A
OA8	Female	61	0.5	Novice	Brand B
OA9	Female	73	2	Intermediate	Brand A
OA10	Female	66	2	Novice	Brand A
OA11	Male	77	1.5	Intermediate	Brand B
OA12	Female	65	2	Novice	Brand B
OA13	Male	73	1.5	Intermediate	Brand B
OA14	Female	64	1	Novice	Brand A
OA15	Female	73	1.5	Novice	Brand A
OA16	Male	73	1	Intermediate	Brand B
OA17	Male	62	0.5	Intermediate	Brand B
OA18	Male	64	1	Novice	Brand B
OA19	Female	69	2	Novice	Brand A
OA20	Female	70	1.5	Intermediate	Brand B

[a]The actual time that the participant starts to use the smart speaker regularly (self-reported).

[b]Individuals' ability to discern the usefulness of a smart speaker and their comfort in using it for various purposes (evaluated by the Artificial Intelligence Literacy Questionnaire proposed in [33], Multimedia Appendix 1).

[c]OA: older adult.

Data Collection

A literature review of technology use among older adults informed the development of a flexible and semistructured interview guide. The interview guide was developed in consultation with a professor with expertise in qualitative data collection and analysis. One preliminary interview was conducted with the included community coordinator (aged 58 years) to ensure the fluency of formal interviews (eg, whether questions are easy to understand). As the goal of our study was to better understand older adults' long-term use of smart speakers in home environments, the research questions were developed encompassing their practices, experiences, values, and expectations about using the smart speaker (Multimedia Appendix 2).

All interviews received written consent and were conducted in a private confidential environment such as the community activity room and private homes between November 2022 and September 2023. The participants were encouraged to give examples to contextualize their daily practices of using the smart speaker. The interviews ranged in length between 30 and 60 minutes. Participants who had limited knowledge or experience in using smart speakers had shorter interviews. All interviews

were audio-recorded. During the interview, we conducted regular summaries to ensure the validity of the collected data.

Data Analysis

All interviews were transcribed. The interview transcripts were reported in a way to ensure the anonymity of the participants. The collected data were interpreted by inductive content analysis [34], with a focus on how older adults use the smart speaker in their home environments, and why the speaker is used in the observed way. The transcripts were analyzed in NVivo (version 12; Lumivero) following the process proposed by Braun and Clarke [27]. After a data familiarization stage, 2 authors (FC and LS) separately extracted text segments related to the research goal and categorized them into codes. Applying an iterative process, the relationships between codes were analyzed and the subthemes were formed by grouping related segments together. The 2 authors compared the codes and subthemes and resolved any differences in coding through discussion. The assignment of text segments to the subcategories was repeatedly checked to see if they reflected the same meaning. Data saturation was determined when no new themes and relationships among the interview data were found [35]. As a result, a list of 4 themes and 12 subthemes, upon which the authors achieved an agreement, was generated [36].

Results

Overview

We identified 4 dimensions of the long-term use of smart speakers among older adults, including functional integration, spatial integration, cognitive integration, and semantic integration (Table 2).

Table 2. Identified themes, subthemes, and code examples related to the long-term use of smart speakers among older adults.

Themes and subthemes	Code examples
Functional integration	
Entertainment	• Using it for listening to music • Chatting with the small thing for fun • Telling some stories
Information collection	• Hear daily news • Weather information • A useful tool for knowing what is going on
Medication reminders	• The speaker can send out medication reminders • When I see it, I know, “Oh I need to take pills”
Companionship	• Enjoy hearing the speaker’s answers • The speaker is accompanying me, he is a friend • Love sitting in the coach, with her beside me
Environment modification	• Just need to say “Turn off the lights” • Connect it with the switch • Connect to the camera to show who is knocking on the door
Emergency calls	• Call for help if falling on the ground
Spatial integration	
Smart speaker location	• Decide the device’s location according to daily habits • Put it beside the medicine box for task convenience
Appliance connection	• Locate the smart speaker in the bedroom for device connection • Put the smart speaker beside the door for better internet • Put it on the bedside table for easily hearing the doorbells
Cognitive integration	
Learning and problem-solving	• Memorize the required voice commands • Handle the emerging technical hurdles
Mental adaptation	• Overcome skepticism and building trust • Realize the benefits of smart speakers for personal convenience
Semantic integration	
Enjoyable experience	• Save energy in memorizing things • Assist older adults in performing multitask operations
Affective bonds	• Feel a shared and caring presence through the technology use • Experience tranquility while reading with the smart speaker

Functional Integration of Smart Speakers

Functional integration relates to the ways in which older adults use smart speakers to meet various functional needs in their daily lives. This dimension focuses on the practical and functional aspects of smart speaker use and how they are integrated into daily practices. Our findings revealed the diversity of use genres that had been developed in older adults’ use of smart speakers in their living environments. Though most participants were using a smart speaker of the same brand, the ways of using the device were multiple, including entertainment, information collection, medication reminders, companionship, environment modification, as well as emergency calls.

The most commonly mentioned use genre was entertainment. Almost all participants said they use the smart speaker to listen to music.

> *...I often listen to songs [via the smart speaker]. Some songs could be used for our square dance.* [Female, age 69 years]

In addition to listening to music, 1 participant mentioned that he once used the smart speaker to recognize the name of a song.

> *...I was recalling the name of a song. My granddaughter told me if I sang the song’s melody, the speaker could tell me the song’s name.* [Male, age 73 years]

Similar to the example above, using the smart speaker for information collection was widely found in the interviews. Our participants used the smart speaker to gain information such as daily weather, local news, and safety tips related to the COVID-19 pandemic.

The smart speaker was also commonly used for medication reminders. The participants indicated that they had to always remember when to take medicines before using the smart speaker. With the help of their families or relatives, they set up the smart speaker to remind them to take medicines at a specific time.

> *...I have to take medicines every day.... Now the speaker can remind me of taking medicines.* [Female, age 66 years]

Besides, the participants emphasized that they benefited from the companionship of the device. The following example showed how older adults saw the smart speaker as a person who accompanied them, and enjoyed the conversation with the smart speaker.

> *...My smart speaker is a well-behaved little girl, just like my granddaughter. She wakes me up every morning. I say good morning to her sometimes. Sometimes I ask her some questions that I know the answers.... I am just curious about how she would reply to me, and enjoy hearing her answers.* [Male, age 73 years]

Another use genre was about environment modification. A few participants used the smart speaker to control other smart appliances in their living environments. For instance, 1 participant explained that the smart speaker helped overcome the inconvenience caused by switches that were in distant places.

> *The switch in my bedroom is beside the door.... I had to get out of bed, switch off the light, and then get into the bed in the darkness.... Now I just need to say "turn off the lights.*" [Female, age 72 years]

Finally, 1 participant mentioned that she had not used the smart speaker for emergency calls, but she knew she could call her daughters through the smart speaker or a "white button" when necessary.

> *I asked the smart speaker to call my daughter, her phone rang. I clicked the white button, her phone rang...[a white button, about 5 cm in diameter, is shown in her hand]*. [Female, age 61 years]

Spatial Integration of Smart Speakers

Spatial integration relates to the ways in which older adults use the physical space and placement of their smart speakers to shape and organize their daily routines. This dimension focuses on the physical aspects of smart speaker use. Our findings suggested that participants located their smart speakers in different living spaces, including the living room, the bedroom, the study, the bathroom, and the balcony. By spatially organizing the speaker, and connecting it with other smart appliances or daily tasks in these contexts, the participants built up the use contexts under which they are comfortable interacting with the smart speakers, and actively changed and reshaped their daily practices.

The following example showed how participants decided the locations of the smart speaker and formed new daily practices according to the purposes for using the smart speaker and the existing daily practices.

> *...I wanted to take the pills, I had to get water from the kitchen, so I put the speaker, together with the medicine box, in the corner of my kitchen now.* [Female, age 73 years]

Some participants incorporated the smart speaker by connecting it with the existing appliances in their living environments. In doing so, their practices of completing specific tasks were simplified.

> *...The light in my bedroom can be connected and controlled by the smart speaker, I thus put it in my bedroom. Now I just need to say "turn off the lights" when I want to sleep.* [Female, age 72 years]

Cognitive Integration of Smart Speakers

Cognitive integration relates to the way in which older adults adapt to and incorporate smart speakers into daily habits and routines from a cognitive perspective. Participants shared their experiences of familiarizing themselves with the smart speaker's user interface and functionalities. The impact of successful problem-solving was evident in the participants' narratives. Many acknowledged that navigating through and resolving issues not only enhanced their understanding of the device but also strengthened their overall intention to use the smart speaker in the long term. Overcoming learning or technical challenges contributed to a sense of accomplishment and increased confidence in using the smart speaker.

Almost all participants mentioned the challenges in learning voice commands and the overall functionality of the device, as well as resolving technical hurdles. They also mentioned the importance of adept problem-solving skills when facing these challenges. Some participants recounted instances of encountering glitches such as software malfunctions, intermittent connectivity issues, and occasional misinterpretations of voice commands by the smart speaker. One participant shared a specific experience, recalling:

> *There were times when it simply didn't respond, leaving me puzzled. I had to delve into troubleshooting methods to identify the issue.* [Female, age 64 years]

Another participant highlighted the initial difficulty in grasping the full range of functions, expressing:

> *Mastering the voice commands posed a bit of a challenge. Instead of saying "XX, I need..." you have to initiate with "Hi, XX."...took me some time to unravel the full range of functions it offered.* [Male, age 62 years]

In response to these challenges, older adults demonstrated resilience and resourcefulness in addressing technical issues. Problem-solving strategies ranged from seeking help from

family members or friends to experimenting with different emotional and cognitive aspects of smart speaker use. Some engaged in hands-on exploration, experimenting with different commands to enhance their functional and mental understanding. Additionally, participants discussed seeking guidance from families, internet-based resources, and user manuals to expedite the adaptation process. As 1 participant shared:

> *I watched some tutorial videos online and read the manual, and asked my family. It helped me get a better grasp of what the smart speaker could do.* [Female, age 65 years]

As smart speakers became integrated into daily routines, participants described making gradual adjustments. The learning curve transformed into a journey of mental adaptation, with older adults incorporating the device into activities such as setting reminders, checking the weather, or even incorporating it into their medication routines. One participant shared the experience of overcoming skepticism and building trust with the smart speaker over time.

> *I was skeptical at first...But as I gradually used it, I found myself relying on it more.* [Male, age 73 years]

The transformative power of smart speakers was evident in their ability to enhance social interactions during family gatherings. One user realized the potential of the device in this context, stating:

> *I realized the potential of using the smart speaker during family gatherings. Now, we use it to play music, share interesting facts, and even settle debates.* [Male, age 64 years]

Similarly, another user's experience highlighted the versatile nature of the smart speaker. Initially used for simple tasks like checking the weather and setting alarms, the device became a gateway to a multitude of possibilities.

> *Initially, I used it mainly for weather updates and setting alarms. But then, I discovered I could ask it to read audiobooks or provide cooking tips. It's like unlocking a treasure trove of possibilities.* [Female, age 70 years]

Semantic Integration of Smart Speakers

Semantic integration refers to the emotional and meaningful connections that older adults develop with their smart speakers over time. This dimension focuses on the emotional and cognitive aspects of smart speaker use. According to our data, although the smart speakers had occasional functional errors that annoyed the participants, all participants acknowledged, appreciated, and valued the benefits offered by using the smart speakers. The benefits included not only enjoyable experiences to complete daily tasks but also bonds with the device from an affective dimension. The enjoyable user experiences and the strong bonds with the smart speaker enhanced the participants' positive attitudes toward their device, making them feel that occasional functional errors were acceptable.

The participants claimed that the smart speaker enabled them enjoyable experiences such as helping them access more information and enjoy more forms of entertainment. Besides, some said the speaker empowered them to multitask and saved time and energy. Yet, looking solely at the daily tasks completed by smart speakers, participants thought the smart speakers were not unreplaceable. As 1 participant indicated:

> *Apparently the smart speaker makes the completion of some daily tasks easier...but if only looking at the tasks it supports, I feel it doesn't have that much uniqueness.* [Female, age 69 years]

The same person, however, emphasized that her affective bonds with the smart speaker meant a lot to her.

> *...what I feel uniqueness is the companionship offered by the smart speaker...by using it, I feel as if someone is experiencing every day together with me, and taking care of me.* [Female, age 69 years]

Other participants also emphasized the importance of companionship offered by the smart speaker. Some stated that they started to develop bonds with the smart speaker because of its capability for task completion, but the bonds were strengthened and maintained through the companionship over time, driving them to maintain their use behaviors.

> *...My son bought the smart speaker for me, because my friend in the community said it was convenient to listen to music.... Gradually [the speaker] becomes a "person" accompanying me.... I feel peace of mind when I am reading a book while he is just beside me, in the room together with me.* [Male, age 67 years]

The functional errors that emerged during the technology use were spontaneously mentioned by our participants. However, people looked at the errors with charity. Some even treated these errors as fun. For example, 1 participant mentioned that sometimes the smart speaker may be activated by the television sound.

> *Once, the leading actor said "I don't love you," the smart speaker replied "That is heartbreaking" [laughing].... I like it, I think these so-called "functional errors" are acceptable, but sometimes are also fun.* [Male, age 67 years]

In this case, the smart speaker was not viewed as a pure device whose fluency in function operations was prioritized. Instead, the participant treated the smart speaker as a social agent as its inappropriate responses activated by television was unexpected social actions (ie, conversations between different devices).

Discussion

Principal Findings

The study aimed to investigate how smart speakers are integrated into the daily practices of older adults in the long term. The findings of our study illuminate a nuanced understanding of how older adults seamlessly integrate smart speakers into their lives, encompassing functional, spatial, cognitive, and semantic dimensions. This integration aligns with existing literature, shedding light on the multifaceted benefits and challenges associated with the adoption of smart speaker technology among older populations.

Integrate Multiple: Functional, Spatial, Cognitive, and Semantic Technology Integration

The functional integration of smart speakers among older adults is characterized by a rich diversity of use genres, reflecting the adaptability of these devices to meet various needs. Entertainment emerged as a dominant use genre, with participants expressing a universal affinity for using smart speakers to listen to music, transforming the device into a musical companion for activities like square dancing. This aligns with previous studies emphasizing the role of smart speakers in enhancing leisure activities for older adults [37]. Beyond entertainment, the device's pivotal role in information collection, medication reminders, and environment modification resonates with literature, highlighting smart speakers as valuable tools for health management and home automation among older adults [38]. The potential for emergency calls, while not frequently used, aligns with the findings of studies emphasizing the importance of safety features for older adults [39]. The acceptance of smart speakers as reliable companions for various tasks aligns with the idea that these devices can address specific needs and preferences, contributing to the overall well-being of older users [40].

Spatial integration revealed how older adults strategically positioned smart speakers to shape and organize their daily routines. The participants allocated their speakers across diverse living spaces, from the living room to the bedroom, study, bathroom, and even the balcony. This spatial organization facilitated the creation of specific use contexts, where the smart speaker seamlessly blended into existing daily practices. This personalized approach aligns with literature emphasizing the importance of tailoring technology to older adults' physical environments [41]. The integration of smart speakers with daily routines, such as pill-taking in the kitchen or controlling bedroom lighting, showcases the adaptability of older adults in incorporating technology seamlessly into their daily lives, emphasizing the active role older adults play in shaping their living environments to accommodate and optimize the technology functionality [42,43].

Cognitive integration illuminated the adaptive processes through which older adults familiarized themselves with the smart speaker's functionalities and overcame learning challenges. The initial hurdles in mastering voice commands and comprehending the device's full range of functions were common experiences. Yet, the participants' narratives highlight their resilience and problem-solving acumen, aligning with studies that stress the importance of user support and educational resources in facilitating older adults' technology adoption [44]. The gradual adjustments and incorporation of the smart speaker into daily habits reinforce the idea that cognitive integration is an ongoing process, transforming initial challenges into a journey of mental adaptation [45].

Semantic integration delved into the emotional and meaningful connections older adults forged with their smart speakers. Despite occasional functional errors, participants universally acknowledged and valued the benefits offered by these devices. The smart speaker's role in facilitating enjoyable experiences, multitasking, and saving time and energy contributed to positive attitudes among older adults. The findings speak against the common discourse that technical issues and occasional functional errors could significantly diminish the overall positive impact and perceived value of smart speakers among older adults [46]. Instead, participants not only accepted these imperfections with understanding but also found moments of humor and enjoyment in the device's occasional quirks. This resilience toward technical glitches underscores the robust emotional and meaningful connections formed between older adults and their smart speakers [24,47], highlighting that the perceived benefits and companionship offered by the technology far outweigh occasional operational hiccups.

To sum up, the integration of smart speakers among older adults is a holistic process that involves functional use, spatial organization, cognitive adaptation, and semantic connection with the device. Understanding the interplay of these dimensions provides a comprehensive insight into how smart speakers become integral components of older adults' daily lives, offering not only practical functionalities but also emotional fulfillment and companionship.

Design Implications

Being Aware of the Heterogeneity in Older Adults' Technology Use

In our study, older adults used the smart speaker in different physical spaces, through different actions, and for different purposes. The underlying reasons could be the diversity of personalities [33], the differences in sociocultural and socioeconomic situations [48], and the disparities in individual digital literacy [49]. The heterogeneity in older adults' technology use may pose challenges for designers and developers to transform ideas and insights into concrete designs. Merely focusing on a specific issue met by older adults would limit the benefits of smart speakers to older adults. The complex entanglement of space, practices, and user needs that may affect technology use at different sites should be carefully considered. We thus suggest designers and developers to zoom out and get the big picture of older adults' daily practices before zooming in to define the design problem to solve.

Serving for the Existing Activities in Older Adults' Home Environments

Despite the discourse that smart speakers can support older adults to explore unexperienced activities, in our study, participants used the device to enhance the quality of their existing activities. For instance, the smart speaker supports medication reminding, turning on or off the lights, and music listening. Consequently, we suggest designers and developers to pay more attention to the issues or opportunities related to older adults' existing activities at home, rather than new activities that are not commonly experienced among this group of population.

Attaching Importance to Additional Devices Centered on the Smart Speaker

Our findings show that some additional devices connecting to the smart speakers were used by older adults. For instance, a "white button," designed for emergency calls was carried by a

participant all the time. The solution of connecting smart speakers to light switches in case of harm in darkness was also acknowledged. The 2 cases suggest that additional devices, especially the ones ensuring personal safety, have a market in the aging groups. Because many older adults have difficulties using the apps on mobile phones [3], we argue more additional devices centered on the smart speaker are needed.

Leaving Space for the Agency of Older Adults

Older adults are usually treated as inexpert technology users, and judged to be risky to do technology appropriation [50]. Yet, our findings show how participants spatially organized the smart speaker, and actively defined, changed, and reshaped their practices after using the device. In our cases, older adults created solutions that suit their specific needs [51]. These solutions were not predefined or preformatted by someone else, but specifically for older adults themselves [52]. We believe this may contribute to developing strong affective bonds between older adults and the device, driving their maintainable use behaviors, and promoting their resilient attitudes toward functional errors. Hence, we call for more studies about the association between older adults' agency in technology use and their affective bonds with technology. We also encourage designers and developers to carefully consider the space for the agency of older adults in terms of technology appropriation.

Getting to Know the Preferences of Communities

The most commonly mentioned genre of using the smart speaker was listening to music in our study. This is understandable as many participants are from a square dancing community. It shows that the community where older adults are involved can implicitly manifest their preferences toward the purposes of technology use. Therefore, we encourage designers and developers to shift partial attention from individuals to communities when investigating the preferences of older adults.

As smart speakers swiftly reach the mainstream, understanding the detailed, nuanced experiences of older adults using these devices becomes paramount. Our research delves into the intricacies of daily use. By unraveling the complexities and diverse experiences during older adults' long-term engagement with smart speaker technology, we aim to bridge the gap between technology and aging, offering insights that go beyond design considerations to impact policies and interventions. Moreover, our study seeks to contextualize the significance of understanding older adults' experiences within the broader sociotechnological landscape. The potential benefits of these devices in health care, chronic disease management, and emergency identification align with broader societal challenges in health care accessibility and aging populations. In an age where digital advancements redefine societal norms, the integration of smart speakers into the lives of older adults is not just a technological trend; it is a pivotal factor in ensuring their inclusion in the digital revolution. Consequently, this research does not merely contribute to the attractiveness of smart speakers for older users but serves as a critical voice in the ongoing dialogue about healthy aging in the digital era.

Conclusions

This paper focuses on the integration of smart speakers into older adults' daily practices. We aim to understand how older adults routinely use smart speakers and integrate them into their daily lives, which in turn enables us to propose suggestions for designers and developers. A total of 20 older adults who have used a smart speaker for over 6 months were interviewed. The findings demonstrate that older adults integrate smart speakers into daily use through functional integration, spatial integration, cognitive integration, and semantic integration. Based on the findings, we proposed several suggestions for designers and developers to better design smart speakers that promote maintainable use behaviors by older adults.

Limitations

Our findings must be evaluated within the context of several limitations. First, participants were recruited from 2 communities, potentially impacting the generalizability of the results. The risk of selection bias or unaccounted factors, such as the homogeneity of participant characteristics within the same facility, may have influenced interview responses. Yet, the study indeed highlighted the intricate nature of long-term technology use among older adults in these specific communities, offering valuable insights for designers and developers in the context of smart speaker design. Second, our study only investigated the long-term use of smart speakers, without paying much attention to the discontinuation of using smart speakers in the long term. The investigation of the discontinued use of smart speakers may reveal more insights into older adults' technology use. However, we believe that it is important to examine the integration of smart speakers in older adults' daily practices, as the findings may contribute to the maintainability of older adults' technology use.

Acknowledgments

The authors would like to thank the participants in the study for sharing their experiences and perceptions. We also thank the Ageing Dancing community and Bright community for making the study possible. This research was funded by a Chinese postdoctoral grant (2023M732231) and a Design School Innovation grant (WH102243005/201/004).

Abstract

Background: Different kinds of mobile apps are used to promote communications between patients and doctors. Studies have investigated patients' mobile app adoption behavior; however, they offer limited insights into doctors' personal preferences among a variety of choices of mobile apps.

Objective: This study aimed to investigate the nuanced adoption behaviors among doctors in China, which has a robust adoption of mobile apps in health care, and to explore the constraints influencing their selection of specific mobile apps. This paper addressed 3 research questions: (1) Which doctors opt to adopt mobile apps to communicate with patients? (2) What types of mobile apps do they choose? (3) To what degree do they exercise personal choice in adopting specific mobile apps?

Methods: We used thematic content analysis of qualitative data gathered from semistructured interviews with 11 doctors in Hangzhou, which has been recognized for its advanced adoption of mobile technology in social services, including health care services. The selection of participants was purposive, encompassing diverse departments and hospitals.

Results: In total, 5 themes emerged from the data analysis. First, the interviewees had a variety of options for communicating with patients via mobile apps, with the predominant ones being social networking apps (eg, WeChat) and medical platforms (eg, Haodf). Second, all interviewees used WeChat to facilitate communication with patients, although their willingness to share personal accounts varied (they are more likely to share with trusty intermediaries). Third, fewer than half of the doctors adopted medical platforms, and they were all from tertiary hospitals. Fourth, the preferences for in-person, WeChat, or medical platform communication reflected the interviewees' perceptions of different patient cohorts. Lastly, the selection of a particular kind of mobile app was significantly influenced by the doctors' affiliation with hospitals, driven by their professional obligations to fulfill multiple tasks assigned by the hospitals or the necessity of maintaining social connections with their colleagues.

Conclusions: Our findings contribute to a nuanced understanding of doctors' adoption behavior regarding specific types of mobile apps for patient communication, instead of addressing such adoption behavior of a wide range of mobile apps as equal. Their choices of a particular kind of app were positioned within a social context where health care policies (eg, limited funding for public hospitals, dominance of public health care institutions, and absence of robust referral systems) and traditional culture (eg, trust based on social connections) largely shape their behavioral patterns.

KEYWORDS

medical platforms; doctor-patient communication; social networking apps; thematic content analysis; China

Introduction

The widespread usage of smartphones, embraced by over 6 billion individuals, has facilitated the proliferation of mobile apps among users worldwide. Within this landscape, the integration of mobile apps to facilitate online medical services has emerged as one of the most rapidly evolving sectors in the health care industry. The term "mobile health", or "mHealth," is defined by the World Health Organization (WHO) as "medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, Personal Digital Assistants (PDAs), and other wireless devices" [1]. In addition to mHealth, eHealth [2], telehealth [3], and other newly emerged terms have also been used to describe the dynamic evolution of contemporary online health services. As demonstrated by numerous recent studies, the adoption of mobile apps in health services has immense potential to enhance doctor-patient communications, primarily through 2 types of mobile apps: online medical platforms and social networking apps. In this context, exploring the functioning mechanisms of these mobile apps has become imperative for identifying barriers to mHealth penetration, thereby offering insights to inform the targeted expansion of specific app types to improve the quality and efficiency of health care delivery procedures.

In China, more than 1 billion people used mobile phones in 2022 [4]. As the stressful relationship between health care providers and patients persists as a longstanding issue in the context of China's health care system [5], the adoption of mobile apps presents a promising strategy to mitigate this tension to some extent [6]. Recent studies have highlighted the benefits conferred by mobile apps, including promoting health care delivery procedures regardless of geographical barriers [7], contributing to the alleviation of urban-rural health care disparities by offering online medical consultation to those living in remote areas [8], and expanding the range of service areas for health care professionals who provide quality specialized care via mobile connections [9]. As such, the adoption of mobile apps proves to be a vital strategy for advancing both health care delivery and the doctor-patient relationship.

The adoption of mobile apps has brought numerous benefits, yet scholars have raised concerns regarding various issues encountered during implementation. Among these concerns, protecting patients' online personal information stands out as a significant security challenge [10]. In addition, health care professionals' use of social media apps might lead to an identity crisis, blurring the boundaries between their personal and professional lives [11]. Most studies have emphasized individual-level factors as major determinants of personal preference, yielding diverse findings on aspects such as social and economic returns [12], extrinsic and intrinsic motivations [13], their disciplines [7], their professional titles [14], anticipated rewards [15], and monetary incentives [13].

Despite different findings and conclusions, these studies were based on an implicit assumption that these doctors have full control of their choices, which means that doctors have the freedom to decide how to spend their spare time at their own will. However, in China, this assumption warrants scrutiny due to the well-known issue of excessive workload faced by health care professionals, leaving them with limited leisure time after extended hours [16].

Previous studies have identified the level of doctors' affiliated health care organizations as a potential factor that affects the adoption of web-based health information technologies. For example, Li et al [14] found that quality doctors from tertiary hospitals exhibit greater activity on web-based medical consultation platforms. However, the underlying mechanism of this influence requires further explanation, not to mention that some macrolevel influences remain to be explored, such as the impact of national health care policies. These influences are beyond doctors' personal choices. Nevertheless, a few exceptions from the current literature managed to analyze meso- and macrolevel factors, in addition to individual-level factors. Peng et al [17] applied social ecosystem theory to understand the determinants of physicians' online uptake and regarded their perceptions of law and regulation of online health as macrolevel factors. However, these meso- and macrolevel factors proposed for analysis primarily pertain to online health care services, thus neglecting the potential impacts of the particular contexts. Other scholars have conducted review studies describing the current status of China's mHealth industry, with emphasis of the overall impacts of the health care system, but have not provided details of the underlying mechanism [6].

To address the existing gap in the current literature, this study aimed to address the nuanced mobile app adoption behaviors of doctors in China and explore the factors influencing their choice of specific mobile apps, rather than merely examining general adoption behavior. We conducted thematic analysis of semistructured interviews with selected doctors in Hangzhou, focusing on these 3 questions: (1) Which doctors opt to adopt mobile apps to communicate with patients? (2) What type of mobile apps do they adopt? (3) To what degree do they exercise personal choice in adopting specific mobile apps?

Methods

Research Design

The inductive approach was used to facilitate exploratory research, and interviews were conducted to understand interviewees' inner thoughts about the issue being investigated [18]. Thematic content analysis was then used to uncover subtle concerns underlying their adoption behavior. This qualitative method has been used to explore health care services provision from the supply side in order to understand health care professionals' perception of internet hospitals [19], as well as their use of mHealth in practice to deliver health care services [20]. Thus, the self-reported narratives from interviewees provided direct responses to the set of research questions we previously proposed.

Study Setting

We conducted our study in Hangzhou, the provincial capital of Zhejiang Province. Hangzhou City is situated on the east coast of China, approximately a 2-hours ride from Shanghai. We selected this city as the research setting mainly out of 3

considerations. First, with a population of 12.20 million and a local gross domestic product (GDP) per capita of Renminbi (RMB) 149,900 (~US $21,122) [21], significantly higher than the national average of RMB 80,000 (~US $11,273) in 2021 [22], the city has a relatively affluent population. This means local residents are more likely to use their out-of-pocket money to pay the fee charged by medical platforms. Second, this city is renowned for its technical advancement and has attracted a lot of mobile app companies (eg, Taobao, the biggest online shopping company in China) to build their headquarters there. Third, this city is home to 3 hospitals ranked among China's top 50 hospitals, where highly skilled health care professionals are more likely to embrace advanced health information technology [23]. Therefore, this city presents an ideal research environment for investigating the current landscape of mobile app adoption in China's clinical settings and exploring the issues and concerns perceived by health care professionals during their practical interactions with mobile apps.

Data Collection

We conducted purposeful sampling to select participants for in-depth interviews. Given that investigating doctors' personal choice of mobile apps might involve disclosure of their or their patients' private information, securing cooperation from the doctors proved challenging.

We selected participants using the following criteria: First, they were under 50 years old, as older individuals are less likely to adopt new technology. Second, we tried to cover different levels of medical agencies, including local health community clinics and tertiary hospitals. Considering that doctors working in tertiary hospitals are more likely to use mobile apps to provide online medical consultation services [14], more than half of the interviewees were selected from tertiary hospitals. Third, we tried to cover doctors specializing in different areas, as well as with different professional titles. Fourth, as most medical agencies in China are public agencies, we selected our interviewees primarily from public hospitals.

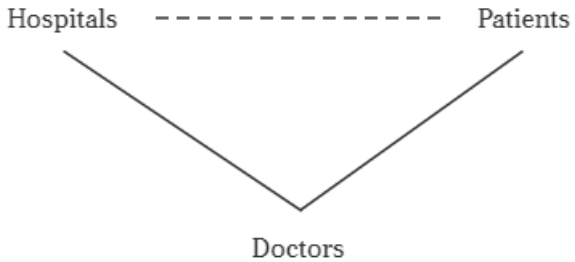
Interviews

Prior to interviews, the researchers sent the topic list to the interviewees so that they could prepare for the interviews ahead. All 11 interviews occurred within hospital settings, with the interviewers maintaining impartiality. Four of the researchers conducted the interviews, two of whom (authors DC and JP) possessed previous research experience with interviewees, while the other two (authors WH and YY) received training in interview skills. Field notes were taken during interviews, and audio recordings were made with the interviewees' consent. Each interview commenced with a brief introduction of the interviewer's research background and the research project. The interviewees were given the option to decline participation, although nobody dropped out. We conducted the interviews from June to December 2022, and each interview lasted for approximately 30-60 minutes. Interviewees received RMB 200-400 (~US $27-55), depending on the interview duration. Data saturation was achieved after interviewing 11 doctors.

Primary Model and Interview Questions

Different from previous studies focusing on a straight relationship between doctors and patients, we added another bilateral relationship between doctors and hospitals to our analyses, forming a basic framework to approach this research. Current studies have underscored the interconnectedness between offline and online health care services [15,24]. It is necessary to investigate institutional impacts posed by their affiliated hospitals, which are also the employers of their offline practice. We devised a triangular model to understand the dynamics between doctors, patients, and hospitals, as depicted in Figure 1. This model delineates 3 sets of dual relationships: doctor-patient, doctor-hospital, and patient-hospital. We constructed our interview questions based on this model and collected interviewees' responses to each question accordingly. The interview questions are listed in Multimedia Appendix 1.

Figure 1. The relationship triangle between doctors, patients, and hospitals.



Data Analysis

Two researchers (DC and WH) transcribed all the recorded files and reviewed them for accuracy. According to Braun and Clarke [25], both manual coding and software coding are applicable for thematic analysis. Drawing from the interviewees' spoken words, we used manual open coding to identify potential themes. The analysis included both inductive and deductive coding [26]. The primary model outlined in Figure 1 guided deductive coding, while transcribed data yielded unanticipated themes, necessitating inductive coding. The two researchers (DC and WH) read through the interview transcripts and applied both inductive coding and deductive coding to generate an individual code book independently. Next, they cross-referenced their respective code book, and any discrepancies were resolved through discussion with a third researcher (JP), ultimately reaching consensus on overarching themes. Following 11 interviews, no new themes emerged and saturation was reached. The researchers adhered to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist to report the empirical research process [27].

Ethical Considerations

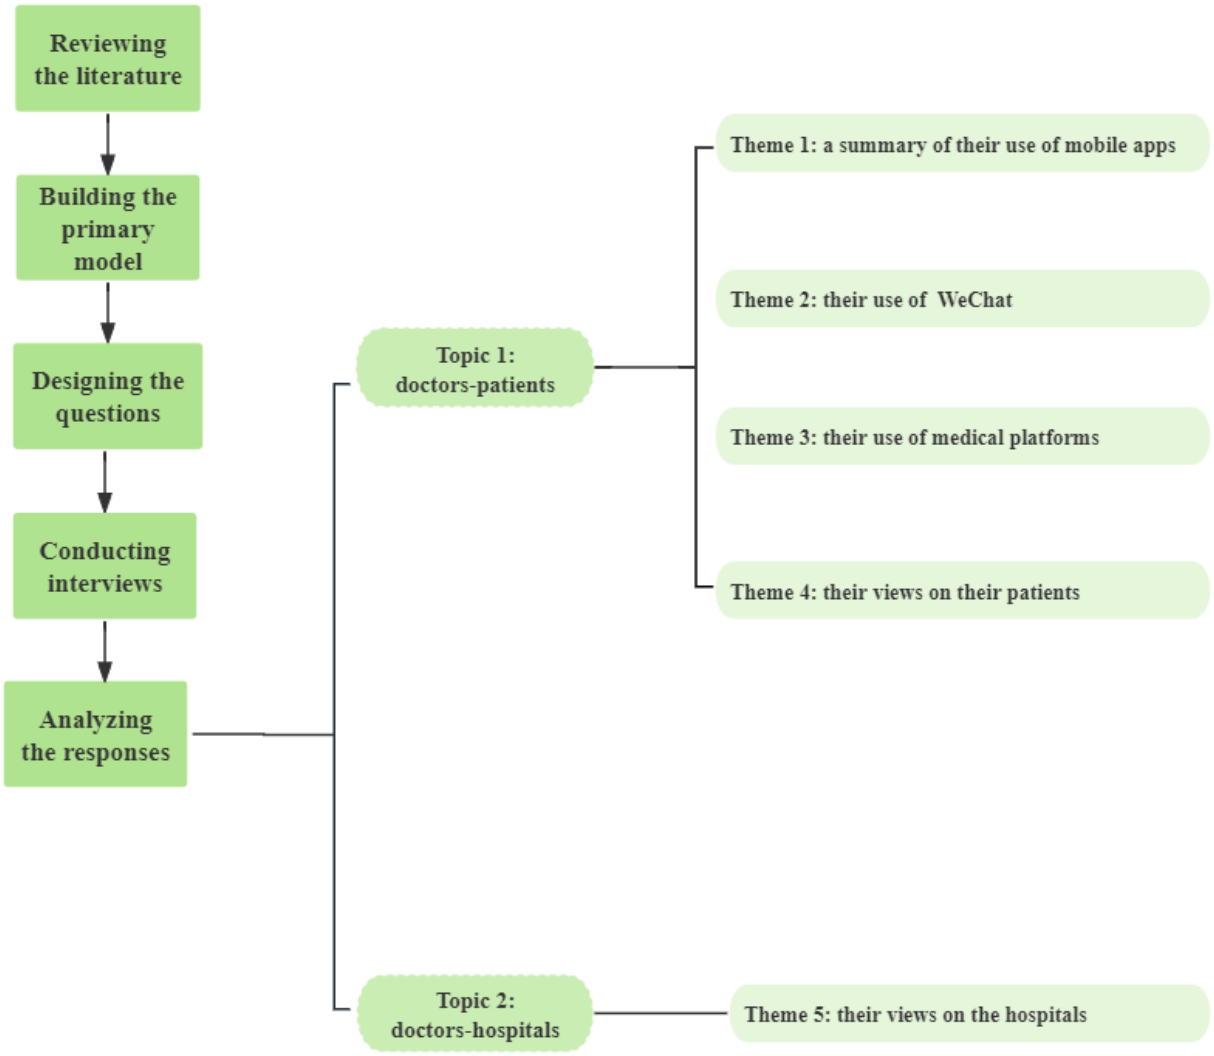
Ethical approval for this research was obtained from News and Communication Research Institute, Communication University of Zhejiang. Prior to interviews, the researchers assured the interviewees of the anonymization of their personal information, and all interviewees provided written informed consent.

Results

Research Process

Each step of the research process is presented in Figure 2. We extracted 5 themes from the data analysis, including a summary of the interviewees' mobile app usage, the specific use of 2 primary kinds of mobile apps, and the interviewees' views on patients and affiliated hospitals.

Figure 2. Stages of the research process.



Summary of Interviewees' Use of Apps

We interviewed a total of 11 participants, 9 (82%) of whom were from tertiary hospitals, with 2 (18%) from top-tier hospitals in China, ranked among the top 50 hospitals. Table 1 delineates the key characteristics of each interviewee. We added 1 category to the table to describe the varying degrees of difficulty in making an appointment with these doctors. Specifically, "very difficult" means that a waiting period of approximately 1 month is necessary for potential patients to compete for a possible slot either over the phone or through the online registration system, while "difficult" suggests a shorter waiting time of 1-2 weeks. For the remaining doctors, no appointment is required in advance, as they provide readily accessible services to patients on their clinical days.

Table 1. Characteristics of interviewees (N=11) collected from June to December 2022.

Characteristics	Interviewees, n (%)
Gender	
Male	8 (73)
Female	3 (27)
Age (years)	
30-40	3 (27)
40-50	8 (73)
Professional title	
Chief physician	2 (18)
Associate chief physician	5 (45)
Attending doctor	4 (36)
Type of affiliated hospital	
Public tertiary hospital	9 (82)
Community clinic	1 (9)
Private clinic	1 (9)
Difficulty in making an appointment	
Very difficult	3 (28)
Difficult	4 (36)
Not difficult	4 (36)
Department director or not	
Department director	3 (27)
Not department director	8 (73)
Affiliated department	
Surgery	2 (18)
Internal medicine	2 (18)
Traditional Chinese medicine	4 (36)
Gynecology	1 (9)
Dentistry	2 (18)

According to the interviewees, they used a variety of mobile apps for patient communication, with the predominant ones being social networking apps (eg, WeChat) and medical platforms (eg, Haodf). All interviewees used WeChat to communicate with patients, either through 1-to-1 chats or group chats, although their willingness to share their personal WeChat accounts with patients varied. Only 4 (36%) interviewees reported using medical platforms at the time of the interviews, with detailed use discussed in later sections.

In terms of communication style (the number of people engaged in the communication), 1-to-1 chats via WeChat involve 2 people. WeChat-facilitated group chats entail the participation of multiple individuals, commonly including 1 or several doctors, alongside a group of patients. These discussions typically focus on medical consultation for specific conditions or the dissemination of supportive information, such as guidance on appointment scheduling. The medical platforms enable doctors to have 1-to-1 conversations with anonymous patients, and these conversations or the feedback on them can be further reviewed by other end users whenever they access the same medical platforms. Meanwhile, patients' medical examination results and their identification information remain confidential.

The Use of WeChat

WeChat is the most widely embraced social media app in China. In addition to text-based messages, it supports multimedia communication through the sharing of images, recordings, and videos, alongside the integration of numerous miniapps. Table 2 presents a summary of the interviewees' use of WeChat to communicate with patients or potential patients. Notably, 1-to-1 chats were the most personalized and confidential mode of communication, involving interactions between 2 individuals.

Table 2. Interviewees' use of specific WeChat functions to communicate with patients from June to December 2022.

Interviewee ID	Specific WeChat function			
	One-to-one chat[a]	Group chat	WeChat Moments (friend circle)	WeChat short-term video
1	Likely	—[b]	Yes	—
2	Rare	—	—	—
3	Very likely	—	Yes	Yes
4	Very likely	Yes	Yes	Yes
5	Rare	—	—	—
6	Very likely	Yes	—	—
7	Likely	—	—	—
8	Rare	—	Yes	Yes
9	Rare	—	Yes	—
10	Likely	Yes	—	—
11	Very likely	—	Yes	—

[a]The frequency of 1-to-1 chats was measured based on the average number of patients with whom these interviewees had WeChat conversations in 1 week: <5 patients measured as "rare"; 6-8 patients as "likely"; ≥9 patients as "very likely".

[b]Not applicable.

Of the 11 doctors, 4 (36%) exhibited a propensity to share their personal WeChat accounts with patients very likely; these doctors were all from low-risk departments, including internal medicine, dentistry, or traditional Chinese medicine. In contrast, 4 (36%) doctors rarely did so due to safety concerns with potential patients.

> *Yes, I will share my WeChat account with patients. After I joined this private dental clinic, my patients were first allocated by the clinic. Later, as these patients found satisfaction with my services, they began to introduce my account to other people, and I have more and more patients.* [Interviewee 3]

Additionally, a few doctors adopted a discerning approach, depending on initial interactions with newly admitted patients, regarding assessments of medical compliance as a determining factor.

> *I will make an evaluation of patients when deciding to share my WeChat account with them. I select those patients who are reasonable and cooperative, with a good sense of medical compliance. I am very cautious against those picky patients. Usually, doctors do not have obligations to share their personal account with patients. We do so only for the sake of their conveniences.* [Interviewee 10]

Furthermore, all interviewees expressed a willingness to share their personal accounts with those introduced by well-acquainted intermediaries.

> *I will not share my WeChat account with patients. The rare exceptions are for some special patients, depending on whether patients' parents are easy to communicate with and their diseases need long-time follow-up. In addition, I will share my account with those who are introduced by my familiar colleagues, friends, and relatives. China is a society replete with social connections, and I cannot avoid these connections.* [Interviewee 8]

Group discussions are another frequently used communication form on the WeChat platform, especially for patients with chronic diseases requiring long-term care and occasional relapse. Some WeChat groups can be created by institutions, hospitals, or departments. One local clinic (the employer of interviewee 10) created WeChat groups including 2 or 3 family doctors to meet the needs of local residents. Alternatively, interviewees may initiate their own groups. Here is an interviewee's response.

> *In my WeChat account, I have ten WeChat patient groups. Each group has 500 patients. Those initially added to the group invited their friends and relatives, and the number of each WeChat group reached the maximum capacity of 500 very quickly.* [Interviewee 6]

Doctors' adoption of WeChat facilitates effective knowledge dissemination in the form of photos, articles, and short video demonstrations (eg, WeChat Moments and WeChat short-term video-sharing functions). Some doctors, such as a department chair (interviewee 8) from a newly established department, demonstrate high levels of proactivity in using video-sharing functions to promote their reputation in order to attract new patients.

The Use of Medical Platforms

In China, medical platforms serve multiple functions, primarily facilitating medical appointments, medical consultations, and online prescriptions. Except an interviewee from a private dental clinic, all remaining interviewees' affiliated hospitals have already offered online platforms to execute some basic functions. These hospitals have created their own WeChat official accounts to provide supporting services via integrated miniapps in WeChat, such as making medical appointments and checking medical exam results, or created their own medical platforms

to provide a wider range of services. Table 3 outlines the hospitals' involvement in mHealth, enhancing patients' convenience in scheduling appointments via mobile apps. However, considering this kind of functionality does not necessitate interactions between doctors and patients, our investigation primarily focused on functionalities reliant on patient-doctor interactions on medical platforms.

Table 3. Affiliated hospitals' involvement in mHealth[a] adoption from June to December 2022.

Involvement of interviewees' employers in mHealth	Specific functions	Interviewees (N=11), n (%)
mHealth functions built into the hospitals' official WeChat account	• Making medical appointments • Reviewing medical exam results	10 (91)[b]
Their own medical platform exclusively designed for 1 hospital	• Making medical appointments • Reviewing medical exam results • Preparing prescriptions • Having online consultations with both first-time and follow-up patients	1 (9); interviewee 5
Official partnering with a medical platform designed for many hospitals	• Making medical appointments • Reviewing medical exam results • Preparing prescriptions • Having online consultations with both first-time and follow-up patients	1 (9); interviewee 8
No mHealth app	N/A[c]	1 (9); interviewee 3[d]

[a]mHealth: mobile health.

[b]Although these interviewees' affiliated hospitals were involved in mHealth to varying degrees via official WeChat accounts, the interviewees were not involved, since there was no need to communicate with patients via accounts at the time of the interviews.

[c]N/A: not applicable.

[d]The interviewee was from a private dental clinic.

Based on our findings, interviewees' use of medical platforms to communicate with patients was not as frequent as their use of WeChat. Of the 11 doctors, only 4 (36%) were using medical platforms at the time of the interviews, including Haodf (the largest commercial medical platform in China), Nali (a platform having an official partnership with some hospitals), the affiliated hospital's official platform, and Gancao Doctor (a commercial platform focusing on traditional Chinese medicine). They were all from tertiary hospitals. Of these 4 doctors, 2 (50%) were from esteemed top-tier hospitals (interviewees 5 and 8) and the other 2 (50%) from average tertiary hospitals (interviewees 6 and 9). They used multiple medical platforms simultaneously, with Haodf being the most popular.

The motivations behind interviewees' choices of specific platforms varied. Building departmental reputation (interviewees 8 and 9) and providing more convenience to offline patients (interviewees 5, 6, and 9) were reported as 2 key incentives for interviewees who need to perform surgeries. These interviewees have too many offline patients, which makes it rather difficult for some of those patients to make a timely appointment in the offline service. As admitted by these interviewees, the volume of patients using medical platforms is quite limited compared to their offline patients, and some of the online patients are diverted from offline services to seek more further suggestions.

One department director (interviewee 9) highlighted that using a medical platform could enable doctors to earn an extra income, and encourages subordinates, particularly young doctors, to use medical platforms to provide medical consultations to patients and then to attract more online patients to offline services. A young attending doctor (interviewee 6) reported actively using a medical platform (Gancao Doctor) to prescribe traditional Chinese medicine to patients. As explained by this doctor, following the initial in-person medical consultation that occurs at the hospital, subsequent follow-ups can be conducted online, which significantly enhances the convenience for those living in remote areas and generates an additional income for the doctor.

Some interviewees had different reasons for not using medical platforms. Interviewees 1 and 4 had tried medical platforms but ultimately discontinued their usage due to the limited number of patients engaged on those platforms. Some interviewees were overwhelmed by their offline duties and, thus, were not willing to further sacrifice their precious spare time (interviewees 1-3 and 7). Interviewee 10 from a local clinic was not busy but was still reluctant to use mobile apps related to work beyond working hours, due to family obligations. Interviewees 3 and 11 regarded WeChat as an effective approach to maintaining their connections with their patients, and they perceived WeChat as a more convenient alternative to medical platforms.

Cross-comparing the interviewees' responses on whether use medical platforms presented a contradictory understanding of the possible influence of heavy workloads from offline services. A heavy workload can either discourage or encourage the adoption of a medical platform. A cross-sectional study found no statistically significant association between workloads and doctors' uptake of e-hospitals [28]. Our interviewees' responses highlighted the underlying reason. Their different choices reflected their views on how to maintain a balance between professional duties and personal life. More than half of the interviewees from average tertiary hospitals preferred focusing

solely on offline patients to preserve some personal time. Conversely, both interviewees from esteemed top-tier hospitals were extremely busy, leaving little opportunity to prioritize their personal life during spare moments. Despite these divergent choices, interviewees from tertiary hospitals unanimously agreed that personal time is severely limited.

Interviewees' Views on Patients

The interviewees had a mixed view on the strengths and weaknesses of different communication methods, and they all preferred face-to-face communication. In addition to more comprehensive examinations of patients' symptoms, they contended that such in-person communication would facilitate the detection of subtle signs and symptoms with greater precision. Another concern arising from online conversations was the heightened cautiousness that doctors exhibit during conversations, as indicated by interviewee 8's response. The reason is that all conversations are documented in written form and might serve as evidence in the case of patient complaints. However, they admitted that the strength of online mobile communication lies in its convenience to patients, such as enabling them to review their medical exams results and providing follow-up suggestions.

> *I have many years' working experience, and I have a strong sense of cautiousness when dealing with online communication risks. I will add some preconditions with uncertain conditions. I will phrase many sentences structured as "if…, you need to do…"* [Interviewee 8]

When communicating via mobile apps, patients might be viewed differently by doctors, depending on the app selected. A notable distinction is between the 1-to-1 conversation on WeChat and communication via medical platforms. Based on the aforementioned responses of the interviewees and observations of the content of the Haodf app, we collated the disparities between these 2 communication modalities, as shown in Table 4. This table indicates that 1-to-1 messaging on WeChat is more restricted to known patients than interactions on medical platforms; in the latter case, doctors can communicate with both known and unknown patients. Medical platforms are accessible to everyone on the internet, allowing interested parties to review feedback from other patients and search for their desired doctors.

Table 4. Differences between 2 kinds of communication modalities.

Feature	WeChat (1-to-1 chat)	Medical platform
Patients	Acquaintances	Known and unknown patients
Trust	Based on reliable intermediaries or multiple rounds of communications	Based on cumulative feedback from patients on the platform
Outsiders allowed or not	Closed to outsiders	Open to outsiders
Boundary between personal and professional lives	The lack of boundary between personal life and professional work	Being professional
Cashing in on knowledge	Unable to cash in on one's knowledge immediately	Able to cash in on one's knowledge immediately

Regarding WeChat-facilitated communication, it is noteworthy that this is an enclosed mode of communication that only occurs between well-acquainted individuals, thus safeguarding the privacy of conversations. As previously discussed, the interviewees had varying degrees of willingness to share their personal accounts with others. Of the 4 (36%) interviewees using medical platforms, 3 (75%) rarely shared their WeChat accounts with patients. In China, doctor-patient communication is intertwined with social connections (*guanxi*). All interviewees were willing to share their personal WeChat accounts with patients if they were introduced by well-acquainted intermediaries, such as colleagues, relatives, or friends in hometowns or other acquaintances who could provide mutual benefits in other domains.

Interviewees' Views on the Hospitals

Of the 11 interviewees invited to participate in our study, 3 (27%) were department directors, thus expressing attitudes reflective of those of their affiliated hospitals. As reported by these interviewees, the hospitals have never hindered employees from using mobile apps to connect with patients; instead, they have actively implemented supportive strategies to promote online mobile services, such as making online medical appointments via their official portals. Nevertheless, such affiliation with hospitals still imposes certain constraints on doctors' adoption of mobile apps.

The primary factor influencing doctors' reliance on mobile phones for improved work efficiency is the multitude of tasks assigned to them. Except an interviewee from a local community clinic, all remaining interviewees reported the issue of overworking in hospitals, dedicating an average of 50 hours per week to their duties. The heavy workload prompts some doctors to use medical platforms to enhance communication efficiency with patients. Additionally, busy daytime schedules necessitate the use of WeChat for coordination tasks within departments and hospitals. Moreover, doctors in public tertiary hospitals are burdened with research and academic responsibilities, adding to their workload. Here is 2 (18%) interviewees' feedback with regard to their typical working situations.

> *For every week, I have 2 surgery days, Monday and Wednesday, and I won't be able to get off work until 9:00 p.m. or 10:00 p.m. on these days. Sometimes, it will be as late as 1:00 a.m. and 2:00 a.m. I have 2 half days scheduled for outpatients, one with around 50 patients and the other with around 35 patients. I need to work almost every day, even for the weekend. Besides, I need to have 1 night staying in the hospital in each week.* [Interviewee 5]

> *In addition to being a doctor, I am also an associate professor in a medical school… For each school year, I teach 4-5 courses to students, and I am also an advisor to 4 graduate students (master students)… I am not only in need to publish academic articles for myself in order to get higher professional titles, I also need to push my graduate students to publish articles... Using WeChat for working happens very often, and I have to tell them not to bother me after 10:00 p.m.* [Interviewee 7]

Despite the various tasks assigned by their affiliated hospitals, health care professionals' compensation remains comparatively low in China. Among the interviewees working in public hospitals, more than half mentioned that their income is not satisfactory, especially compared to their counterparts in private hospitals with higher incomes. This point of view was shared by interviewee 3, who left a public hospital and joined a private dental clinic due to an unsatisfactory income. Under such circumstances, the adoption of medical platforms could increase doctors' income, such as interviewee 6, who managed to make extra money by prescribing medications to online patients on medical platforms.

Despite the challenging tasks for interviewees in tertiary hospitals, most of them were still reluctant to leave their affiliated hospitals. For example, 2 (18%) interviewees pointed out 2 major reasons that made it unlikely for them to disconnect their affiliation with their employers: the institutional support provided by the hospitals and the hospitals' reputation to attract more patients. As stated by interviewee 1, relying solely on medical platforms is not a feasible option for them, as it is their affiliation with hospitals that provides institutional support for their careers. Interviewee 2 emphasized the predominant role of hospitals' reputation in attracting new patients.

> *Online medical platforms are operated only for profits from doctors' work. Once the disputes between doctors and patients break out, these platforms could not do anything to protect doctors and they only turn in the online communication records between doctors and patients. Doctors could hardly count on these platforms to protect them.* [Interviewee 1]

> *In China, most people care more about hospitals than doctors. If Chinese people care more about doctors, that will be a positive impact upon doctors to build their personal reputation. However, doctors are indispensable with their hospitals in China. We cannot survive without our hospitals.* [Interviewee 2]

In addition to the formal affiliation, these interviewees also have strong informal connections with their employers, particularly with their colleagues within the same organization. According to the interviewees, most doctors value their connections with their colleagues and quite often receive requests from them to provide medical services to their friends. These connections serve as crucial intermediaries for new patients, helping identify the most appropriate medical expertise for specific conditions, as mentioned by interviewee 9. However, such strong ties might also become a burden for some doctors, as exemplified by interviewee 3, who chose to leave their former employer due to the perceived disturbance caused by these connections.

> *My colleagues often introduce patients to me. I will also introduce some patients to my colleagues. We cooperate with each other. We are very clear about the inside information with regard to which doctor is good at which disease. When we introduce some patients to other doctors, we make comprehensive evaluations on their medical skills, as well as their personality.* [Interviewee 9]

> *When I worked with a previous employer (a public tertiary hospital), the relationship between me and my colleagues was very close. We were like a family. Now my connections with my colleagues in this private clinic are straight working cooperation. My former colleagues were kind of disturbing for me. I rarely introduced my friends to other doctors, because I thought it would bring some extra burden for others. However, my former colleagues would bring many patients to me. I do not like this kind of relationship, and this is one of the reasons that I chose to leave my former employer.* [Interviewee 3]

Discussion

Principal Findings

According to the semistructured interview responses, we extracted 5 themes from the verbal data of the interviewees' narratives. First, doctors have a variety of options for communicating with patients via mobile apps, with the predominant ones being social networking apps (eg, WeChat) and medical platforms (eg, Haodf). Second, all interviewees use WeChat to facilitate communication with patients, although their willingness to share personal accounts varies; they are more likely to do so with reliable intermediaries. Third, fewer than half of the doctors, all from tertiary hospitals, have adopted medical platforms. Fourth, preferences for in-person, WeChat, or medical platform communication reflect doctors' views on different patient cohorts. Fifth, doctors' choices of a particular kind of mobile app are largely affected by their affiliation with their employers, which stems from their professional duties to accomplish multiple tasks assigned by hospitals or the necessity of maintaining social connections with their colleagues.

Our findings are consistent with previous research in some aspects. Several studies have documented the use of WeChat for improving doctor-patient communication for managing certain diseases, such as advanced pancreatic ductal adenocarcinoma in China [29]. The interviewees' reservation to share personal accounts has also been echoed in previous studies on the controversies arising from the use of personal social media for medical services [30]. Meanwhile, the finding that those adopting medical platforms are all from public tertiary hospitals is also consistent with prior results [31].

However, in contrast to previous studies, our study revealed that doctors' choices of mobile apps are more than just their personal choice. A heavy workload, as mentioned in theme 4; comparatively low incomes; and strong social connections

between colleagues, as mentioned in theme 5, demonstrate that there are strong bonds between interviewees and hospitals. These constraints were consistently observed across all interviewees from public tertiary hospitals. Previous studies [32,33] and media reports [34] have documented the popularity of these issues in China. Even though most interviewees in tertiary hospitals complain about the stressful workload and low income, few of them are willing to give up their positions in their hospitals. As discussed in theme 5, they rely on these tertiary hospitals to provide institutional support, such as attracting patients and safeguarding against potential disputes.

In terms of the particular type of mobile app to facilitate doctor-patient communication, most interviewees tend to choose the ones enabling them to complete various tasks assigned by their affiliated hospitals beyond regular working hours. In other words, their online communication with patients in mobile apps is an extension of their offline clinical service. They are bonded by not only their affiliated hospitals but also their social connections with others. Some studies from Western contexts have often highlighted doctors' privacy concerns regarding mobile communications [11]. However, such privacy concerns were not prominent among the interviewees, who share their personal social medial accounts with certain patients.

Within these bonds, it is difficult for doctors to reach their individual goals of increasing their income by using medical platforms, such as Haodf, or having more spare time by not using any mobile apps after work. The findings provide some support for the validity of the single-triangle model, demonstrating the impact of the doctor-hospital relationship on the patient-doctor relationship. However, this model cannot explain why these bonds are so influential. Thus, the model we proposed at the beginning warrants reassessment to enhance our comprehension of doctor-patient interactions facilitated by mobile apps within China's health care landscape.

Remodeling the Relationships Among Doctors, Patients, and Hospitals

Behind the possible influence of hospitals are macrolevel factors. In the revised model (Multimedia Appendix 2), the triangle involving doctors, patients, and hospitals serves as a projection from a bigger triangle involving state, society, and health care provision. This double-triangle model indicates that the equilibrium within the former triangle is influenced by the dynamics of the latter triangle.

The influence of the state represents governmental influence. Governmental involvement in China's social and health care spheres is pervasive, manifesting in regulations governing mobile businesses and the oversight of medical institutions. The most notable manifestation of the state's involvement can be seen in the current prevailing status of public hospitals [35]. However, governmental funding for these public hospitals is insufficient to support their long-term growth [36]. Under such circumstances, these hospitals need to accommodate increasing patient loads to sustain their development. This explains why the interviewees from public tertiary hospitals are obligated to work for prolonged hours in order to accomplish various tasks assigned by their employers.

The influence of society embodies China's social traditions, particularly its reliance on social connections for various activities. As members of this society, doctors also need to comply with these traditions. Our findings indicate a popular pattern among the interviewees to offer informal medical advice, particularly via WeChat, to patients introduced by colleagues, relatives, friends, or fellow townspeople. Previous studies suggest that social connections play a role in building patient-doctor trust in offline services [37], and our study provides evidence for trust building through communication via mobile apps.

The influence of health care provision refers to the general characteristics of China's health care service, with 2 being particularly important. First, patients in China are not constrained by stringent referral policies, which enables them to have more flexibility in choosing their doctors [37]. Second, the patients are more inclined to go to tertiary hospitals to seek medical services, even for mild ailments [38], which is connected to the first characteristic. In this context, doctors working in those hospitals (eg, interviewees 5 and 8) are more likely to use medical platforms as a means to promote their departmental or personal reputations to attract more patients.

Rethinking the Influence of Mobile Apps

Following the discussion of the significant role of hospitals in the doctor-patient relationship, a further question arises regarding the potential impact of mobile apps on the patient-doctor-hospital dynamic. In the extant literature, online health care, including web-based consultation, has emerged as a vital alternative solution to offline health care provision, especially in terms of addressing the flaws and deficiencies persistently embedded in offline services [17]. However, our results suggest that the impact of mobile apps might be more nuanced than we initially assumed. On the one hand, their impact on offline services might be misunderstood to some extent. Although newly emerged mobile apps are gaining increasing prominence, their potential is not strong enough to challenge the predominant position of offline services, especially in the context of China's health care system. On the other hand, they might exert indirect impacts on those involved in doctor-patient communications, which might be neglected. Doctors could leverage mobile apps to promote their personal reputation, rather than simply relying on their institutional prominence to attract new patients.

Online vs Offline Health Care Provision

In our study, we found that 4 of 11 interviewees (4 of 9 doctors from tertiary hospitals) have adopted medical platforms and taken advantage of medical platforms as a more convenient means to deliver medical services to patients or to enhance their reputation to attract more potential patients for in-person hospital visits. However, it is noteworthy that offline patients remain the primary focus. For complex and severe diseases, offline services provide more advantages, as face-to-face interactions and on-site medical examinations could provide more reliable information. In a relevant study on patients' selection of doctors from Haodf, Chen et al [39] reached a similar conclusion that online health services are well connected to offline services,

especially for those departments requiring medical tests and surgeries.

Additionally, as the foremost offline service providers, hospitals have never been passive observers of emerging medical platforms but have taken a series of actions to address such challenges posed by medical information technologies. These hospitals never discourage their doctors from using medical platforms or WeChat for medical consultation purposes; rather, they are becoming more proactive in the implementation of such mobile apps to enhance the accessibility of medical services to patients [40], especially since the outbreak of COVID-19 [9]. As reflected in Table 3, almost all interviewees' employers have created official WeChat accounts for the public to access, via which patients can make medical appointments or review their medical exam results. Alternatively, they could develop their own medical platforms with functionalities mirroring existing commercial medical platforms.

Based on our observations, an isomorphic pattern might better characterize the development of both online and offline services. The predominant role of public tertiary hospitals as the primary providers of offline services is likely to persist in the realm of online medical service provision. With the adoption of online services becoming a universal trend among all hospitals, the value of online platforms tends to mainly lie in their supportive functions.

Traditional Society vs Modern Mobile Technology (Individuals vs Institutions)

The choices that doctors make regarding mobile apps might be impacted by their affiliations with particular hospitals, and the future progress of online health care services might also be closely tied to these institutions. However, by facilitating interactions between doctors and patients outside conventional clinical settings, these apps provide more opportunities for doctors to communicate with patients and to promote their professional reputation.

The establishment of individual doctors' personal reputation as competent health professionals is crucial for their career development [41]. As reported by interviewee 2, patients often rely on their employers' reputation or doctors' professional titles to search for an appropriate doctor, especially for the initial medical visit. For those using medical platforms, interviewee 6 (an attending doctor) diverts some offline patients to online medical platforms, suggesting that a patient tends to choose them based on their personal reputation rather than their affiliation with an esteemed hospital or professional title. With the advent of medical platforms, patients can review feedback from other patients when searching for desired doctors. As Table 4 suggests, these doctors' medical skills and ethical values are more accessible to those outside of conventional clinical settings.

Social networking apps could also contribute to the dissemination of doctors' professional reputation. Using 1-to-1 communication with patients via WeChat, doctors can provide convenient medical consultation to patients, or they can use group discussions to facilitate information dissemination to a wider audience. As Table 2 indicates, 6 of 11 interviewees use WeChat Moment functions, and 3 of 11 use short-term video functions, sharing the success stories of their medical treatments.

Although both kinds of apps, medical platforms and social networking apps, can facilitate doctors' reputation, the choice of apps represents a different pattern of social interaction. As Table 4 suggests, social connections have been further used in social networking apps, while medical platforms are more reflective of modern society's norms of personal interactions. *Guanxi* is a prominent property of traditional societies, where interpersonal trust largely relies on well-established social connections [37,42]. With the help of WeChat, the traditional interaction pattern continues in doctor-patient communication.

In contrast, medical platforms are more likely to attract the registration of new patients than social networking apps. The practice of being open to strangers on medical platforms aligns with the norms of personal interactions in modern society. Patients can easily access detailed information under doctors' profiles to understand their professional skills and experiences, without having to rely on their friends or relatives in hospitals to obtain that information. Moreover, each doctor could maximize the utility of their professional skills by cashing in on their knowledge immediately, without having to depend on their social connections for potential benefits in the future.

In the modern era, medical platforms and social networking apps are among the most innovative creations. Through the assistance of medical platforms, patients are empowered to choose their preferred doctors by following guidelines on how to acquire detailed information about doctors' skill sets and experiences [43]. Our study suggests that doctors are also empowered as they can expand their personal reputation beyond hospital confines.

Limitations

Several limitations of our study should be acknowledged. First, it remains controversial whether the sample of doctors we selected for interviews was representative enough to reflect the general situation of all doctors in the medical community. Nevertheless, the qualitative research methodologies we adopted in this study did have great potential to investigate underresearched topics and population groups. This study provides meaningful implications for future studies that might consider incorporating quantitative methods to add more potent evidence in this field. Second, another issue arises due to the overwhelming number of doctors from tertiary hospitals. As suggested by previous studies, doctors from these hospitals are more inclined to using medical platforms, and residents tend to seek medical services from these hospitals even for nonsevere conditions in China. As such, the overrepresentation of doctors from these hospitals might not undermine the validity of findings from our study. However, it is highly suggested that future studies conduct more in-depth investigations to understand the distinct behavior patterns of doctors from tertiary hospitals as compared to their counterparts from community clinics. Third, the selection of Hangzhou might merit questions about the external validity of the findings. Hangzhou is the most dynamic city in terms of its acceptance of mobile apps, as mentioned in the *Methods* section. If doctors in Hangzhou have reservations

about choosing a particular kind of mobile app, doctors in other cities probably will have similar concerns.

Conclusion

In contrast to the previous studies focusing on a single type of mobile app, our study further revealed doctors' adoption patterns across a wide range of mobile platforms, and the findings suggest their choices are aimed at improving their communication with patients, depending on the specific needs in offline services. Despite constraints posed by their affiliation with health care institutes, doctors still retain some autonomy in the adoption of medical information technologies. This autonomy enables them to leverage their medical expertise for disseminating knowledge or providing convenience to patients through social networking apps or medical platforms. The proliferation of medical information technologies offers doctors an alternative avenue to promote their own professional reputation without the necessity of relying on institutional support.

Our findings suggest that doctors' adoption of mobile apps is affected by macrolevel factors, particularly institutional interventions stemming from hospital affiliations. The presence of a state-society-health care provision nexus plays a pivotal role in shaping the doctor-patient-hospital relationship. Such findings also provide meaningful implications to inform doctors' adoption behavior in other countries, especially lower- and middle-income countries, which are confronted with similar issues of transitioning from traditional to modern societies. By addressing these macrolevel constraints, strategies can be devised to enhance the quality and efficiency of medical service delivery through mobile apps.

Abstract

Background: Mobile health (mHealth) interventions have the potential to improve health outcomes in low- and middle-income countries (LMICs) by aiding health workers to strengthen service delivery, as well as by helping patients and communities manage and prevent diseases. It is crucial to understand how best to implement mHealth within already burdened health services to maximally improve health outcomes and sustain the intervention in LMICs.

Objective: We aimed to identify key barriers to and facilitators of the implementation of mHealth interventions for infectious diseases in LMICs, drawing on a health systems analysis framework.

Methods: We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist to select qualitative or mixed methods studies reporting on determinants of already implemented infectious disease mHealth interventions in LMICs. We searched MEDLINE, Embase, PubMed, CINAHL, the Social Sciences Citation Index, and Global Health. We extracted characteristics of the mHealth interventions and implementation experiences, then conducted an analysis of determinants using the Tailored Implementation for Chronic Diseases framework.

Results: We identified 10,494 titles for screening, among which 20 studies met our eligibility criteria. Of these, 9 studies examined mHealth smartphone apps and 11 examined SMS text messaging interventions. The interventions addressed HIV (n=7), malaria (n=4), tuberculosis (n=4), pneumonia (n=2), dengue (n=1), human papillomavirus (n=1), COVID-19 (n=1), and respiratory illnesses or childhood infectious diseases (n=2), with 2 studies addressing multiple diseases. Within these studies, 10 interventions were intended for use by health workers and the remainder targeted patients, at-risk individuals, or community members. Access to reliable technological resources, familiarity with technology, and training and support were key determinants of implementation. Additional themes included users forgetting to use the mHealth interventions and mHealth intervention designs affecting ease of use.

Conclusions: Acceptance of the intervention and the capacity of existing health care system infrastructure and resources are 2 key factors affecting the implementation of mHealth interventions. Understanding the interaction between mHealth interventions, their implementation, and health systems will improve their uptake in LMICs.

Introduction

Mobile health (mHealth) technologies, defined by the World Health Organization (WHO) as "the use of mobile and wireless technologies to support health objectives," have the potential to improve health outcomes globally, including in low- and middle-income countries (LMICs) [1-6]. This is achievable through improving patient education, improving disease self-management, decreasing health care costs, and performing remote monitoring of patients, as reported in a recent systematic review of mHealth in LMICs [3]. In addition, mHealth can support preventative measures, facilitate disease management, or support health workers to strengthen the delivery of health care [7-10]. The WHO has highlighted the need to advance national digital health strategies that can facilitate universal health care [11]. The WHO's "Recommendations on digital interventions for health system strengthening" highlights that digital technologies, including mHealth, can directly address health system challenges by supporting more widespread coverage across population groups and improving the quality and affordability of health care [6]. This digital transformation of the health care system has been made possible by the widespread availability of affordable digital technology; currently, 95% of the world population has internet access [12].

mHealth interventions targeting infectious diseases care have the potential to greatly transform the health care landscape of LMICs, where infectious diseases still represent a substantial burden [13,14]. This is particularly important given health system challenges such as low health service utilization, poor adherence to clinical protocols among health workers, and geographic inaccessibility of health facilities [6].

The success and sustainability of mHealth interventions require overcoming context-specific barriers and enhancing facilitators of mHealth implementation; these factors must be considered prior to intervention design. The WHO's "Global Strategy on Digital Health 2020 - 2025" acknowledged the need to adapt digital health intervention implementation to unique national contexts, health situations, and trends, as well as a country's vision, available resources, and core values [11]. The WHO's "Recommendations on digital interventions for health system strengthening" further identified key implementation enablers including health content aligning with recommended practices, intervention functionality, and greater leadership and governance [6]. The WHO has emphasized that recognizing and addressing digital health implementation challenges uniquely faced by the least-developed countries is a large factor influencing the scalability and sustainability of emerging mHealth technologies [11].

mHealth interventions in LMICs have had limited success due to a range of health system factors not considered during the development and implementation of interventions [3-5,15-17]. Many mHealth interventions in LMICs remain as pilot studies that investigate feasibility, usability, and effectiveness, and they have not been scaled-up for integration within the broader health care system [17,18]. mHealth initiatives have often been developed for use in higher-resource health systems, with little consideration of differing contexts affecting implementation, such as social norms around a health-promoting behavior or access to resources [17]. Industry representatives, such as those from mobile phone providers, often push the scale-up of mHealth interventions rather than researchers, governments, or health workers [19]. This excludes crucial end user perspectives when developing mHealth interventions and risks having market-driven motives unrelated to health care encouraging the scale-up of interventions [19]. mHealth intervention teams also often fail to understand the relationship between users and mHealth technologies [2,19-21]. Previously reported barriers to the widespread adoption of mobile technologies that uniquely concern LMICs include poor mobile network coverage, limited health care workforce capacity, limited data access, or negative health worker and patient perceptions toward mHealth interventions [3-5,15-17].

Among the limited number of published reviews evaluating mHealth implementation, there is a lack of rigorous evaluation regarding the design and implementation of mHealth interventions to aid policymakers [3,16,20,22,23].

We therefore conducted a narrative review of the existing literature to understand the determinants of mHealth implementation for infectious diseases in LMICs. The review aims to consider the broader context, drawing on a comprehensive health systems analysis framework.

Methods

We searched MEDLINE, Embase, PubMed, CINAHL, the Social Sciences Citation Index, and Global Health. We collected studies that were the earliest available indexed in the above databases, up to and including May 31, 2023; the studies were exclusively in English.

Selection Criteria

Inclusion Criteria

1. Study population: We included individuals (of any age) with infectious diseases in LMICs. We took LMIC search terms from the Cochrane Effective Practice and Organisation of Care LMIC filters, defined according to the World Bank Classification (2022) [24]. We did not restrict the type of participants in the intervention (ie, we included health workers, patients, carers, general community members, and multiple types of participants).
2. Intervention: We defined mHealth interventions as per the WHO [6]. These interventions included SMS, electronic decision-support tools, educational tools, apps, and other strategies to improve health care delivery. We included interventions that used either mobile phones, smartphones, or tablet devices, conducted at any level of the health care system.
3. Comparator: We included studies where the current standard of care was a comparator, where applicable, in addition to studies without a control group listed.
4. Outcomes: We included qualitative and mixed methods studies that included a description of the mHealth intervention and implementation processes and reported on factors affecting implementation (eg, acceptability,

feasibility, essential resources) based on interviews or discussion groups.

Exclusion Criteria

We excluded formative research studies (ie, studies conducted before fully developing or implementing an intervention); study protocols; interventions involving computers or web-based health care (eg, websites); telehealth interventions (defined as consultation with a health worker via a mobile phone either through SMS or phone calls); and quantitative studies including randomized controlled trials, Likert scale surveys, and impact evaluations, as they did not provide in-depth reporting of qualitative factors affecting implementation. We excluded studies where mHealth was part of a larger complex intervention, studies from high-income countries, and studies that combined analysis of determinants across multiple countries where it was not possible to separate out findings from LMICs versus high-income countries.

Data Extraction and Analysis

Overview

The full search terms and strategy for the databases are detailed in Multimedia Appendix 1. Briefly, we included terms pertaining to LMICs, infectious diseases (eg, communicable disease), and mHealth terms (eg, mHealth, text message, mobile app). We did not include additional filters for qualitative versus quantitative studies.

Extracted Data

One reviewer (JGO) screened the titles and abstracts of the search output for relevant studies. As a next step, we conducted full-text screening. Where eligibility criteria were unclear, final consensus on article eligibility was based on discussions with another member of the author team (HMY).

We extracted characteristics of the mHealth intervention including intervention setting (country, LMIC status, health care setting); intervention design; content and purpose; target disease and population; and its quantitative impact on health outcomes originally targeted by the intervention, as reported in the included qualitative study. This was to aid our interpretation of how the qualitative implementation determinants we identified may have affected targeted health outcomes. The original quantitative impact evaluations were not sourced for this review. We also extracted data on details of the qualitative implementation study setting, study population, research question, data collection method, and study size, as well as broad implementation determinants considered by the authors.

Data Analysis and Reporting: Tailored Implementation for Chronic Diseases Framework

We performed a framework analysis of determinants affecting implementation based on the Tailored Implementation for Chronic Diseases (TICD) framework [25]. The TICD framework is a comprehensive checklist of determinants of clinical practice developed to inform implementation research projects that are tailored to local conditions [25,26]. The framework can be applied beyond contexts of chronic diseases, as the framework broadly focuses on health system components that determine quality of care. It identifies 7 key domains: guideline factors (clinical care guidelines or mHealth as a “guideline”); health worker factors; patient factors; professional interactions; incentives and resources; capacity for organizational change; and social, political, and legal factors. Its strength lies in its emphasis on ensuring tailoring to local conditions, which is valuable to consider for LMIC interventions, and inclusion of contextual (including political and legal) and patient factors affecting implementation. The TICD framework is a comprehensive health systems framework aligned with the systems thinking framework, which considers interactions with the broader context and patient needs in addition to the structural components of a health system [27].

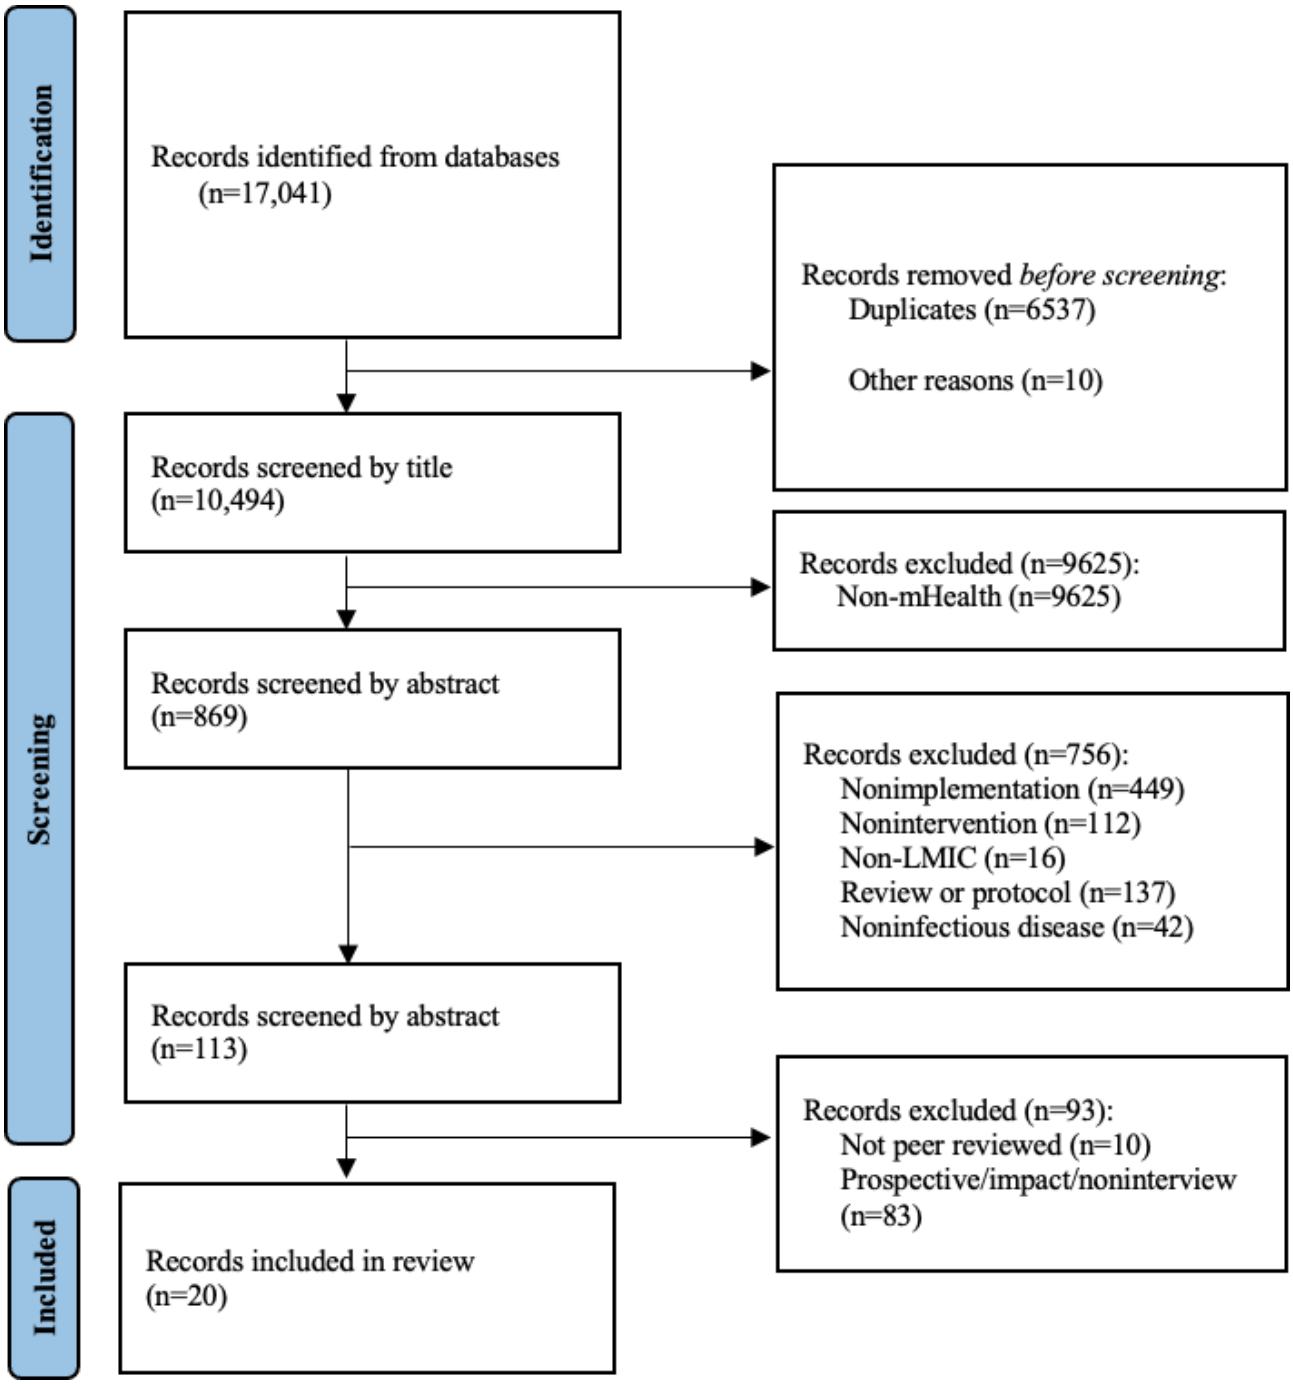
The framework was used to initially categorize the reported determinants of mHealth intervention implementation and was used to structure the reported findings in the results. Additional emergent themes, such as intervention design and forgetfulness, were extracted.

Results

Screening Results

A total of 17,041 records were initially identified. After removing 6537 duplicates, 10 non-English studies, and 9625 non–mHealth-related studies, a total of 869 studies underwent abstract screening in 2 rounds, each examining different criteria, as seen in Figure 1. A total of 20 studies were included for data extraction and final analysis.

Figure 1. PRISMA flow diagram. Screening strategy and PRISMA reported according to flow diagram for systematic reviews, including database searches. mHealth: mobile health; LMIC: low- and middle-income countries; PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Characteristics of Included Studies

Details of the intervention including study setting; intervention type and purpose; target disease and population; and quantitative impact evaluations (as reported in the included qualitative manuscripts) are presented in Table 1. Table 2 details qualitative studies analyzed in this review. Among the 20 included studies, 9 were apps and 11 were SMS interventions. Based on the World Bank 2022 Country Group by Income LMIC status [28], 8 were low income [8,9,29-34], 6 were lower middle income [10,35-39], and 6 were upper middle income [7,21,40-43]. Of the 20 studies, 7 focused on people living with or at risk of acquiring HIV [7,21,31,33,34,39,41]; the remaining studies targeted malaria [8,30,35,36], tuberculosis [31,38,42,43], pneumonia [10,30], dengue [37], a grouping of "respiratory illnesses" [9] or "childhood chronic infectious diseases" [29], HPV [40], or COVID-19 [32]. There were 2 studies that addressed multiple diseases [30,31]. Half (10/20) of the interventions targeted health workers [9,10,21,30,31,35,36,39,40,42,43], while the remainder were for patients, individuals at risk of disease, or general community members [7,8,21,29,32-34,37,38,41]. Most studies (11/20) involved community level health care [7,8,10,21,29,32,33,36,37,39,41].

Determinants of mHealth implementation are reported according to the 7 TICD domains and additional emergent themes.

Table . Characteristics of mHealth intervention among included studies.[a]

Country, author, year, reference	World Bank country income classification	Level of health care; health care context	mHealth intervention	Study design of original quantitative study/comparator	Content of the intervention	Purpose of the intervention	Target disease(s)	Target user(s)	Quantitative impact of mHealth intervention on targeted health outcome(s) as reported in the qualitative study
Argentina, Straw et al, 2023 [40]	Upper middle	Primary; primary hospital and primary health care centers consisting of community health workers	SMS	C-RCT[b]/standard of care	Reminder messages to women with HPV[c], and one to community health workers about women with no triage 60 days after positive HPV test	Improve Pap triage of HPV-positive women	HPV	HPV-positive women and health workers	Both acceptability of the intervention by HPV-tested women and its adoption by health workers were high: 15% increase in percentage of women with triage Pap after HPV result. Statistical significance not reported
Ghana, Ginsburg et al, 2016 [10]	Lower middle	Community; health centers and community-based health planning and service centers in rural Ghana	App (phone or tablet)	Not reported	Software-based breath counter and a pulse oximeter to count child's breaths, off-the-shelf reusable pediatric pulse oximeter to detect hypoxia	Improve pneumonia diagnosis and treatment and childhood illnesses in general in accordance with the Integrated Management of Childhood Illness guidelines	Pneumonia	Health workers	Not reported
Kenya, Jones et al, 2012 [35]	Lower middle	Primary; government dispensaries and health centers	SMS	C-RCT/control group	Pediatric outpatient malaria case management accompanied by "motivating" quotes to health worker's personal mobile phones. Two messages per day across five working days for the duration of the study (26 weeks)	Improve health worker's malaria case-management practices, specifically drug dispensing and management	Malaria	Health workers	Intention-to-treat analysis showed 24% improvement compared to baseline in correct antimalarial drug management immediately after the intervention, sustained effect of 25% six months later. Statistical significance not reported

Country, author, year, reference	World Bank country income classification	Level of health care; health care context	mHealth intervention	Study design of original quantitative study/comparator	Content of the intervention	Purpose of the intervention	Target disease(s)	Target user(s)	Quantitative impact of mHealth intervention on targeted health outcome(s) as reported in the qualitative study
Malawi, Ide et al, 2019 [29]	Lower	Community; village clinic in Northern Malawi	App	Not reported	App-directed assessment and management of the visit; the visit was documented in both the app and the village clinic register	Improve assessment, classification, and treatment of seriously ill children, facilitate disease monitoring and surveillance [44]	Childhood infectious disease outbreaks	Health surveillance assistants, caregivers	Not reported
Malawi, Kaunda-Khangamwa et al, 2018 [30]	Lower	Primary and tertiary; health facilities operated by government or private care (including tertiary hospitals)	SMS	C-RCT/control group with no messages	Twice-daily text message reminders on case management of malaria, pneumonia, and diarrhea sent to clinicians and drug dispensers	Improve case management of malaria, diarrhea, and pneumonia	Malaria, diarrhea, pneumonia	Health workers	Nonsignificant, 4% improvement in correct malaria case management. Statistical significance not reported
Mali, Mangam et al, 2016 [8]	Lower	Community; rural district community	SMS	3 pilot intervention villages against 3 nonintervention villages	Educate and instruct households about indoor residential spraying campaign	Lower malaria prevalence through preventative measures	Malaria	Households	Significantly lower among the mobile-messaging villages than the door-to-door mobilization villages (86% vs 96%, respectively; P=.02) and significantly lower structural preparedness in households mobilized through the mobile-messaging approach compared with the door-to-door approach (household and food items removed; 49% vs 75%, respectively; P=.03)

Country, author, year, reference	World Bank country income classification	Level of health care; health care context	mHealth intervention	Study design of original quantitative study/comparator	Content of the intervention	Purpose of the intervention	Target disease(s)	Target user(s)	Quantitative impact of mHealth intervention on targeted health outcome(s) as reported in the qualitative study
Mozambique, Nhavoto et al, 2017 [31]	Lower	Primary; health care centers providing intense ART[d] and tuberculosis care	SMS	RCT[e]/no comparator	Structured series of SMS text messages sent automatically based on appointments and scheduled drug pick-ups. Messages were sent 7 and 2 days before appointment or drug pick-up	Support retention in ART and tuberculosis treatment	HIV and tuberculosis	Patients and health workers	The majority of HIV patients (61/68, 90%) and the majority of tuberculosis patients (60/68, 88%) reported not having missed any appointments. Majority of the patients (HIV: 56/68, 82%; tuberculosis: 65/67, 97%) reported not having missed medication pick-up at any time
Myanmar, Win Han et al, 2021 [36]	Lower middle	Community; ICMV[f] managed by Myanmar's National Malaria Control Programme and its implementing partners	App (phone)	Mixed method/paper-based reporting control group	Malaria case-based data entered by ICMVs directly in the app on their mobile phones, which is instantly uploaded onto the dedicated District Health Information System 2 database	Enabled more accurate and complete data reported to improve integrated community malaria volunteers' malaria prevention, diagnosis, treatment and referral services	Malaria	Health workers	Not reported

Country, author, year, reference	World Bank country income classification	Level of health care; health care context	mHealth intervention	Study design of original quantitative study/comparator	Content of the intervention	Purpose of the intervention	Target disease(s)	Target user(s)	Quantitative impact of mHealth intervention on targeted health outcome(s) as reported in the qualitative study
Nepal, Bhattarai et al, 2019 [37]	Lower middle	Community; rural households in district highest in dengue outbreaks	SMS	Nonrandomized quasi-experimental design. Control group (standard of care), dengue prevention leaflet only group, dengue prevention leaflet with mobile SMS intervention group	Disseminate preventative health messages via mobile phone twice per week	Change in dengue preventative knowledge and practice of respondents	Dengue	Households	Dengue prevention leaflet and SMS intervention combination significantly improved dengue prevention knowledge (mean 32.7, SD 13.7 vs mean 13.3, SD 8.8) and practice (mean 27.9, SD 11.4 vs mean 4.9, SD 5.4) compared to without SMS (P<.001)
Pakistan, Mohammed et al, 2012 [38]	Lower middle	Secondary; hospital in low-income industrial area (free)	SMS	No control group	Daily reminders sent and patients were asked to respond after taking their medication. Motivational message, followed by a reminder to respond to the system	Improve tuberculosis drug adherence	Tuberculosis	Patients with tuberculosis	Mean response rate of 57% for all participants. The mean response rate fell from 62% during the first 10 days to 49% during the last 10 days across the 30-day intervention. Statistical significance not reported.

Country, author, year, reference	World Bank country income classification	Level of health care; health care context	mHealth intervention	Study design of original quantitative study/comparator	Content of the intervention	Purpose of the intervention	Target disease(s)	Target user(s)	Quantitative impact of mHealth intervention on targeted health outcome(s) as reported in the qualitative study
Russian Federation (Siberia), Hodges et al, 2022 [7]	Upper middle	Community; inpatient and outpatient settings in the tuberculosis referral hospital and AIDS center	App (phone)	Not reported	Daily patient check-ins or queries regarding stress, mood, and ART adherence; appointment reminders; tailored educational resources; access to HIV-related lab results; community message board for anonymous peer messaging; direct messaging with clinic care team members outside of the clinic	Enhance linkage of HIV/tuberculosis coinfected patients to HIV care and promote sustained engagement with and integration of HIV and tuberculosis care	HIV	People with HIV	Improved rates of linkage to care at the AIDS center, improved medication refill rates, reduced virologic failure at 6 months on ART. Related statistics were not reported.
Rwanda, Babili et al, 2023 [32]	Lower	Community; home-based care	SMS	Not reported	Automated check-in message sent daily for 14 days, contact tracing, and data centralization	Real-time remote monitoring and support of COVID-19 cases and contacts	COVID-19	Patients with COVID-19	Nonresponse rate 25% - 30%
South Africa, Adeagbo et al, 2021 [41]	Upper middle	Community; rural and periurban HIV hyperendemic area	App (tablet)	C-RCT/standard of care	Enable user to hear the “story” of a chosen character portrayed on the app	Improve HIV testing and linking with care in rural South Africa	HIV	Male participants at risk of HIV	83% consented to and used a home-based rapid HIV test, 33% received HIV testing for the first time in the annual HIV surveillance. Statistical significance not reported.

Determinants of mHealth Implementation: TICD Framework

Guideline Factors

There were 6 studies that reported on how lack of clarity and understanding of the intervention hindered its uptake. For example, users did not respond to mHealth intervention text message prompts because they were uncertain about how to use the personal identification number, were uncertain about how to respond to the message, or received little to no information about the background of the intervention [7,30,33,39,40,43]. Compatibility of the intervention with users' past experiences with either the technology and its use in health care, or the intended change in health care practice, was a key facilitator that aided in implementation. Existing familiarity with the intended behavior promoted by the intervention—such as antiretroviral treatment adherence, HIV testing, or general interactions with the health care system—facilitated uptake [21,29,35,38,41]. The mHealth intervention in Babili et al's study—WelTel, assessed for COVID-19 case and contact management—was previously implemented for HIV epidemic virtual care, which facilitated its implementation as users were familiar with the platform and its functionality [32]. Similarly, health workers commented on how an app's alignment with existing practices of using the village clinic register increased the likelihood of engagement [29]. Existing mobile phone use or interest in the use of new technologies were additional facilitators, as users were already familiar with making appointments, making calls, or using SMS technology [8-10,32,33,36,37,42]. Trustworthiness of the source of the recommendation given by the mHealth intervention facilitated implementation, particularly when the mHealth intervention intended to aid health workers in improving their health care practice or disease management [10,29,32,35,40].

Individual Health Care Worker Professional Factors

mHealth being perceived as useful by end users in improving existing health care practices facilitated the uptake and integration of the intervention. For instance, after initial use of the intervention, a perception that it might improve existing clinical practices, improve patient engagement with services, or relieve strain on the health system were key for implementation [9,29-32,35,36,39,40,43]. Health workers in Ide et al's study perceived the app as advantageous over existing systems, as the intervention aided in conducting more accurate, error-free community case management of malaria, diarrhea, and pneumonia, which facilitated uptake [29].

Furthermore, for interventions for which the main users were health workers, attitudes toward the intervention were impacted by the perceived effect of the use of the intervention on the health worker's reputation. Ellington et al identified that the perceived loss of trust between patients and health workers in the health worker's ability to diagnose and treat patients due to their reliance on technology to deliver health care was a barrier to using the app [9]. In contrast, Ide et al commented on how the app facilitated perceived professionalism [29]. Twimukye et al commented on how the health worker's use of the app improved how the patient perceived the health worker's attention to detail and care [34].

Patient Factors

Patients perceiving the intervention as beneficial in improving health outcomes through increased convenience, awareness, or reminders facilitated implementation of the intervention [34,38,41,43]. Adeagbo et al commented on how the app's positive messages about HIV testing and adherence promoted users to adopt new behaviors by improving individual competency to make informed, healthy decisions concerning sexual health [41]. Language literacy was a barrier that limited engagement with 2 SMS intervention studies targeted at patients or community members [8,38].

Professional Interactions

Limited supervision and follow-up of the intervention implementation by the research team leading the intervention was noted as a barrier, as users requested feedback and confirmation of correct intervention use [30]. Lack of or limited access to training to provide necessary skills to effectively engage with the mHealth intervention was a barrier to implementation for health workers [9,36]. Access to professional training was a facilitator of implementation [10,29,40].

Incentives and Resources

Several studies reported that access to resources and essential infrastructure influenced implementation. Specifically, 6 studies reported that poor telecommunications networks, problems with electricity, a lack of phone coverage, limited staffing, and a lack of equipment to implement the behavior change were barriers to implementation [10,30,33,37,40,42]. Network problems were particularly prominent in geographically remote areas. Other barriers included technology that repeatedly malfunctioned (such as periodic freezing and system crashes) and limited access to technology support systems to troubleshoot technological problems [7,29,32-34,36,38,42,43]. Access to technological resources and support in case of malfunctions facilitated implementation [33].

Capacity for Organizational Change

Financial instability, existing patient overflow, incompatible technological equipment, and length of appointment time within the clinic hindered the implementation of mHealth interventions [7,9,30,37,39]. Kaunda-Khangamwa et al reported that 90% of the health worker respondents blamed existing high workloads and drug stockouts as factors discouraging health workers to respond to SMS reminders that promoted infectious disease case management [30]. Similarly, Ellington et al's study identified that the existing length of the appointment time was not compatible with mHealth intervention use as the time to complete a health assessment through the app took longer than the appointment duration [9]. Straw et al commented on the compatibility of the mHealth intervention with the existing organization functionality to facilitate normal workflow as a facilitator of implementation [40]. A lack of management and ownership of the intervention by health workers further contributed to a limited capacity for embedding the intervention within the health care facility [39].

Social, Political, and Legal Factors

One study commented that the costly nature of airing messages during the daytime and limited funding for the intervention were barriers to successful implementation [42]. Receiving national-level support on a political level including the Minister of Health or district leadership was a facilitator of implementation [9,10,32]. Babili et al commented on how the Rwandan government's support of digitization across all governmental sectors by offering resources for implementation aided the adoption of the digital health intervention [32]. Furthermore, shared responsibility and corporate social responsibility felt among the wider community was an enabler, as the charitable community assisted in reducing costs and improving uptake [37].

Emergent Themes

A novel factor not directly addressed in the TICD framework is the importance of considering app or SMS design features. Frequency of messages, language, and integration of local narratives to engage users were reported as affecting ease of use and user uptake [9,10,30,34,35,37,41,42]. mHealth interventions that adapted content toward the intervention context by using local proverbs, narratives, or language facilitated uptake of the intervention [7,30,35,41]. Moreover, features such as a user-friendly interface and a streamlined workflow facilitated implementation, while an intervention design that increased the workload of health workers was a barrier to implementation [32].

The study by Mangam et al, whose reminder SMS system replaced the existing door-to-door reminders, uniquely commented on how the absence of face-to-face reminders increased the rate of forgetfulness and patients ignoring the messaging, thereby affecting its implementation [8].

mHealth Impacts on Target Health Outcomes and How Implementation Determinants May Have Influenced These Outcomes

As described in Table 1, there were 8 studies that identified that mHealth had a positive impact on health outcomes or behavior, whether that was through increased HIV testing, reduced errors in drug and disease management, or improved disease prevention knowledge, results collection, or linkage to care for better clinical practice [7,29,31,35,37,39-41]. In 4 studies, the mHealth intervention did not lead to an improvement in the health outcome—responses to SMS prompts were low, preventative measures were worse than in the non-mHealth control group, or user uptake was low [8,33,38,42]. There were nonsignificant changes in health outcomes or behavior in 2 studies [30,43]. Quantitative health outcomes were not reported in 6 of the reviewed studies [9,10,21,32,34,36].

Improved outcomes may be explained by familiarity with the health behavior or technology [7,29,35,37,41], positive attitudes among health workers toward the technology [29,31,35], or ease of use of the mHealth technology [7,35,37,41]. Technological barriers, lack of familiarity with technology, and resource limitations [8,30,33,38,42,43] may have reduced engagement with the intervention or the participants' ability to

implement the behaviors enforced by the intervention, therefore diluting the intervention effect.

Discussion

Principal Findings

Findings from the 20 reviewed studies and categorization into the TICD framework were synthesized to deduce two overarching themes that influenced the successful implementation of mHealth initiatives in LMICs: (1) the acceptance of the intervention by patients and health workers (as well as on a sociopolitical level), regardless of the target user, and (2) the capacity of existing infrastructure and resources to implement the intervention, which was strongly tied to the health system's capacity for change. This relationship is visually depicted in Figure 2. The logic flow diagram in Figure 3 further represents these reported factors according to inputs required for mHealth interventions and the required processes for success.

Figure 2. Model of factors influencing implementation of mHealth interventions in LMICs. The two main factors are presented in large boxes: (1) acceptance of the intervention and (2) capacity of the existing infrastructure and resources to accommodate mHealth. Acceptance, in turn, was mainly influenced by perceived usefulness of the intervention, amount of training and communication, and previous experience with the guideline behavior and mHealth or technology. The health care system's capacity and infrastructure and resources were influenced by funding, network availability, and technological support. mHealth: mobile health.

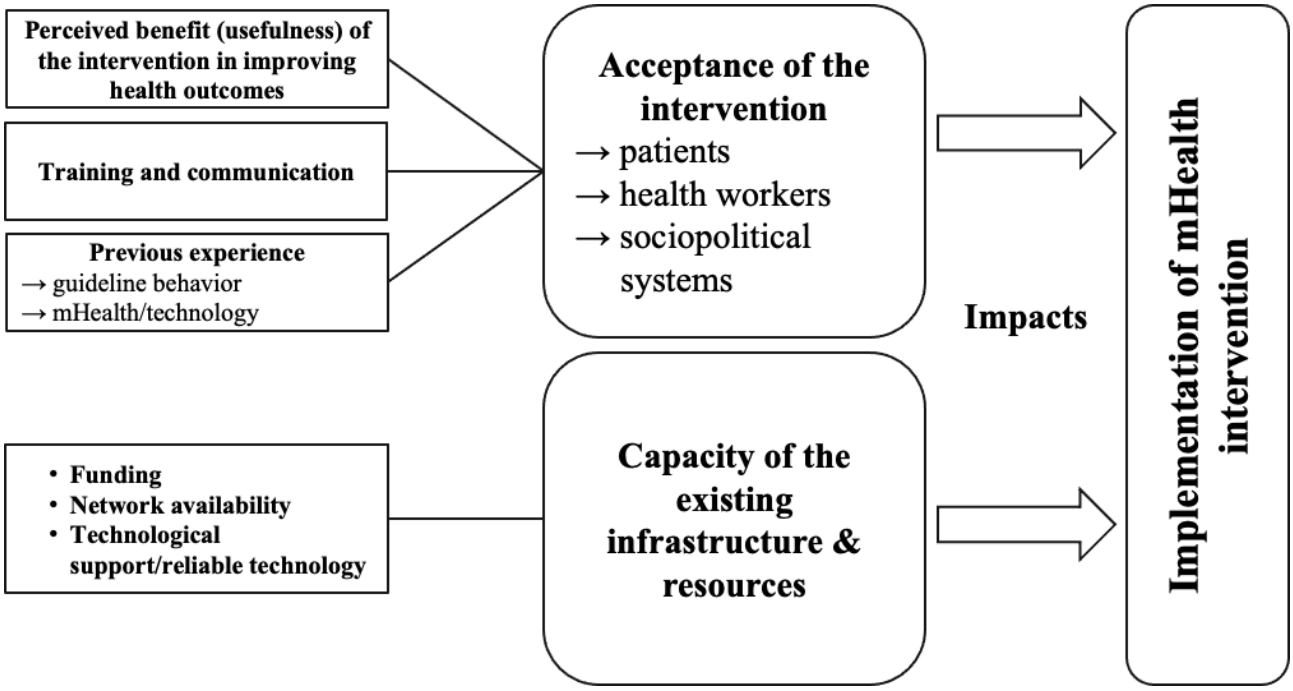

Figure 3. Logic diagram depicting determinants of successful mHealth implementation. Overview of mHealth implementation determinants from the mHealth design and resource input stage to the process of implementation and the desired outcomes and impact. mHealth: mobile health.

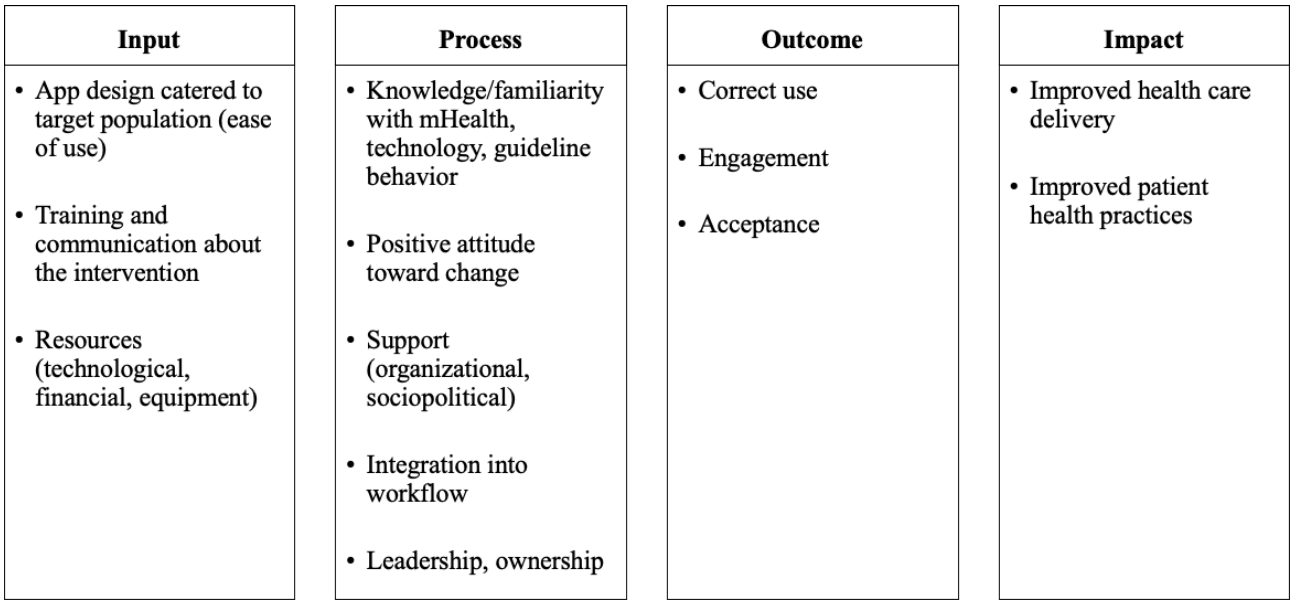


Acceptance of the Intervention

Overview

Acceptance of the intervention was strongly linked to uptake of the intervention, which facilitated implementation of the intervention and its potential to improve health outcomes. Patients and health workers were influenced by the perceived benefits of the intervention in improving health outcomes, the extent of training, and previous experience with the guideline behavior or mHealth.

Perceived Benefit of the Intervention

Perceived benefit of the intervention was influenced by ease of use and design of the intervention [9,10,30,32,34,35,37,41,42]. Where an app or SMS design engaged users in a way that improved health outcomes, patient engagement with health care services, or health care efficiency, participants were less likely to perceive the use of the mHealth technology as burdensome, facilitating successful implementation [9,29-32,34-36,38-41,43]. An intervention that provided a clear advantage compared to existing practice facilitated the perception of it being beneficial, as supported by the intervention's design and ease of use. These findings were consistent with Davis's Technology Acceptance Model and its application in health care, which suggests that perceived ease of use and usefulness both affect attitudes toward and use of technology [46,47]. Design considerations was an emergent factor unique to mHealth and technology-related interventions, emphasizing the value of iterative design of the mHealth intervention before implementation [9,10,30,34,35,37,41,42]. Further reviews reporting on mHealth in the context of antiretroviral therapy adherence and maternal health have identified the importance of intervention design, including tailoring SMS messages and the frequency of reminders [48,49].

Political support of the intervention ensured effective implementation; this included stakeholder buy-in and approval of the intervention, and support from health administrators on a district level [9,10,32]. The importance of understanding the need for the intervention to reduce disease burdens or improve health care services is supported by a previous review by Opoku, Stephani, and Quentin [50]. Therefore, regardless of the target user, perceived benefit of the intervention is crucial for implementation of the initiative, emphasizing the community-wide, integrated nature of mHealth interventions.

However, studies by Kaunda-Khangamwa et al and Mangam et al noted that, despite the users' positive attitudes toward the intervention, factors such as lack of communication regarding intervention use and limited resources to implement the behavioral guideline hindered implementation [8,30]. Perceived value of the intervention and acceptance alone therefore cannot guarantee successful implementation and positive outcomes from an intervention.

Training and Communication

Users who received communication and training on the intervention and its use before or during its implementation engaged well with the intervention and intended guideline practice [9,10,29,36]. Lack of awareness and clarity regarding how to engage with the intervention were consistently noted across studies with limited user engagement [30,33,43]. Sufficient training has been previously noted in a review as a contributing factor to mHealth intervention implementation, which is closely linked to the perceived ease of use [2]. For interventions aimed toward health workers, training was either provided by the intervention research team members or between health workers; follow-up on correct use was identified as being important for encouragement and continued intervention use [7,9,10,30,42].

Compatibility With Existing Health Care Practices and Social Norms

Familiarity With the Guideline Recommendation

Among studies that had high engagement with mHealth and improved health outcomes, existing familiarity with the guideline behavior, such as treatment adherence or HIV testing, was recurringly noted as a facilitator of implementation [7,37,39,41]. This suggests that successful mHealth initiatives complemented normative behavior, existing health care practices, and "new" practice (eg, interventions to improve treatment adherence), given their importance was already understood. This suggests mHealth has limited value in establishing new behavioral practices but rather is advantageous in complementing existing practices. Compatibility with existing behavior was strongly linked to the perceived benefit of the intervention; when the intended guideline was not yet an established practice or initially perceived as useful, mHealth interventions that encouraged this behavior were less likely to be accepted by the user [21,29,35,38,41]. Ide et al's study commented on how the mHealth intervention facilitated existing practices of childhood infectious disease management and improved reliability of the tests [29].

Although social norms (such as stigma) were only reported in 1 study [34], a number of studies commented on how users who were already comfortable sharing diagnoses or their health status were more engaged in the mHealth intervention, suggesting mHealth success is dependent on existing social norms and behaviors [34,39,43].

Attitudes and Familiarity With mHealth

Lack of familiarity with mobile phone use was a clear barrier to implementation; this barrier was particularly noted in studies with limited successes [8,43]. An existing understanding of the benefit of mHealth interventions—or previous positive experiences with mHealth—also affected user uptake. This was indirectly seen in mHealth intervention uptake being influenced by the perceived impact of use on provider-patient relationships [9,29,34]. This factor was conflicting across multiple studies, as Ide et al and Twimkukye et al commented on how the mHealth intervention facilitated perceived professionalism and improved provider-patient relationships, while Ellington et al noted the perceived decreased patient trust of the health worker to diagnose and treat the patient [9,29,34]. A systematic review of maternal health interventions also identified that technological literacy and previous experience of mHealth use were enablers of mHealth uptake, among a range of other factors [51,52].

Capacity of Existing Infrastructure and Resource Availability

The importance of capable infrastructure and resource availability have been noted by existing systematic reviews as key determinants of implementation [2,5,15,50-52]. Reviewed studies further confirmed this and noted the importance of staffing, network availability, technological support, and reliable technology in facilitating the implementation of the intervention [9,29,33,34,36-38,42,43]. These factors were tightly linked to social, political, and legal factors (such as limited staff funding or unstable network coverage to remote areas); these barriers often reflected the greater health care system's resourcefulness. Analysis of the factors influencing implementation therefore emphasized the interaction of health system components and the importance of considering the broader context beyond the health care system, as described in the systems thinking framework [27]. It is possible that due to the targeted, narrow nature of some of interventions, there was insufficient technological support or insufficient resources for successful implementation. Increased health data reporting on a health care system level could also contribute to improved resource allocation and policy decisions from sociopolitical organizations that could aid in mHealth implementation [53]. This further emphasizes the importance of understanding the value of the intervention in improving health outcomes across all stakeholders, as it could result in securing increased funding for the improved implementation of the initiative.

Further determinants of implementation included the system's capacity for change, such as how the intervention fit into existing appointment durations and organizational leadership structures [9,36]. This limited capacity for change could reflect the unstable foundation and support of the health care systems within these communities and indicates a potential lack of preparation for future changes or health challenges. Existing reviews on mHealth implementation have also commented on the importance of considering the existing health care system, such as government funding and capacity, when implementing mHealth interventions [2,15,16].

Strengths and Limitations

This review is valuable in its consideration of findings across a range of different LMIC settings in Africa and Asia, with a particular focus on periurban and rural areas. The diversity of study settings provides a broad range of factors to consider during implementation in different LMIC contexts. This review synthesized findings by drawing on a comprehensive health systems framework [25] and additional themes, further contributing to its novelty.

However, our review had several limitations. First, most studies (15/20) were conducted in Africa, limiting generalizability to other regions. Second, it was challenging to weigh the relative importance of each implementation determinant in each study, as the included studies were all qualitative. Regardless, the findings provide insights that quantitative results would not have been able to capture. Third, all studies were limited in that data were mainly from patients, health workers, administrators, or assistants, rather than from a sociopolitical level. Fourth, we did not source the primary quantitative impact evaluations of mHealth interventions. For further study, quantitative outcomes from impact studies can be better correlated with the specific determinants—and their respective strength of association—of implementation.

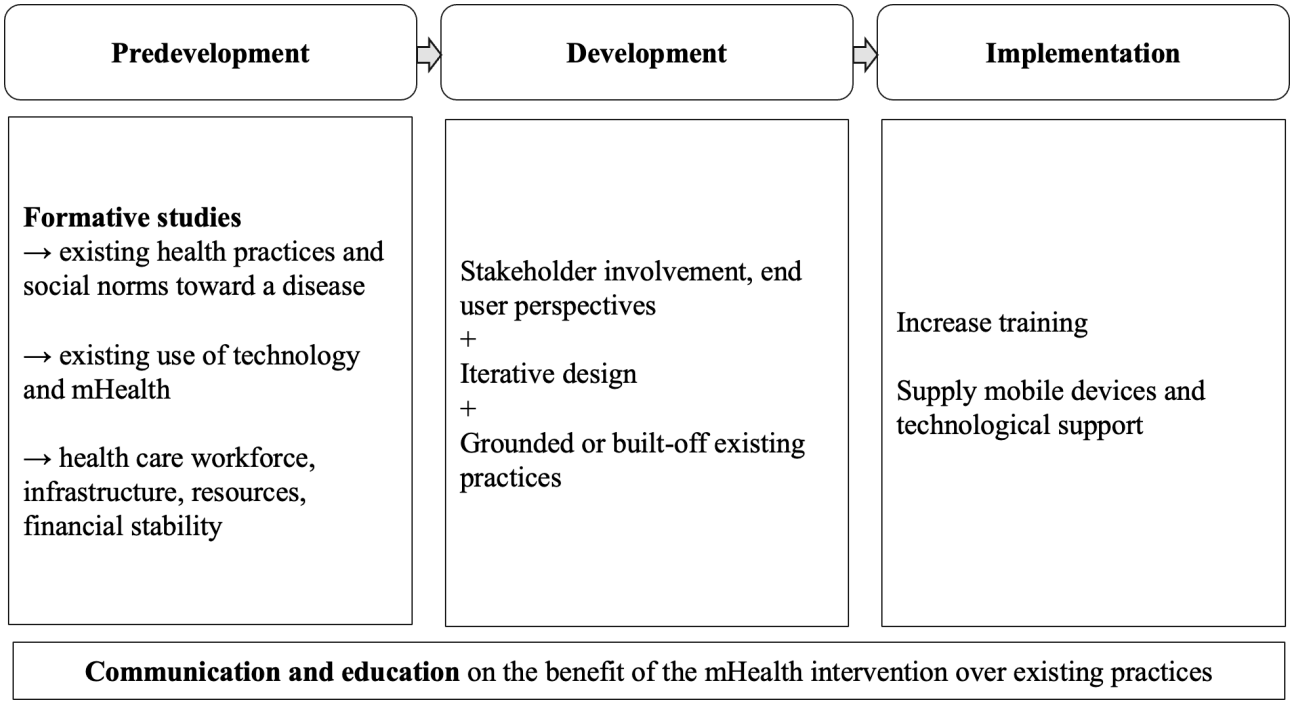
Recommendations

Overview

Insights from this review can help shape health policies and identify key considerations when developing mHealth interventions to improve their efficacy and sustainability in improving health outcomes. A full list of recommendations as reported in each study is noted in Multimedia Appendix 2.

When interpreting findings, it is important to consider the different contexts within which mHealth interventions are implemented, as they must be tailored to the context. Several considerations are important during predevelopmental, developmental, and implementation phases of the mHealth intervention, as seen in Figure 4.

Figure 4. Identified recommendations for successful implementation of mHealth interventions. mHealth: mobile health.



Predevelopmental Considerations

A thorough understanding of existing health and technology practices and social norms toward a disease are crucial to predict the feasibility of an mHealth intervention in a specific context. This understanding of the cultural context and structural factors—such as the broader health care workforce, capacity of existing infrastructure, and resource availability—can be achieved through formative research [42]. Communication and education about the importance of health care practices and mHealth's ability to facilitate health can aid in the acceptance of the mHealth intervention.

Development of the Intervention

There were 4 studies that performed prepilot testing and designed the intervention iteratively to maximize participant engagement with the intervention during implementation [7,8,31,42]. For example, through pilot testing, Mangam et al identified the need to incorporate interactive voice messaging in their SMS intervention, as many users were unable to read or understand the texts [8]. To complement the theoretical foundations of an intervention, studies emphasized the importance of stakeholder involvement in the iterative design process during the development of the initiative [2,8,15,16,19,20,42].

Implementation of the Intervention

As most interventions require a change in knowledge or behavior, it is important to communicate the benefit of the mHealth intervention compared to existing practice, prior to and during implementation. Increased training will increase confident user engagement with the intervention for long-term improvement of health outcomes [10,33,36]. Supplying mobile devices and offering technological support were recommended by studies to mitigate technological barriers [9,10,36].

It is important to tailor mHealth interventions to complement existing health services and face-to-face practices to optimize the desired health outcome. Adeagbo et al commented on how the mHealth intervention alone was insufficient in completely removing the barrier of accessing HIV testing and health care services [41]. Mangam et al discussed how future mHealth-based mobile communication should complement the community's existing familiarity with interpersonal communication, particularly as their SMS notifications of health prevention measures were not met with improvement compared to the non-mHealth, face-to-face status quo [8]. An example of complementing mHealth with non–technology-based communication is seen in the study by Bhattarai et al, who paired SMS text messaging with pamphlets [37].

Conclusion

This review provided comprehensive insight and an analysis of factors influencing the implementation of mHealth initiatives in LMICs. This review underscores the importance of iterative development of the intervention and deep consideration of the structural factors and cultural context before mHealth implementation to ensure scalability and sustainability to improve communicable health outcomes in LMICs.

Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files.

Abstract

Background: Promoting physical activity (PA) and healthy feeding (HF) is crucial to address the alarming increase in obesity rates in developing countries. Leveraging mobile phones for behavior change communication to encourage infant PA and promote HF is particularly significant within the Mexican context.

Objective: This study aims to explore the effectiveness and feasibility of mHealth interventions aimed at promoting PA and HF among primary caregivers (PCs) of Mexican children under the age of 5 years. Additionally, the study aims to disseminate insights gained from intervention implementation amidst the COVID-19 pandemic and assess the potential of behavior change mHealth interventions on a broader population scale.

Methods: NUTRES, an mHealth intervention, underwent an effectiveness-implementation hybrid trial. Over 36 weeks, participants in the intervention group (IG), totaling 230 individuals, received approximately 108 SMS text messages tailored to their children's age. These messages covered topics such as PA and HF and emphasized the significance of proper child nutrition amidst the COVID-19 pandemic. NUTRES participants were recruited from both urban and rural health units across 2 states in Mexico. Given the COVID-19 context, both baseline and follow-up surveys were conducted via mobile or fixed telephone. The evaluation of effectiveness and implementation used a mixed methods approach. Qualitative analysis delved into participants' experiences with NUTRES and various implementation indicators, including acceptance, relevance, and coverage. Grounded theory was used for coding and analysis. Furthermore, difference-in-differences regression models were used to discern disparities between groups (comparison group [CG] versus IG) concerning knowledge and practices pertaining to infant PA and HF.

Results: Of the total 494 PCs enrolled in NUTRES, 334 persisted until the end of the study, accounting for 67.6% (334/494) participation across both groups. A majority of PCs (43/141, 30.5%, always; and 97/141, 68.8%, sometimes) used the SMS text message information. Satisfaction and acceptability toward NUTRES were notably high, reaching 98% (96/98), with respondents expressing that NUTRES was "good," "useful," and "helpful" for enhancing child nutrition. Significant differences after the intervention were observed in PA knowledge, with social interaction favored (CG: 8/135, 5.9% vs IG: 20/137, 14.6%; *P*=.048), as well as in HF practice knowledge. Notably, sweetened beverage consumption, associated with the development of chronic diseases, showed divergence (CG: 92/157, 58.6% vs IG: 110/145, 75.9%; *P*=.003). In the difference-in-differences model, a notable increase of 0.03 in knowledge regarding the benefits of PA was observed (CG: mean 0.13, SD 0.10 vs IG: mean 0.16, SD 0.11; *P*=.02). PCs expressed feeling accompanied and supported, particularly amidst the disruption of routine health care services during the COVID-19 pandemic.

Conclusions: While NUTRES exhibited a restricted impact on targeted knowledge and behaviors, the SMS text messages functioned effectively as both a reminder and a source of new knowledge for PCs of Mexican children under 5 years of age. The key lessons learned were as follows: mHealth intervention strategies can effectively maintain communication with individuals during emergencies, such as the COVID-19 pandemic; methodological and implementation barriers can constrain the effectiveness

of mHealth interventions; and using mixed methods approaches ensures the complementary nature of results. The findings contribute valuable evidence regarding the opportunities and constraints associated with using mobile phones to enhance knowledge and practices concerning PA and HF among PCs of children under 5 years old.

Introduction

Because of the short and long-term adverse effects of overweight/obesity on health and human capital, the World Health Organization (WHO) emphasizes its prevention early in life as a critical priority [1]. There is mounting evidence indicating that children from low socioeconomic backgrounds exhibit higher rates of overweight/obesity [2,3]. Mexico is particularly alarmed by the escalating prevalence of overweight/obesity among children under 5 years old, with the most recent national estimates projecting a combined rate of approximately 8% in 2022 [4]. Nevertheless, socioeconomically disadvantaged families are often more challenging for the health sector to engage with, and they may be less inclined to participate in programs promoting healthy behaviors [5]. Mobile health (mHealth) technologies and telecommunications present themselves as appealing low-cost interventions capable of reaching vast and remote populations [6].

In low- and middle-income countries [7], resources have been directed toward the development of mHealth interventions, including behavior change communication (BCC) strategies [8]. A 2019 systematic review [9] revealed that the most commonly used mHealth technology was SMS text messaging (60%). Additionally, there is evidence suggesting that eHealth and mHealth interventions are effective in promoting physical activity (PA) and healthy feeding (HF) in developing countries [10].

Hence, leveraging mobile phones for BCC interventions presents a promising opportunity to advocate for HF and PA practices among primary caregivers (PCs) of the Mexican child population. This is especially significant considering the rising and widespread use and accessibility of this technology, which has increased from 71.5% of the total population in 2015 to 79.2% in 2022 [11]. In particular, in emergency contexts where health services are disrupted and face-to-face information dissemination to the population is hindered, as was evident during the COVID-19 pandemic, leveraging innovative mHealth interventions becomes crucial. In this regard, testing and evaluating such interventions in emergency settings can significantly contribute to the existing evidence on mHealth. Moreover, it can serve to stimulate further research endeavors to complement and expand upon the findings of this study.

Hence, this research aimed to assess the effectiveness and implementation of an mHealth intervention, referred to as NUTRES, in promoting PA and HF practices among Mexican PCs of children under 5 years. A secondary objective was to document the lessons learned from implementing and evaluating an mHealth intervention during the COVID-19 pandemic.

Methods

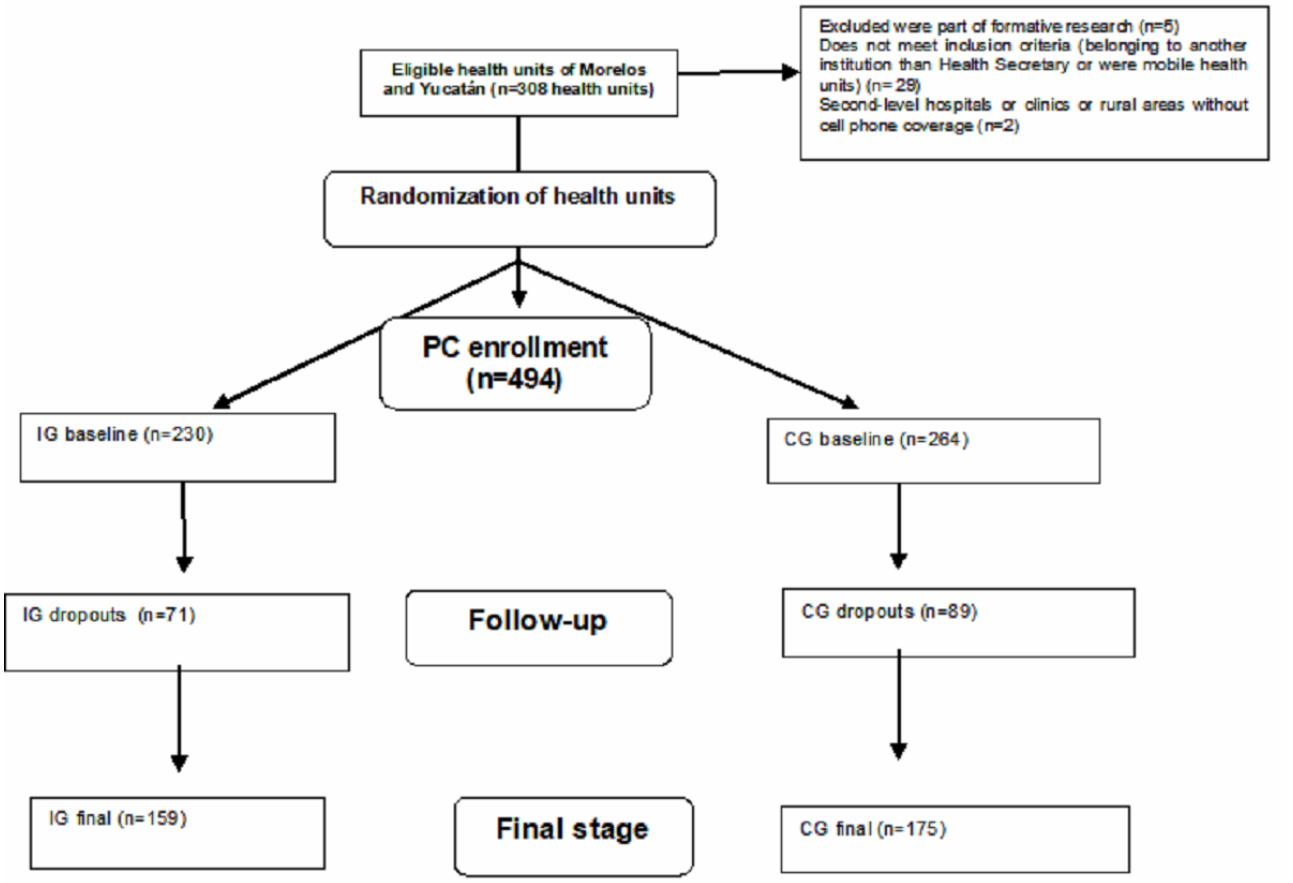
Study Design

This study constitutes an effectiveness-implementation hybrid trial [12], incorporating elements from both effectiveness and implementation research. The trial is registered under the Trial Registration ID NCT04250896. We used a mixed methods approach [13], utilizing a “convergent advanced design” [14]. This design involved the simultaneous use of qualitative and quantitative methods, allowing for the triangulation of results from both methodologies. By combining statistical findings with insights gleaned from individuals’ real-life experiences, we aimed to gain a comprehensive understanding of the effects and implementation process of NUTRES.

Eligibility Criteria and Recruitment of Participants

NUTRES participants were recruited from urban and rural health units situated in 2 states of Mexico: Morelos in the central region and Yucatán in the southern region. Randomization was conducted at the health unit level. Inclusion criteria comprised being a primary health care unit, being located in an area with access to a mobile phone network, having more than 50 registered users under 5 years, and having over 80% of the population with Spanish as their first language. A total of 308 eligible urban and rural health units from the 2 states were included in the study, assigned either to the intervention group (IG) or the comparison group (CG) (Figure 1).

Figure 1. Flow diagram of NUTRES participants. CG: comparison group; IG: intervention group; PC: primary caregiver.



The eligibility criteria for participants in both the IG and the CG were being the PC of an infant under 5 years, having ownership/access to any type of mobile phone, being able to speak and read Spanish, being aged 18 years or older, and being a resident in the coverage area of the participating health unit. Participants were recruited through 3 methods: (1) invitation from primary health providers, (2) snowball sampling, and (3) face-to-face encounters by field workers at health units. The CG had the same eligibility criteria for recruitment, except for the requirement of mobile phone ownership/access.

Sample Size

Quantitative

Sample size calculations indicated that 100 participants per study group would yield 80% power at the .05 significance level to detect a 20%-point difference in the proportion of change for at least one outcome variable (eg, knowledge, attitudes, or practices related to infant PA or HF) between study groups, using a 2-sided test. These calculations accounted for a design effect ranging between 1.5 and 1.9 [15] and factored in a 20% dropout rate [16]. Notably, this sample size estimation did not consider states or areas as strata, thus precluding intergroup comparisons based on geographical regions.

Qualitative

The sample selection was purposive, with the aim of capturing a diverse range of experiences associated with NUTRES. Informants were chosen from both rural and urban areas, encompassing caregivers with children aged 0-23 months and 2-5 years, representing varying levels of interactivity. The use of 2-way SMS text messaging served as an indicator of their engagement with NUTRES (details on interactivity provided below).

NUTRES Intervention

NUTRES is an mHealth BCC strategy designed to prevent childhood overweight/obesity. It achieves this by disseminating SMS text messages to PCs of children under 5 years, as well as to health personnel operating within primary unit services in 2 Mexican states. In this paper, we will primarily concentrate on the outcomes of the SMS text messaging interventions aimed at promoting infant PA [17] and HF [18]. For a comprehensive understanding of the development of NUTRES, readers are referred to previous publications [19,20].

In essence, the NUTRES intervention comprised 1- or 2-way SMS text messages, each containing fewer than 150 characters, disseminated to PCs over 9 months (equivalent to 36 weeks). Participants in the IG received approximately 108 SMS text messages, adjusted based on the child's age. These SMS text messages addressed various aspects, including attitudes and practices concerning infant PA and HF. Additionally, SMS text messages addressing nutrition within the context of the COVID-19 pandemic were incorporated due to the emergency situation. The design of the SMS text message content was informed by extensive formative research [21], which aimed to identify both barriers and facilitators to the adoption of healthy practices within the target population. Every factor that could either facilitate or hinder behavior change was systematically

addressed in line with the Theory of Planned Behavior [22,23]. This was accomplished through the dissemination of truthful information, practical tips, healthy recipes, challenges, and socioemotional support messages to PCs. All SMS text messages were meticulously aligned with the latest national [24] and international guidelines concerning infant PA and HF [17]. See Multimedia Appendix 1 for examples of SMS text messages delivered.

PCs who consented to participate in NUTRES were asked to provide details about the child's name, age, and gender during registration. This information was used to personalize and tailor SMS text messages for each participant accordingly. NUTRES incorporated 2 types of SMS text messages: 1- and 2-way (the latter being sent following a response from PCs to the initial SMS text messages). On average, participants received approximately 3 SMS text messages per week. In addition to informational messages, a weekly positive socioemotional support SMS text message was dispatched to PCs, as research has demonstrated its effectiveness in fostering participation and maintaining interest [25]. These SMS text messages were programmed to be automatically delivered to PCs via the Rapid Pro platform [26], and interactivity, including responses from PCs, was recorded and tracked.

Data Collection and Analysis

Overview

Data collection took place from September 2020 to September 2021. The quantitative component encompassed both the IG and the CG, involving both baseline and final assessments. Meanwhile, the qualitative component solely focused on the IG, conducted after 36 weeks of exposure to NUTRES. Both the qualitative and quantitative teams, consisting of approximately 4 members each, possessed extensive fieldwork experience and proficiency in communication technology. They underwent a week-long virtual training session via Zoom (Zoom Video Communications, Inc.).

Quantitative Data

Because of the COVID-19 context, both baseline and follow-up surveys were conducted via mobile or fixed telephone. The surveys covered a range of topics, including sociodemographic information, health status, and knowledge pertaining to infant PA and HF. Knowledge of recommended practices was assessed by querying respondents about the advantages, disadvantages, or known recommendations regarding PA and HF. Each answer was assigned a score based on its correctness, as outlined in Multimedia Appendix 2.

Furthermore, exposure to NUTRES was gauged by querying PCs regarding their receipt of the SMS text messages, as well as their perception of the usefulness and practicality of the messages. For instance, PCs were asked if they recall a specific message from NUTRES that they had implemented in practice, and their responses were recorded without any prompts or suggestions from the interviewer.

Data collection was conducted using the REDCap (Research Electronic Data Capture; Vanderbilt University) app, with daily verification and backup procedures in place. Following data collection, thorough exploration, cleaning, and recategorization processes were undertaken to prepare for descriptive statistics and basic comparative analyses between study groups. Topics of interest were examined and translated into knowledge and practice indices, with summary variables generated for each question. Practices were categorized into 3 equally sized tertiles for evaluation: the first tertile was termed "limited," the intermediate tertile was termed "moderate," and the tertile with higher values was termed "adequate." Lastly, we used a double-difference approach [27] to evaluate the variance in the change of outcomes between the presence (IG) and absence (CG) of the intervention. A significance level of $P<.05$ was deemed significant. All statistical analyses adhered to an "intention-to-treat" principle [28] and were conducted using the Stata version 14.2 statistical package (StataCorp).

Qualitative Data

Interviews were conducted after the quantitative survey and delved into various topics, including opinions regarding NUTRES; technical issues encountered with receiving, reading, and responding to SMS text messages; overall impressions of the SMS text message content; behaviors encouraged by the messages; and the perceived impact of the intervention on the intention or ability to carry out recommended practices. Additionally, we explored 3 implementation indicators with PCs from the IG:

- "Acceptance" of NUTRES and behaviors promoted by SMS text messages.
- "Pertinency," which examines the relevance of information and behaviors promoted by the SMS text messages in NUTRES.
- "Coverage," which examines the extent to which PCs received the SMS text messages.

The first 2 implementation indicators were proposed by Proctor and colleagues [29], while the last one was by Peters and colleagues [30]. According to these authors, these indicators are crucial determinants of the success, in terms of both implementation and expected outcomes, of an intervention.

The interview guide underwent a pilot phase involving role-play to ensure its smooth flow and enable interviewers to practice its implementation. Telephone interviews typically lasted between 40 and 80 minutes, and they were recorded and transcribed verbatim. Following the principles of grounded theory [31], data analysis was conducted using a coding tree [31] to streamline the coding process. This analysis was performed utilizing NVivo 2020 (QSR International). See Multimedia Appendix 3 for the category tree used for coding.

Ethical Approval and Consent

This study received approval from the Ethics, Research, and Biosafety Committees of the National Institute of Public Health (INSP) of Mexico, with the reference number CI 1547. All participants provided verbal informed consent to take part in the study.

Results

General Data About Design, Participants, and Sample Size

Quantitative

The total number of participants at baseline was 494 PCs, with 230 in the IG and 264 in the CG. Out of these, a total of 334 participants completed the study, comprising 118 from Morelos and 216 from Yucatán (Figure 1) [32]. The primary reasons for the loss to follow-up were the inability to locate the PC for final measurement, accounting for 9.1% (20/220) from the IG and 18.1% (41/227) from the CG, and the unwillingness of some participants to continue with the research, constituting 4.3% (8/187) from the IG.

The baseline characteristics of PCs revealed that the majority were young, with an average age of approximately 28 years. Most PCs were married or cohabiting and had a low level of education, with less than one-quarter having completed primary education. Additionally, at baseline, it was observed that the children of PCs from the CG were on average 3.7 months older than those from the IG (P<.001). Furthermore, PCs from the CG were less likely to report having a paid job compared with PCs from the IG (P<.004; Table 1). Baseline characteristics were found to be similar between PCs who continued in the study and those who were lost to follow-up. This is detailed in Multimedia Appendix 4, which presents the descriptive characteristics of individuals lost to follow-up versus those who completed the study.

Table 1. Sociodemographic characteristics of the primary caregivers (N=494) at baseline and final line, by study group (NUTRES, 2020-21).

Sociodemographic characteristics	Baseline		
	Comparison group (n=264)	Intervention group (n=230)	*P* value
States of Mexico, n (%)			.80
Morelos	90 (34.1)	88 (38.3)	
Yucatán	174 (65.9)	142 (61.7)	
Area, n (%)			.86
Urban	162 (61.4)	148 (64.3)	
Rural	102 (38.6)	82 (35.7)	
Age of primary caregiver, mean (SD)	27.5 (7.25)	27.1 (6.80)	.49
Relationship to the child, n (%)			.49
Mother	259 (98.1)	226 (98.3)	
Grandmother	1 (0.4)	2 (0.9)	
Aunt/sister	3 (1.1)	1 (0.4)	
Father/grandfather	0 (0)	1 (0.4)	
Sex of child, n (%)			.44
Girl	126 (47.7)	104 (45.2)	
Boy	138 (52.3)	125 (54.3)	
Age of child (months), mean (SD)	20.5(16.8)	16.8 (15.7)	.001
<24, n (%)	165 (62.5)	164 (71.3)	.12
24-59, n (%)	99 (37.5)	66 (28.7)	
Marital status (married/free union), n (%)	232 (87.9)	191 (83.0)	.33
Schooling (basic or less), n (%)	10 (3.8)	27 (11.7)	.35
Employment with payment (last week) (yes), n (%)	22 (8.3)	40 (17.4)	.004
Socioeconomic status[a], n (%)			.19
Tertile 1	105 (39.8)	72 (31.3)	
Tertile 2	90 (34.1)	67 (29.1)	
Tertile 3	69 (26.1)	91 (39.6)	
Beneficiary/affiliation social program (yes), n (%)	64 (24.2)	61 (26.5)	.51

[a]Socioeconomic status (tercile 1 represents the lowest welfare conditions).

Qualitative

Twenty-four PCs from the IG were interviewed, with 12 participants from each state. These PCs had an average age of 30.2 years, with 14 participants having completed high school education or higher. The majority of interviewed PCs were homemakers, totaling 16 individuals. Multimedia Appendix 5 provides further details on the main characteristics of PCs interviewed for the NUTRES study conducted between 2020 and 2021. Interestingly, only a few differences were observed in the experiences reported by PCs of children aged 0-23 months and those aged 24-59 months, as well as between rural and urban areas. Consequently, qualitative findings and PC experiences are presented in a general manner.

NUTRES Intervention Implementation

PCs expressed appreciation for the SMS text messages from NUTRES, noting that they valued their brevity and clarity. Informants unanimously agreed that the NUTRES strategy was "good," "useful," and "helpful." PCs highlighted that NUTRES served as a "reminder" of previously acquired knowledge, while also introducing "new" information, particularly regarding the promotion of PA. PCs also remarked that the changing topics in the SMS text messages as their children grew made them feel supported and motivated to implement the recommendations, highlighting the acceptability and pertinence of the intervention (Textbox 1; Multimedia Appendix 6). Additionally, an overwhelming majority of PCs (96/98, 98%), expressed their desire to continue receiving NUTRES SMS text messages. However, some PCs raised concerns about sharing sensitive information, such as personal data, during the registration phase. Furthermore, a portion of PCs, specifically 32/145 (22%), reported encountering barriers to receiving SMS text messages from NUTRES. These barriers were damaged equipment (11/32, 34%) and issues related to connectivity or lack of mobile phone credit (7/32, 22%), indicating challenges in coverage (Table 2). Additionally, PCs indicated that they consistently use (43/141, 30.5%) and interact (27/140, 19.3%) with the 2-way SMS text message feature. Testimonies revealed that low interaction by PCs did not necessarily correspond to a lack of interest or rejection of NUTRES but rather to external circumstances such as a lack of credit or signal to receive SMS text messages, or a lack of awareness about the reply option (Textbox 1).

Textbox 1. Implementation indicators (English quotes) of NUTRES by primary caregivers exposed to NUTRES.

Acceptance

- Well, I don't know, I say how....one year, I don't know...because I still don't feel as prepared for...as for...well...yes, well yes, I do feel prepared for my baby, but I still don't know how many things, so it does help me [#14]
- They make me feel calm [the messages]. (S) how do I explain it? They make me feel calm because they are helping me" (...) and it helped me a lot with the advice is reaching me (...) [#15].
- Mmm, well, it's a program that helps us, helps us complement what we already do at home for the children [#24].

Pertinency

- Since I am a first-timer, I felt that it helped me in the sense that, like right now, because of the Covid, there is no need for you to take, for example, to your health clinic, so there they told you how the processes that touched them...in what month could you give certain foods to your baby [#5].
- Yes, because they were at the age, they were perfectly fine at my son's age. Hey? forever! [#13].

Coverage

- Good. Well, in fact, we had to answer "Yes, No", or if the goal was achieved or not, I tell him. There were times that the same and maybe I did not realize some messages because there was no coverage, they did not enter. Sometimes several days passed, and until I went out to some place that did exist, I was aware of the messages [#23]
- And I told him "it's that they don't reach me", that only when I go to a higher part or I left here, they began to reach me. And I tell him, when I'm away, well, yes, I answer them, yes or...like no or something, well, the things they asked me [#21]
- Here in the town the current fails a lot, and the signal goes away...it's been like [P] four months now that the current goes out constantly here in the town and it's in parts [#6].
- Well, almost all of them because it was at the beginning when I began to receive the messages that they were going to charge me. And then, well, this...well, my recharge ran out very quickly, so to speak, and I preferred to just read them and put them into practice...Sometimes I would send them and say no, that I had to charge I don't know what...things like of money or something like that, and others if they let them answer [#14].
- What happens, that as there was a problem, that the telephones were lost. There came a time when this number that I have, my husband had it, and since we removed the chip, it disappeared [#5].

Table 2. Reception and reading of SMS text messages and the most useful format to put them into practice in primary caregivers participating in NUTRES.

Responses	Values (n=145)[a]
Difficulties receiving NUTRES SMS text messages (n=145), n (%)	32 (22.1)
Reading of NUTRES SMS text messages (n=144), n (%)	
Always	96 (66.7)
Sometimes	45 (31.3)
Use of NUTRES SMS text messages (n=141), n (%)	
Always	43 (30.5)
Sometimes	97 (68.8)
Interactivity of NUTRES SMS text messages (n=140), n (%)	
Always	27 (19.3)
Sometimes	71 (50.7)
PCs[b] reported barriers to receiving NUTRES SMS text messages (n=32), n/N (%)	32/145 (22.1)
Dropped telephone line, n (%)	3 (9.4)
Lack of telephone signal, n (%)	7 (21.9)
Change of phone number, n (%)	1 (3.1)
Lack own mobile phone equipment, n (%)	3 (9.4)
Damaged equipment, n (%)	11 (34.4)
Lack of connectivity or mobile phone credit, n (%)	7 (21.9)
Problem or difficulty was solved (yes), n (%)	11 (34.4)
Reasons for not reading NUTRES SMS text messages (n=3), n/N (%)	3/145 (2.1)
Other (damaged or missing equipment), n (%)	3 (100.0)
Reasons PCs did not implement NUTRES SMS text messages (n=1), n/N (%)	1/145(0.7)
Lack of time, n (%)	1 (100.0)
Reasons PCs did not respond to NUTRES SMS text messages (n=42), n/N (%)	42/145 (29.0)
Lack of time and participants did not respond to SMS text messages within 12 hours, n (%)	7 (16.7)
It is complicated, many issues, n (%)	1 (2.4)
Information is missing, n (%)	2 (4.8)
Other (eg, lack of own equipment, the economic burden for payment of phone line, error when sending responses, read SMS text messages later), n (%)	31 (73.8)
Does not know/no comments, n (%)	1 (2.4)
Perception of NUTRES (satisfied and very satisfied) (n=141), n/N (%)	141/145 (97.2)
Because is practical, n (%)	92 (65.2)
A good resource in times of COVID-19, n (%)	10 (7.1)
Received interesting messages, n (%)	83 (58.9)
Other (eg, because of the interest they show toward the family, important messages for the health of babies), n (%)	7 (5.0)
Reasons for dissatisfaction or some dissatisfaction with NUTRES (n=3), n/N (%)	3/145 (2.1)
Unclear or confusing information, n/N (%)	1/145 (0.7)
Relevance of NUTRES (relevant/appropriate and highly relevant/very appropriate) (n=140), n/N (%)	140/145 (96.6)
It helps them with feeding and PA[c] of their daughters and sons or with counseling of health providers, n (%)	87 (62.1)
You can apply the recommendations in your daily life, n (%)	53 (37.9)
Would you like to continue receiving SMS text messages from NUTRES? (Yes) (n=98), n (%)	96 (98.0)
Recommendations to improve NUTRES from PCs (n=159), n (%)	

Responses	Values (n=145)[a]
Have a balance or credit/signal	28 (17.6)
Have access to cell phone	3 (1.9)
Know what to respond/clear instructions	6 (3.8)
Have time	9 (5.7)
Include images or videos (eg, WhatsApp)	16 (10.1)
Be interesting	5 (3.1)
Have training	8 (5.0)
Other (eg, have a follow-up, include information about diseases, more examples, include foods from the region, make it face-to-face, more interaction, none)	51 (32.1)
Do not know/no answer	63 (39.6)
Most useful PA SMS text message format for PC (n=133), n (%)	
Challenge	61 (45.9)
Socioemotional support	17 (12.8)
Informative	21 (15.8)
Recipes	2 (1.5)
Tips	13 (9.8)
With examples	15 (11.3)
Links for more information	2 (1.5)
Do not know/no answer	4 (3.0)
Most useful HF[d] SMS text message format for PC (n=142), n (%)	
Challenge	25 (17.6)
Socioemotional support	20 (14.1)
Informative	36 (25.4)
Recipes	24 (16.9)
Tips	21 (14.8)
With examples	8 (5.6)
Links for more information	2 (1.4)
Do not know/no answer	5 (3.5)

[a]Totals may vary because of missing data.

[b]PC: primary caregiver.

[c]PA: physical activity.

[d]HF: healthy feeding.

The majority of PCs (92/141, 65.2%) reported that the SMS text messages were practical. Additionally, 57/145 (39.3%) PCs expressed a preference for the informative format over other formats, such as tips or challenges. PCs particularly appreciated the challenges related to PA, with 61/133 (45.9%) expressing appreciation because it involved other family members (Table 2). This aspect was particularly valued, especially in the context of COVID-19.

> *What I liked most about the SMS was that they sent advice, physical activity, not only for Mateo, but for the whole family and everything. And the same advice for the whole family to follow, not just for the baby, for my son* [#3]

PCs recalled messages regarding the importance of avoiding certain unhealthy food items for their children, such as sugar-sweetened beverages or sausages. These messages emphasized that these items were not suitable for children and were associated with the risk of early chronic diseases.

> *I remember that they recommended not to give him boxed juices, but to give him plain water or natural juice, that is, natural fruit juice* [#2]

> *The same, [NUTRES] would send us, for example (...) the sausages and all that, because it was not the right thing to do, because they have fat, if not, that it was better for them to eat chicken, pork, beef* [#2]

NUTRES Intervention Effectiveness

At baseline, PCs from the IG exhibited greater knowledge and awareness regarding the risk of developing anxiety or depression due to lack of PA compared with the CG (4/179, 2.2% vs 13/149, 8.7%, respectively; *P*=.02). Following the intervention, significant differences between the 2 groups were observed, with the IG showing higher rates of favoring social interaction and integration in relation to knowledge of PA (CG: 8/135, 5.9% vs IG: 20/137, 14.6%; *P*=.048). Regarding HF practices, significant differences were observed between the IG and the CG in recognizing that diabetes and chronic diseases can develop as a consequence of sugar-sweetened beverage consumption (CG: 92/157, 58.6% vs IG: 110/145, 75.9%; *P*=.003; Table 3). However, in the difference-in-differences model, there was no significant improvement observed in the practice of infant PA and HF (*P*>.05; Table 4). The only significant increase between the study groups was observed in terms of knowledge about the benefits of PA (CG: mean 0.13, SD 0.10 vs IG: mean 0.16, SD 0.11; *P*>.02; Table 4). Nevertheless, several PCs reported improvements in their perceived control and intention related to some of the behaviors promoted by NUTRES, although detailed data on this aspect are not shown.

> *Well, as far as I know, I used to give my older children juice...soda, and [now] I don't want to give her, I mean, any sweets* [#16]

Table 3. Knowledge and practices about infant physical activity and healthy feeding from primary caregivers: baseline versus final line (NUTRES, 2020-21).[a]

Knowledge and practice	Baseline			Final line		
	Comparison group (n=264)	Intervention group (n=230)	*P* value	Comparison group (n=175), %	Intervention group (n=159), %	*P* value
Physical activity (PA[b]), n/N (%)						
Main benefits of PA identified	177/264 (67.0)	158/230 (68.7)	.43	135/171 (78.9)	137/157 (87.3)	.09
Strengthens muscles and bones	103/177 (58.2)	91/158 (57.6)	.92	76/135 (56.3)	76/137 (55.5)	.89
Strengthens the immune system	45/177 (25.4)	21/158 (13.3)	.17	28/135 (20.7)	19/137 (13.9)	.16
Improves cognitive function, school performance, or both	42/177 (23.7)	43/158 (27.2)	.55	30/135 (22.2)	30/137 (21.9)	.94
Promotes relaxation and well-being and improves sleep patterns	11/177 (6.2)	17/158 (10.8)	.18	15/135 (11.1)	19/137 (13.9)	.56
Helps to prevent chronic diseases	44/177 (24.9)	26/158 (16.5)	.07	25/135 (18.5)	37/137 (27.0)	.09
Helps to improve chronic disease control	35/177 (19.8)	21/158 (13.3)	.32	16/135 (11.9)	19/137 (13.9)	.62
Helps to avoid anxiety/depression	3/177 (1.7)	4/158 (2.5)	.67	3/135 (2.2)	4/137 (2.9)	.70
Promotes socialization and social interaction	12/177 (6.8)	14/158 (8.9)	.47	8/135 (5.9)	20/137 (14.6)	.048
Promotes water consumption (improves hydration)	1/177 (0.6)	__[c]	.34	1/135 (0.7)	3/137 (2.2)	.33
Others (less constipation, promotes growth, gives them energy, they express themselves better)	16/177 (9.0)	16/158 (10.1)	.83	6/135 (4.4)	4/137 (2.9)	.56
Do not know/answer	1/177 (0.6)	—	.36	1/135 (0.7)	2/137 (1.5)	.53

[a]Difference-in-differences models adjusted for the baseline age of the child and maternal employment.

[b]Applied to all participants.

[c]An index of PA and healthy feeding practices was calculated, whose score was divided into tertiles to obtain the categories of "adequate," "moderate," and "limited" practices according to children's age (annex 6).

[d]PA: physical activity.

[e]N/A: not applicable.

[f]PC: primary caregiver.

[g]Applied only to PC of children >24 months.

Discussion

Principal Findings

To our knowledge, this study represents the first report on the feasibility of implementation and effectiveness of an mHealth intervention aimed at preventing childhood overweight/obesity in Mexico within the context of COVID-19. This research offers valuable insights into the implementation process of NUTRES and its impact on expected outcomes. Although NUTRES demonstrated limited impact on target knowledge and behaviors, the SMS text messages served as reminders or sources of new knowledge among PCs of Mexican children under 5 years.

The absence of significant effects observed in this study may be partially attributed to methodological adaptations necessitated by the COVID-19 context, such as recruitment and data collection conducted via telephone. However, it is conceivable that NUTRES could have served to mitigate the impact of the pandemic on the participating population. Given that the COVID-19 pandemic exacerbated food insecurity and contributed to increased consumption of ultra-processed products, along with physical inactivity during lockdowns, the intervention may have provided some degree of protection to the population involved [33]. Furthermore, the COVID-19 pandemic severely disrupted health services, significantly limiting the population's access to essential nutritional counseling [34].

Additionally, the lack of significant effects could be attributed to the high rate of loss to follow-up, which, although not markedly different between the study groups (71/230, 30.9%, loss in the IG and 89/264, 33.7%, loss in the CG), represented a loss to follow-up exceeding 20% (160/494, 32.4%) [35,36]. However, considering a sample size of 150 participants per study group and assuming a correlation of 0.6 between repeated measures within participants, our analysis sample achieved an approximate power of 83% to detect a difference of 0.15 in the change of proportions [37]. Nevertheless, it is plausible that the registration and follow-up process, which involved requesting contact information such as the child's name or age, may have discouraged the participation of PCs due to concerns about privacy and security. To address this issue, other studies have implemented strategies such as providing payments or reminders, resulting in a high retention rate of over 80% [38]. Such approaches could potentially enhance participant engagement and retention in future interventions.

Another important consideration to mention is that, due to the nature of the intervention, access to and use of a mobile phone was a prerequisite for inclusion in the IG. This aspect could introduce potential selection bias [39], especially considering that mobile phone ownership was not a requirement for the CG and mobile phone ownership might be correlated with income level. However, this potential bias was addressed in the analysis by adjusting for paid maternal employment (40/230, 17.4%, in the IG vs 22/264, 8.3%, in the CG), among other baseline characteristics. Adjusting for these baseline characteristics helps mitigate the potential influence of confounding factors on the study outcomes.

Previous studies have not consistently shown significant effects of exposure to BCC mHealth interventions on the intended audience [8]. In this trial, although 96/144 (66.7%) PCs always read NUTRES SMS text messages, only 43/141 (30.5%) always used the information provided. However, based on PC testimonies, NUTRES served as a reliable source of recommendations or reminders for child care, which they incorporated into their practices. Simultaneously, these recommendations empowered them within their immediate family and social environment. Furthermore, while PC narratives expressed some enthusiasm, the limitations of conducting telephone interviews prevented the observation of informants' physical responses, hindering further exploration and discussion of their enthusiasm. Therefore, future mHealth interventions should incorporate features to enhance engagement over time, using various methods such as incentives, push notifications, and other interactive elements. These strategies could help sustain interest and participation in the intervention among the target audience.

The results from both the qualitative and quantitative components of NUTRES are consistent with the lack of effectiveness observed in other studies regarding the impact of mHealth interventions on PC practices related to PA and HF. For example, a study conducted in China found that a weekly SMS text messaging intervention over 12 months had no significant effect on infant feeding practices [40]. It could therefore be speculated that the 9-month duration of exposure in NUTRES may have been insufficient to bring about changes in infant HF practices. However, NUTRES did demonstrate an improvement in PC knowledge regarding some benefits of PA. Indeed, PCs emphasized in interviews that family challenges played a crucial role in guiding and supporting them in implementing the recommendations provided by NUTRES. While the effectiveness of NUTRES could not be conclusively demonstrated, the mixed methods methodology used in this study identified that the obstacles to implementation were primarily external to NUTRES and largely technological in nature. Similarly, other studies conducted in Mexico have documented persistent barriers to mHealth implementation, such as the cost of mobile phones, lack of network infrastructure, and low digital literacy [41]. These barriers to implementing mHealth interventions may diminish the potential impact of smaller-scale studies and hinder their scale-up [41].

Our findings suggest that multicomponent and multichannel interventions have greater potential to promote behavior change compared with single-channel multitheme interventions. While the original design of NUTRES aimed for health providers to reinforce the intervention topics among PCs, this approach was not feasible due to the disruption of health services during the COVID-19 pandemic [42,43]. Nevertheless, an mHealth intervention could serve as a promising channel to maintain contact when face-to-face interaction is not feasible, complementing other remote interventions such as telemedicine [44,45].

One strength of this study is its effectiveness-implementation hybrid trial with an advanced convergent design, which enabled the comparison and interpretation of quantitative and qualitative results. Using a mixed methods approach, we were able to

comprehensively observe the effects of the intervention and implementation process [13]. For example, our study revealed that the low interaction with SMS text messages by PCs did not necessarily indicate a lack of interest in NUTRES. Instead, it was often attributed to external factors such as poor signal reception, economic constraints, and other challenges. However, despite these insights, we were generally unable to demonstrate a significant effect of the NUTRES intervention on the target behaviors. Nevertheless, previous studies [46] investigating the usefulness of SMS text messages, as reported by PCs, suggest that valuable behavioral changes could potentially be achieved in the long term. Additionally, our difference-in-differences models were adjusted for child age and maternal employment, which were variables that differed between the groups at baseline. This adjustment allowed us to estimate the specific effect of the intervention. Furthermore, the double-difference approach accounts for time-invariant observed factors (eg, education) and unobserved variables (eg, motivation to comply) [27], providing a more robust analysis of the intervention's impact.

Lessons Learned

The positive feedback received through both quantitative and qualitative data aligns with findings from another mHealth intervention [47,48]. A systematic review conducted in 2019 [9] identified the top 3 barriers among participants, which included signal coverage, lack of equipment (unaffordable phones), and technology gap (limited knowledge of how to use a phone). In this study, despite the participants' positive perceptions, similar challenges were encountered in terms of interaction with SMS text messages. For instance, some participants reported that SMS text messages were blocked, requiring them to contact their mobile operator to resolve the issue, which they were often unaware of. Additionally, other reasons for not receiving the SMS text messages were dropped lines, being out of coverage area, or changes in phone numbers (15/32, 47%). When participants did not respond to the SMS text messages within 12 hours, they were removed from the screen (7/42, 17%), and a significant portion of participants dropped out of the study (160/494, 32.4%). Overcoming such barriers is crucial to increase exposure to the intervention, thereby enhancing its impact and sustainability [49].

Based on the results presented here, this study provides valuable insights that can serve as a foundation for further research using mHealth interventions. The advantages of mHealth interventions, including broad coverage, cost-effectiveness, and feasibility of implementation in the population, underscore the potential for future studies in this area. It is suggested that future research should focus on addressing the identified challenges to improve the effectiveness, efficiency, and scalability of interventions. Some potential areas for improvement are (1) using WhatsApp (Facebook, Inc.) instead of SMS text messages (or in addition to SMS text messages), as it is a useful and accepted medium among the target population; (2) using informative material to recruit PCs; (3) improving SMS text message reception; (4) clarifying that SMS text message interaction has no cost; and (5) including resubscription for loss/change of mobile phone (Table 2).

Another valuable lesson learned is the importance of engaging key health care providers [50] and identifying informal strategies to recruit participants during emergency situations [33]. Furthermore, we have observed that mHealth interventions during lockdowns may represent the sole means of supporting socioeconomically vulnerable populations, who were often the hardest hit [51].

Conclusions

The findings contribute to the existing evidence on the opportunities and limitations associated with mHealth interventions for BCC aimed at enhancing knowledge and practices related to PA and HF among caregivers of infants. Integrating mobile phone technology into BCC interventions facilitates the promotion of healthy lifestyles, particularly during emergency situations and among vulnerable populations. Moreover, the integration of effectiveness and implementation findings is valuable for optimizing mHealth interventions in particular settings, enhancing their sustainability, and fostering their application in diverse contexts [52].

Abstract

Background: Mobile health (mHealth) wearable devices are increasingly being adopted by individuals to help manage and monitor physiological signals. However, the current state of wearables does not consider the needs of racially minoritized low–socioeconomic status (SES) communities regarding usability, accessibility, and price. This is a critical issue that necessitates immediate attention and resolution.

Objective: This study's aims were 3-fold, to (1) understand how members of minoritized low-SES communities perceive current mHealth wearable devices, (2) identify the barriers and facilitators toward adoption, and (3) articulate design requirements for future wearable devices to enable equitable access for these communities.

Methods: We performed semistructured interviews with low-SES Hispanic or Latine adults (N=19) from 2 metropolitan cities in the Midwest and West Coast of the United States. Participants were asked questions about how they perceive wearables, what are the current benefits and barriers toward use, and what features they would like to see in future wearable devices. Common themes were identified and analyzed through an exploratory qualitative approach.

Results: Through qualitative analysis, we identified 4 main themes. Participants' perceptions of wearable devices were strongly influenced by their COVID-19 experiences. Hence, the first theme was related to the impact of COVID-19 on the community, and how this resulted in a significant increase in interest in wearables. The second theme highlights the challenges faced in obtaining adequate health resources and how this further motivated participants' interest in health wearables. The third theme focuses on a general distrust in health care infrastructure and systems and how these challenges are motivating a need for wearables. Lastly, participants emphasized the pressing need for community-driven design of wearable technologies.

Conclusions: The findings from this study reveal that participants from underserved communities are showing emerging interest in using health wearables due to the COVID-19 pandemic and health care access issues. Yet, the needs of these individuals have been excluded from the design and development of current devices.

Introduction

Background

As mobile computing has advanced, wearable technologies have become more ubiquitous; however, in their current state, wearables threaten to worsen digital and health inequities and perpetuate structural harm in the health care sector and society as a whole [1,2]. Health disparities persist that limit the positive health outcomes of those from low–socioeconomic status (SES) backgrounds. The inequitable allocation of resources prevents many from low-SES communities from accessing quality health care, and systemic racism continues to pervade the health care system on both an individual provider and more macro level [3-6]. Further, the social determinants of health, which include factors such as economic status and race, are now understood to be the primary drivers of health outcomes, meaning that health disparities can manifest from societal structures even before an individual interacts with the health care system [7,8]. As a result, current systems fail to adequately provide for the health of Latine and low-SES communities, contributing to the preventable higher rates of illness and death among these groups.

Wearable devices are electronic smart devices delivered in a range of form factors including accessories and clothing that can sense biological and environmental factors and perform influential predictive computations. Most recent wearables, such as the Apple Watch (Apple Inc), have opened new avenues for capturing important physiological data such as measuring heart rate, tracking sleeping, and capturing electrocardiogram data. While wearables have demonstrated their potential to improve the health of low-SES communities by helping them increase physical activity through fitness trackers [9], research shows that wearable devices have primarily been designed with the participation of more affluent communities, and low-SES communities have historically been and continue to be excluded from their design [2-6]. The exclusion of low-income communities in technological design can have unintended and harmful consequences [10]. For example, the photoplethysmography sensor, commonly used for measuring heart rate, detecting arrhythmia, and tracking sleep, has been shown to be less accurate or fail to function properly for individuals with darker skin tones [11,12]. Given that poverty rates are over twice as high for Black and Hispanic or Latine or Latinx groups (hereby referred to as Latine) in comparison to White individuals [13,14] inaccurate readings from a photoplethysmography sensor may disproportionately impact low-SES communities. This is particularly troubling, given that our research participants all identified as members of low-income Latine communities. There is a critical need for wearables to overcome existing access and accuracy issues for these marginalized communities and to be developed directly with community members to ensure goal and value alignment.

Objectives

The development and design of current health wearables have predominantly been driven by the experiences of affluent communities. Consequently, there is a need to collaborate with low-SES community members to better understand the potential of wearables for addressing their health needs, goals, and experiences. Through an exploratory qualitative research study, we aimed to understand (1) how members of low-SES communities perceive mobile health (mHealth) wearable devices and (2) identify the barriers and facilitators toward adoption. The results point to requirements and recommendations for designing and developing better mHealth wearable devices more equitably, enabling low-SES community members to understand and self-manage their health and well-being.

Methods

Study Design

This exploratory qualitative study aimed to identify low-income community members' perspectives and needs toward wearable devices. This study was part of a larger project investigating low-SES community members' perspectives of wearable devices and the barriers and facilitators toward adoption [15]. We conducted 19 semistructured interviews with members of low-SES Latine communities from 2 metropolitan cities in the United States. Interviews were conducted separately in 2 different rounds. Our initial interviews, consisting of 8 participants, aimed at understanding low-SES community members' perspectives on wearable technology more broadly to obtain an understanding of community members' needs and expectations. Though questions on the impacts of COVID-19 and its relation to wearable devices were not asked, the topic was brought up by participants so frequently that we felt the topic warranted more in-depth discussion. Therefore, we ran a second round of interviews with 11 additional participants, in which questions were focused on participants' perspectives on how mHealth wearables can support them in their everyday lives. This research study was conducted from December 2021 to March 2022. Due to the COVID-19 Omicron variant, all interviews were conducted in English over a Zoom (Zoom Video Communications, Inc) video call. The results are reported following the Standards for Reporting Qualitative Research by O'Brien (see Multimedia Appendix 1) [16].

Recruitment

We were interested in working with low-SES community members in the United States. Flyers containing information about this study and a link to a Qualtrics (Qualtrics) screening survey were posted on the research team's social media sites, such as Facebook and Instagram (Meta Platforms). Interested participants completed a screening survey that asked for basic demographic information (eg, race, education level, household income, and the number of persons in the household). The inclusion criteria were determined if participants identified as (1) aged older than 18 years, (2) BIPOC (Black, Indigenous, and people of color), and (3) of low-income. Criteria 3 was met if an individual's income level fell at or below the low-income threshold according to their county's Department of Housing and Community Development (in the United States, the

Department of Housing and Community development uses State Income Limits provided by the US Department of Housing and Urban Development [17]). Individuals were excluded if they did not meet all the above criteria. After an eligible participant signed a digital consent form (see Multimedia Appendix 2), an online semistructured interview session was scheduled. We note that all participants came from 2 metropolitan cities in the United States but being from a particular city or location was not part of the eligibility criterion.

Study Procedure

Overview

Interview sessions were conducted by the lead author. All interviews were 45 to 60 minutes in length and were conducted over a Zoom video call. In these interview sessions, we sought to learn about participants' opinions regarding wearable technology for health.

A preliminary round of interviews centered on exploring participants' access to Wi-Fi connectivity, technology, and any resource constraints they may encounter was conducted. Additionally, we delved into their perspectives on wearable technology, their community's perception of wearables, their likes and dislikes about current wearable devices, and the features they would like to see in future wearable devices; interview questions from the preliminary study can be found in Multimedia Appendix 3.

A second round of interviews was initiated to focus on participants' views of mHealth wearable devices, their opinions on the general health and well-being of people in their neighborhood and community, the impact of COVID-19 in their community, and the types of health information considered by participants to be useful for them. The participants were asked if they had an idea what a wearable device was, and if they were unfamiliar, the interviewer described a brief definition and example. Interview questions from the second part of this study can be found in Multimedia Appendix 4. Interviews were halted once saturation was reached. All interview sessions were audio recorded and participants were compensated with a US $40 gift card at the end of the interview.

Data Analysis

Audio recordings of the interviews were transcribed, resulting in a total of 21 hours of interviews. During the preliminary investigation, the authors performed open coding on the transcripts and analyzed the data using a grounded theory approach, following the methods defined by Charmaz and Belgrave [18]. Further, 2 members of the research team performed open coding on the transcripts and identified initial themes. The research team then reviewed the transcripts and collaboratively discussed associated codes to look for consistencies and differences in the data. Through a collaborative process involving group discussions, an iterative refinement of themes was conducted. Among the emerging themes, one stood out as particularly significant: the relationship between health and wearables in the context of COVID-19. This theme was subsequently used to develop the interview guide for the second round of interviews.

In the secondary investigation, the lead author and fourth author once again performed open coding on the transcripts and analyzed the data using a grounded theory approach. Author 3 was added to the research team to help identify and narrow themes. The research team once again reviewed the transcripts and collaboratively discussed associated codes to look for consistencies and differences in the data. Codes were merged into subthemes and then grouped into 4 prominent themes. Consensus was reached by involving the sixth author to determine the final themes.

Research Reflexivity

The research team consisting of the first, third, and fourth authors are part of Latine low-SES communities. The first author, a doctoral student, recruited participants, designed this study, conducted the semistructured interviews, and analyzed the transcripts. The third and fourth authors are doctoral students and helped collect and analyze the data. All other authors contributed to drafting and revising this paper.

Ethical Considerations

This project's study protocol was reviewed and approved by Northwestern University's institutional review board (STU00216152).

Results

Participants

We recruited 19 adults from low-SES communities in 2 metropolitan cities in the United States. In total, 8 participated in the first round of interviews and 11 in the second round. All participants identified as Hispanic or Latinx and had low income. Additionally, 2 participants identified as members of the LGBTQ+ (lesbian, gay, bisexual, transgender, and queer) community. Furthermore, 94.7% (18/19) of the participants were from Los Angeles and 5% (1/19) of the participants were from Chicago. Participants' ages ranged from 18 to 54 (mean 29.7, SD 10.81) years. Table 1 summarizes participant demographics.

Themes

Overview

Four major themes emerged from our data analysis: (1) how COVID-19 changed community members' interest in wearables for health; (2) barriers to health care resources, seeking alternatives through wearables, (3) distrust in the medical system, motivating the needs for wearables as a potential solution; and (4) community-based technical requirements. All participants said they were aware of wearable technology. We discuss our results in more depth in the following sections.

Theme 1: How COVID-19 Increased Interest in Personal Health Monitoring Through Wearables for Health

The impact of COVID-19 on underrepresented communities was significant and had a clear and direct effect of exacerbating existing health disparities [19]. Even though the COVID-19 public health emergency has ended, the residual effects of the pandemic have left individuals with long-term symptoms.

Participants (n=14) shared that they themselves had been infected with COVID-19 and had long-lasting health problems as a result. Participants (n=7) mentioned that they were still experiencing breathing problems despite having no health issues before being infected. Further, 1 participant elaborated as follows:

> *I got COVID the first time, right when the pandemic started... Afterwards it was hard for me to breathe when walking... The second time around that I got it, which was recently, it hit me a lot harder. Before I got COVID, I was healthy like there was nothing wrong with me. So, it's definitely taking its toll. I was used to walking 5 miles a day. I was walking 20 something miles a week so you know it wasn't normal for me to have breathing problems.*

As a result of experiencing ongoing COVID-19 symptoms, participants shared that for the first time, they are considering how health data, such as monitoring their oxygen levels, could be helpful. This led to conversations about how participants wished they had wearable tools that automatically measured their oxygen levels and allowed them to monitor the data themselves. Participants expressed the following:

> *I guess the one thing that scares me that I never even thought of until I got COVID were like my oxygen*

> *levels. Like, am I at normal levels? Is that an issue that I need to kind of think about, you know?*

Another participant commented:

> *One thing I noticed, especially with COVID right now which is, I think a very big topic. The timing of getting all your vitals measured can actually save somebody's life. So, I think that's a very important thing. Like oxygen levels to be measured.*

Through these interviews, we uncovered overwhelming interest in the types of data that can be provided through health wearables, primarily as a result of the long-term consequences of COVID-19 and resulting interest in engaging in personal health monitoring.

Theme 2: Barriers to Health Care Resources, Seeking Alternative Health Monitoring Through Wearables

Participants frequently discussed a severe lack of health resources and infrastructure in their communities, made worse by COVID-19, and expressed interest in potential alternatives to manage their health care through wearables to compensate for the lack of local health resources. Specifically, participants shared that the hospitals in their neighborhoods were shut down, forcing community members to seek health care in small clinics. A participant explained:

> *Most Hispanics don't have health care. I do not have that great health care myself and I have two jobs ... We lost, we had a hospital down the street, and they went bankrupt. Right now, all we really have is small clinics. So, I'm pretty sure that's all the help that anybody around here can get and it's really busy.*

Many participants (n=11) mentioned that these small clinics were completely inaccessible due to overcrowding.

> *It's overly populated. Even if you make an appointment, you're there all day. Whatever time you go, whatever day you go, it's always crowded, because it's one of the very few [clinics] that accepts Medi-Cal. So low-income communities, they don't have the resources, it's always crowded.*

Lack of health care coverage was another stressor all participants cited in conversation. Participants mentioned they could not be seen or treated and were left to fend for themselves. Individuals who experienced more critical symptoms were not able to receive treatment and passed away.

> *Health coverage was a very big issue, because not everybody was able to afford to, let's say, be able to get seen or get treated. A lot of stuff was very limited, especially to the community. If you got sick, well, your best guess to do was rub VapoRub on yourself cause that's what we only have. … A lot of these people didn't get treated and passed [away].*

Many participants felt the impact of COVID-19 could have been mitigated if the proper health care infrastructures were implemented. However, the idea of having wearables that can potentially measure vital signs and other health parameters that do not require doctor visits came up often in conversations as a practical alternative. Participants shared how they felt wearables could be useful for individuals who live in underserved areas and who do not have access to the proper health care infrastructure.

> *If [the wearable] was easy for people to use then for sure. Just knowing when people who are in areas that need more resources or who need more hospitals. Like knowing what's going on with people without having them come into the hospital to find out, because how often do people really go to the clinic and get their vitals checked, so just maybe having an idea of what is going on with people beforehand, that would be really cool.*

Thus, we found that undersourced and poor health care infrastructure has led participants to express interest in using wearable technologies for health self-management.

Theme 3: Distrust in Health Care Infrastructure and Systems Is Motivating a Need for Wearables

We found that community members' distrust of their health systems increased their interest in health wearables. Participants described experiences that led to their mistrust and fear of the health care system. For example, being turned away from immediate hospital care resulted in a participant's family member's medical conditions deteriorating leading to their death.

> *My uncle, that's another issue, they didn't want to give him a covid test for some reason and he just stayed at home for like 2-3 weeks feeling sick and only [when]he had very large symptoms he [got seen at] the hospital, and he died there two days later.*

The participants expressed that inadequate infrastructure and being denied medical assistance have made digital health care tools, like wearables, a valuable option for health testing and monitoring. The participants desired tools that could enable them to receive timely care and prevent late hospital visits. A participant highlighted that community members' lack of trust in doctors, coupled with high medical expenses, made seeking medical help unfeasible. Nonetheless, they suggested that this distrust in the health system could motivate people to take charge of their health and use wearable devices to conduct essential vital tests, rather than relying solely on medical professionals.

> *I think if you're worried about a wearable device running tests on people, cause let's be honest. Hispanic people don't go to the doctor because they don't believe in the doctor. They think the doctors are gonna kill them and then they're poor, so they can't pay for the doctor. So, like if [a wearable] could do basic [vital] tests that would be great.*

Participants suggested that wearables could offer patients a new avenue to engage in health care, especially in cases where conventional medical services are not accessible or when patients are hesitant to rely on data collected by their physicians. By using wearables instead, users can set and track their own health goals through data, alleviating dependence on the health care system to gain ownership over personal preventative health strategies. Consequently, participants also expressed a desire

to have ownership of their health data and to better understand the significance of this information for their personal health.

> *I think the biggest benefit to wearables will probably be the health aspect, like if you want to be constantly measuring your heart rate or measuring how many steps you walked in a day, I think that's where those devices will be very useful.*

Further, 17 other participants echoed this comment and expressed enthusiasm for having the ability to track health data that is important to them. Additionally, 18 out of the 19 participants expressed a strong interest in adopting wearables to support their health goals. Only 1 participant felt that they did not see the benefits of current wearables, specifically because they felt they could cheat on how their physical activity is being tracked by moving their hand around instead of moving to obtain their steps. Table 2 provides an overview of the most sought-after health parameters for monitoring. Notably, we observed that individuals from low-SES communities demonstrated a heightened interest in wearables and identifying the most critical health information to track.

Table 2. Signals participants (N=19) want to capture through wearable sensors.

Signal category	People, n
Heart rate sensors	18
Physical activity	17
Oxygen levels	13
COVID-19 symptoms	11
Blood pressure	11
Diabetes	10
Vitals	10
Breathing	7
Temperature	5
Stress	4
Glucose	4
Mental health	3
Cholesterol	3
Blood sugar	3
Allergies	1

Theme 4: Community-Based Technical Requirements

Participants shared several contextual considerations on how wearables can be designed to meet the needs of marginalized groups. The most common technical requirements emphasized throughout the interviews were durability, autonomy over data, and affordability.

Durability for Employment Reasons

As mentioned earlier, participants live in communities where most of the population identify as Hispanic or Latinx and they tend to work in more physically demanding environments. Hence, a common preference participants discussed if a wearable device were to be designed to meet the constraints of low-income communities was durability. A participant elaborated on the importance of durability:

> *I do think that it has to be very durable because the purpose is [for] low income communities. They don't have money to replace it. We just don't have comfy jobs. A lot of us work more physically demanding jobs. Some of us are plumbers, some are construction workers, some of us are gardeners. Some of us run a business and like that business involves pots and pans like we're restaurant workers. If [the device] breaks, they're just gonna say oops and throw it away. Or they're gonna like cry about it and be really upset. And they're like how do I pay for this again, you know? If it is more durable that's one of the biggest keys to wearing it.*

Participants demonstrated a significant inclination toward health wearables, specifically those that monitor vital signals such as oxygen levels. However, since such wearables must be worn continuously throughout the day, their durability becomes a critical factor. Therefore, it is imperative to ensure that these wearables are built to last and withstand the rigors of daily wear.

Autonomy: Would Rather Have Control Over Data

Privacy and having control over their own data was another critical component participants discussed. Participants did not feel comfortable having their data shared with big tech companies or a single health system due to the mistrust of both entities:

> *I think that's actually one of the biggest things that stops me from getting these, 'smart stuff.' It can measure your heart rate, has your location and all that. That sounds cool but for me my concern is how do I know if they're not sending it to a server? If it's*

> *being sent to server and I wouldn't feel comfortable with [tech companies] having access to all that data and just knowing where I'm going, what my vitals are that's just for me a bit Orwellian. I think the big thing for me is feeling comfortable and having control [over data].*

Participants shared conflicting viewpoints on this topic. For instance, 1 participant said:

> *People will be skeptical, you know they'll say, 'oh, now they're gonna read my mind or something'. Especially in low-income communities, because unfortunately we don't have the same education. A lot of people rush to conclusions and say ' oh, that's not real' or 'they're just trying to track me'. So I am thinking from that point of view, because I do have relatives that think that way. But at the same time, you always have the batch of people who are like, well, you know, let's try this [technology].*

Overall, these findings highlight diverse opinions regarding privacy and information sharing with big tech companies.

Affordability: Can Health Insurance Cover the Cost of Wearable Devices?

All participants mentioned that affordability was a barrier to adopting wearable devices, in particular wearables that are designed for health purposes.

> *I feel it's really limited because you either get a cheaper wearable technology and it's just not that advanced or not as reliable or you get expensive wearable technology that is honestly out of your price range. We would have to save up for it. And if you don't have access to like insurance then it sucks. My mom doesn't have access to one of those skin sugar sensors they have come out with. because insurance just doesn't cover it… wearable technology it definitely works, it's just expensive.*

Community members often face a challenging trade-off between functionality and affordability. Further efforts are necessary to cultivate innovative strategies that can ensure the reliability and affordability of such devices. Participants highlighted the potential health impacts of wearable devices on their lives, but they also expressed concerns about the way wearables are currently designed. Table 3 summarizes our study's findings and implications.

Table 3. Summary of key findings and implications.

Theme	Summary of participant needs	Recommendations in technical solutions moving forward
Theme 1: how COVID-19 increased interest in personal health monitoring through wearables for health	• Increased interest in tools to monitor health signals through wearables to monitor long-term COVID-19 symptoms.	• Hardware: develop embedded electronic sensors in mobile health and clinical tools that do not perpetuate racial disparities. • Software: algorithms deployed for signal processing and machine learning must not perpetuate bias.
Theme 2: interest in self-checking vital signs in response to health care access barriers	• In light of systemic challenges, participants wanted alternatives to self-manage their health care through wearables when limited resources are available.	• Develop low-cost, low-power sensors that are still capable of measuring physiological signals robustly. • Repurpose and upcycle existing hardware components. • Open-source hardware and software for transparency and reliability. • Increase service life for affordability and repairability.
Theme 3: distrust in health care infrastructure and systems is motivating a need for wearables	• Participants expressed a desire to use health wearables to set and monitor personal health goals, with a focus on preventive health measures, such as increased exercise.	• Develop wearables that robustly measure important physiological signals (as shown in Table 2) and allow individuals to self-manage these health parameters.
Theme 4: community-based technical requirements	• Participants require durability due to physically demanding blue-collar jobs. • Participants held varying opinions on privacy and the sharing of their health data with large tech corporations. • Cost was the most commonly discussed barrier to adoption.	• Wearable devices must be long-lived, durable, and adaptable for individuals who work in occupations that demand physical labor. • Wearables should allow users to have autonomy over how their data are disseminated. • Enhancing the affordability of wearables is crucial to ensure wider accessibility.

Discussion

Principal Findings

Overview

This study examined how members of minoritized low-income communities perceive mHealth wearable devices, what their needs and preferences are for using wearable devices, and understood the important contextual considerations for designing wearables in these communities.

The participants of this study expressed a newfound interest in health wearables for addressing their most critical health needs. Participants expressed a need for wearable devices that enable them to track vital signs and longitudinal symptoms (particularly those related to COVID-19) for setting and achieving preventive health goals, as illustrated in Table 2. Additionally, the participants emphasized that the wearable devices must be durable, reasonably priced, and within their budget or covered by their insurance, particularly state-provided insurance. It is evident from our study that the significant consequences of the COVID-19 pandemic on low-SES communities have led to an increased interest in health engagement and, subsequently, health wearables. However, current wearable devices fail to account for these individuals' lived experiences. Below, we elaborate on this, discussing how mHealth wearable devices can be better designed to improve the health care experience of low-income community members by integrating with medical systems, increasing autonomy, and empowering them to make informed decisions about their care.

Overcoming Technology Limitations

Though participants expressed strong interest in using wearable devices to improve and promote their understanding of their health, existing wearables are not currently built to meet their needs.

According to Table 2, monitoring heart rate, physical activity, and oxygen levels were the top 3 areas of interest for participants. However, current commercial wearables' optical sensors and the signal processing methods used to measure physiological signals are not reliable on darker skin tones [11]. This is a troubling concern because our study's participants identify as Latine or Latinx, which are a minoritized group of color, are members of low-SES communities, and they stand to be disproportionately affected by inaccurate photoplethysmography sensors.

Photoplethysmography sensors are widely used in pulse oximeters to measure blood oxygen saturation levels. However, earlier research has demonstrated that the accuracy of pulse oximeters decreases when used on individuals with darker skin [19-22]. Sjoding et al [22] highlighted the dangers of relying on pulse oximeters, particularly during the COVID-19 pandemic. Patients who identified as Black were three times more likely to be incorrectly classified as having normal oxygen levels in the blood than their White counterparts. Such misclassification can result in a failure to detect hypoxemia (low oxygen levels in the blood), which can lead to severe health consequences. To address this issue, the Food and Drug Administration has cautioned against using pulse oximeters on individuals with dark skin tones, thick skin, poor circulation, and other factors that can impact the precision of the results [23].

Given the significant limitations of this technology, we see a clear need to (1) develop new embedded electronic sensors in mHealth and clinical tools that do not perpetuate racial disparities and (2) in software, we must ensure that the algorithms deployed for signal processing and machine learning do not perpetuate bias.

Regarding the development of new sensors, a couple of avenues of research hold promise. In light of the complications found in photoplethysmography sensors, researchers are now looking at multiwavelength photoplethysmography signals to target a deeper range of measuring blood pressure and other cardiovascular parameters from the skin and show potential for being implemented in future wearables [24]. Single-channel bioimpedance [25] is another method being investigated by researchers and shows promise for potentially being implemented in future wearable devices. The key to making these hardware modifications usable in future wearable devices and minimizing racial bias is to diversify subject testing and include individuals with a broad spectrum of skin tones.

The signal processing, machine learning, and high-level algorithmic approach to prediction from these sensors must be considered at the software level so as not to perpetuate racial bias. Software mitigations for poor sensor resolution and precision are commonplace in critical systems—similar approaches are needed here. Wearable devices have the potential to perpetuate racial bias unless addressed. Many machine learning approaches to things like recidivism prediction for parolees [26], mortgage loans [27], and facial recognition [28] have already proven that without care and attention in their design and training, these software systems perpetuate racial discrimination among racially minoritized individuals. Software and firmware developers of wearables must ensure that the algorithms they deploy to capture data from biomedical sensors do not perpetuate these racial harms. Our study extends this work by establishing wearable devices as an important application for these sensor and software developments. By leveraging more equitable research on both the hardware and software level, we can address the health concerns exacerbated by the COVID-19 pandemic.

Durability and Adaptability for Diverse User Groups

Designing wearables acutely attuned to resource-constrained populations requires ensuring that the tools are both durable and scalable. As mentioned by participants, if wearables are being designed with low-income community members in mind, they must be made more durable as most individuals from these communities work in "more physically demanding jobs."

Taking into consideration their income and employment concerns, we see a need to ensure that wearables built to serve the general public also scale to this already underserved subset of the broader population. This is particularly important since literature has shown that technology that serves broader populations may not scale to subgroups [29,30].

Our findings point to the need to rethink the development of wearable technology. Strategies for improving the durability and affordability of wearable devices are to develop and make use of low-cost low-power sensors that are still capable of robustly sensing physiological signals, reuse and upcycle existing materials such as hardware components, increase service life by allowing wearable devices to be repairable inexpensively, open-sourcing hardware and software would allow wearables to be more affordable because people will not have to pay for licensing fees, and exploring different form-factors of wearable design beyond smartwatches. We argue that devices that can withstand the pressures of the everyday difficulties faced by our study population would better serve them and be a tool by which teams building wearables encode the values and preferences of underserved populations, thus promoting health equity.

Autonomy Over Data

In contrast to previous research where test subjects claimed they would like to share their data with health care providers [31], participants in our study were skeptical about sharing too much information with their health care providers due to a lack of trust in the health care system and fear of being monitored by big technology companies. Prior research discusses that the distrust of technology and the medical system among racialized low-SES communities is not new and increases barriers to adopting technology [32-34]. However, in our study, most participants believed that they should have more control over how their data is used and shared. Thus, we see interesting and important tension in participants' desire to use health technologies but concern about using them in partnership with health care systems due to a history of distrust. This points to important future research on how such tools might be able to foster patient or provider collaboration and communication within these communities where such distrust is prominent.

Serious privacy concerns regarding the data collected by wearable devices have also been reported and highlight the lack of protection of consumers' data [35]. Health insurance and tech companies such as Aetna and Apple have partnered to offer Apple watches at a discounted price; customers have to meet their fitness goals in 24 months or pay the full price if goals are not met [36]. The implications of these partnerships between insurance companies and tech companies raise privacy concerns as the health data collected by wearables allow insurance companies to determine which customers seem profitable and can raise the premium rates or deny insurance for others who are not meeting their fitness goals [37]. Apart from the privacy concerns, the potential consequences of insurance companies using data collected by wearable devices to raise insurance rates or deny health insurance to customers can lead to further health disparities for individuals from low-SES communities who may not have the funds to purchase the device even at a discounted price or have the ability to meet their fitness requirements due to other family and work responsibilities. Members of low-SES communities are already being denied access to health care, wearables should not be used as another tool to perpetuate health disparities among these populations.

Studies on contact tracing [38,39], COVID-19 mobile apps [40], and health informatics adoption among low-income individuals [32,41] have shown that data privacy is important to general users. This is especially true for low-income populations due to their mistrust of the health care system. Previous research in human-computer interaction has demonstrated the feasibility of creating privacy-preserving tools for mobile apps [42,43], software tools [44-46], and Internet of Things devices [47-49] that help users retain control and autonomy over their data.

Despite the significant progress in disseminating privacy tools to the general public, these tools have yet to be extended to the wearable space. Therefore, further research is necessary to develop privacy-focused tools for wearables, such as mobile apps or wearable-based interfaces, that enable individuals to manage and comprehend their data flow. Additionally, these privacy tools must be accessible and user-friendly to promote fair use among underserved communities.

Potential solutions for addressing privacy concerns call for stronger privacy regulations and encouraging tech companies to be more transparent about their data collection and usage. Additionally, individuals must have the autonomy to selectively share data that they feel comfortable disclosing to health care providers and tech companies. This can be facilitated through user-centric mobile apps or wearable interface privacy tools that empower people to understand and manage the flow of their data.

Beyond addressing participants' privacy concerns and data autonomy needs, we see an interesting and important tension between participants' desire to use health technologies and concern about using them in partnership with health care systems due to a history of distrust. While health wearables provide tools that can be empowering and engaging for patients, they are not meant to circumvent health care systems or medical care. We see a critical need for future research on how such tools might be able to foster patient or provider collaboration and communication within these communities where such distrust is prominent.

Affordability

The 18 participants who expressed interest in adopting wearables in their daily lives all mentioned that affordability was the strongest barrier toward adoption. These findings are in line with previous works [1,15,31]. Of participants who already owned a wearable device, 3 mentioned that they were gifted with the device and would not have been able to afford one otherwise. The remaining participants who already owned a wearable reported that they either "*bought it during a Black Friday sale*" or saved up to buy one.

Possible solutions for making wearables more affordable include exploring form factors of wearables that can be redesigned to be more affordable. Many wearables are overdesigned and engineered for sleekness, small size, and fashion, as well as feature sets that may not align with the needs of low-SES communities. In essence, the question is what specific features might be more useful than having a general-purpose platform that does it all (but therefore is much more expensive). Similar to how low-feature phones (text, phone call, and light browsing

ability) are a 10th of the price of a smartphone, wearable devices must also explore this avenue of sacrificing features (like sophisticated GPUs and video streaming accelerators or advanced machine learning processing) for things like optical respiratory rate measurement.

From an academic perspective, as stated previously, including low-SES communities in research studies is important to diversify participant populations to reduce potential racial bias. However, wearable researchers can take a step further and allow participants from low-SES communities to keep any technology used within the research. Giving people technology for a 2-month deployment and then taking it away when they do not have the means to obtain something like that themselves is a serious ethical concern.

Limitations and Future Directions

We acknowledge that our work has sampling limitations. This study was exploratory, and though our intentions were not meant to only target participants from Hispanic or Latine low-SES communities from 2 metropolitan cities, we were not able to sample the perceptions of other racially minoritized BIPOC communities from smaller cities or rural areas. City representation was likely due to the research team members being from these 2 cities. In future work, examining the differences in how members from other racially minoritized groups perceiving wearables could vary would provide valuable insights.

Conclusions

This research study aimed to investigate the needs and perspectives of individuals from low-income communities regarding the adoption and usage of wearable devices. Our findings indicate that there is considerable interest among members of these communities in employing wearables to promote their well-being. Participants expressed frustration with the current health system citing how the lack of health resources and the health effects of the COVID-19 pandemic has led them to seek alternative methods to manage their health. Participants recommended design considerations for the utility of wearable devices that included, durability, sustainability, and accessibility. Additionally, autonomy on how their data is used was important for the majority of participants. Affordability was the primary barrier to the adoptability of wearable devices. Participants believe that if health insurance companies can help pay for partial costs of wearable devices, more people in the community would be more interested in using them. The insights from this study serve as a first step for researchers and technology companies in the domain of wearable technology to develop tools that account for the contextual and cultural perspectives of low-SES communities to help democratize the utility of wearable devices.

Abstract

Background: The high prevalence of uncontrolled hypertension in Pakistan is predominantly attributed to poor medication adherence. As more than 137 million people in Pakistan use cell phones, a suitable mobile health (mHealth) intervention can be an effective tool to overcome poor medication adherence.

Objective: We sought to determine whether a novel mHealth intervention is useful in enhancing antihypertensive therapy adherence and treatment outcomes among patients with hypertension in a low- to middle-income country.

Methods: A 6-month parallel, single-blinded, superiority randomized controlled trial recruited 439 patients with hypertension with poor adherence to antihypertensive therapy and access to smartphones. An innovative, multifaceted mHealth intervention (Multi-Aid-Package), based on the Health Belief Model and containing reminders (written, audio, visual), infographics, video clips, educational content, and 24/7 individual support, was developed for the intervention group; the control group received standard care. The primary outcome was self-reported medication adherence measured using the Self-Efficacy for Appropriate Medication Adherence Scale (SEAMS) and pill counting; the secondary outcome was systolic blood pressure (SBP) change. Both outcomes were evaluated at baseline and 6 months. Technology acceptance feedback was also assessed at the end of the study. A generalized estimating equation was used to control the covariates associated with the probability of affecting adherence to antihypertensive medication.

Results: Of 439 participants, 423 (96.4%) completed the study. At 6 months post intervention, the median SEAMS score was statistically significantly higher in the intervention group compared to the controls (median 32, IQR 11 vs median 21, IQR 6; U=10,490, *P*<.001). Within the intervention group, there was an increase in the median SEAMS score by 12.5 points between baseline and 6 months (median 19.5, IQR 5 vs median 32, IQR 11; *P*<.001). Results of the pill-counting method showed an increase in adherent patients in the intervention group compared to the controls (83/220, 37.2% vs 2/219, 0.9%; *P*<.001), as well as within the intervention group (difference of n=83, 37.2% of patients, baseline vs 6 months; *P*<.001). There was a statistically significant difference in the SBP of 7 mmHg between the intervention and control groups (*P*<.001) at 6 months, a 4 mmHg reduction (*P*<.001) within the intervention group, and a 3 mmHg increase (*P*=.314) within the controls. Overall, the number of patients with uncontrolled hypertension decreased by 46 in the intervention group (baseline vs 6 months), but the control group remained unchanged. The variables groups (adjusted odds ratio [AOR] 1.714, 95% CI 2.387-3.825), time (AOR 1.837, 95% CI

1.625-2.754), and age (AOR 1.618, 95% CI 0.225-1.699) significantly contributed (P<.001) to medication adherence. Multi-Aid-Package received a 94.8% acceptability score.

Conclusions: The novel Multi-Aid-Package is an effective mHealth intervention for enhancing medication adherence and treatment outcomes among patients with hypertension in a low- to middle-income country.

Introduction

Hypertension is a significant health challenge worldwide and a leading cause of morbidity and mortality [1]. In the 21st century, hypertension has become a growing health issue worldwide. It is expected to increase from 918 million individuals in 2000 to 1.56 billion in 2025 [1]. Compared to high-income countries, the prevalence of hypertension among adults is more remarkable in low- and middle-income countries (LMICs) [2,3]. Hypertension is responsible for approximately 9.4 million fatalities worldwide, making it a significant cause of death [4]. These deaths are mostly preventable, as lowering the systolic blood pressure (SBP) can lessen fatalities from all causes and cardiovascular disease (CVD) [5].

The risk of mortality due to cardiovascular events and stroke is lowered by twofold for each 20 mmHg drop in the SBP or each 10 mmHg drop in the diastolic blood pressure (DBP) between the ages of 40 and 69 years [6]. The dosage of blood pressure medications administered and adherence to therapy are 2 important aspects that influence blood pressure control in patients receiving treatment with clinically corrected blood pressure levels. Patient compliance is a critical aspect of blood pressure management, and medication is worthless for those who refuse to take it [7]. What is more worrying is the chronic nature of hypertension and the need to be compliant with the medications usually for more than 1 year. It has been noted that 1 year after starting antihypertensive medication, 50% of patients still use it [8,9]. Unfortunately, in general, the percentage of treated patients with hypertension who achieve control levels is only between 20% and 50% [2,10].

In Pakistan, hypertension is a crucial matter of public health, where nearly 19% of the youth and 33% of individuals older than 45 years have hypertension, with the majority of the population with hypertension having poor blood pressure control [11]. Poor medication adherence has been noted to contribute to poor blood pressure control in Pakistan [12]. A recent investigation found that 37.7% of patients fail to take their antihypertensive medications, as directed [12]. This situation is of concern because as mentioned, medication adherence is a proven and cost-effective treatment for hypertension [13], in addition to lifestyle modification and medical risk assessment. Furthermore, medications may lower the risk of stroke and myocardial infarction by 30% and 15%, respectively, among the population with hypertension [14]. Lower levels of adherence are connected to poorer blood pressure control and unfavorable outcomes [15].

For a few years, there has been an upsurge in the use of mobile health (mHealth) apps to improve medication compliance [16,17]. Using mobile technology, such as cell phones, personal digital assistants, patient-monitoring equipment, and other wireless devices, for medical care is referred to as “mHealth” [18]. mHealth is an ideal tool for LMICs due to its low cost and ease of use. For mHealth, all that is required are mobile devices, cellular communication technologies, and an internet connection. According to the Pakistan Telecommunication Authority, more than 137 million Pakistanis use cell phones, corresponding to a cellular density of 77% of the population [19]. However, despite the growing popularity of cell phones in LMICs, mHealth approaches in these countries remain limited.

Furthermore, no specific association between the use of mHealth apps and enhancement of medication adherence in CVD in LMICs has been shown to date [20]. Several studies have suggested that further investigations be conducted to determine whether mHealth can enhance medication adherence in LMICs [20,21] compared to traditional methods [22]. WhatsApp facilitates the collection of real-time data over both time and place. WhatsApp offers a plethora of health-related uses, including optimizing communication and the delivery of health education [23,24]. A survey found that Pakistanis primarily use social media for communication and information exchange in the health sector, with WhatsApp and YouTube being the most widely used social media platforms for health-related topics [25]. Several important observations, particularly those gleaned from the body of the existing literature [25], guide our decision to use WhatsApp in implementing this cutting-edge intervention, since it is an efficient way to provide interventions with respect to cost, time, and dissemination.

Using the Health Belief Model [26] and self-determination theory [27] as a foundation, we developed a novel mHealth intervention module for the population with hypertension in LMICs, particularly Pakistan. The module is called “Multi-Aid-Package.” It is a multifaceted intervention integrated with educational guidelines and a reminder component. The module addresses individual patients’ perspectives and concerns and incites health-related beliefs toward better medication adherence. This trial’s distinctive feature was its all-encompassing, multimodal strategy, which combined various previous interventions [28-30] into a single intervention. Second, animated images and videos were used in place of text in this

study. Therefore, as far as we are aware, this is the first study in Pakistan to develop and assess the efficacy of a comprehensive and multifaceted mHealth intervention.

Consequently, this study sought to use the mHealth-based multifaceted intervention with the aid of WhatsApp to help patients who were not adhering to their medication and to assess the efficiency of Multi-Aid-Package in optimizing adherence to medication and manage the SBP among patients with hypertension in the LMIC context. We hypothesized that this mHealth module intervention would improve medication adherence, lower the SBP, and eventually lower the mortality and morbidity due to hypertension.

Methods

Trial Design

This trial was a parallel, single-blinded, superiority randomized controlled study that lasted for 6 months and had a 2-arm, parallel design. The trial was carried out following the CONSORT (Consolidated Standards of Reporting Trails) Statement 2010 standards [31]. Participants were randomly concurrently allocated 1 of 2 groups (intervention or control) in a 1:1 ratio. The intervention group underwent the Multi-Aid-Package intervention, while the control group received regular treatment (as per the hospitals' routine practice) [32]. Evaluations were carried out at baseline and 6 months after the implementation of the intervention. The trial was registered with Clinical Trials (NCT04577157; registration date October 6, 2020) before the start of recruitment, which began on January 3, 2021.

Sampling Method and Study Setting

A 2-stage random sample procedure was used to carry out sampling. The first stage required selecting a hospital at random from a list of hospitals, and the second stage entailed randomly selecting patients with hypertension from the selected hospital.

The study site selected was a public tertiary care hospital in Punjab's provincial capital, Lahore. Lahore is Pakistan's second-biggest city and has a population of 11,302,285, with a gross domestic product (GDP) of US $84 billion [33].

Study Participants

Study participants were selected from among patients diagnosed with hypertension at the hospital's cardiology and medical outpatient departments. Patient screening involved identifying those who were registered as hypertensive for the past month. The selection process was conducted by specially assigned registrars who screened patients using the Self-Efficacy for Appropriate Medication Scale (SEAMS) [34] and by asking the patients the number of pills they consumed during a specified period [35]. Although these 2 approaches to measure medication adherence are distinct, both adherence measures were used in this trial for inclusion/exclusion considerations. Only those patients who satisfied both criteria were recruited. Due to the selection criteria's restriction to using both approaches, any participant could be classified as nonadherent. These results indicated the patients' medication adherence status. Based on these assessments and other eligibility criteria, 439 participants were selected. The data collected included sociodemographic information, health-related profiles, baseline SEAMS score, and number of pills (representing medication adherence status). All the information was collected through face-to-face interviews conducted by trained research staff. In addition, each participant's baseline SBP reading was also recorded.

Eligibility Criteria

The inclusion criteria were as follows: patients who were at least 18 years old, diagnosed with hypertension within the previous month, prescribed antihypertensive medications, had poor medication adherence (a low SEAMS score ranging from 13-21 and pill-counting rate<80% were coded as nonadherent), had a smartphone with WhatsApp installed, and had the ability to read and send messages using WhatsApp.

The exclusion criteria were as follows: patients who had plans to leave the study area during the study period that would prohibit them from accessing cell signals; had a history of cancer, as they would need medication adjustments over time; would undergo a planned surgery or intervention; had blood pressure>220/120 mmHg (in the hypertensive emergency category); or were pregnant, breastfeeding, or 3 months postpartum.

Sample Size

The sample size was estimated to assess a 1-point difference in SD (SD 2) on the major outcome metric of adherence change when comparing the 2 groups. To evaluate the 2-tailed hypothesis, the α level (type 1 error) was set at .05, with a 95% CI interval, Z=1.96, and strength to obtain a power of 90% [36]. The adherence reference value was as determined by a recent study [17]. After a 30% attrition rate, using Lemeshow et al's [37] formula:

the calculated sample size for this study was 440 participants, equally allocated to the intervention and control groups (n=220, 50%, per group).

Randomization and Concealment

A simple complete randomization method was used [38]. First, a random sequence was generated in Microsoft Excel using the formula =ROUNDUP (RAND ()*440,0). Participants were then split into 1 of 2 groups at random in a 1:1 ratio using their unique identification numbers. Opaque envelopes were used to disseminate information concerning participant allocation.

An independent biostatistician performed all the subsequent randomization steps. In addition, the staff involved in the randomization assessment and intervention delivery were separated, thus ensuring they did not know which patient belonged to which group.

Blinding

The research team, which consisted of the research supervisor and research assistants responsible for data collection, was unaware of the intervention and control groups [39]. Due to the subjective nature of the intervention, participants were aware of their allocation to either the intervention or the control group.

Outcome Measures

The primary outcome was the change in antihypertensive medication adherence at 6 months. This change was measured using the SEAMS questionnaire and self-reported pill counting (number of pills consumed over a certain period divided by pills prescribed for that specific period) [35]. SEAMS is a validated and reliable questionnaire, a 13-item assessment of medication self-efficacy in managing chronic conditions, found appropriate for individuals with limited literacy [34]. SEAMS uses a 3-point answer scale, where 1 denotes a lack of confidence, 2 denotes a moderate level of confidence, and 3 denotes a high level of confidence. A conceivable score is 13-39 points. Greater medication adherence is associated with higher scores, and vice versa. Based on prior studies, a cutoff value of 80% was used to distinguish between adherence status and nonadherence status. Participants were questioned regarding the number of pills they had been prescribed for a certain period, the number of pills they had consumed, and the number of pills they had forgotten to take during that certain period. Adherence rates were then calculated [35]. Patients who scored <80% were categorized as nonadherents, while those who scored ≥80% were classified as adherents [40]. At baseline, all participants were nonadherent; therefore, no further analysis could be conducted.

The secondary outcome was the SBP change at 6 months. This outcome was assessed in the hospital by a nurse who was not aware of the allocation of the study participants. The blood pressure was measured using a calibrated upper-arm mercury sphygmomanometer (MODEL-605P YAMASU). Standard principles were used to measure each participant's blood pressure [41].

Interim Analysis

At baseline, 3 months, and 6 months, both primary and secondary outcomes were evaluated. The 3-month analysis was used as a bridge to evaluate attrition rate patterns and the trends of change in outcomes. It was performed as an interim analysis; therefore, its results were not reported. The 6-month analysis was regarded as final.

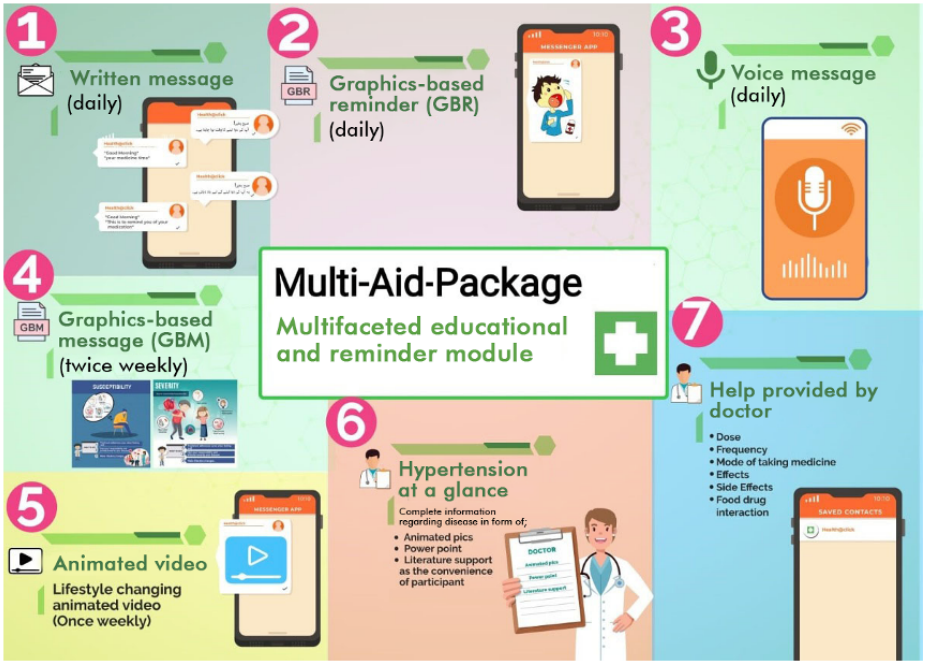
Intervention

The intervention's main objective was to enhance adherence to antihypertensive therapy in the intervention group using Multi-Aid-Package, a novel mHealth module. Multiple procedures were used in the intervention development. The first step was a thorough literature search for the theories and determinants of medication nonadherence. Additionally, hypotheses on patient acceptance of electronic/mobile devices were looked up in the accessible literature. The procedure for consulting with a group of specialists came next. Experts in epidemiology, behavioral intervention, health education, IT, and cardiology specializing in hypertension management used the Health Belief Model, self-determination theory, and relevant clinical standards and recommendations in the development of this module.

The content of this module included 7 items, a multifaceted approach with educational instructions, and reminders. Multi-Aid-Package comprised written and voice reminders, as well as graphics-based reminders (GBRs) and graphics-based messages (GBMs), which were all disseminated daily and weekly to participants in the intervention group via WhatsApp.

Reminder text and voice messages for medication intake were in Urdu, as it was the most commonly used language among the study participants. Examples of such messages are "Good morning, it's time for your medication" and "Good morning, this is a reminder for you to take your pills" (see items 1 and 3 in Figure 1).

Figure 1. Contents of Multi-Aid-Package. AI: artificial intelligence.



GBMs were an animated series of messages developed with the help of a professional team of software developers (see item 4 in Figure 1). Furthermore, an animated video was also created by IT professionals with the help of clinical experts. The resulting animated video was divided into 3 sections: (1) awareness of hypertension, (2) the negative consequences of uncontrolled hypertension, and (3) medical and lifestyle changes for better health (see item 5 in Figure 1). In this module, participants were also provided with the "Hypertension at a Glance" component, a portfolio of instructional and educational tools that shows details of the condition's causes, diagnosis, treatment, complications, and prognosis (see item 6 in Figure 1).

In addition to the components mentioned earlier, the module also contained live support provided by a certified doctor 24 hours a day. The support included information on the medicine's dose, the dose frequency, the administration method, the effects of therapy on the present sickness, adverse effects, and interactions with particular meals (see item 7 in Figure 1). Live support and the "Hypertension at a Glance" portfolio were provided on a demand or need basis to only those participants who encountered problems from day 1 of the intervention, while the remaining components of Multi-Aid-Package were disseminated following the timetable provided. The contents of Multi-Aid-Package are summarized in Figure 1.

Pilot Testing

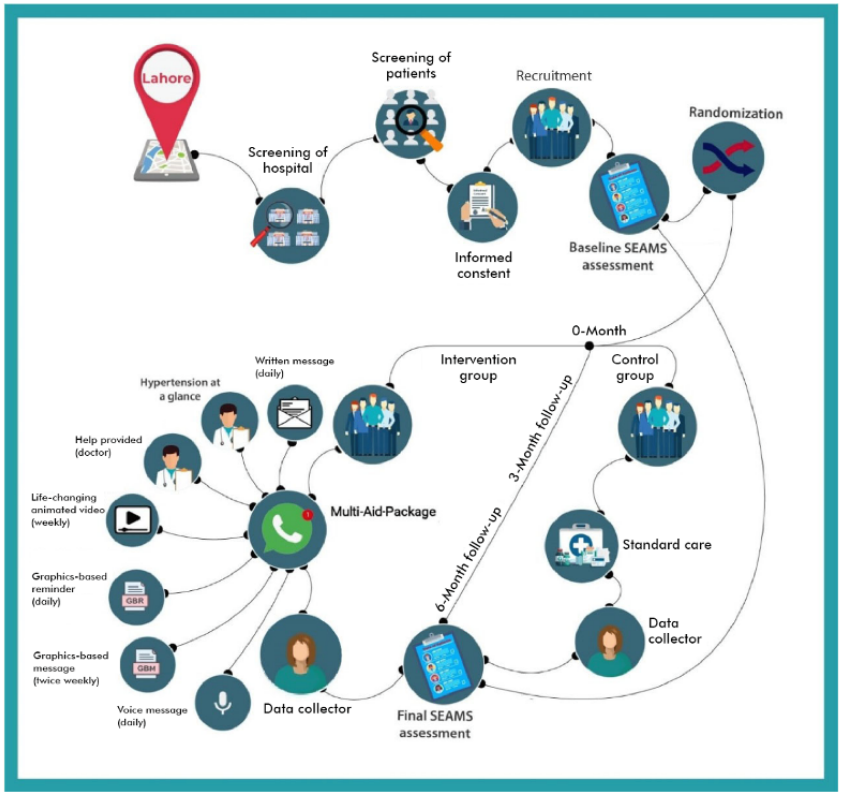
In addition, the Multi-Aid-Package was subject to a pilot test among 44 patients with hypertension to determine if they could understand the module's contents. As per usual hospital practice, only standard care was given to those in the control group. After being pilot tested, the intervention didn't change significantly. Only a few minor issues were seen, such as delivery issues, network issues, being outside of the coverage region, and unsuccessful file and video downloads. During the trial, this application's final version was made available.

Implementation of Multi-Aid-Package

The trial's design and execution adhered to the 2010 CONSORT criteria, which included a rigorous protocol for the provision of interventions to participants. This included the validation of the Multi-Aid-Package intervention in a pilot study, and an orientation and training session on the intervention was provided to the participants. Contact numbers were also provided to the participants in case they experienced any inconvenience. Moreover, a strict protocol was followed to disseminate the various contents of the multifaceted intervention. The implementation of Multi-Aid-Package was coordinated with the assistance of an IT specialist and 2 trained research assistants. In essence, these individuals were tasked to oversee the dissemination of the various contents of Multi-Aid-Package to the intervention group's participants via WhatsApp and to support data collection. WhatsApp was used in this study because it contains a feature on its interface that indicates to the sender whether the receiver has seen the message: a sign on the message sent through this app changes its color to blue when the recipient sees the message. This was the only way to check whether the participants had read the message. Second, the outcome results illustrated whether the participants took their medication, as prescribed. Research staff members were trained and the intervention pretested to ensure quality control. Using a pre-established curriculum for training by experts, 2 days of on-site instruction sessions on hypertension and questionnaire completion and how to respond to typical queries related to medication adherence were provided to all recruited research workers. Finally, the intervention module was rolled out to the selected participants in the trial. Figure 2 shows the overall flow of the study implementation.

No financial or other benefits were provided to the participants, except 6 months of free-of-cost WhatsApp use. There were no other direct benefits provided.

Figure 2. Trial flow. SEAMS: Self-Efficacy for Appropriate Medication Adherence Scale.



Participants' Timeline

The recruitment process was completed from January to May 2021, and a total of 439 participants were included. From June to December 2021, the intervention group received the Multi-Aid-Package intervention. The intervention duration was 6 months. The 6-month time frame of the intervention was chosen based on data from the previous literature on the topic, which included studies conducted over 2 and 3 months [30,42], and the fact that 6 months is a reasonable time limit to observe changes in behavior.

Data Collection

The data collection tool was a questionnaire in Urdu and English languages. The questionnaire was divided into 4 sections: A, B, C, and D.

Section A collected data on sociodemographic and health-related variables. Section B was the validated SEAMS questionnaire [34]. Section C collected self-reported pill-counting activity. Section D was a postintervention survey performed to assess the acceptability of the intervention. A 5-item Likert scale, with each item having 7 options, was used to evaluate participants' perceptions of their intervention experience with regard to usefulness, simplicity of use, and fulfillment of information.

Validity and Reliability of the Study Instrument

The internal consistency of SEAMS was good (Cronbach α=0.89). The test-retest reliability was moderate (Spearman coefficient=0.62, P<.001). The item total correlation coefficients ranged from 0.36 to 0.67, and the mean interitem correlation was 0.32 (range 0.08-0.71) [34].

The SEAMS questionnaire was translated from English to Urdu (SEAMS-U) in Pakistan using the standard "forward-backward" procedure. A convenient sample of 1011 patients with hypertension who were being treated at a tertiary care hospital in Lahore, Pakistan, was used to validate the translated version. The internal consistency of the translated questionnaire was good (Cronbach α=0.897). Cronbach α for part 1 was 0.838 and for part 2 was 0.789 using split-half reliability. The test-retest reliability was moderate (Spearman correlation=0.686, P<.001), and the intraclass correlation coefficient score was 0.814. The entire translation validity and reliability process was performed by our team and during publication.

Data Management and Statistical Analysis

Data management was the responsibility of a study supervisor, a biostatistician, and 2 research assistants. First, the research assistants ensured that no data collection form was incomplete or missing. Next, the research supervisor received all the data in sealed boxes. If there were any missing pieces of information in the data, the participants were contacted via a phone call to finish the form. Lastly, a biostatistician entered, cleaned, and analyzed the data. SPSS version 26.0 (IBM Corp) and RStudio (version 4.0.3; Posit PBC) were used to analyze the data.

The intention-to-treat analysis was used in this study [43]. The Shapiro-Wilk test was performed to determine whether the data were normally distributed. Categorical data were represented using frequencies and percentages, while continuous data were represented using medians (IQRs). The nonparametric Mann-Whitney U test was used on the data for the primary and secondary outcomes between groups, while the Wilcoxon signed rank test was used for within-group differences between baseline and 6 months. For categorical variables, the chi-square test was

used. The significance test was run with a *P* value of <.05. In addition, missing data were reported and treated using the single imputation approach. A generalized estimating equation (GEE) was used to control the covariates associated with the probability of affecting adherence to antihypertensive medication and the covariates that were significantly different between the intervention and control groups.

Adverse Events

No other adverse results were reported, except the primary and secondary outcomes that were reported in relation to the participants and our intervention strategy. All COVID-19 standard operating procedures were strictly followed during recruitment, randomization, and data collection. Furthermore, no issues were reported regarding COVID-19.

Ethical Considerations

The University Putra Malaysia (UPM) Ethical Committee on Human Research approved the research protocol (reference number: JKEUPM-2020-391) and the Institutional Review Board of the Sheikh Zayed Medical Complex Lahore (SZMC/IRB/163/2021). Participation in this trial was discretionary, and informed consent was obtained in writing from each participant before the start of the study. Strict confidentiality and privacy were ensured by assigning each participant an identification number to protect their identity [44]. The confidentiality of participant data was also ensured. This study was designed according to Good Clinical Practice (GCP) [45,46].

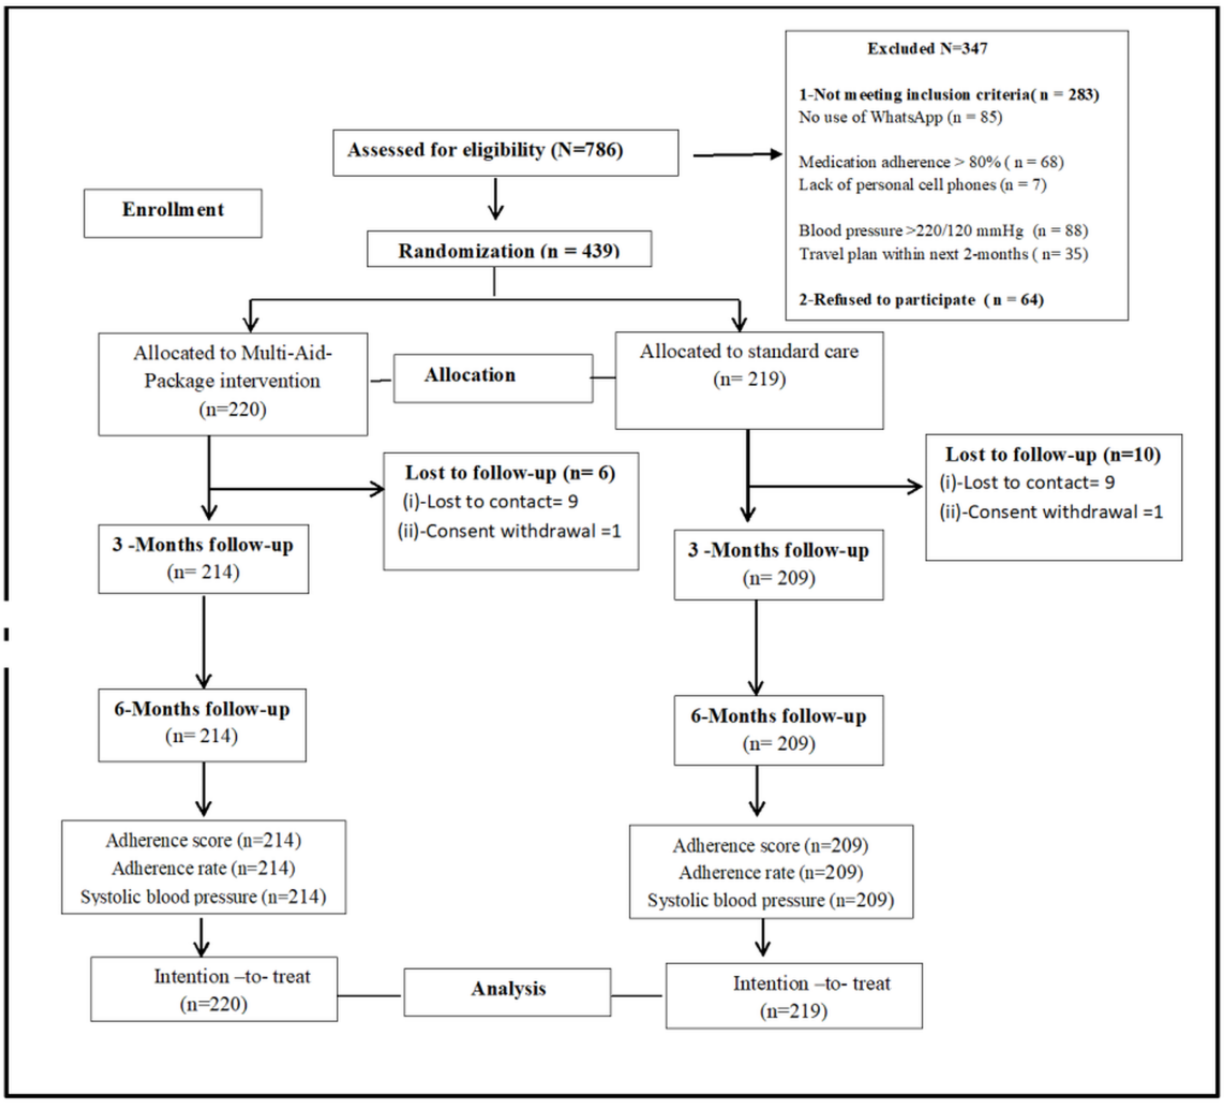
The study was designed to barely cause any risk to both patients and medical personnel. The participants were questioned in a private room, away from onlookers, in order to prevent minor psychological discomforts related to personal issues involving their income and the embarrassment that they might experience when answering questions about their subpar adherence status.

Results

Response Rate

From January to May 2021, a total of 786 participants were initially assessed based on the eligibility criteria. Of these, 347 (44.1%) participants were excluded based on inclusion criteria (n=283, 81.6%) and refusal to participate (n=64, 18.4%) in the trial. The details of the subcategories under “not meeting inclusion criteria” are elaborated in Figure 3. Of them, in June 2021, 439 participants fulfilled the criteria, consented to participate, and were randomly assigned to either the control group, which received standard care (n=219), or the intervention group, which received the Multi-Aid-Package (n=220). The randomization was performed according to the CONSORT flow diagram [31,47] (Figure 3). The total response rate at the end of the intervention was 423 (96.3%), with 209 (95.4%) participants in the control group and 214 (97.2%) participants in the intervention group until the completion of follow-up in December 2021. In the control group, 10 (4.8%) participants were lost to follow-up, while 1 (0.5%) participant withdrew consent. In the intervention group, 6 (2.8%) participants were lost to follow-up. The reason for the failure to follow up was loss of contact. No mortality was reported.

Figure 3. CONSORT flow diagram. CONSORT: Consolidated Standards of Reporting Trails.



Baseline Demographic Characteristics

At baseline, the 2 groups did not differ statistically significantly from each other across most of the variables, except gender, which had substantial differences among both groups (P=.02). In general, the intervention group's baseline characteristics were similar to those of the control group regarding age, ethnicity, marital status, education, family status, employment, and monthly income. Most of the participants were aged between 30 and 49 years old and were male, with a graduate level of education and a high-income status (Table 1).

Table 1. Baseline characteristics of study participants according to their group allocation (N=439).[a]

Characteristics	Intervention group (n=220), n (%)	Control group (n=219), n (%)	*P* value[a]
Age (years)			.30
≤50	91 (41.4)	102 (46.6)

Baseline Health-Related Characteristics

Regarding health-related characteristics, there was no significantly significant difference between the 2 groups. Additionally, the median SEAMS score of the control group was substantially higher than that of the intervention group (*P*=.03). Otherwise, the 2 groups had a balanced distribution of subjects regarding the duration of hypertension, comorbid conditions, the number of medications used daily, dose frequency, SBP, and controlled status of SBP<140 mmHg (Table 2).

Table 2. Comparison of health-related characteristics between intervention and control groups (N=439).[a]

Effect of the Multi-Aid-Package Intervention on Medication Adherence

The effect of the Multi-Aid-Package intervention on medication adherence on the 2 groups at baseline and 6 months was measured using the median (IQR) SEAMS score. At baseline, the median SEAMS score was 19.5 (IQR 5) for the intervention group and 21 (IQR 6) for the control group. Compared to the intervention group, the control group's median SEAMS score was significantly higher (1.5 points; *P*=.011). At 6-month follow-up, the median SEAMS score was significantly different between the intervention and control groups (*P*<.001).

Regarding the medication adherence status, at baseline, all participants were nonadherent; therefore, no further analysis

could be performed. At 6 months, however, there was an increase in adherent patients between the intervention and control groups (difference n=81, 18.4% of patients; *P*<.001; Table 3).

The effect of the Multi-Aid-Package intervention on medication adherence within groups at baseline and 6 months was also measured using the median (IQR) SEAMS score. At baseline, the median SEAMS score within the intervention group was 19.5 (IQR 5), which increased to 32 (IQR 11) at the 6-month follow-up, with a median difference of 12.5 points. The median SEAMS score statistically significantly changed from baseline to 6 months (*P*<.001), while there was no statistically significant change in the median SEAMS score in the control group from baseline to 6 months (*P*=.29). A total of 83 (37.7%) participants achieved adherent status in the intervention group (*P*<.001), while 2 (0.9%) participants achieved adherent status in the control group (*P*=.78) from baseline to 6 months (refer to Multimedia Appendix 1).

Table 3. Primary outcomes for the intervention and control groups from baseline to 6 months (N=439).

Variable	Intervention group (n=220)	Control group (n=219)	Difference (intervention – control)	Test statistics	*P* value
SEAMS[a] score at baseline, median (IQR)	19.5 (5)	21.0 (6)	–1.5	*U*[b]=20,717.500	.01
SEAMS score at 6 months, median (IQR)	32.0 (11)	21.0 (6)	11	*U*=10,490.000	<.001
Adherence status at 6 months, n (%)	83 (37.72)	2 (.91)	81	95.266[c]	<.001

[a]SEAMS: Self-Efficacy for Appropriate Medication Adherence Scale.

[b]Mann-Whitney *U* test.

[c]Fisher exact test.

Effect of the Multi-Aid-Package Intervention on the SBP

At baseline, there was no difference in the SBP between the 2 groups. At 6 months, however, the median SBP was statistically different between the intervention and control groups (*P*<.001). A binary variable "controlled systolic blood pressure" was computed to evaluate the success of the treatment. The controlled SBP code was "Controlled <140 mmHg and uncontrolled >140 mmHg."

Overall, at 6 months, the number of patients with uncontrolled hypertension decreased by 46 in the intervention group (*P*<.001) but remained unchanged in the control group (*P*=.724; Table 4).

At baseline, the median SBP in the intervention group was 159 (IQR 23) mmHg, which decreased to 155 (IQR 29) mmHg, with a median difference of 4 mmHg. The median SBP significantly changed from baseline to 6 months (*P*<.001), while there was no statistically significant change in the median SBP in the control group from baseline to 6 months (*P*=.31). A total of 49 (22.3%) participants achieved controlled SBP status in the intervention group (*P*<.001), whereas there was no change in the control group's controlled SBP status (*P*=.78) from baseline to 6 months (refer to Multimedia Appendix 1).

Table 4. Secondary outcome change between intervention and control groups from baseline to 6 months (N=439).

Variable	Intervention group (n=220)	Control group (n=219)	Difference (intervention – control)	Test statistics	*P* value
SBP[a] (mmHg) at baseline, median (IQR)	159 (23)	159 (27)	0	*U*[b]=23,768.000	.81
SBP (mmHg) at 6 months, median (IQR)	155 (29)	162 (17)	–7	*U*=18,276.000	<.001[c]
Controlled SBP (mmHg) at baseline, n (%)	3 (1.36)	4 (1.83)	–1	N/A[d]	.72
Controlled SBP (mmHg) at 6 months, n (%)	49 (22.27)	4 (1.83)	45	43.221[e]	<.001[c]

Covariates Affecting Medication Adherence

A GEE was used to control the covariates associated with the probability of affecting adherence to antihypertensive medication using pill counting and the covariates significantly different between the intervention and control groups. We used the forward method. A working correlation matrix was gender. A total of 3 factors were found significant: group, time, and age. The group variable significantly contributed to medication adherence. The intervention group had a 1.714 times higher probability of being adherent to antihypertensive medication than the control group (adjusted odds ratio [AOR] 1.714, 95% CI 2.387-3.825; *P*<.001). Time points also contributed significantly to medication adherence. A 6-month postintervention time had a 1.837 times higher probability of showing adherence to antihypertensive medication than baseline

(AOR 1.837, 95% CI 1.625-2.754; *P*<.001). Age also contributed significantly. The 18-29 years of age group was found more likely to be adherent to antihypertensive treatment, with a 1.618 times higher probability than the other 2 age groups (AOR 1.618, 95% CI 0.225-1.699; *P*<.001). Income was a significant predictor for adherence to antihypertensive treatment (Table 5).

Technology Acceptance Feedback

At the end of the study, an intervention acceptance survey for Multi-Aid-Package was performed. A total of 214 (97.3%) participants from the intervention group participated in the survey. The survey consisted of 5 questions on (1) the information provided by Multi-Aid-Package about the disease, disease management, and complications (1 question); (2) how easy the participants found the intervention to use (2 questions); and (3) utility (2 questions). Each question offered 7 possible answers. Ratings ranged from 7 to 35. The minimum score was 7, while the maximum score was 35. Next, the mean score was calculated for the 214 (97.3%) participants. The Multi-Aid-Package intervention received a mean score of 33.21 (SD 4.39) of 35 points (94.8%), with good feedback on its usefulness, simplicity of use, and fulfillment of information for treating hypertension.

Discussion

Principal Findings

The comprehensive and unique multifaceted Multi-Aid-Package comprised 7 potential components, including continuous reminders integrated with education and support components. Multi-Aid-Package was designed for the intervention group and revealed a significant increase in adherence to antihypertensive medication and a substantial reduction in SBP in patients with hypertension. This study showed that using Multi-Aid-Package led to a significant improvement in medication adherence among patients who were nonadherent to their antihypertensive medication at the beginning of the trial.

Similar results from an existing body of literature concur with this trial's findings, where SMS text message interventions revealed positive results in patients with hypertension compared to controls [17,29]. Some trials have also shown significant results in patients with hypertension using advanced cell phone apps [48-50]. Overall, mHealth technology interventions have revealed positive results in patients with CVD [51]. In another trial, an SMS text message intervention demonstrated substantial improvement in adherence to treatment, from 49% to 62.3%, in patients with hypertension [52]. In the previous literature, mHealth interventions have been reported to lower blood pressure and improve medication adherence, with adequate acceptance and feasibility [16,23,53-56]. Patients also significantly benefit over time with self-management and blood pressure control [57-60]. However, a few trials were unable to reveal any significant improvement in medication adherence post intervention: one used a mobile app, while the other studies used a web-based talking intervention to enhance medication adherence in CVD [16,30]. Similarly, another trial using mailing and automated calls [61] and one using video interventions in patients with stroke [62] were unable to reveal any substantial change. mHealth is also paramount in medication adherence in other chronic illnesses, such as tuberculosis, CVD, diabetes, and chronic liver diseases [63-66].

Research Innovation and Clinical Implications

Multi-Aid-Package is a modified version of the preexisting literature on this subject as it contains multiple facets (SMS text messages, apps, interactive messages, and calls) in 1 application compared to only 1 or 2 facets per app in other interventions. Previous trials have used different facets of mHealth, for instance, SMS text messaging interventions used to improve adherence to antihypertensive medication [29,67], interactive voice interventions [68], talking treatment interventions [30], advanced mobile apps [48,50], and mail-outs [61]. Some of these interventions have demonstrated positive results, while others have been unable to reveal any improvement or insignificant improvement in adherence to antihypertensive medication. The unique aspect of this study is that the Multi-Aid-Package intervention combines multiple facets in 1 intervention. Multi-Aid-Package is superior because it contains 7 different parts, such as SMS text messaging, videos, and graphics.

Multi-Aid-Package is a comprehensive and effective tool for enhancing antihypertensive medication adherence and subsequently managing the SBP. Much preexisting literature supports our findings. In most studies, intervention group participants have reported being adherent more likely compared to the controls, where the intervention eventually altered health beliefs concerning medication adherence but was unable to show any significant effect on the SBP. For example, a cell phone app for patients with hypertension improved medication adherence but failed to significantly control the SBP in an intervention arm compared to the control arm [48]. Similarly, another 12-month trial found a minor change in the SBP [29] compared to our study, which revealed better results, even with a shorter duration. mHealth interventions are also influential in changing lifestyles [67]. Although there can be various explanations for no significant or even a minute change in the SBP despite considerable improvement in medication adherence, factual evidence shows that a reasonably long time is needed to see a change in clinical outcomes. Nevertheless, becoming highly adherent to therapy is essential. The literature also emphasizes that to obtain more clinical benefits, patients must strictly adhere to their antihypertensive medications [69]. There is no evidence of the efficiency of interventions in lowering the DBP, although an increased SBP is the primary aim of antihypertensive medication. Furthermore, according to epidemiological research, untreated hypertension, especially the SBP, ought to be the main goal for hypertension treatment [70].

It is crucial to emphasize that using Multi-Aid-Package in the framework of clinical care in a resource-limited setting can alone help support patients in managing their hypertension. Several studies have found that improving medication adherence

has a higher impact on clinical outcomes linked to additional assistance, primarily through connections to health care professionals [71]. Some effective interventions has shown that support via a cell phone can be provided without further blood pressure monitoring [72] and with nonadherent patients not being contacted by any health care providers [73]. In our study, there was no permanent connection between the patient, the health care provider, and the targeted blood pressure monitor.

Conclusively, to the best of our knowledge, this multifaceted approach is the first technology-based intervention in Pakistan to be built comprehensively and uniquely using only WhatsApp, which was cost-, time-, and resource-efficient. In contrast to prior cell phone–based interventions, this multifaceted intervention has a more substantial impact on antihypertensive medication adherence and SBP outcomes.

Future Suggestions

Further exploration by covering multiple cities, a large sample size, and a longer duration of follow-up is required to validate the results of this study. Our findings cannot be generalized to populations with different sociodemographic and medical profiles, so more diverse studies are required to generalize the findings to a wider population. There are recommendations for more sophisticated designs and efficient interventions to enhance medication adherence in CVD [21]. To improve outcomes, we suggest implementing new educational interventions with more effective designs and sophisticated adherence measurement techniques (mobile apps or devices) at a relatively low cost and implementing successful treatments in clinical settings. A recent study compared an innovative mHealth strategy to peer counseling to improve adherence to medication in patients with hypertension [51]. Future trials should consider the type of antihypertensive medication being taken. Finally, high-quality research is needed to explore mixed qualitative evidence with quantitative studies.

Strengths and Limitations

Two methods were used to measure medication adherence to strengthen the method of measurement and to obtain robust findings, supported by a preexisting body of literature on the subject [74]. The SBP was also assessed as a secondary outcome to increase the credibility of adherence to medication in patients with hypertension. An interim analysis was performed to monitor the dropout status, increasing the trial's strength. All the steps in the trial were in line with recent SPIRIT guidelines [75]. The Multi-Aid-Package intervention could help minimize inequity and prevent discrimination among different sociodemographic groups. Technology acceptance feedback was also assessed at the study's end, and the intervention received excellent feedback.

This trial also has a few limitations. First, the trial was a single-center study conducted in only 1 city due to time constraints, limited funds, and response burden. Therefore, extension over the entire province or multiple towns might be impossible. The possible effect size at various sites may vary, which may potentially affect the findings and may constrain external validity. In addition, the study continued for 6 months; consequently, the researchers might not be able to ascertain the effect of adherence to medication on treatment outcomes for a longer duration. The study also did not consider the difference in gender between groups, and this might be a good area for future research. Finally, self-reporting was used to assess medication adherence. Social desirability bias could cause self-report questionnaires to overestimate genuine adherence [76]. However, several technology-based or mHealth methods exist to follow and measure adherence, which could not be used in the study due to the nonavailability of such devices, poor communication of patients, or fear of loss to follow-up. Please refer to the eHealth CONSORT checklist for more information about this Multi-Aid-Package trial [77].

Conclusions

In the context of this study, the multifaceted Multi-Aid-Package is an effective mHealth intervention that increased medication adherence among patients with hypertension and subsequently improves their SBP readings. The findings revealed a statistically significant change in the medication adherence score and pill-counting rates and a reduction in the SBP 6 months after the intervention began. The outcomes also demonstrated that users value Multi-Aid-Package for its applicability, ease of use, and informational content for the management of hypertension. Multi-Aid-Package should be considered as an approach for boosting the adherence of hypertension patients to their medication in Pakistan and other similar LMICs.

Acknowledgments

We acknowledge Professor Dr Sunil Kripalani, Professor of Medicine and Director, Center for Clinical Quality and Implementation Research, Emory University, who graciously allowed us to use the Self-Efficacy for Appropriate Medication Adherence Scale. We are also grateful to the patients, doctors, and nurses who participated in this study.

Abstract

Background: Climate change increasingly impacts health, particularly of rural populations in sub-Saharan Africa due to their limited resources for adaptation. Understanding these impacts remains a challenge, as continuous monitoring of vital signs in such populations is limited. Wearable devices (wearables) present a viable approach to studying these impacts on human health in real time.

Objective: The aim of this study was to assess the feasibility and effectiveness of consumer-grade wearables in measuring the health impacts of weather exposure on physiological responses (including activity, heart rate, body shell temperature, and sleep) of rural populations in western Kenya and to identify the health impacts associated with the weather exposures.

Methods: We conducted an observational case study in western Kenya by utilizing wearables over a 3-week period to continuously monitor various health metrics such as step count, sleep patterns, heart rate, and body shell temperature. Additionally, a local weather station provided detailed data on environmental conditions such as rainfall and heat, with measurements taken every 15 minutes.

Results: Our cohort comprised 83 participants (42 women and 41 men), with an average age of 33 years. We observed a positive correlation between step count and maximum wet bulb globe temperature (estimate 0.06, SE 0.02; *P*=.008). Although there was a negative correlation between minimum nighttime temperatures and heat index with sleep duration, these were not statistically significant. No significant correlations were found in other applied models. A cautionary heat index level was recorded on 194 (95.1%) of 204 days. Heavy rainfall (>20 mm/day) occurred on 16 (7.8%) out of 204 days. Despite 10 (21%) out of 47 devices failing, data completeness was high for sleep and step count (mean 82.6%, SD 21.3% and mean 86.1%, SD 18.9%, respectively), but low for heart rate (mean 7%, SD 14%), with adult women showing significantly higher data completeness for heart rate than men (2-sided *t* test: *P*=.003; Mann-Whitney *U* test: *P*=.001). Body shell temperature data achieved 36.2% (SD 24.5%) completeness.

Conclusions: Our study provides a nuanced understanding of the health impacts of weather exposures in rural Kenya. Our study's application of wearables reveals a significant correlation between physical activity levels and high temperature stress, contrasting with other studies suggesting decreased activity in hotter conditions. This discrepancy invites further investigation

into the unique socioenvironmental dynamics at play, particularly in sub-Saharan African contexts. Moreover, the nonsignificant trends observed in sleep disruption due to heat expose the need for localized climate change mitigation strategies, considering the vital role of sleep in health. These findings emphasize the need for context-specific research to inform policy and practice in regions susceptible to the adverse health effects of climate change.

Introduction

Climate Change and Health

Anthropogenic climate change has led to a mean global temperature increase of approximately 1 °C from preindustrial levels, with projections indicating a continued rise if substantial reductions in greenhouse gas emissions are not achieved; this warming trend poses profound health risks in low-and middle-income countries (LMICs) due to limited resources for environmental adaptation [1,2]. An emerging body of research indicates that wearable devices (wearables)—compact, noninvasive electronic devices capable of continuously monitoring various health metrics—may offer valuable insights into assessing the health impacts of climate change, especially in LMICs, where data on climate change and health are limited [3-5]. Climate change disproportionately affects regions such as sub-Saharan Africa, where increased temperatures exacerbate vulnerabilities, adversely impacting human health and agricultural productivity [2,6]. Kenya, the focus of our study, is increasingly vulnerable to climate change, with forecasts anticipating higher temperatures and more frequent extreme weather events; yet, there remains a lack of preparedness for necessary adaptation measures [1,7].

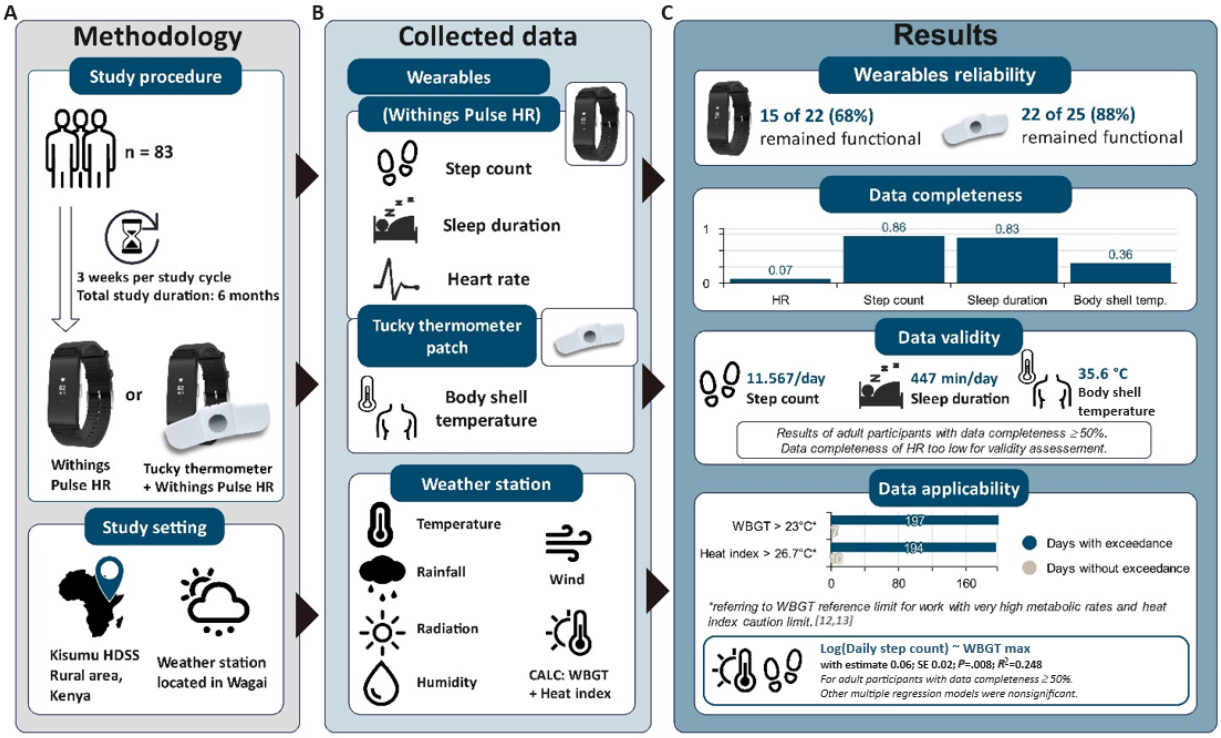
Need for Nuanced Understanding

In LMIC settings, a more nuanced understanding of individual exposure to extreme weather events and the resulting health outcomes is essential for creating tailored interventions and allocating resources efficiently [2]. Wearable devices, given their ability to monitor health metrics continuously and noninvasively, provide valuable insights into the health risks faced by vulnerable communities due to climate change [4,8]. Numerous large-scale studies in high-income settings have explored the use of wearables in health care [9,10], highlighting their potential as early warning systems for outbreaks of flu-like illnesses, among other applications. Although wearables have been utilized in studies within LMICs, notably in India [11], there is a lack in research concerning their use in other LMICs, particularly for assessing the impacts of climate change [3,4].

Objective of This Study

The primary aim of this study was to assess the feasibility and effectiveness of wearable devices in continuously and objectively monitoring the health impacts of weather exposures on individuals, particularly in a rural setting in Siaya, Kenya (Figure 1). We will integrate these technologies into routine data collection methods of the Health and Demographic Surveillance Systems (HDSS) in Siaya, Kenya, aiming to fill the data void in LMICs by providing measured health metrics that can approximate health impacts, thus offering individual-level, objectively measured health responses to weather exposures.

Figure 1. Schematic overview of the observational case study. Reference values are according to Parsons [12] and the National Weather Service [13]. Wearables depiction provided by Withings and e-TakesCare. (A) Methodology involves 83 participants from rural Siaya Health and Demographic Surveillance System, Kenya, equipped with wearables for a 3-week data collection period (total study duration: 9 weeks), coupled with local climate monitoring via a state-of-the-art weather station. (B) Collected data include metrics such as sleep duration, step count, pulse rate, and body temperature, as well as environmental data. (C) Results explore the reliability, completeness, and validity of data, with implications for climate change and health research. HDSS: Health and Demographic Surveillance System; HR: heart rate; WBGT: wet bulb globe temperature.



Methods

Ethics Approval

Ethics approval was granted by the Kenya Medical Research Institute (KEMRI/RES/7/3/1) and the ethics committee of the University Hospital Heidelberg, Germany (S-294/2019). This study is reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement [14].

Study Design and Participants

This study employs an observational case study methodology in Siaya, a rural county situated in western Kenya, conducted from September 2021 to April 2022. For comprehensive details on the study protocol and a related case study from Burkina Faso, please refer to [15,16]. The Siaya county, about 40 km from Kisumu and 1000 meters above the sea level, hosts the Kenya Medical Research Institute–operated Siaya HDSS, covering an area of 700 km² and serving a population of around 260,000 people [16,17]. The HDSS has over 20 years of retrospective health and demographic data since 1990. Our study's sample population was stratified by gender, age, and wearable type, with age categories of 6-16 years, 17-45 years, and >45 years. Participants were assigned to either a group with the Withings Pulse Heart Rate (WPHR) wearable or a group using WPHR and the Tucky thermometer patch. Eligibility criteria included age >6 years, living within 5 km of Wagai health center, not planning to move during the study, and providing informed consent. Recruitment methods varied by age, with random selection for those older than 22 years and snowball sampling for those aged 6-22 years.

Procedures

The study protocol required participants to provide demographic and anthropometric data for wearable calibration, collected during each 3-week study cycle at the Wagai health center. Participants received a compensation of 200 Kenyan shillings (US $1.82) for travel, a smartphone with mobile data for data sync, and a battery pack for charging the wearables. Field personnel conducted weekly visits for data synchronization. Participants wore either the WPHR or both WPHR and a thermometer patch, with WPHR monitoring activity, sleep, and pulse rate, and the patch measuring body shell temperature at night (for detailed information, see Multimedia Appendix 1 [18,19]). The initial inventory consisted of 22 WPHR and 25 thermometer patches. Before reuse, both devices were cleaned and sanitized. This study also used a weather station in Wagai to record various weather parameters. The wet bulb globe temperature (WBGT), indicating heat strain, was calculated using a specific formula incorporating wet bulb temperature, global radiation, relative humidity, and air temperature [20]:

$$WBGT = (0.7*w) + (0.2*[0.009624*y - 0.00404*z + 1.102*x - 2.2776]) + (0.1*x)$$

where w represents wet bulb temperature, y represents global radiation, x represents relative humidity, and z represents air temperature.

Statistical Analysis

Participants were categorized into 4 age groups: school children (6-11 years), adolescents (12-18 years), young adults (19-45 years), and older adults (>45 years). BMI was classified as underweight (<18.5 kg/m^2), normal weight (18.5-24.9 kg/m^2), and overweight (>25 kg/m^2), following World Health Organization guidelines [21]. A descriptive analytical approach was used for demographic details and participant dropouts. BMI for adults was measured at recruitment. Wearable condition and wear were tracked for reliability assessment, and community interviewers' implementation challenges and infrastructure needs were thematically analyzed.

We analyzed 4 variables to ensure data quality: sleep duration, total step count, heart rate, and body shell temperature. The measured pulse rate was assumed to be equivalent to the participant's heart rate. We systematically excluded data that showed significant bias or anomalies such as unusually high or low heart rate readings (>expected maximum heart rate or <30 bpm) [22,23] and body shell temperature measurements indicative of protein denaturation or hypothermia-triggered loss of consciousness [24] (detailed criteria for data analysis can be found in Multimedia Appendix 2). Expected maximum heart rate was derived using the equation 208 – 0.7 × age [23]. Based on literature and the WPHR user guide, sleep measurements less than 3 hours (including naps) and those exceeding 13 hours were excluded as nonvalid. Wake times recorded by the wearable were not considered part of sleep duration [25,26]. Sleep episodes exceeding 3 hours were combined if the last episode began before noon on the following day. Differences across gender, study arm, and BMI for adult participants as well as across age groups were analyzed using Welch 2-sided *t* test and Mann-Whitney *U* test, with a 95% CI for error calculation.

To evaluate data completeness, we assessed the proportion of study duration covered by the measurements of the 4 key variables from wearables: sleep duration, step count, heart rate, and body shell temperature. The criteria for data completeness were based on existing literature (detailed in Multimedia Appendix 2 [15,22-28]). For external data validity, we combined individual measurements into a descriptive summary, including data from participants with at least 50% completeness per variable.

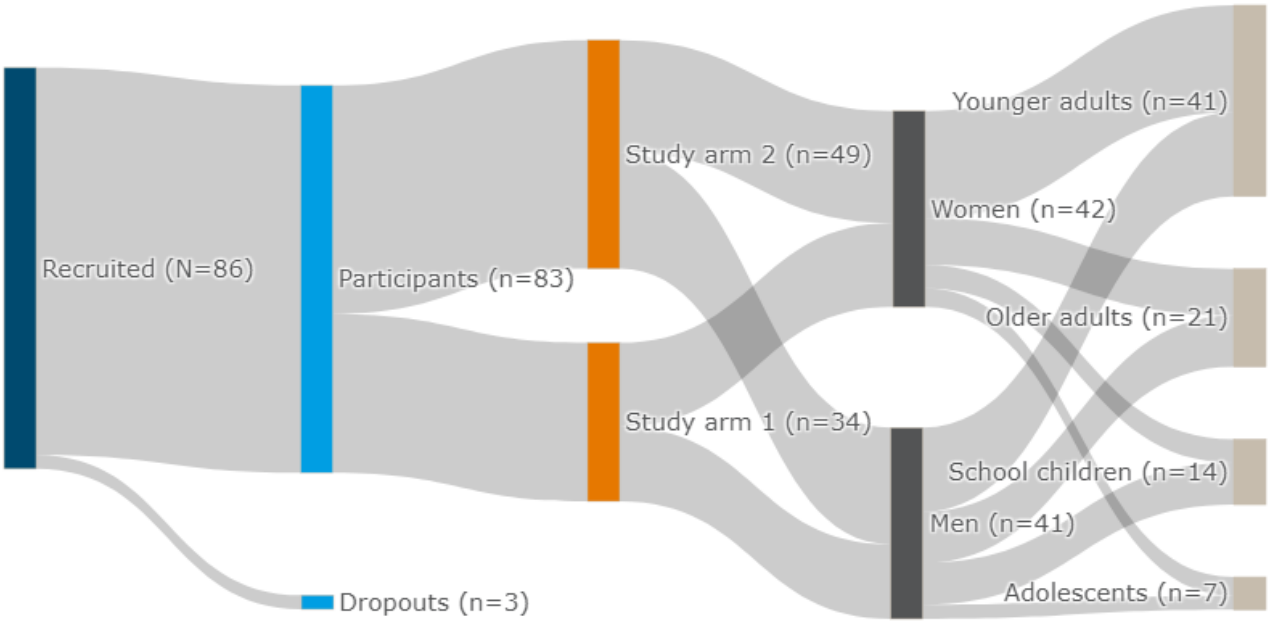
We descriptively analyzed the weather profile during the study period and correlations between weather events and adult study participant's health metrics that had at least 50% data completeness (sleep duration, step count, and body shell temperature). The measurements of WBGT and heat index were categorized using the reference values according to Parsons [12] and the National Weather Service [13]. We employed unadjusted linear regression and multilinear regression analyses [4,8,29-32] considering factors such as maximum daily and minimal nighttime heat and heavy rainfall. The multilinear models further considered gender, age, and BMI as confounders. This study did not account for within-subject trends or the effects of prior day heat stress due to the limitations of the 21-day duration of wearable usage by each participant. Analyses were conducted on R4.1.2 (RStudio version 4.1.2; PBC) with stats3.6.2 for statistics and ggplot2 and car packages for visualization, providing standard error and adjusted R^2 for error quantification and model assessment (see Multimedia Appendix 3 for variable plots and residual plots of the regression models). Numerical values with final digits <5 were rounded down, while numerical values with final digits >4 were rounded up.

Results

Demographics of the Participants

We initially enrolled 86 participants in our study; 3 withdrew their consent, resulting in 83 participants for analysis (Figure 2). In the 2 study arms, 34 (41%) participants wore solely the WPHR wearable, while the remaining 49 (59%) wore both the WPHR and the thermometer patch. The mean age of the participants was 33.3 (SD 19) years (range 6-83 years). A further breakdown of this age distribution showed that our study involved 14 school children (17%, age range 6-11 years), 7 adolescents (8%, age range 12-18 years), 41 young adults (49%, age range 19-45 years), and 21 older adults (25%, age >45 years). Women comprised 51% (42/83) of the all the participants. In the adult demographics, which accounted for 75% (62/83) of the participants, the average BMI calculated was 23.8 (SD 4.7) kg/m^2 (range 16.0-37.4 kg/m^2).

Figure 2. Participant stratification in this study.



Wearables' Reliability

Of the 22 WPHRs and 25 thermometer patches initially deployed, 7 (32%) WPHRs and 3 (12%) thermometer patches malfunctioned, primarily from physical damage. Technical issues, including data synchronization, were frequent initially but reduced over the study's duration. Physical damage was the predominant reason for WPHR failures, causing 5 (23%) devices to malfunction due to broken components or overall failure. One WPHR and its charger (5% of the total) were lost. As for thermometer patches, 2 (8%) had damaged charging ports, 1 (4%) was lost, and 2 (8%) had nonretrievable data, despite being intact.

Data Completeness

Data quality varied across health metrics and participant demographics. Accelerometer metrics such as step count and sleep duration exhibited high completeness, registering 86.1% (SD 18.9%) and 82.6% (SD 21.3%), respectively. Photoplethysmography-based heart rate measurements lagged behind at 7% (SD 14%), while body shell temperature recorded 36.2% (SD 24.5%) completeness. Data completeness was calculated as percentage of study duration covered with measurements in distinct intervals for all participants. Sleep data completeness varied by age: younger adults (19-45 years; n=41) recorded lower data completeness (79%) than older adults (>45 years; n=21; data completeness 90%) (*t* test: *P*=.02; 95% CI –0.20 to –0.02; Mann-Whitney *U* test [MWU] test: *P*=.03; 95% CI –0.14 to 0.00). Further, adult women (n=33) showed less data missingness (87%) than adult men (n=29, 78%) (MWU test: *P*=.03; 95% CI 0.00-0.14). Heart rate data completeness in adult women (12%) was significantly higher than that in men (2%) (*t* test: *P*=.003; 95% CI 0.04-0.17; MWU test: *P*=.001; 95% CI 0.01-0.04). Body shell temperature data completeness for school children (6-11 years; data completeness 47%) was higher than that for adolescents (12-18 years; data completeness 23%) (*t* test: *P*=.03; 95% CI 0.03-0.45; MWU test: *P*=.03; 95% CI 0.05-0.48). After correcting for multiple tests using Holm sequential Bonferroni method [33], only the difference in the completeness of heart rate data between men and women remained statistically significant (*t* test: *P*=.02; MWU: *P*=.004). For detailed data measurements stratified by age, gender, study arm, and BMI, as well as data completeness results corrected for multiple testing, refer to Multimedia Appendix 4 [33].

Environmental Exposure

During the 204 days study, rainfall was recorded on 97 (47.6%) days. Out of these, heavy rain (≥20 mm per day) was recorded on 16 (7.8%) days. The average daily heat index and WBGT were 22.1 (SD 1.1) °C and 20 (SD 0.7) °C, respectively. The heat index caution limit (26.67 °C or 80 °F) was reached on 194 (95.1%) of 204 days, and the extreme caution limit (32.22 °C or 90 °F) exceeded on only 2 (<1%) days. For the WBGT, reference values for outdoor work with very high metabolic rates were met on 197 (96.6%) days and for work with high metabolic rates on 96 (47.1%) days. Figure 3 illustrates the instances where individual reference values for WBGT, as proposed by Parsons [12], and the heat index, as per the standards of the National Weather Service [13], were exceeded (Table 1).

Figure 3. Average daily wet bulb globe temperature in °C (dark blue line) and average daily heat index in °C (orange line) with daily ranges (daily wet bulb globe temperature range in blue ribbon; daily heat index range in orange ribbon). WBGT: wet bulb globe temperature.

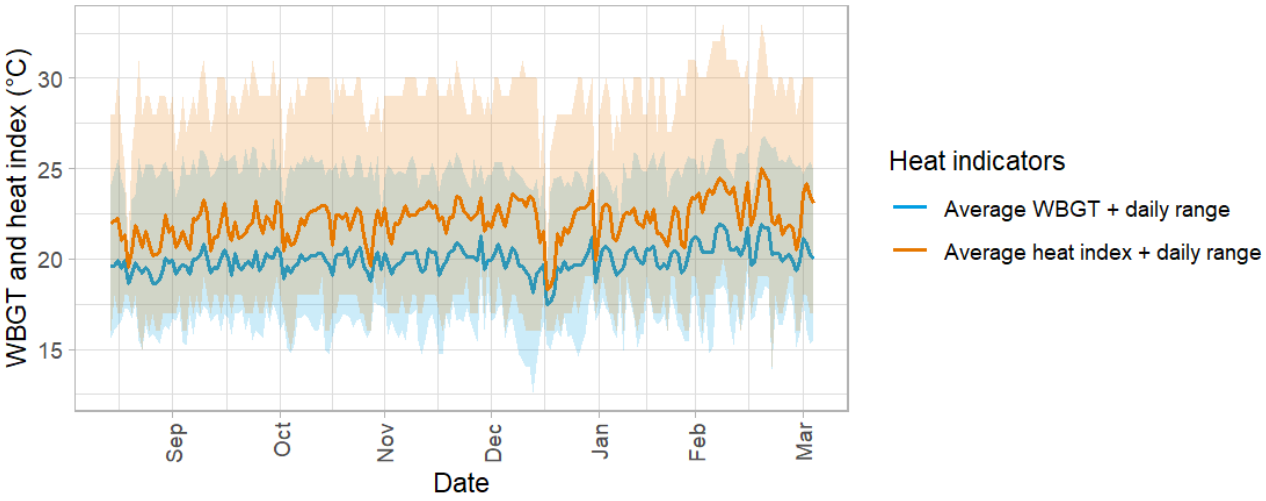


Table 1. Allocation of the respective reference values for wet bulb globe temperature and heat index to the individual risk levels for heat-related diseases depending on the type of work performed and listing of the proportion of days in the observed study period in which these reference values were exceeded. Reference values are according to Parsons [12] and the National Weather Service [13].

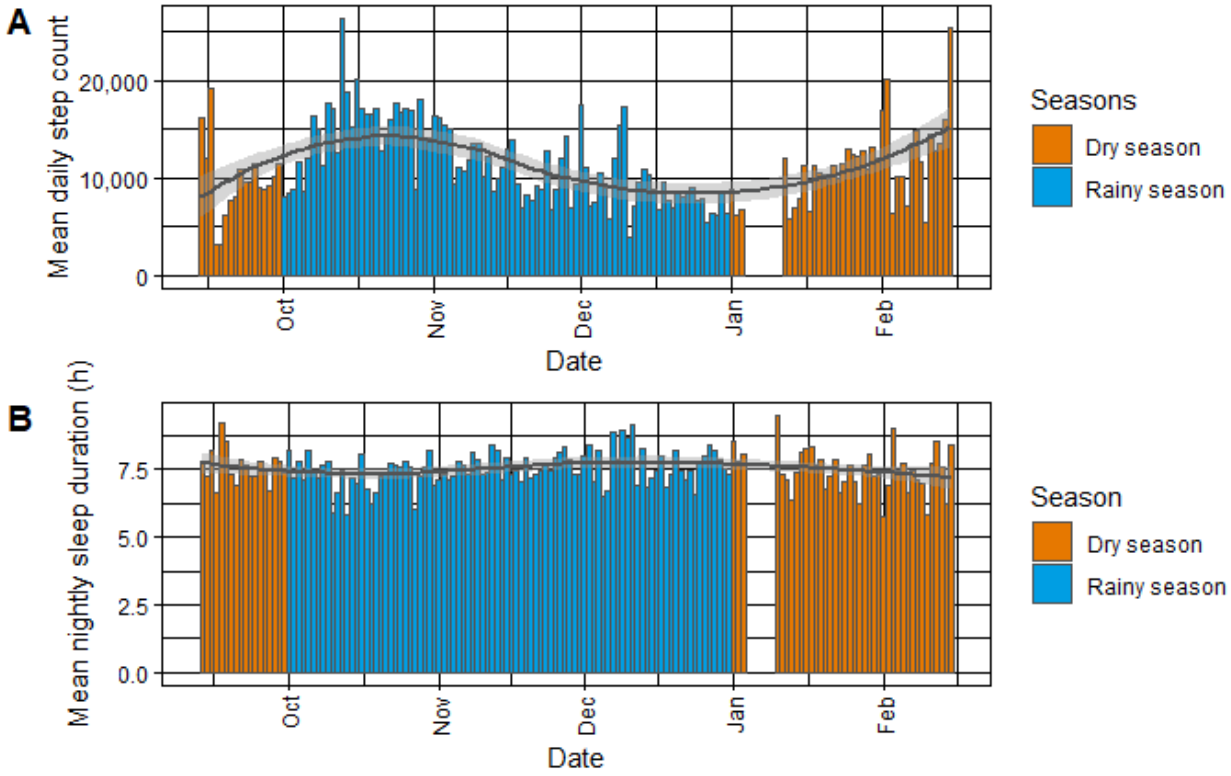
Reference	Days with exceedance (n=204), n (%)
Wet bulb globe temperature reference [12]	
Limit for work with a very high metabolic rate (metabolic rate>260 W/m^2)	197 (96.6)
Limit for work with a high metabolic rate (200 W/m^2<metabolic rate<260 W/m^2)	96 (47.1)
Limit for work with a medium metabolic rate (130 W/m^2<metabolic rate<200 W/m^2)	0 (0)
Heat index reference [13]	
Caution limit (26.67 °C/80 °F)	194 (95.1)
Extreme caution limit (32.22 °C/90 °F)	2 (0.1)
Danger limit (39.44 °C/103 °F)	0 (0)

Data Applicability: Heat Exposure and Health Outcomes

The unadjusted regression analysis for daily step count indicated a significant positive correlation with maximal daily WBGT and heat index (WBGT: estimate 974.4, SE 242.3; P<.001; heat index: estimate 317.6, SE 152.4; P=.04) with a low R^2 value (WBGT: R^2=0.014; heat index: R^2=0.003). On days without heavy rainfall, a similar positive yet nonsignificant correlation was observed for daily step count (estimate 1466.2, SE 852.9; P=.09; R^2=0.002). The analysis for daily maximal temperature did not demonstrate any predictive power for step count (R^2=–0.001; estimate 87.54, SE 145.08; P=.55). After a logarithmic transformation of the dependent variable (step count) due to a funnel shape observed in residuals, the confounder-adjusted models revealed a significant positive relationship with the maximum WBGT (estimate 0.06, SE 0.02; P=.008; R^2=0.248) (see Figure 4 for details). Other heat indicators showed positive yet nonsignificant associations with daily step count. Age and BMI emerged as significant predictors of daily step count (P<.001).

Figure 4. (A) Mean daily step count of adult participants per day and season, wherein dry season is highlighted in orange and rainy season is highlighted in blue. (B) Mean daily sleep duration per adult participant per day and season. Trend lines are added using locally weighted scatterplot smoothing; seasons are classified according to Odhiambo et al [17].



For sleep duration in minutes, the linear regression model revealed a negative, however nonsignificant, correlation with minimal nighttime temperature and heat index at small *P* values, but with low predictive power (temperature: estimate –5.61, SE 3.24; *P*=.08, R^2=0.002; heat index: estimate –4.77, SE 2.91; *P*=.10; R^2=0.002). For minimal nighttime WBGT and sleep duration, simple linear regression had no explanatory power (R^2=–0.001, estimate –0.67, SE 2.98; *P*=.82). Similarly, the multiple linear regression analysis indicated that an increase in minimum nighttime temperatures and nightly minimal heat index corresponded with nonsignificant reductions in sleep duration, that is, by 5.56 minutes per °C increase (*P*=.09; SE 3.234; R^2=0.006) and 4.50 minutes per °C increase (*P*=.12; SE 2.905; R^2=0.006), respectively. We did not detect a significant relationship between nightly minimum WBGT and sleep duration (estimate 0.07 minutes; *P*=.98; SE 2.985; R^2=0.003). Age proved to be a significant determinant of sleep duration across all models (*P*=.03).

Unadjusted linear regression analysis of body shell temperature and minimal nighttime heat had no explanatory power giving their negative adjusted R^2 of –0.003 across all heat indicators (temperature: estimate 0.05, SE 0.07; *P*=.51; WBGT: estimate 0.05, SE 0.07; *P*=.51; heat index: estimate 0.04, SE 0.07; *P*=.53). The multiple linear regression models of nightly body shell temperature did not show significant results either, however at relatively high explanatory power, as indicated by their R^2 values (0.168, 0.170, and 0.170, respectively; temperature: estimate 0.03, SE 0.07; *P*=.63; WBGT: estimate 0.05, SE 0.07; *P*=.42; heat index: estimate 0.05, SE 0.06; *P*=.41, respectively). Gender (*P*<.001) and BMI (*P*=.04) were significant predictors in all 3 models.

The additional analysis incorporating the temporal confounder of weekday or weekend, detailed in Multimedia Appendix 5, did not reveal any significant impact in the models. Regression models were not applied to heart rate measurements, as only the data sets of the 3 participants met the required 50% completeness. A summary of all the multiple regression models, including estimates, standard errors, *P* values, and other considered confounders for each health parameter and the associated extreme weather indicators is provided in Table 2.

Table 2. Regression analysis results for health parameters.[a]

Health parameter, variable	Temperature		WBGT[b]		Heat index		Precipitation <20 mm	
	Estimate (SE)	*P* value	Estimate (SE)	*P* value	Estimate (SE)	*P* value	Estimate (SE)	*P* value

[a]This is a logarithmically transformed model for step count and standard models for sleep duration and body temperature. The table includes estimates, standard errors, and *P* values for each health parameter—sleep duration, step count, and body temperature—along with their associated extreme weather indicators. Health parameters were included of adult participants having at least 50% data completeness for the respective health parameter. Depending on the model, the weather indicators considered were temperature, heat index, wet bulb globe temperature, and precipitation. Additionally, the multiple linear regression models incorporated gender, age, and BMI, as the data validity analysis demonstrated the significance of these confounders.

[b]WBGT: wet bulb globe temperature.

[c]Not available.

Discussion

Principal Results

The findings of our study highlight the advantages and challenges associated with the use of wearable devices for the continuous monitoring of vital signs in rural sub-Saharan populations. We found using wearables a pertinent approach for understanding individual impacts of weather exposures. Our research emphasizes the feasibility and effectiveness of integrating wearable technology into health research, in particular, to understand individual exposures and activity patterns such as daily steps and sleep duration. We identified a correlation between weather exposures and various health metrics. Notably, there is a positive relationship between daily step count and the maximum WBGT as well as a potential negative association between nighttime temperatures and sleep duration. These findings contribute to our understanding of the possible health impacts of climate change, with a particular focus on rural regions in western Kenya.

Comparison With Prior Work

Our study shows environmental exposures such as frequent heavy rainfall and extreme heat, with approximately 20.7% (4044/19,576) of our weather station readings surpassing the heat index caution threshold [13]—a pattern consistent with WBGT findings. We found a strong positive correlation between daily step count and maximum WBGT across both models. Additionally, a positive relationship with the heat index was observed in the unadjusted model. Although many studies indicate a negative link between heat and physical activity [30], the relationship between temperature and activity levels remains inconsistent. This discrepancy necessitates further investigation. For instance, a study [34] conducted in Qatar utilizing wearable pedometers discovered negative correlations between daily step count and both precipitation and temperature. However, that study reported varying associations with WBGT depending on the analytical model employed. Our findings emphasize the need for deeper investigation into this relationship [4]. External factors such as seasonal farming activities illustrated in Figure 4 or specific mitigation practices might significantly influence

this correlation and therefore merit additional investigation [17], especially given the scarcity of objectively generated data on activity levels and physical activity profiles in rural sub-Saharan African populations [35].

In our study, we observed a negative trend between minimum nighttime temperature and sleep duration as well as between the minimal nighttime heat index and sleep duration, but these relationships were not statistically significant in either model. However, this trend aligns with previous research that has linked warmer nights to shorter sleep durations, suggesting that climate change could significantly affect sleep health [4,8,32]. For example, a comprehensive study by Minor et al [8] utilizing sleep data of 47,628 participants across 68 countries found a correlation between shorter sleep duration and warmer nights. In line with these findings, all studies in the scoping review of Koch et al [4] reported a negative correlation between sleep duration and heat. These studies underscore the risk of insufficient sleep, in light of the expected impact of global warming due to climate change on local heat exposure [8]. The review of Caddick et al [36] suggests that optimal ambient temperatures for sleep lie between 17 °C and 28 °C, with 40%-60% humidity, although this may vary based on other factors. Insufficient sleep, whether due to short duration or disruptions, can negatively affect human health, potentially compromising the immune system [37] and increasing cardiovascular risk [38].

Regarding body shell temperature, our study did not find significant associations with average nightly body shell temperature and heat. However, previous studies [4,31] have suggested a possible connection. In our analysis, gender and age emerged as critical factors in all 3 models, emphasizing the importance of demographic and physiological factors in body temperature regulation. The inconclusive results in our study might be attributed to the limited sample size and issues with data integrity. Furthermore, natural thermoregulatory processes such as evaporation and the thermoregulatory behaviors of participants should be considered when evaluating body shell temperature [24].

Our study shows improved data completeness compared to previous research in Burkina Faso [15] and the United States [27], especially in thermometer patch data, likely due to enhanced adhesion using medical tape [15]. However, heart rate data showed lower completeness, which may have been affected by technical factors such as the proximity of the sensors to the skin, the impact of motion, and potential device errors. Similar studies using certain wearable devices reported data loss due to wearable malfunctions such as connection issues [39]. Other factors such as blood vessel thickness, skin thickness, obesity, and age might also affect measurement quality and completeness, potentially explaining the gender-specific differences observed in our data, where factors such as thinner skin in women or older populations or thicker blood vessels in men could enhance photoplethysmography signals [40,41]. Other factors that have been mentioned in the scientific literature are the skin pigmentations of the participants; several studies have noted a correlation between the Fitz-Patrick skin scale and heart rate measurements via photoplethysmography, suggesting reduced heart rate measurement accuracy in individuals with higher Fitz-Patrick scale values [40,42], although some studies [43] did not find this correlation. To mitigate this, wearables are starting to implement enhanced photoplethysmography sensors or infrared measurements [42]. Moreover, gender may present contradictory effects on the data collection [40]. The influence of BMI on signal quality remains uncertain [40], with additional variables such as blood vessel dilation during physical activity also playing a role [40]. Participant adherence challenges were also observed, as some felt uncomfortable wearing the device continuously, especially at night.

Our research aligns with previous studies on average daily activity and sleep duration, particularly regarding the influence of age [15,32,34]. Although body shell temperature readings aligned with physiological norms, indicating their usefulness in identifying individual anomalies [24], they were notably low, suggesting potential nighttime evaporation processes [24]. As with prior research, factors such as gender and BMI affected body shell temperature [4,24], necessitating further research to comprehensively grasp temperature impacts.

Limitations

The internal validity of the wearables used in this study was not evaluated; however, models older than the WPHR used here, some requiring manual sleep initiation, have shown largely satisfactory results. Gruwez et al [44] identified a significant correlation between Withings wearables and a research-grade actigraph for step count during daily activities. However, a review by Fuller et al [45] revealed an underestimation of step count in Withings wearables in most examined studies. Comparisons of Withings wearables to polysomnography revealed no significant differences in sleep duration measurements [39], and various studies have noted consistent correlations with polysomnography-recorded total sleep duration [39,44]. Regulatory constraints restricted the recruitment of younger participants in our study, affecting its generalizability. Furthermore, smartphone usage restrictions in Kenyan boarding schools, especially pertinent to the substantial under-15 years demographic, could pose challenges for future research [17]. In addition, as explained in the methods section, only the data sets of the adult participants were analyzed with regard to weather effects. Our study has other limitations such as uncorrected multiple testing and potential influences of the COVID-19 pandemic on data. In Kenya, the COVID-19 pandemic caused governmental restrictions on public life such as nighttime curfew until October 20, 2021, which affected 22 (26.5%) participants during their study participation—likely influencing the data collected [46]. Research during the 2020 COVID lockdowns reported reduced total sleep duration and increased napping [47], and a South African study observed decreased mobility, particularly on weekends [48]. Future research should consider a wider range of variables, account for the carryover effects of prior day heat strain [49], and address technical challenges such as inaccessible raw data, software issues, high data missingness for heart rate due to factors such as skin type [40], and possible algorithmic biases. Our study does not account for factors such as clothing, air circulation, bedding, and individual differences such as gender, which can influence the relationship between heat and sleep duration [36].

Conclusions

Our study shows the potential of wearable devices to monitor vital signs and assess the impact of environmental exposures on health in rural sub-Saharan settings, with implications for understanding the nuanced effects of climate change. Despite a robust data set, our findings indicate the need for improved wearable technology to ensure data completeness across diverse demographic groups, acknowledging the impact of factors such as age, gender, and BMI. The positive correlation between physical activity levels and high WBGT offers new insights into behavior during extreme weather conditions, while the nonsignificant trends in sleep duration in relation to temperature call for further investigation. These observations are crucial for public health strategies in climate-vulnerable regions, guiding the integration of wearables in longitudinal health monitoring and climate resilience research. Future studies should expand on the relationship between weather and health outcomes, including a broader demographic and addressing technical challenges identified in wearable data collection. This research contributes to a growing body of knowledge that will inform both technological innovation in health monitoring and the development of interventions to mitigate the health impacts of global climate dynamics.

During the preparation of this work, the author(s) used ChatGPT in order to improve language and readability of this manuscript. After using this tool/service, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Data Availability

Deidentified wearable data, weather data, and R scripts will be available for scientific purposes with publication on reasonable request to the corresponding author SB (barteit@uni-heidelberg.de).

Authors' Contributions

SB, TB, and SM planned this study and led its implementation. SM, DO, DK, JOM, COO, and IM conducted and supervised the study on site, remotely advised by SB and IM. SH, MK, MAM, SB, and IM assessed the data and performed the data analysis. IM analyzed the data, supervised and verified by SB. All authors critically and freely contributed to the final draft and confirmed the publication.

Abstract

Background: Maternal mortality remains a persistent challenge in low- and middle-income countries, where evidence-based interventions of obstetric triage and prehospital communication remain sparse. There is limited implementation evidence for technology-based approaches to improve obstetric care in such contexts. Liberia struggles with maternal mortality, particularly in rural areas where deaths are attributable to delays from absent triage and interfacility communication. We implemented a Mobile Obstetric Referral Emergency System (MORES) in rural Bong County to improve prehospital transfer, health worker attentiveness, and patient care for critical obstetric patients. MORES consisted of triage training and a 2-way, templated WhatsApp communication system to reduce delays among patients transferred from rural health facilities (RHF) to hospitals.

Objective: This study aimed to examine MORES implementation outcomes of usability, fidelity, effectiveness, sustainability, and scalability, as well as additional impacts on the wider health system.

Methods: A structured case study design interview was developed by Liberian and US experts in obstetric triage. Participants included 62 frontline obstetric health providers including midwives (38/62, 61%), nurses (20/62, 32%), physicians assistants (3/62, 5%), and physicians (1/62, 2%) from 19 RHFs and 2 district hospitals who had used MORES for 1 year. Individual interviews were conducted on MORES implementation outcomes, transcribed, and analyzed in NVivo (version 12; Lumivero) with a team-based coding methodology. Content analysis with a deductive approach examined implementation outcomes of usability, fidelity, effectiveness, sustainability, and scalability, while an inductive approach categorized the unanticipated impacts of MORES on the wider health system.

Results: Four domains were identified regarding MORES implementation: Usability and Fidelity, Effectiveness, Sustainability and Scalability, and Health System Impact. All participants perceived MORES to have high usability and fidelity, as the triage and messaging system was implemented as intended for critical obstetric patients (62/62, 100%). For effectiveness, MORES accomplished its intended aims by improving prehospital transfer (57/62, 92%), increasing health worker attentiveness (39/62, 63%), and contributing to improved patient care (34/62, 55%). MORES was perceived as sustainable and scalable (62/62, 100%), particularly if technological barriers (21/62, 34%) and staff training (19/62, 31%) were addressed. MORES impacted the wider health system in unanticipated ways including improved coordination and accountability (55/62, 89%), feedback mechanisms for hospitals and RHFs (48/62, 77%), interprofessional teamwork (21/62, 34%), longitudinal follow-up care (20/62, 32%), creating a record of care delays (17/62, 27%), and electronic health record infrastructure (13/62, 21%).

Conclusions: MORES was perceived to have high usability, fidelity, effectiveness, sustainability, and scalability by frontline obstetric providers in rural Liberia. MORES accomplished the intended aims of improving prehospital transfer, increasing health worker attentiveness, and contributing to improved patient care. Additionally, MORES strengthened the health system through

6 domains which impacted individual and system levels. Future studies should quantitatively evaluate delay and morbidity reductions and strategies for scaling MORES.

Introduction

Despite increased attention, funding, and innovation, maternal mortality continues to disproportionately affect low- and middle-income countries (LMICs) [1]. Liberia in West Africa has one of the highest maternal mortality ratios in the world with 652 deaths per 100,000 births [2]. This inequity is due to many factors including resource limitations, workforce shortages, and an overall unstable and underfunded health system following decades of conflict, the 2014-2016 Ebola epidemic, and COVID-19 pandemic [3]. A major contributing factor impacting Liberia's high maternal mortality is a lack of standardized obstetric triage protocols and prehospital communication systems between health facilities [4]. Such systems allow for efficient patient transfer and have consistently been shown to improve maternal and neonatal health outcomes [5,6]. In Liberia, a lack of standardized triage, referral, and transfer systems leads to care delays and increases morbidity at the prehospital and intra-facility level, also known as the "third delay," which occurs after patients arrive at health facilities [7]. This lack of infrastructure creates a critical blind spot for timely maternal care, especially for patients in rural areas who must travel hours on foot or by personal car to reach a health facility.

Over the last decade, the Liberian Ministry of Health has emphasized the importance of combating maternal and perinatal mortality at community and national levels [8]. Rural health facilities (RHFs) are community clinics established throughout rural areas of Liberia to serve as the first line of care for patients living far from district hospitals [9]. RHF staff, midwives, and nurses are the frontline obstetric health workers in Liberia, responsible for preliminary assessments, treatment and stabilization, and escalation of care by referring patients to district hospitals when necessary [10]. However, care delays persist due to system limitations. Verbal autopsy reports of 35 maternal deaths from Bong County, Liberia revealed 2 major contributors to maternal death: inadequate staff training and ineffective communication between RHFs and hospitals [4]. A promising solution to improve maternal transfer and prehospital communication systems leverages mobile health interventions (mHealth), including messaging platforms to transmit patient information from a referring facility to the hospital prior to arrival [11]. Such systems may be a promising intervention to reduce prehospital and intrafacility delays by allowing health workers to prepare resources for immediate intervention upon patient arrival [12]. Several mHealth approaches have been successful in reducing care delays in LMICs including Ghana, and a recent study by our team showed high desirability for such a program among 130 health workers from RHFs and hospitals in Bong County [13,14].

In response, our team developed and implemented the Mobile Obstetric Referral Emergency System (MORES) among 20 RHFs and 2 district referral hospitals in Bong County, Liberia. MORES has two main components as follows: (1) triage capacity building training among obstetric health workers, and (2) implementation of a mobile, WhatsApp-based communication platform, aimed at reducing prehospital and intrafacility care delays [15]. Specifically, the intended aims of MORES were to reduce care delays through improved prehospital transfer, increased health worker attentiveness, and improved patient care. MORES works in the following ways: when a pregnant patient presents to an RHF in critical condition, she will undergo standardized triage by a community nurse midwife to assess acuity. If the RHF midwife determines that this patient requires higher level or urgent care at the district hospital, the RHF midwife will send a templated WhatsApp message to the district hospital with information including the patient's condition, past medical and obstetric history, any interventions administered, and method of transport to the hospital. Immediately upon receiving this message from the RHF midwife, hospital obstetric nurses begin preparing for that patient's arrival including gathering needed medications, informing physicians, readying the emergency department, and preparing the operating room if urgent surgical intervention is anticipated. If delays emerge during patient transport, the RHF and facility providers can work collaboratively through MORES messaging to overcome these barriers. Upon arrival at the hospital, the referred obstetric patient will undergo an additional standardized triage by the obstetric nurses and receive a green, yellow, or red wristband corresponding to acuity level before admission or initiation of urgent intervention. Implemented in March 2022, MORES demonstrated significant improvements in triage knowledge and was used by more than 50 health workers to send 359 referral messages to transfer patients over the course of a year.

In this qualitative study, we evaluated the implementation outcomes of MORES including usability, fidelity, effectiveness of accomplishing intended aims, sustainability, and scalability. We also evaluated if MORES had additional impacts on the health system more broadly beyond its intended impacts.

Methods

Study Setting

This study took place in Bong County, Liberia, the third most populous and primarily rural county in Liberia [14]. Researchers at the University of Liberia and the University of Michigan

partnered with the Bong County Health Team to design and implement MORES. Further detail of the MORES intervention, including its impact on health outcomes, is published elsewhere [15]. This study was conducted 1 year post implementation. Bong County was selected as the study site following efforts by the Liberia Ministry of Health to focus on improving maternal outcomes in this region given recent increases in maternal deaths [4]. Additionally, we have strong institutional partnerships between researchers and the County Health Team. Prior to MORES, Bong County had limited prehospital infrastructure consisting of 2 ambulances, no medical dispatch, and limited avenues for RHFs to communicate with hospitals. Health workers previously documented all medical information on a referral paper, which the patient was responsible for carrying and presenting to the referral hospital upon arrival. Often taking hours to arrive at said hospital, these papers would frequently be lost or damaged in transit.

Mores Implementation

In March 2022, specialists from Ghana and the University of Michigan with extensive experience in mHealth prehospital obstetric systems conducted capacity-building training among health workers from 20 RHFs and 2 district hospitals. Details regarding the templated communication messages and initial MORES training have been described [15]. Following this training, health workers returned to their respective health facilities to train colleagues in MORES. The 2 district hospitals were provided with smartphones to be used in the emergency department solely for MORES, while RHF workers used their personal cell phones. RHF and hospital workers were supplied cellular scratch cards to reload data at regular intervals throughout the study.

Study Design

To determine health worker perceptions of MORES implementation outcomes, we conducted a qualitative study using content analysis, following 1 year of MORES implementation in Bong County. First, US and Liberian experts in obstetric care and qualitative methods developed a structured interview script. The interview script was reviewed with Liberian health workers to adjust the language to the local context, purge repetitive items, and consolidate questions. The final interview script contained 20 items evaluating 6 major metrics including demographics, MORES purpose, usability, impact on referrals, facility linkages and feedback, and areas of strength and improvement (Multimedia Appendix 1).

Data Collection and Participants

In March 2023, 10 research assistants (RAs) from the University of Liberia traveled to Bong County to conduct interviews. The RAs consisted of both male and female Master of Public Health Students who had completed their course of study and were working on their Master theses and Master students who had completed a qualitative methods course. All were bachelor degree holders in various health-related fields and had extensive prior experience conducting qualitative interviews, which was a criterion for RA selection. During the data collection period, participants knew that RAs were students from the University of Liberia with an interest in obstetric health access and part of the research team who would be studying the implementation of MORES within their health system. A prior relationship with the study team had been established, given that this group was the same that implemented MORES 1 year prior.

In collaboration with the Bong County Health Team, RAs invited all health workers from the 20 RHFs and 2 district hospitals who had used MORES in the past year to participate using purposive sampling. Health workers were eligible if they were 18 years or older, currently employed by a Bong County health facility, and had used MORES at least once. Participants were excluded if they were unable to allocate sufficient time for an uninterrupted interview (10 minutes) or had never used MORES. RAs approached eligible participants face-to-face and invited them to complete the interview. Written consent was collected from eligible health workers who were willing to participate. It was made clear that the interview was anonymous, voluntary, and that their answers or decision of whether to participate would not influence their employment or ability to use MORES in the future. Individual interviews were conducted in a private location at the RHF or hospital according to participant preference. Each interview took approximately 10 minutes, and the interviews were audio recorded and stored in a secure lock box for transport to the University of Liberia. Researchers from Liberia and the University of Michigan met periodically throughout the data collection period to determine data saturation. Though saturation occurred after approximately 30 interviews, the opportunity to participate remained available so that all health workers who wished to share their perceptions were able to.

Data Analysis

Interviews were transcribed in Microsoft Word and immediately uploaded to a secure Dropbox folder only available to study researchers. All identifiable information was omitted during transcription. Two researchers began analysis through iterative immersion in the data, using content analysis with a deductive approach to categorize implementation outcomes of usability, fidelity, effectiveness, sustainability, and scalability to guide codebook development. Upon immersion in the data, it was determined that additional, unanticipated themes of MORES impact on the wider health system were frequently mentioned throughout the interviews. Therefore, a combined deductive-inductive content analysis approach was used to generate codes that categorized study aims while also accounting for the emergence of new themes. Once domains and major themes were identified, the codebook was further refined to identify subthemes under the major themes [16]. Transcripts were imported to NVivo (version 12; Lumivero) and coded using the codebook with a content analysis approach to answer the research question: “What are health workers’ perceptions on the implementation of MORES in light of its intended aims and impact on the wider health system?” [17]. Multiple measures were taken to ensure trustworthiness including (1) triangulation of interviews from multiple health specialists, (2) creation and validation of a consensus codebook, (3) inclusion of Liberian health workers as core members of the analytic team, and (4) member checking with Liberian health workers regarding key results.

Ethical Considerations

This study was approved by the University of Michigan institutional review board (HUM00195449) and the University of Liberia institutional review board (IRB00013730), whose protocols were followed throughout the entire study period. All participants underwent a process of written, informed consent prior to participation and all data were deidentified prior to analysis. This study adheres to COREQ (consolidated criteria for reporting qualitative research) guidelines for reporting in qualitative research [18].

Results

Participant Demographics

Sixty-two health workers from 19 RHFs and 2 district hospitals participated, representing 95% of total facilities taking part in MORES (Figure 1). Health workers from one facility included in the original training did not transmit any messages due to the lack of a smartphone with WhatsApp capability, therefore health workers from 19 facilities were included in our data collection. Participants included registered nurses, midwives, physician assistants, and medical doctors (Table 1). Three participants had additional specialization as neonatal specialists, and 12 occupied leadership roles, including nursing officer-in-charge (n=9), obstetrics supervisor (n=2), and chief medical officer (n=1). Most participants were between 35 and 45 years old, with years of professional experience ranging from 1 to 19 years (median 8 years, IQR 5-10). Across facilities, participants working in hospitals were slightly older and had more work experience than those in RHFs.

Four major domains were used to evaluate the implementation of MORES: (1) usability and fidelity, (2) effectiveness of intended impact, (3) sustainability and scalability, and (4) health system impact. Among these domains were 15 themes and 43 subthemes, outlined in Figure 2.

Figure 1. Rural health facilities and hospitals participating in the Mobile Obstetric Referral Emergency Systems (MORES) in Bong County, Liberia. Hospitals are denoted in yellow (2), with RHFs in red (19).

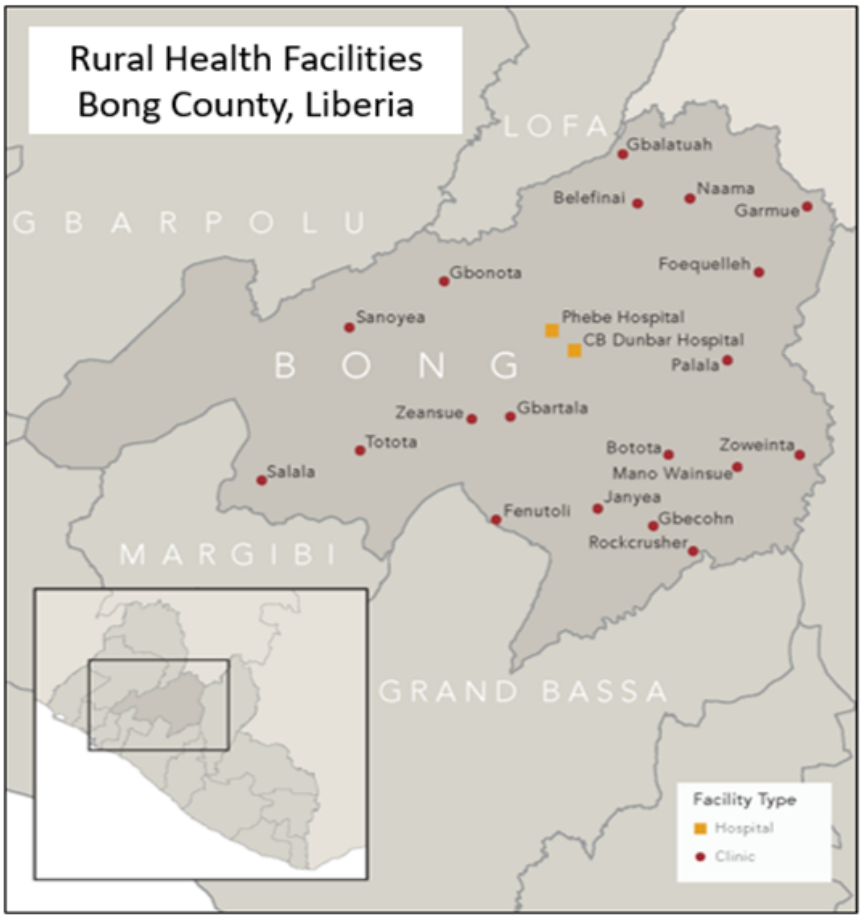

Table 1. Participant demographics for the Mobile Obstetric Referral Emergency System (MORES) evaluation study in Bong County, Liberia.

	Total (N=62)	Rural health facilities (n=33)	Hospital 1 (CB Dunbar) (n=15)	Hospital 2 (Phebe) (n=14)
Age (years), n (%)

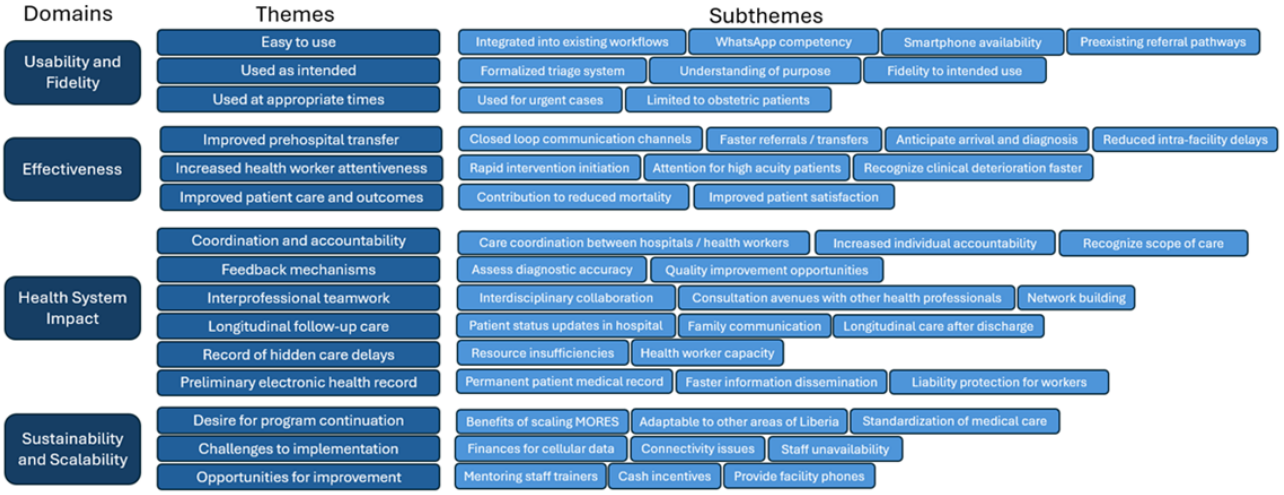
Figure 2. Organization of domains, themes, and subthemes from MORES interviews. MORES: Mobile Obstetric Referral Emergency System.



MORES Usability and Fidelity

MORES was evaluated for its usability and fidelity, meaning if participants used MORES as it was intended to be implemented. For usability, all 62 participants affirmed the MORES intervention was easy to use and beneficial to the patients they served (100%). They described MORES as easily integrated into existing workflows within their health system, as most had access to smartphones, knew how to use WhatsApp, and used MORES as part of a preexisting RHF-hospital referral system. For fidelity, participants described how they used MORES as it was intended to be implemented, including for making patient referrals, interfacility communication, and triage upon hospital arrival: “We get the patient’s name, age, reasoning of referral, mode of transfer. If referring through an ambulance or commercial car, we can place it in the WhatsApp group chat and send it” [P41].

Upon arrival at the hospital, patients were immediately triaged with a green, yellow, or red wristband according to acuity: "The band is there to help us to separate patients according to the conditions. The red is a critical condition; yellow is for someone that has a bad condition but not very critical; and the green is for normal patients" [P29]. Bands were worn until discharge, with health workers continually monitoring patients for changes in the category and exchanging wristbands appropriately.

All participants expressed that they used MORES for acutely sick patients at appropriate times. For hospitals, this was multiple times per day, given their high volume: "We use it all of the time, when the patient arrives in the facility. Any patient that comes in the labor room or the entry point, the ER" [P15]. At RHFs with smaller catchment areas, rates of emergency presentation were less frequent: "Sometimes in a month, we can get 4-6 [emergencies]. All depends on how the patients will come" [P31].

There was a clear understanding of the purpose of MORES from all providers and facilities, as every participant (62/62, 100%) accurately defined at least 1 goal of the program:

> *[MORES] is a quick emergency guide that will inform you where to refer, because you put the patient's information on the WhatsApp platform and send it to the referral site. They will receive it and be preparing for the patient* [P56]

MORES Effectiveness

MORES was evaluated for effectiveness, meaning whether or not the program accomplished its intended purpose. These goals included improving prehospital transfer, increasing health worker attentiveness, and improving patient care and outcomes. Nearly all participants reported improved prehospital transfer (57/62, 92%). A major factor for improved transfer was that MORES established an avenue for rapid, prehospital communication between RHF and hospital health professionals, which facilitated closed-loop communication:

> *If [RHFs] communicate that they are sending a patient and we reply, 'yes, we're awaiting the patient' then they are aware that we have received the message. Then we have to give them feedback that the patient came and arrived at this time. We send information like the patient came with this kind of condition and we've started management or the patient is improving or the patient is on treatment. Until that patient can be discharged, we still have to give them feedback.* [P1]

Participants believed that this communication resulted in more timely referrals from RHFs to hospitals (53/62, 85%). MORES also allowed health professionals to collaboratively overcome referral and transport facilitation barriers and informed clinicians on patient arrival times and conditions: "Before, people were not there to receive the patient on time. But now, if you send information, they will already be standing at the entrance waiting to receive the patient" [P48]. This led to a reduction in transfer time and intrafacility, or third delays, at hospitals, which was especially important for urgent cases requiring surgical intervention: "It has helped us limit delays from patients being referred. It informs the ER and OB Ward in times of emergency and gives us prior notice about a referred patient that has limited time for surgery" [P21].

Participants reported being able to prepare operating rooms and gather needed materials for urgent intervention before patient arrival, to more quickly evaluate and treat critically ill patients upon arrival: "As a health worker, it's helpful in the sense that before my patient arrives, I've already received their information and setup. The moment they arrive, immediate intervention starts" [P6].

Second, health workers believed that MORES increased their attentiveness toward patients (39/62, 63%). One stated "It's useful because it helps to keep us focused and makes us know that there's an emergency that you need to act right away" [P9]. Another agreed that MORES trained her to recognize clinical deterioration faster: "Most often, if a patient comes, I will already know and be on guard to monitor because any time the patient's condition can change" [P7].

This attentiveness was partially attributed to improved triage capacity following the triage training sessions and wristband implementation (35/62, 56%). One hospital health worker described the case of a woman with peripartum hemorrhage who received timely care because of the triage system. Another affirmed that the triage wristbands helped focus health workers' urgency, with patients with red wristbands being seen first on clinician rounds (Table 2).

Finally, more than half of the participants (34/62, 55%) believed that MORES contributed to improving patient outcomes. They perceived MORES as helping to improve maternal and neonatal mortality, as well as patient satisfaction:

> *It has helped me to save lives that were to be lost, especially in pregnant women cases. If someone has a ruptured ectopic, before the person comes, we already know the person's condition…and the person will receive the care in time.* [P14]

Table 2. Effectiveness domain: themes, subthemes, and representative quotes.

Theme and subtheme	Representative quote
Theme 1: Improved prehospital transfer (57/62, 92%)	
Closed loop communication channels	*It provides information ahead of time to inform a bigger facility that a patient is coming with their diagnosis. It allows for information dissemination.* [P50]
Faster referral and transfer times	*It helps reduce the time if you're referring a patient. You have to give the patient's information, then the health worker, doctor, or midwife will be able to know the condition that is coming and prepare before time to avoid delays.* [P34]
Anticipate patient arrival and diagnosis	*If the RHFs have any critical patients, they will send a message before the patient reaches the hospital, and we will already know the type of patient that is coming and their condition so that we can get prepared for the patient.* [P18]
Reduced intrafacility delays through materials preparation and intervention initiation	*When we know the case coming, we will setup and get prepared. Whatsoever materials that they will need like drugs, the team will get everything set as they arrive, so we just start our care. No more going to look for MgSO4 for an eclamptic patient. You get your tray set so as soon as they enter, you start treatment.* [P1]
Theme 2: Increased health worker attentiveness (39/62, 63%)	
Formalized and improved triage system	*[MORES] improves care quality because when the patients come to the emergency room and they are already triaged, they will place the band on the patients' hands to know the kind of patients so everyone will be on the guard to monitor the patients.* [P7]
Increased attention for high acuity patients	*The moment the doctors enter the emergency room (ER), they go directly to the patients with the red band because they are patients of concern. It provides information on which patient to see first.* [P6]
Recognize patient deterioration or complications faster	*Staff that is on shift will receive the patient and label them for the next person who is coming. As soon the person enters the place and sees the patients, they will know who to care for first; who to start with or who's the patient of concern. Patients with red are our patients of concern. If green, you know it's a normal patient; someone who's in yellow will require attention because they can change to red.* [P1]
Theme 3: Improved patient care and outcomes (34/62, 55%)	
Contribution to reducing mortality	*It helps the pregnant woman to be well taken care of and to help save their lives and that of the babies.* [P29]
Patient satisfaction	*Because information is disseminated and prompt referral is given before patient arrival, it makes patients happy.* [P50]

MORES Sustainability and Scalability

Interview responses reflected an overwhelmingly positive desire for MORES to continue and expand (62/62, 100%): "My recommendation is for the program to continue because it's really helpful to us and reduces our maternal deaths" [P35]. Participants discussed the benefit of scaling MORES to other RHFs, who: "complained on why they are not part of the program," and citing that, "there are some terrible cases that come from the other facilities that are not trained" [P6]. They believed benefits could be realized in standardization of medical care, reduction in error, and ultimately improvement in maternal and neonatal mortality if the program was scaled to other counties in Liberia. Participants directly cited MORES usability, feasibility, and effectiveness as justification for its scaling potential.

Despite successes, there were ongoing challenges to be addressed prior to scale-up, with 89% (n=55) of participants naming at least 1 issue. Challenges included financial support for cellular data (39/62, 63%), poor cellular networks preventing connectivity (21/62, 34%), and staff unavailability due to high turnover and limited motivation (19/62, 31%). RHF health workers were more likely to mention poor cellular networks than hospital staff, who worked in urban and suburban settings. Three participants also explained how conflict could arise between patient care and MORES, particularly when checking messages on a busy service: "Especially at the emergency unit, sometimes we are busy and forget to check the WhatsApp phone. If you have an emergency, you will be busy with that while other clinics are sending messages." [P10].

From these challenges, participants offered suggestions for improvement. For workforce shortages, participants encouraged mentoring more staff to be MORES trainers to onboard new health workers: "If the knowledge of nurses can be increased and incorporating more nurses and increasing the training method, it will help support the program." [P21]. Others suggested increasing staff motivation through cash incentives and providing facility phones to all RHFs with mechanisms for data recharging, rather than relying on personal phone use.

MORES Health System Impact

In addition to evaluating MORES implementation based on intended aims, there were multiple effects of MORES on the wider health system that were not part of the original design. In total, 61 (98%) participants described ways that MORES implementation strengthened aspects of the health system beyond the intended aims of implementation. Participants identified 6 ways in which MORES contributed to broader health systems strengthening (Figure 3). First, participants noted increased coordination and accountability among health workers

and facilities when caring for patients (55/62, 89%). This was perceived through rapidly updated information and the ability to coordinate care between receiving hospitals which previously had limited communication:

> *I appreciate the program because care is on time these days and people are aware. When a patient is coming but C.B Dunbar is crowded and there's no space, as long we get the message, we send it to Phebe for preparations. It helps a lot.* [P1]

Coordination and accountability were also experienced at a personal level, with health workers reporting increased responsibility to their patients, including their scope of care: "[MORES] got us to be on our guard and to know which case is above our limit and needs to be transferred to a bigger facility" [P54]. Workers felt more comfortable acknowledging personal limitations and used the MORES system to consult higher-level colleagues more frequently than prior.

Second, feedback mechanisms for hospitals and RHFs were a key benefit of the 2-way WhatsApp messaging (48/62, 77%). Hospital staff offered constructive feedback to RHF workers on their care and referral process. This feedback included the accuracy of diagnoses and opportunities for quality improvement:

> *Based on the feedback, we will know that we are doing good work or understanding the referral system. Using the paper-based system, getting feedback used to be difficult, but now it comes as soon as the patient arrives* [P37]

Feedback was rapid, with 89% of RHF health workers receiving updates within the first 24 hours (n=55). Such communication also facilitated improved interprofessional teamwork (21/62, 34%). Participants reported reduced work tensions between RHF and facility providers and improved interdisciplinary collaboration through network building: "It is helpful because my community health assistants and midwives are working together. If a patient is not willing to come, they will continue encouraging the patient" [P40]. RHF health workers appreciated that they could consult dozens of other professionals when managing complex patients, establishing consultation avenues for health workers who are often the sole clinicians working in a low-resource facility, and learning from the outcomes of one another: "I use it to refer, but also see if my colleagues are using it, because we all are trying to stop the maternal death rate in Liberia. I use it to see the outcome of my colleagues' referral" [P47].

Fourth, MORES facilitated longitudinal follow-up care for RHFs (20/62, 32%), especially through patient tracking while still in the hospital. These updates helped family members unable to visit loved ones: "It makes us know more about our patients because the hospital will give [updates]. If the patient's relatives don't have a phone, we will be able to inform them on the status" [P35]. Hospitals additionally used MORES to communicate discharge instructions to RHFs for patients requiring follow-up. One RHF midwife elaborated on how MORES empowered her to help a patient continue her hospital-prescribed medication following discharge (Table 3).

Figure 3. Six themes of health systems strengthening which emerged from the implementation of MORES according to participant interviews. MORES: Mobile Obstetric Referral Emergency System; RHF: rural health facility.

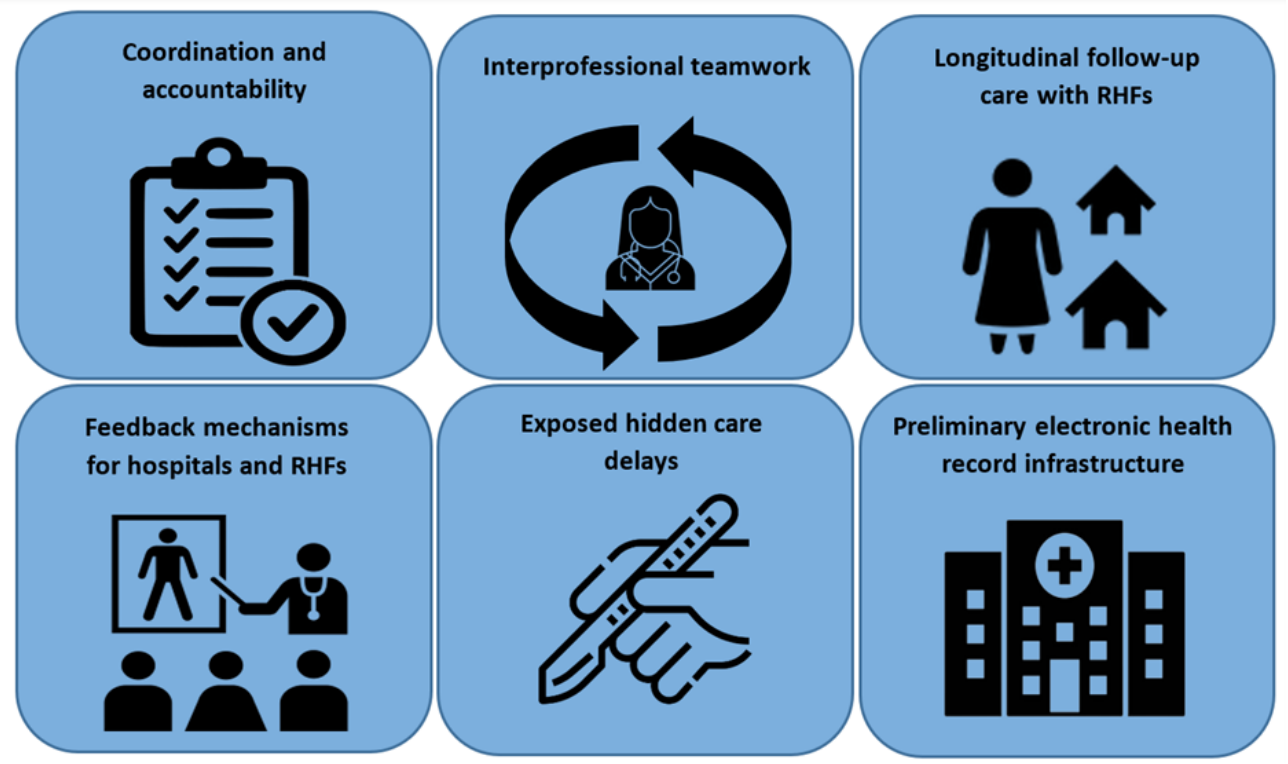


Table 3. Health system impact domain: themes, subthemes, and representative quotes.

Theme and subtheme	Representative quotes
Theme 1: Coordination and accountability (55/62, 89%)	
Care coordination between hospitals and health workers	*When the patient comes as an emergency, if we call and can't get the ambulance, as soon as we send the information the people at Phebe will inform the ambulance team to come for the patient.* [P35]
Increased individual accountability	*Before, there was conflict. Midwives would delay the patients and write referral notes to suit their taste while patients were saying something different. No one was willing to take the blame.* [P24]
Recognize scope of care	*It's very helpful because we don't have to keep cases that we know we can't manage. Once they come to the facility, if the case is in our reach, we can handle it, but if not, we refer them.* [P41]
Theme 2: Feedback mechanisms for hospitals and RHFs (48/62, 77%)	
Identify quality improvement opportunities	*It's helpful. Sometimes we get negative feedback from the patients, like if a patient gives birth and loses her baby.* [P49]
Assess diagnostic accuracy	*You are doing work and get feedback. It can help you in your diagnosis because if the people at the hospital diagnose the same thing, you can be confident of yourself* [P30]
Theme 3: Interprofessional teamwork (21/62, 34%)	
Interdisciplinary collaboration	*Using [MORES], I will be in communication with hospital nurses at CB Dunbar or Phebe to know if the patient is in good condition or if there is something that should make me concerned.* [P38]
Consultation avenues with other health workers	*The program is good; it gives information. Whatever happens in Palala Clinic is being communicated in all facilities and we are aware of all our patients.* [P50]
Network building	*It helps us do plenty things. It makes us to know lot of people and how to really deal with the phone. It also makes us to know every patient information that needs to be communicated.* [P42]
Theme 4: Longitudinal follow-up care with RHFs (20/62, 32%)	
Patient status updates in the hospital	*It makes us help our patients get quick health services at the higher facilities and for us to get information on how they are doing.* [P35]
Communication with family members	*The feedback is very helpful because it confirms and updates on the conditions of our patients that we sent. We can use the feedback to tell the patient's people.* [P46]
Longitudinal care after discharge	*The feedback helps us continue the treatment or medication of a patient that has been referred [once discharged].* [P58]
Theme 5: Exposed hidden care delays (17/62, 27%)	
Resource insufficiencies	*[We realized we] need emergency materials to make work easier. All OB cases are actually emergency cases and should be treated.* [P22]
Health worker capacity	*One difficulty we experience is having misdiagnosis from the clinics. Communication sometimes isn't clear.* [P17]
Theme 6: Preliminary electronic health record infrastructure (13/62, 21%)	
Permanent patient medical record	*[MORES is] helping a lot especially with data [capture]. Patient referral and treatment between facilities is being communicated.* [P54]
Faster information dissemination	*We now receive electronic communication. It makes us more confident in our work and we feel satisfied after getting our findings.* [P50]
Liability protection for workers	*It's very helpful to me because it will save me. If I use WhatsApp to refer my patient, the time I refer will be mentioned. If there's any delay, they will know where it comes from. So, it will protect me.* [P55]

Fifth, MORES created a record of hidden care delays in Bong County by documenting reasons for delays as they arose (17/62, 27%). The most common included resource insufficiencies and worker capacity: "The purpose of [MORES] is to do quick referral and…to know where the delay comes from; whether from the community, the relatives or the midwife or from the county because they are responsible to send the ambulance" [P55]. In such situations, even when MORES worked properly, patients still experienced delays. More than half of respondents listed factors outside of MORES that worsened care delays for patients (35/62, 56%), including a lack of medications, intravenous fluids, and ambulance insufficiency.

Finally, MORES benefited the health system by creating a preliminary electronic health record (EHR) infrastructure (13/62, 21%). No EHR exists in Bong, and all documentation occurs on paper charts. Participants appreciated the ease, accessibility, and speed that MORES provided, believing it sped information dissemination:

> *[MORES] enables me to do my work with ease. The time I take to write a whole lot of papers…wastes the patient's time, and it will also waste time at the referral hospital…With [MORES], the hospital will already get the information before the patient can arrive so they will start to attend immediately.* [P47]

This EHR also started a permanent record of patient conditions, transfers, and treatments administered, so that health teams could review patients requiring special accommodations or difficult cases. Finally, health workers appreciated the protections that having a permanent record of electronic communication offered in terms of liability for malpractice.

Discussion

Principal Findings

From this qualitative study of frontline health workers in rural Liberia, we found that implementation of the MORES intervention was perceived as having high usability, fidelity, and effectiveness for its intended aims. Furthermore, MORES had the unanticipated impact of strengthening multiple components of the health system and demonstrated exciting potential for scaling and sustainability. These findings confirmed the results of our preintervention study which showed high desirability and acceptability of the WhatsApp-based triage, transfer, and referral system among rural Liberian health workers to better care for obstetric patients [14]. Our analysis further revealed health worker perceptions regarding the benefits and health system improvement opportunities through MORES. These in-depth results contribute to the findings from other studies on the impact of MORES, including increased rates of cesarean section and lower odds of nonvigorous symptoms in neonates [15].

Users perceived MORES to be highly usable, as it could be seamlessly integrated into existing workflows and referral pathways. MORES use also demonstrated high fidelity, as it was implemented as intended and at appropriate times to refer critical patients. MORES participants reported the program to be effective across its intended aims: improving prehospital transfer, increasing health worker attentiveness, and improving patient care. The triage training and templated, bidirectional WhatsApp communication components of MORES worked collaboratively to address 2 key gaps in rural care delivery in Liberia: a lack of standardized obstetric triage protocols and a limited prehospital communication system. Increasing capacity and infrastructure to support triage protocols and prehospital emergency systems have been shown to significantly reduce patient morbidity and mortality, particularly in LMICs [19]. This opportunity for impact is especially prevalent for maternal mortality, where the third delay accounts for a massive burden of maternal and neonatal deaths, in some cases as high as 80% [20]. Participants were enthusiastic about the impact of MORES and desired its sustainability and scaling to other health facilities throughout Liberia. Continuing to implement and evaluate programs that increase capacity in obstetric triage, prehospital communication, and facility referral and transfer will be important for improving care and understanding the effects of mHealth technologies in resource-limited environments.

Though not an intended aim of implementing MORES, we found that the program facilitated health systems strengthening across 6 themes: coordination and accountability, feedback mechanisms for hospitals and RHFs, interprofessional teamwork, longitudinal follow-up care with RHFs, a record of hidden care delays, and establishment of a preliminary EHR infrastructure. While not the primary goals of MORES, these effects highlight important benefits across many internal and external domains of health system strengthening. For internal effects, participants reported MORES improved personal accountability, quality improvement opportunities, network building, and reduced workplace tensions and stress from liability. Externally, participants perceived faster information dissemination and facility preparation, consultation mechanisms, and care continuity. These findings highlight how MORES contributed to capacity building and the beneficial effects that can be realized when interventions are implemented to improve systems beyond individual disease states [21]. For example, while MORES was intended for obstetric and peripartum referrals, it exhibited the potential to be adapted to other specialties such as emergency medicine and surgery [22]. MORES provides a pragmatic example of how horizontally implementing interventions across multiple facilities, worker levels, and patient conditions can have multiplicative effects on health systems improvement.

This study adds to the growing literature on mHealth implementation in LMICs to reduce delays and improve care access. One comprehensive review of mHealth interventions for maternal health in LMICs showed that health worker buy-in and motivation, perceived intervention usability, and efficient messaging were key implementation-related mechanisms for success [23]. Our findings on MORES account for all 3, showing high usability and desires for sustainability and scaling, with efficient communication mechanisms that were used appropriately, bidirectionally, and rapidly. A study in South Africa demonstrated high usability for a mobile health platform to aid health workers in the management of pregnant women at risk for preeclampsia [24]. From this program, most user issues resulted from phone features including scroll wheels and touch screens. In MORES, we leveraged the free, WhatsApp communication platform already familiar to Liberian health workers, thereby mitigating user errors from unfamiliarity. Similar to our findings on the impact on interprofessional dynamics, other studies have demonstrated the collaborative effects of a WhatsApp messaging platform among obstetric providers, including as avenues for consultation, network building, and interprofessional communication [25]. Recently in Ghana, a WhatsApp messaging technology was implemented among 13 facilities and 81 health workers for more than 600 patient referrals from rural to district hospitals [26]. Findings from this study mirrored ours, including exposing hidden care delays and creating a preliminary EHR. Specifically, the program identified delay factors, referral characteristics associated with faster transport, and timely updates on patient arrival and outcomes more quickly and permanently compared with paper charting. A mHealth intervention among traditional birth attendants for indigenous women in rural Guatemala demonstrated increased referrals to facility-level care but similar complication rates across intervention and control groups [27]. Such inconclusive outcomes data suggest opportunities for future evaluation of maternal mHealth interventions. Results of a meta-analysis from 2016 revealed that out of 15 articles, only 2 studies showed a low risk of bias and 1 demonstrated a mortality benefit when text messaging women during pregnancy [28]. Future quantitative findings regarding the impact of

MORES on maternal outcomes and referral times could clarify the potential clinical impact of well-implemented and highly acceptable maternal mHealth in LMICs.

Limitations

This study had several limitations. First, our qualitative methods and geographic homogeneity limit the generalizability of results. However, this approach was considered most effective given the study aims which allowed for in-depth explanations of MORES usability, fidelity, and effectiveness. Second, our sample had an unevenly distributed representation of health worker roles, with most participants being midwives and nurses. Increasing recruitment of physicians and other personnel who interact with MORES such as ambulance drivers, administrative staff, and patients being referred within the system could capture more in-depth data beyond what was offered by frontline health workers. Finally, we elected not to utilize a preexisting framework for the conceptualization of our results, given that commonly referenced usability, acceptability, and feasibility metrics for mHealth did not align with the evaluative approach and subsequent immersion in the data. This was apparent, especially for the impact of MORES on health system strengthening. To increase study rigor, we used a validated codebook and 4 separate metrics to ensure accuracy including member checking. However, developing flexible frameworks to better conceptualize usability, effectiveness, and broader benefits of mHealth technologies in LMICs could be highly valuable for future studies.

Conclusions

The MORES intervention was perceived to have high usability, fidelity, and effectiveness for reducing delays and optimizing referrals in rural Liberia. MORES also demonstrated 6 components of health systems strengthening which positively impacted accountability among health workers, feedback mechanisms, interprofessional dynamics, longitudinal follow-up care, and system-level efficiencies through recording delay factors and electronic health record infrastructure. Findings from this study suggest that MORES demonstrates high feasibility for scaling to other facilities and counties in Liberia to improve maternal and neonatal referral pathways. These conclusions can have direct policy and program implications for supporting MORES funding, implementation, and scaling at a national level. More widely, these findings can be highly useful to policymakers, clinicians, and researchers intending to implement and scale technology-based obstetric referral systems in low-resource contexts to accomplish intended aims, anticipate challenges prior to implementation, and enhance impacts on health system strengthening.

Acknowledgments

The authors would like to thank T-Max Zorh, BSc, from Cuttington University and Lovetta B Dixon, BSN, from the University of Liberia for their contributions to data collection and transcription in this study. We would also like to thank the many rural health facilities and hospital workers who have used and continued the MORES program in Bong County. This research received funding support from the Bill and Melinda Gates Foundation (INV-023274) and the USAID PEER Grant (project 9–518). The funders, however, did not contribute to the study design, data collection and analysis, manuscript preparation, or the decision to publish.

Conflicts of Interest

None declared.

Abstract

Background: Hearing rehabilitation with auditory training (AT) is necessary to improve speech perception ability in patients with hearing loss. However, face-to-face AT has not been widely implemented due to its high cost and personnel requirements. Therefore, there is a need for the development of a patient-friendly, mobile-based AT program.

Objective: In this study, we evaluated the effectiveness of hearing rehabilitation with our chat-based mobile AT (CMAT) program for speech perception performance among experienced hearing aid (HA) users.

Methods: A total of 42 adult patients with hearing loss who had worn bilateral HAs for more than 3 months were enrolled and randomly allocated to the AT or control group. In the AT group, CMAT was performed for 30 minutes a day for 2 months, while no intervention was provided in the control group. During the study, 2 patients from the AT group and 1 patient from the control group dropped out. At 0-, 1- and 2-month visits, results of hearing tests and speech perception tests, compliance, and questionnaires were prospectively collected and compared in the 2 groups.

Results: The AT group (n=19) showed better improvement in word and sentence perception tests compared to the control group (n=20; *P*=.04 and *P*=.03, respectively), while no significant difference was observed in phoneme and consonant perception tests (both *P*>.05). All participants were able to use CMAT without any difficulties, and 85% (17/20) of the AT group completed required training sessions. There were no changes in time or completion rate between the first and the second month of AT. No significant difference was observed between the 2 groups in questionnaire surveys.

Conclusions: After using the CMAT program, word and sentence perception performance was significantly improved in experienced HA users. In addition, CMAT showed high compliance and adherence over the 2-month study period. Further investigations are needed to validate long-term efficacy in a larger population.

KEYWORDS

hearing loss; hearing aids; hearing rehabilitation; auditory training; mobile program

Introduction

According to a World Health Organization report in 2021, it is predicted that a quarter of people will have some degree of hearing loss by 2050 [1]. Hearing loss is known to be related to the risk of vocational problems, depressed mood, and even cognitive impairment in adults [2-4]. Adult aural or hearing rehabilitation, a multifactorial strategy for patients with acquired hearing impairment, includes 4 main components: sensory management, instruction, perceptual training, and counseling [5]. Sensory management involves enhancing auditory function through the use of hearing aids (HAs), cochlear implants, and alternative devices. Additional perceptual training, including auditory training (AT), seems to be required because sensory management alone has limitations in improving speech perceptual ability [5,6].

Although AT is known to improve hearing performance and lower the HA return rate, it has been not sufficiently provided to patients with hearing loss due to its poor time- and cost-effectiveness [7-9]. In our previous randomized controlled trial, we reported significant improvements in consonant perception and subjective satisfaction after 8 weeks of AT consisting of in-hospital face-to-face education and at-home self-training among HA users [10]. However, we experienced the limitations of in-hospital training programs during the COVID-19 pandemic, and this led us to consider a mobile-based AT program.

Smartphone penetration is rapidly increasing worldwide, and South Korea is a leading county for smartphone use, with a penetration rate of around 93% in 2021 [11,12]. Among the older population, around 94% of those older than 60 years and 60% of those older than 70 years own smartphones, and most of them (80%) use the internet with a mobile device [12,13]. The increasing smartphone penetration rate is a global trend, and mobile-based health care programs are expected to be used effectively even in the older population [14]. We developed a new mobile AT program with a chat-based interface to increase compliance with hearing rehabilitation, with attention to the fact that most of the adult population is familiar with message apps on smartphones [15].

Several mobile and web-based AT programs have been introduced in the last decade. However, many mobile-based AT applications are simple gamified training programs for pediatric patients, and most of them have no clinical validation to support their efficacy [16]. Even though a state-of-the-art review showed AT to be effective for improving auditory perceptions [17], it is unclear whether mobile-based training will still be effective. Digital therapeutics are expected to change the future of the health care system; however, clinical validation should first be performed to prove their effectiveness [18]. In addition, the effect of AT on experienced HA users has been inconsistently reported, while the effect of AT on novel HA users is relatively clear. Of the 16 studies included in a state-of-the-art review on AT, only 3 investigated experienced HA users, and only 1 of these studies showed improvements in speech perception [19-21].

Therefore, this prospective randomized controlled study was conducted to investigate the efficacy of our novel chat-based mobile AT (CMAT) program for 3 aspects of hearing rehabilitation in experienced HA users: speech perception ability, subjective satisfaction, and training compliance.

Methods

Ethical Considerations

This prospective study was approved by the ethical committee of Seoul St. Mary's Hospital (KC21EISI0525) and followed the tenets of the Declaration of Helsinki. The patient records and information were anonymized and deidentified before analysis. All participants provided written informed consent prior to commencement of the study and voluntarily participated in this clinical trial.

Participants

A prospective randomized controlled trial with an unblinded study setting was carried out. Bilateral HA users were recruited from the department of otorhinolaryngology–head and neck surgery at a tertiary referral center between September and December 2021. Study eligibility criteria were as follows: (1) age ≥20 years; (2) bilateral moderate to severe sensorineural hearing loss (mean threshold of pure tone audiometry measured at 500, 1000, 2000, and 4000 Hz was 41 to 80 dB hearing level, and the air-bone gap was less than 15 dB hearing loss); and (3) the patient had been using bilateral HAs for more than 3 months, demonstrated sufficient functional gain, and consistently used the HAs for more than 8 hours per day. Patients were excluded if they had fluctuation in hearing loss, brain tumor, or difficulty using the program or coordinating hearing tests.

The randomization was performed using premade random cards with a 1:1 allocation ratio prepared by a contract research organization (Medical Excellence). The cards were then opened by the health care provider after obtaining informed consent. Participants allocated to the AT group (ATG) were provided instructions about the CMAT program by a coauthor (JL) and were encouraged to use it daily for 8 weeks. One CMAT session consisted of 20 questions, took about 5 to 10 minutes, and was repeated 3 times a day. Those assigned to the control group (CG) did not receive the CMAT. All participants were asked to complete audiologic tests, speech perception tests, and questionnaires before enrollment and at 1 and 2 months after the start of the study, respectively.

Assuming that the effect of offline AT and CMAT would be similar, we determined the number of target participants in the same way as in our previous study [10]. For statistical significance at a .05 confidence level with 80% power, the sample size required for the 2 groups was estimated as 18 patients per group. Allowing for a 10% dropout rate, 42 patients were estimated to be required in total.

Chat-Based AT Program

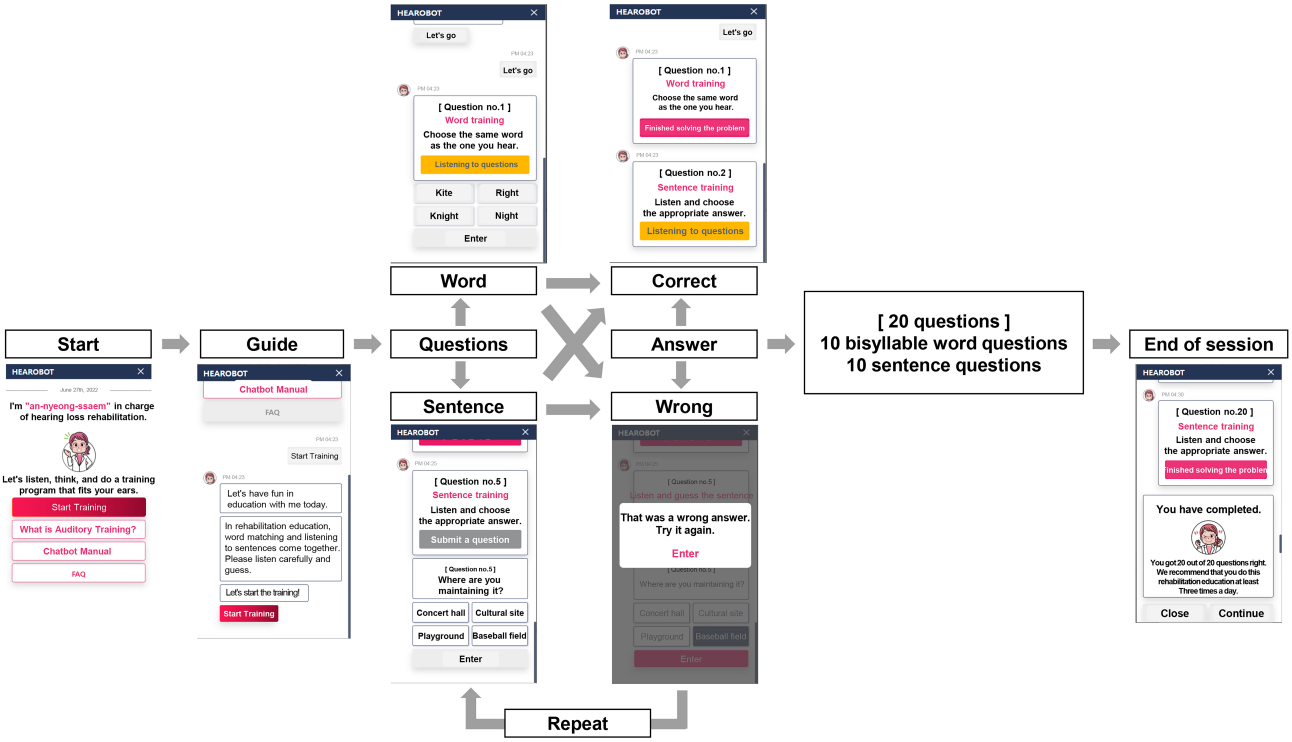
Our CMAT program was developed in the form of a web-based program that can be accessed from computers, tablets, and smartphones. However, all participants were requested to connect with their smartphones to avoid device bias in this clinical trial. When a participant accessed a provided link, the ID and password given during participant registration were required to be entered, and a page was provided to additionally confirm the consent form for clinical trials and the collection of personal information. Afterward, a problem was presented in a chat-based interface. In the chat-based interface, we designed a conversational partner as a character representing a medical professional, intending to give users the feeling of exchanging chat bubbles with a health care provider. Participants could choose 1 of 4 answers, and a message was shown giving feedback after a problem was answered. All participants were instructed to train in a quiet place while wearing their HAs.

The rehabilitation program consisted of 2 parts: word and sentence training. For word training, a total of 1540 two-syllable Korean words that are frequently used in daily life were extracted based on data provided by the National Institute of

the Korean Language. Four words with the same or similar vowels but different consonants were provided, and then one of these words was provided twice. Then, the participant was asked to choose the word that he or she heard. For sentence training, daily phrases consisting of 2- to 12-word phrases were provided, and the frequency of the words used was checked to correct or delete infrequently used words (eg, “We decided to meet at Seoul Station”). A total of 1225 sentences were composed, and a question was made for each sentence. The sentences and related questions were provided once, and 3 words similar to the correct answer were shown with it (eg, “Question: Where would you like to meet?”; “Answers: (1) Sadang Station, (2) Sung-soo Station, (3) Sung-book Station, (4) Seoul Station”).

This CMAT program was presented as if chatting with a virtual character. If a participant answered the question correctly, the next question among the word and sentence training question pools was shown randomly. If a participant chose a wrong answer, the question was repeated up to 3 times. Ten-word and 10-sentence questions were randomly assigned to participants for solving within a single session. AT dosage was planned to be around 30 minutes of training per day, similar to our previous study, as solving 20 questions was expected to take approximately 10 minutes. However, if a participant wanted to solve more questions, they could engage in an additional session. Participants included in the ATG were instructed to repeat this session 3 times a day, spaced out, following a similar approach to our previous study [10]. A schema of the CMAT is shown in Figure 1.

Figure 1. Schematic diagram of chatbot-delivered auditory training program.



The Korean language was used in this program, and words and sentences were synthesized using Google Cloud text-to-speech software. To facilitate scalability for increases in the number of sentences or upgrades in the future, we determined that software-generated voices would be a reasonable choice. The speech was randomly generated using male or female voices provided by the software, and the default settings of the program were used for other suprasegmental characteristics of sentences, including speed, pitch, and volume. The log-in time and the number of questions solved were automatically collected by the program; however, prompts to use the CMAT were not provided.

Outcome Measures

Study Design

All participants completed audiologic tests, speech perception tests, and questionnaires at the 0-, 4-, and 8-week visits, and the results were collected using Excel (Microsoft). Among these measured outcomes, speech perception test results were used as the primary end point, and questionnaire results were used as the secondary end point.

Audiologic Tests

Pure tone audiograms (PTAs) without HAs and sound field threshold audiometry tests with HAs were conducted to exclude changes in hearing level and inappropriate function of HAs. Speech audiometry tests, including the speech reception threshold test and speech discrimination scores, were evaluated both with and without the participants wearing HAs.

Speech Perception Tests

A total of 5 speech perception tests were conducted by a female audiologist in quiet conditions while the patient wore an HA. The Ling Six Sound test was conducted for phoneme detection [22], and the Vowel and Consonant Imitation Test (VCIT) was used to measure phoneme perception [23]. To evaluate word perception ability, monosyllable and bisyllable open-set tests were used [24]. Sentence perception ability was evaluated using

the Korean version of Central Institute for the Deaf (K-CID) test [25].

Questionnaires

Subjective benefits were measured by 3 validated questionnaires. The Korean version of the Hearing Handicap Inventory for the Elderly (K-HHIE) was used to measure situational and emotional handicaps in everyday life due to hearing problems [26]. In addition, the Korean versions of the International Outcome Inventory for Hearing Aids (K-IOI-HA) and Abbreviated Profile of Hearing Aid Benefit (APHAB) tests were conducted to evaluate the subjective satisfaction with HA use [27,28].

Statistical Analysis

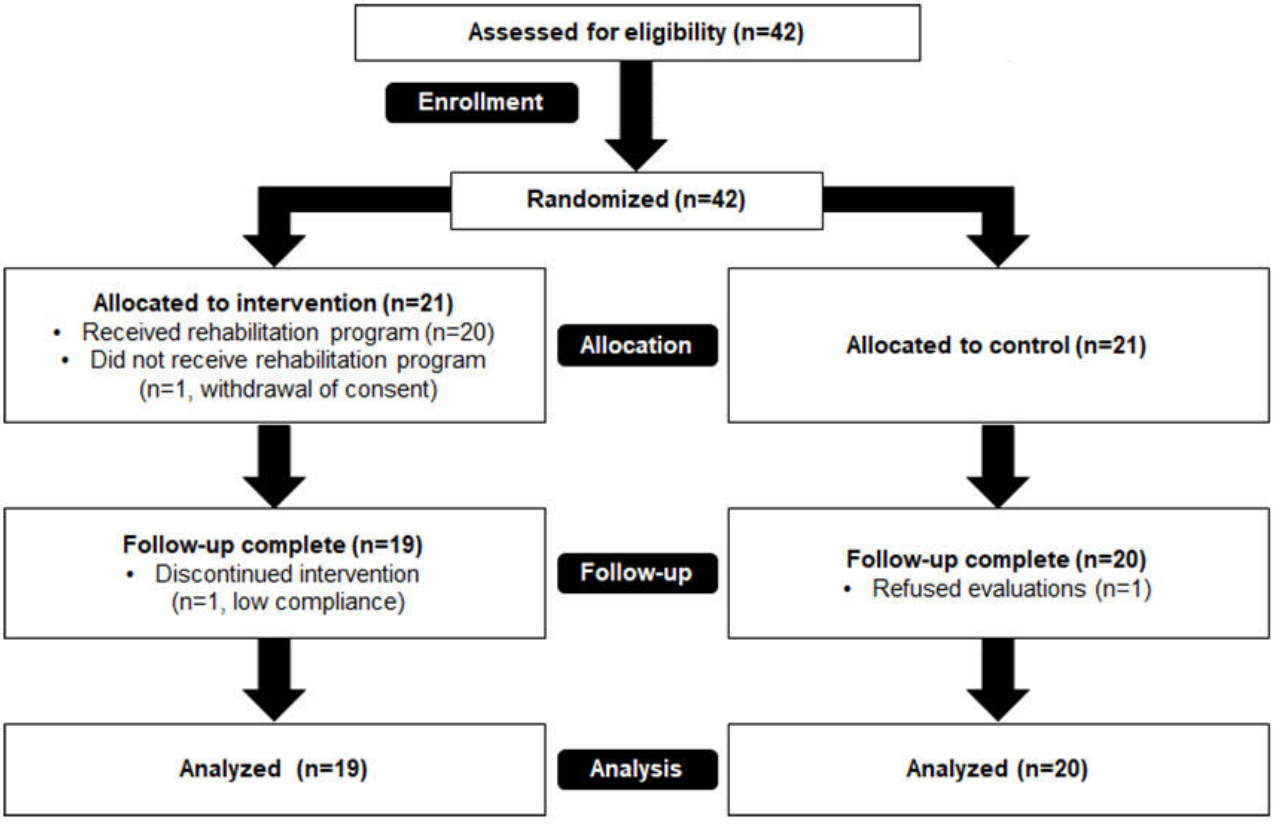
Statistical analysis was conducted using SAS (version 9.4; SAS Institute). The Shapiro-Wilk test was used to examine the normality of the measured variables. Data were expressed as mean, SD, and percentage. *P* values were calculated using the chi-square test or Fisher exact test for categorical variables, the Mann-Whitney test or independent 2-tailed *t* test for pairs of independent variables, and the Wilcoxon rank sum test or paired *t* test for continuous variables. All speech perception tests were collected as percentage data, and as the data did not meet the normality assumption based on the Shapiro-Wilk test, we conducted additional analyses using arcsine transformation. Speech perception tests and questionnaire surveys were analyzed with a linear mixed-effect model and post hoc test. Random effects included the intercept, while fixed effects included group (ATG and CG), time (initial, 1 month, and 2 month), group × time interaction, and the covariate "aided 4 kHz threshold result of the right ear." The inclusion of the aided 4 kHz threshold result of the right ear as a covariate was due to the significant differences between the 2 groups in the initial hearing test despite randomization. Further details regarding this will be provided in the *Results* section. Two covariance structures in the linear mixed model, variance components and compound symmetry, were compared. There were no substantial differences in the results of the fixed effect type 3 test, so we described the variance components estimation. The Akaike information criterion values representing model fit varied depending on the specified model, from 280 to 680. Bonferroni correction was used for multiple comparisons and adjusted *P* values are presented. Correlations between pairs of variables were analyzed with the Pearson correlation test. Differences were considered significant when the *P* value was less than .05.

Results

Clinical Characteristics

A total of 42 participants were initially enrolled after informed consent was obtained. The ATG and CG were each randomly allocated 21 patients, with 1 participant subsequently withdrawn from the ATG due to withdrawal of consent. During the 2-month study follow-up period, 1 participant in the ATG was excluded from the analysis due to low compliance (CMAT completion rate <50%), and 1 participant in the CG was excluded for refusing to perform speech perception tests. Therefore, 19 participants in the ATG and 20 participants in the CG were analyzed. The CONSORT (Consolidated Standards of Reporting Trials) flow diagram is shown in Figure 2. None of the participants in the ATG had any problems using CMAT during the study.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.



There were no significant differences between the 2 groups in age, sex, duration of hearing loss, type of HA being used, or duration of HA use. The detailed patient demographics are shown in Table 1.

Table . Clinical characteristics of the participants.

		Total (n=41)	Auditory training group (n=20)	Control group (n=21)	*P* value
Age (years), mean (SD)		70.0 (10.9)	70.5 (6.9)	69.5 (13.8)	.41[a]
Sex, n					.90[b]
	Male	16	8	8	
	Female	25	12	13	
Hearing aid type, n					.75[c]
	Complete in the canal	67	33	34	
	Invisible hearing aid	10	4	6	
	Receiver in the canal	5	3	2	
Hearing loss duration (months), mean (SD)		103.0 (86.5)	107.9 (83.3)	98.3 (91.3)	.48[a]
Hearing aid use duration (months), mean (SD)		54.5 (62.1)	56.1 (72.2)	53.0 (50.7)	.80[a]

[a]Mann-Whitney test.

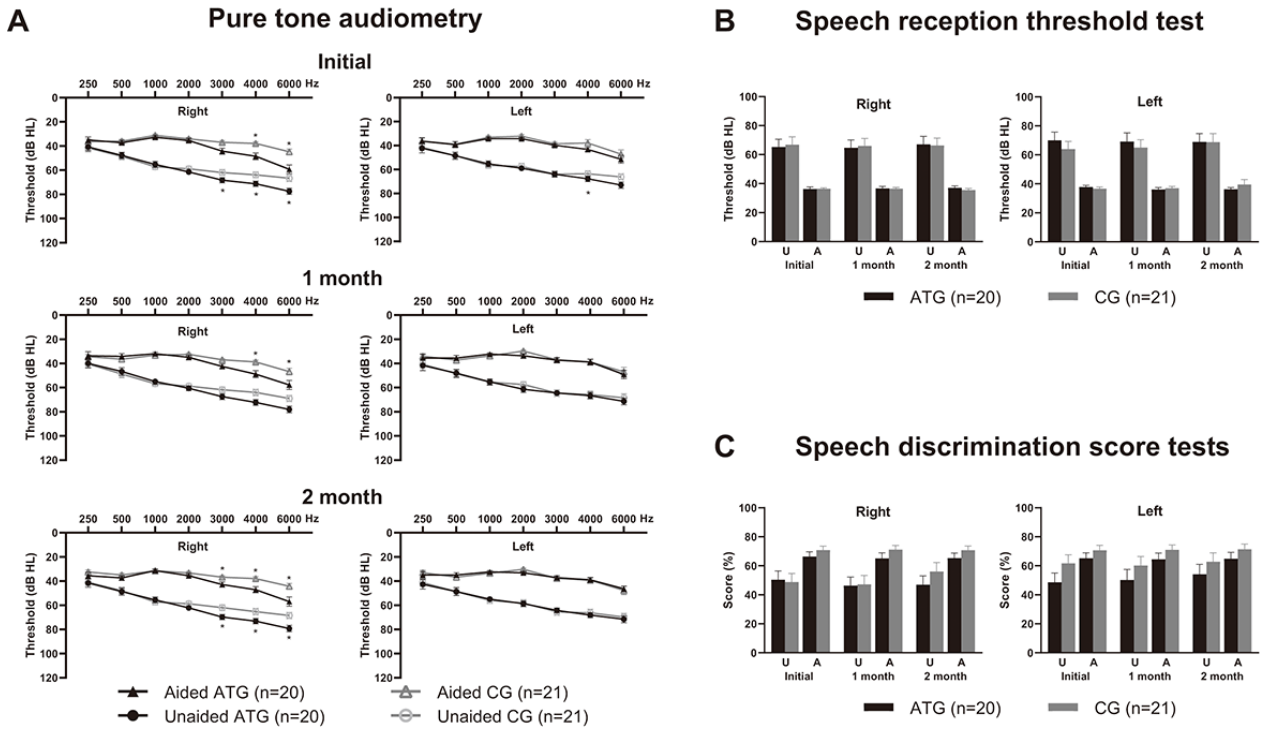
[b]Fisher exact test.

[c]Chi-square test.

Audiologic Evaluations

Although we randomly allocated participants to the 2 groups, there were unintended differences in the baseline hearing tests. In the ATG, the high-frequency thresholds (3000, 4000, and 6000 Hz) of the right ear were significantly higher than in the CG in both unaided and aided conditions (independent *t* test or Mann-Whitney test, all $P<.05$). However, there was no significant difference in the left ear. In speech audiometry, mean values for speech discrimination score were higher in the CG without a statistically significant difference (independent *t* test or Mann-Whitney test, all $P>.05$). No significant changes over time were observed in the repeated audiologic tests under either unaided or aided conditions (linear mixed model, all $P>.05$). These audiologic test results are presented in Figure 3.

Figure 3. Results of audiologic tests. (A) Pure tone audiometry showing significantly higher thresholds in the auditory training group (ATG) at 3000, 4000, and 6000 Hz frequencies in the right ear. (B) Speech reception threshold test showing no significant difference between the ATG and the control group (CG). (C) Speech discrimination scores were higher in the CG without statistical significance. A: aided; dB HL: decibel hearing level; U: unaided. *P<.05; independent t test or Wilcoxon rank sum test.



Speech Perception Tests

With the exception of the vowel imitation test, the initial mean scores for the remaining 5 tests were better in the CG. Although the Ling Six Sound test, monosyllable and bisyllable open-set tests, and the K-CID test showed no significant differences (adjusted P>.05 for all tests; Mann-Whitney test with Bonferroni correction), the initial consonant imitation test exhibited a statistically significant difference (adjusted P=.003; Mann-Whitney test with Bonferroni correction). Therefore, the aided 4 kHz threshold result of the right ear, which exhibited a significant difference in the initial PTA result (P=.002; Mann-Whitney test), was included as a variable in the analysis of the linear mixed model, considering that high-frequency hearing loss is a well-known factor affecting hearing perception [29].

When conducting a linear mixed model that includes the 4 kHz threshold of the right ear as a variable, we observed no significant difference in the initial scores of any speech perception tests (all P>.05).

In the Ling Six Sound test, the VCIT (vowel and consonant) and monosyllable test results showed no significant group differences (all P>.05, linear mixed model). However, in the bisyllable condition, the ATG demonstrated significantly better results compared to the CG (P=.04, linear mixed model). Similarly, in the K-CID test, the ATG showed significantly greater improvement than the CG (P=.03, linear mixed model). These results are visualized in Figure 4, and detailed linear mixed model analyses, including post-hoc P values, are presented in Table 2. Additionally, an arcsine transformation was applied to the percentage values, yielding almost the same results. Detailed values and statistical analyses of both the percentage and arcsine-transformed data are provided in Multimedia Appendix 1.

Figure 4. Results of speech perception tests. The auditory training group (ATG) showed significant improvement in speech perception compared to the control group (CG) in the intergroup analysis of the 2-syllable word recognition test and the K-CID (Korean version of Central Institute for the Deaf) test. ns: not significant; VCIT: Vowel and Consonant Imitation Test. *P<.05; linear mixed model.

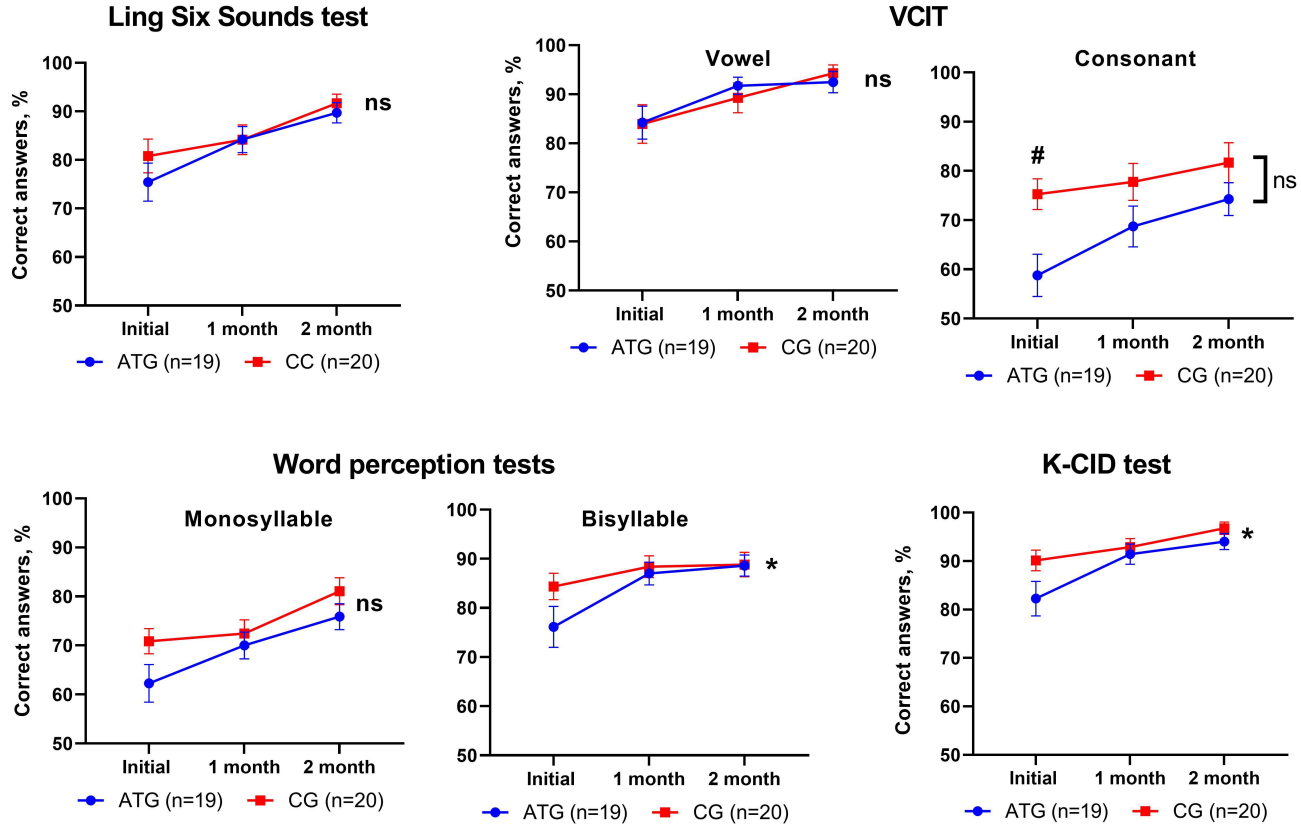


Table . Linear mixed model analysis of speech perception tests.

	Group, post hoc P value			Time, post hoc P value						Group × time, post hoc P value			F (df)	P value[a]
				Auditory training group			Control group							
	Initial	1 mo	2 mo	Initial minus 1 mo	1 mo minus 2 mo	Initial minus 2 mo	Initial minus 1 mo	1 mo minus 2 mo	Initial minus 2 mo	Initial minus 1 mo	1 mo minus 2 mo	Initial minus 2 mo

[a]Group × time interaction effects compared the initial minus 1 month or initial minus 2 months.

[b]VCIT: Vowel and Consonant Imitation Test.

[c]K-CID: Korean version of Central Institute for the Deaf test (linear mixed model).

Subjective Satisfaction

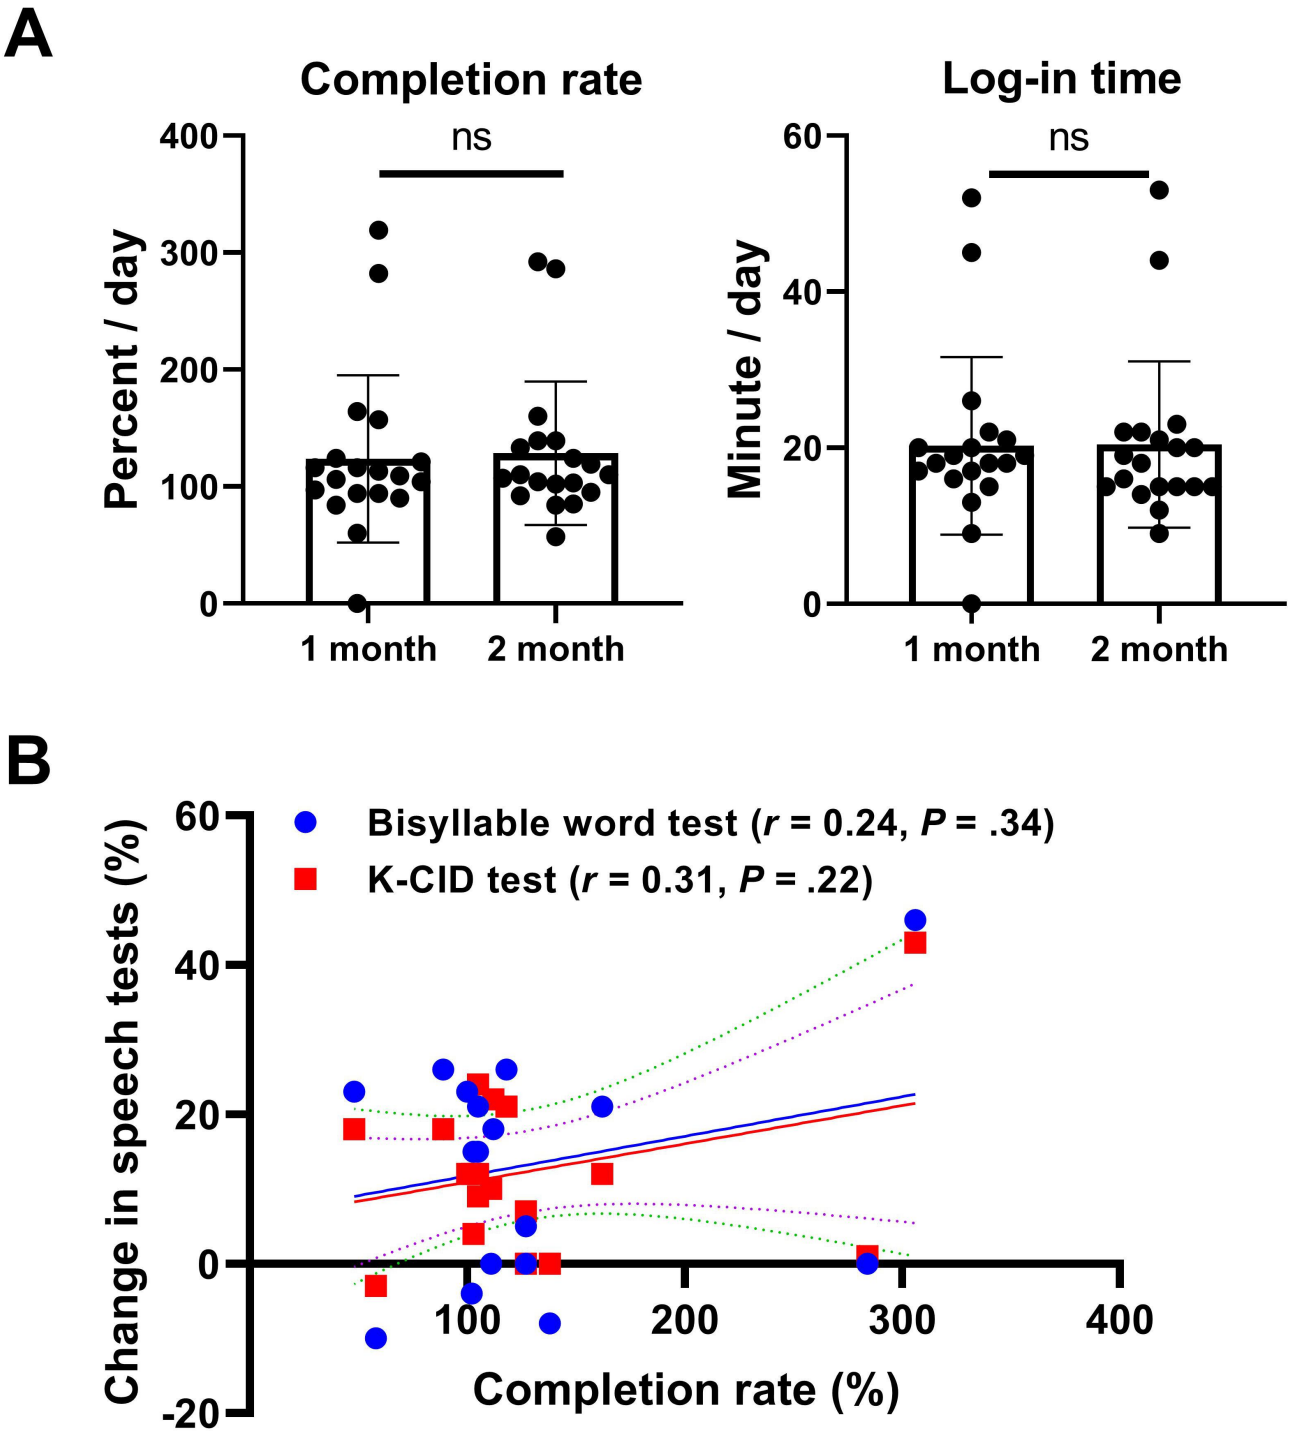
There was no significant difference between the 2 groups in all 3 types of questionnaire surveys (all $P>.05$; linear mixed model). Detailed results are described in Multimedia Appendix 2.

Compliance With CMAT Program

Except for one participant in the ATG who withdrew consent, all participants (n=20) in the intervention group accessed the CMAT program in a mobile environment. One of 20 participants (5%) was excluded from the analysis in this study because the duration of CMAT use was less than 50% of the required AT. The remaining 19 participants (95%) completed at least 50% of the training sessions, and 17 (85%) completed more than the required AT.

Log-in times, completion rates, and scores of all participants were collected by the CMAT program and analyzed. Mean daily application log-in time was 20.3 (SD 11.4) minutes in the first month and 20.4 (SD 10.7) minutes in the second. The completion rate was higher than our recommendation; 123.7% (SD 71.4%) in the first month and 128.5% (SD 61.3%) in the second month. There were no statistically significant differences among these variables ($P=.80$ for completion rate and $P=.50$ for log-in time; Wilcoxon signed rank test) (Figure 5A). The analysis of compliance and speech perception tests revealed no significant correlation (Figure 5B).

Figure 5. Compliance of chatbot-delivered mobile auditory training program and its correlation with speech perception tests. (A) Completion rate (%) and log-in time (min) were similar in the first month and second month (both *P*>.05; Wilcoxon signed rank test; error bars indicate SD). (B) No significant correlations were observed between compliance and speech perception tests (all *P*>.05, Pearson correlation test). K-CID: Korean version of Central Institute for the Deaf.



Discussion

Principal Results

In this study, we developed a new CMAT program in the Korean language, and we confirmed that it was effective in improving speech perception abilities and had high compliance among experienced bilateral HA users.

Our study evaluated speech perception performance at the levels of phoneme, word, and sentence. When the tests were repeated, they all showed improvements in both the ATG and CG. This is a similar finding as our previous report, and it might have been caused by the participants adapting to the test materials [10,30]. Interaction effects implied that compared to the initial time point, at 1 month and 2 months there was a greater performance improvement in the ATG in the bisyllable test and K-CID test. However, no significant findings were observed for the Ling Six Sound test, VCIT, or monosyllable test. The prominent improvement in bisyllable word and sentence perception tests could be explained by the effect of AT having

been achieved only to a limited degree for the trained task. The CMAT program used bisyllable words and sentences, which resulted in marked improvement on the tests assessing the same ability. Several previous studies suggested that the effect of AT appeared only in trained tasks and did not lead to improvements in untrained tasks [21,31,32].

All 3 questionnaires measuring subjective hearing disability and HA satisfaction showed no improvement after 2 months of CMAT, a result that is contrary to our previous study. Our previous study investigated the effectiveness of hospital-based AT and showed significant improvements on the K-IOI-HA and K-HHIE questionnaires in the intervention group [10]. A systematic review suggested that telemedicine has similar feasibility as conventional hearing rehabilitation; however, this review paper was not focused on AT; it focused more on HA fitting, device testing, and counseling [33]. To the best of our knowledge, only 3 comparative studies have been conducted of telemedicine and conventional AT [34-36]. A pilot study comparing the feasibility of tablet-based AT and conventional face-to-face AT in adult cochlear implant recipients reported similar results to our study. Even though tablet-based AT showed better speech improvements in tablet-based training, subjective auditory ability measured by the Oldenburger Inventory-R questionnaire showed partial improvement only in the conventional AT group and not in the teletherapeutic group [36]. The reason why we could not find subjective speech perception improvement in the questionnaire seems to be the lack of interaction between the participants and health care providers, who encourage and reassure patients during each session of conventional AT programs. A relatively short study period might be another reason. A long-term follow-up study or a study with participants who are more exposed to health care providers during CMAT might be needed to support our suggestions in the future.

Of the 20 participants who agreed to CMAT, 17 (85%) completed all or more requested training times, and there was no difference in compliance during the 2-month study. Our completion rate is similar to previous studies [10,37], and it seems that mobile-based AT is easily accessible and that the chat-based interface gives users a more interactive impression [8].

In our study, there was no statistically significant correlation between CMAT compliance and listening performance, which might be due to the high and homogeneous completion rate of an average of 120% of the program in the ATG. However, previous studies suggested that training duration is related to the improvement in listening abilities. A study using the Listening and Communication Enhancement training program in veterans using HAs reported that 84% (42/50) of participants completed the required sessions, and improvement in off-task performance was significantly better in the group of participants who completed all the sessions [38]. Another study examined the use of ReadmyQuips among new HA users and reported a correlation between the words-in-noise test and training time but not between the hearing-in-noise test and training time [39].

Strengths and Limitations

The mobile-based AT program we introduced has several advantages that set it apart from other internet-based AT programs. The first advantage lies in the interface, which features chatting, thus catering to users familiar with mobile messengers and providing a more convenient experience. Simplistic problem-solving might bore users easily, and gamification could come across as juvenile for adult users. Additionally, our interface uses a format in which users chat with a character resembling a medical professional, aiming to give users the impression of receiving remote treatment from experts. The second advantage pertains to the quality and quantity of the provided problems. Other AT programs sometimes present meaningless word lists or scenarios where the sound completely differs from the presented words. However, our CMAT program was designed with the intention of using 1540 frequently used words provided by the National Institute of the Korean Language to offer assistance in users' everyday lives. We aimed to enhance consonant discrimination abilities that are challenging for individuals with hearing impairments by creating problems that categorize cases where the vowels are similar but the consonants differ. Additionally, due to the vast number of questions, each exceeding 1000, participants might not encounter the same question more than once during the 2-month test period.

Nevertheless, CMAT also has its limitations. Recent artificial intelligence (AI)–powered language models like ChatGPT, which enable real-time interactions, were not integrated. The program did not incorporate various user-responsive technologies such as those found in AI-driven tools. Furthermore, additional settings such as background noise or speech speed adjustments were not possible in this version of CMAT. We refrained from including these adjustable settings to maintain the consistency of the training program and avoid introducing bias in the study. However, in the next version, we plan to incorporate features that allow users to adjust the program to their skill level.

From a clinical study perspective, there are several other advantages. Foremost among them is the fact that this is the first well-designed study conducted using a mobile-based AT program using the Korean language. This study also suggests the possibility that AT could be widely applied to the hearing rehabilitation process by showing the effect of AT on users with HA experience, which has been controversial in previous reports [19-21].

However, several limitations that emerged during the course of this study should also be taken into consideration. First, despite the randomization, the high-frequency hearing threshold in the right ear was significantly higher in the ATG than the CG, indicating that the CG score was better in most initial speech perception tests. We considered a subgroup analysis such as participant matching to avoid differences in initial hearing threshold, but we could not conduct such an analysis due to the limitations of a randomized prospective study with a relatively small number of participants. Instead, we tried to minimize unintentional bias by adjusting the 4 kHz threshold of the PTA when analyzing with the linear mixed model; however, there is

a possibility that the effect of CMAT was underestimated due to differences in initial hearing threshold. Further research using a larger number of participants is needed in the future. Second, a 2-month training time and follow-up duration might not be long enough to show the effect of CMAT on all types of hearing performance and subjective satisfaction. Therefore, a future study to evaluate the long-term effects of CMAT with a longer training time is needed. Third, this study was not blinded, and the potential risk of type I error should be considered. Lastly, fitting verification results, such as real-ear measurements, were not included, and data on HA use time during the trial were not included in this analysis. Instead, fitting validation was conducted using sound field tests, and only those who had been using HAs for more than 3 months and for at least 8 hours a day were included in this study. Incorporating more objective fitting verification and HA use time monitoring with data logging would be beneficial in future studies.

Several points for improving this CMAT program can be considered in the future. First and foremost, AI technology can be adapted to enable 2-way interactions between the user and the program. The AI system can generate an almost infinite number of new questions and adjust the question difficulty level based on the user's responses. Additionally, while this study used a chat-based interface for adults, more casual training methods, such as gamified training, could be adopted for pediatric patients with hearing loss.

Conclusions

In this study, we developed a novel mobile-accessible AT program with a chat-based interface and showed that it enhanced speech perception ability in experienced HA users. CMAT seems to increase the accessibility of and compliance to AT, and we expect that it will be used in all stages of the hearing rehabilitation process.

Abstract

Background: Complete documentation of critical care events in the accident and emergency department (AED) is essential. Due to the fast-paced and complex nature of resuscitation cases, missing data is a common issue during emergency situations.

Objective: This study aimed to evaluate the impact of a tablet-based resuscitation record on documentation completeness during medical resuscitations and nurses' perceptions of the use of the tablet app.

Methods: A mixed methods approach was adopted. To collect quantitative data, randomized retrospective reviews of paper-based resuscitation records before implementation of the tablet (Pre-App Paper; n=176), paper-based resuscitation records after implementation of the tablet (Post-App Paper; n=176), and electronic tablet-based resuscitation records (Post-App Electronic; n=176) using a documentation completeness checklist were conducted. The checklist was validated by 4 experts in the emergency medicine field. The content validity index (CVI) was calculated using the scale CVI (S-CVI). The universal agreement S-CVI was 0.822, and the average S-CVI was 0.939. The checklist consisted of the following 5 domains: basic information, vital signs, procedures, investigations, and medications. To collect qualitative data, nurses' perceptions of the app for electronic resuscitation documentation were obtained using individual interviews. Reporting of the qualitative data was guided by Consolidated Criteria for Reporting Qualitative Studies (COREQ) to enhance rigor.

Results: A significantly higher documentation rate in all 5 domains (ie, basic information, vital signs, procedures, investigations, and medications) was present with Post-App Electronic than with Post-App Paper, but there were no significant differences in the 5 domains between Pre-App Paper and Post-App Paper. The qualitative analysis resulted in main categories of "advantages of tablet-based documentation of resuscitation records," "challenges with tablet-based documentation of resuscitation records," and "areas for improvement of tablet-based resuscitation records."

Conclusions: This study demonstrated that higher documentation completion rates are achieved with electronic tablet-based resuscitation records than with traditional paper records. During the transition period, the nurse documenters faced general problems with resuscitation documentation such as multitasking and unique challenges such as software updates and a need to familiarize themselves with the app's layout. Automation should be considered during future app development to improve documentation and redistribute more time for patient care. Nurses should continue to provide feedback on the app's usability and functionality during app refinement to ensure a successful transition and future development of electronic documentation records.

Introduction

Background

The completeness of documentation of critical care events in the accident and emergency department (AED) is essential for (1) the continuity of patient care, (2) medicolegal issues [1], (3) improving accessibility to critical information needed for research [2], and (4) serving as evidence for quality outcome measures [3]. Traditionally, documentation is performed on paper. Due to the fast-paced and complex nature of resuscitation cases, missing data is a common issue during emergency situations. As much as 60% of essential data fields in prehospital paper records can be incomplete [4]. A study in a trauma center also found incompleteness in 18% of the mandatory elements for trauma resuscitation [5].

Over the last 2 decades, there has been a global trend of switching to electronic medical records (EMRs). It was estimated that about 46% of AEDs in the United States used EMRs in 2010 [6]. This percentage is expected to increase in the future. Fully functional EMRs have been shown to improve efficiency in AEDs [7]. Despite the growth in usage, very few studies have explored the impact of EMRs in AED settings. Furthermore, the perceptions toward EMRs are mixed. A study found that nurses and physicians generally had a negative perception toward EMRs in the AED. EMRs are considered to be ineffective, redundant, and prone to error [8]. In contrast, another study found that nurses perceived that their productivity increased and care was better coordinated after implementing EMRs [9].

Among the limited studies in the area, a retrospective review of trauma resuscitations in AED settings showed that EMRs can improve documentation completeness [5,10]. However, there is a lack of studies on medical resuscitations, which are more common than trauma resuscitations [11]. Medical resuscitations are performed on triage category I and II patients with life-threatening conditions such as myocardial infarction, sepsis, and stroke [12]. Medical resuscitations differ from trauma resuscitations in that they do not follow a single protocol. The differences in management protocols can make the process of documenting medical resuscitations different from that of trauma resuscitations.

The EMR system used by the Hospital Authority of Hong Kong is called the Clinical Management System (CMS). It is an integrated platform that allows clinical users to manage the following daily clinical activities [13]: (1) obtain clinical data including consultation notes, laboratory, and imaging results; (2) document clinical activities; and (3) provide clinical decision support.

In AEDs in Hong Kong, medical records are still part paper and part electronic, with the patient's clinical notes being documented on paper. This type of mixed documentation has been shown to hinder effective communication and utilization of information in either record [14].

Recently, there has been a trend of switching to electronic documentation in AEDs. In 2020, 3 of 18 AEDs in Hong Kong had switched to an EMR system called the eAED. It was expected that, by 2023, about two-thirds of AEDs would have switched to the eAED. The eAED is meant to replace paper charts previously used to document a patient's progress [15]. Despite the gradual adoption of EMRs in AEDs in Hong Kong, the use of electronic documentation during medical resuscitations has not occurred owing to the time-critical, fast-paced nature and lack of a suitable application.

However, with advances in computer processing power, a tablet-based system could fill the gap. Documentation efficiency and data precision have improved when a tablet-based app was used, in comparison with a desktop EMR, during a simulation [16]. In Hong Kong, a tablet-based system called "eResus" is being developed by the Hong Kong Hospital Authority for medical and trauma resuscitation documentation. With the implementation of the eAED and eResus, documentation in AEDs would become fully electronic.

Aim and Objectives

This study aimed to evaluate the impact of a tablet-based app on documentation completeness during medical resuscitations. The research questions were the following:

- What are the differences between paper and electronic tablet-based records on the levels of documentation completeness?
- What are the perceptions of emergency room nurses regarding documentation completeness when using eResus?

Hypothesis

This study hypothesized that the completeness of resuscitation documentation using electronic tablet-based records would be higher than that that using paper records.

Methods

Design

To answer research question 1, a randomized retrospective review of paper and electronic resuscitation medical records (N=528) was conducted using a documentation completeness checklist. The study was implemented during the transition from paper to electronic documentation, when only triage category II cases would be documented using the tablet-based app called eResus. Therefore, triage category II records were collected before (from November 2020 to December 2020) and after (from February 2021 to March 2021) implementation of the tablet-based eResus app. Paper records were collected before (Pre-App Paper) and 1 month after (Post-App Paper) implementation of eResus, while electronic records were collected 1 month after (Post-App Electronic) implementation of eResus. We randomly selected 176 records each for the

Pre-App Paper, Post-App Paper, and Post-App Electronic record sets from CMS using a random number generator.

To answer research question 2, emergency nurses' perceptions of the advantages, challenges, and areas for improvement of the electronic app for resuscitation documentation were obtained in individual interviews conducted in mid-April 2021, 3 months after the implementation of eResus. Reporting of the qualitative findings was guided by the Consolidated Criteria for Reporting Qualitative Studies (COREQ) [17], as delineated in the following sections, to enhance rigor.

Ethical Considerations

Ethical clearance (NTWC/REC/20098) from the study hospital and the Human Subjects Ethics Sub-committee of the Hong Kong Polytechnic University (HSEARS20200826001) was obtained before the commencement of the study.

Data

Quantitative Data

A documentation completeness checklist was established based on the literature and a review of the department's current medical resuscitation event documentation. The checklist consisted of 5 essential domains (ie, basic information, vital signs, procedures, investigations, and medications) of medical resuscitation as illustrated in Multimedia Appendix 1. Face and content validity of the checklist were determined by 4 experts in the emergency medicine field [18]. Experts were invited based on the following criteria: (1) worked in an AED and (2) published at least one article related to the accident and emergency field. The expert panel consisted of 1 associate consultant, 1 medical officer, and 2 advanced practice nurses (1 of which was a Fellow in Emergency Nursing). The content validity index (CVI) was calculated using the scale CVI (S-CVI). The S-CVI is calculated based on the number of items in the scale rated by the expert as "quite relevant" or "highly relevant" [19]. The S-CVI was further analyzed by universal agreement (UA) among experts (S-CVI/UA) and the average (S-CVI/Ave). The checklist's S-CVI/UA was 0.822, and the S-CVI/Ave was 0.939.

The medical resuscitation documents were reviewed against the validated checklist by a researcher (CSY), and intrarater reliability was determined to ensure consistency. Intrarater agreement was calculated using the Cohen kappa [19]. We evaluated 5 cases at week 0 and week 2. The agreement between the 2 records was considered acceptable at a κ of 0.884 (95% CI 0.671-1.105; P<.001).

For each resuscitation documentation review, the researcher provided a dichotomous response of "Yes or No" for each item and identified the level of completeness based on the checklist. The patient diagnosis, length of medical resuscitation, initial triage category, and demographics including age and gender were also collected as part of the basic information. However, patient names and identification numbers were not collected. Data were kept anonymous by assigning codes only identifiable to the researcher.

Qualitative Data

Emergency room nurses were guided to discuss their thoughts on the eResus app's features for documentation completeness through individual interviews with an onsite nurse who was one of the researchers (CSY). They understood the aim of the study, and their experience with the app was explored. Participants' demographic data including age, gender, years of experience after graduation, and years of experience in their current specialty were collected for subsequent data analysis.

Sample Size

For the quantitative data, the Chi-square test was used to compare the differences in documentation completeness between the 3 groups. Based on the findings from a level 1 pediatric trauma center in 2015 [10], with an α of .05 and power of 0.80, a minimum sample size of 153 medical records per record set was required. To ensure an adequate sample size, 176 patient records were included in each of the paper and electronic record sets, resulting in a total sample size of 528 records (ie, 176 records each for the Pre-App Paper, Post-App Paper, and Post-App Electronic record sets).

For qualitative data, data saturation is the criterion to determine the sample size. Data are considered saturated when no new theoretical insights are gained from new data [20]. For this study, data saturation was achieved after 10 individual interviews, and 2 more interviews were conducted to confirm the data saturation.

Recruitment

The study was conducted in the AED of 1 hospital in Hong Kong. It is one the major local trauma centers providing 24-hour accident and emergency services and serves more than 190,000 patients per year, with over 300 resuscitation cases per month [21]. The tablet app was scheduled to be implemented in June 2020 but was postponed due to COVID-19. The app was eventually implemented in January 2021.

Quantitative Data Collection Method

In this study, we reviewed 2 types of resuscitation documents, namely paper and tablet-based resuscitation records. Completed resuscitation documents in paper format were attached to the patient's CMS record by optical scanning as per usual practice. These records were stored in the CMS.

Training prior to the implementation of the electronic resuscitation record could lead to bias toward improved completeness of electronic documents [10]. Therefore, paper documentation records were collected before and 1 month after implementation of eResus to address this issue. First, baseline paper resuscitation records were collected prior to implementation of the eResus app (Pre-App Paper). After the implementation of the eResus app with training, there was a washout period of 1 month. After 1 month, the paper (Post-App Paper) and tablet-based (Post-App Electronic) resuscitation records were retrieved for analysis. Both paper and tablet resuscitation records involving trauma team activation or triage category I cases were excluded because the app did not cover these 2 types of cases at this stage.

For the purpose of this study, 3 lists of 3 months of case lists including eligible medical records from the Pre-App Paper, Post-App Paper, and Post-App Electronic record sets were retrospectively generated from the CMS and assigned a serial number. From each group, 176 records were randomly selected using a random number generator.

Qualitative Data Collection Method

In terms of qualitative data collection, purposive sampling was applied. The researcher conducted individual, voice-recorded interviews with each emergency nurse 3 months after the eResus implementation. The nurses were provided an explanation of the study, and written consent was obtained. The inclusion criteria included nurses (1) working in the AED of the hospital, (2) with experience using the eResus app, (3) who spoke Cantonese and were able to read English, and (4) working in their current position for more than 3 months.

Invitation emails were sent to colleagues. Eligible colleagues who replied to the email or expressed interest were invited to be interviewed according to their years of experience. Individual interviews were conducted in a quiet room or via Zoom. Each interview lasted about 1 hour or stopped when the interviewee felt that their viewpoint had been fully expressed. The interview guide is shown in Textbox 1.

Textbox 1. Interview guide.

Opening question:

Can you tell me your experience with using the eResus app until now?

Guiding questions:

1. What are the main advantages and challenges with achieving high documentation completeness when using eResus in the resuscitation room?
2. How do you think eResus can be improved to help you achieve better documentation completeness?

Data Analysis Methods

For the quantitative data analysis, SPSS version 25 (IBM Corp) was used. Descriptive statistics such as means, standard deviations, frequencies, and percentages were used to present the study variables. Normality was tested using the Kolmogorov-Smirnov test, and the data were found to be not normally distributed. The Mann Whitney *U* test was used to compare mean ranks for age and clinical characteristics between the Pre-App Paper and Post-App Paper record sets as well as between the Post-App Paper and Post-App Electronic record sets to ensure the clinical characteristics of the 3 groups were comparable. Subsequently, Chi-square tests were used to compare the differences in proportions, such as the percentage of completeness between the Pre-App Paper and Post-App Paper record sets to determine any historical bias or effect from training and then between the Post-App Paper and Post-App Electronic record sets. Results with a *P* value <.05 were considered significant.

Each resuscitation record was manually reviewed against the study checklist for data element completeness. Each record was reviewed individually. Any incomplete data element was entered as an incomplete domain for the respective domain of the 5 domains, namely basic information, vital signs, procedures, investigations, and medications. For example, for records of the administration of 2 medications that use the same route, the record was treated as 2 separate data entries. If 1 of the data items (such as 1 missing medication name) was incomplete, the medication domain for that case was entered as incomplete. The number of entries for each domain of the resuscitation documentation was analyzed, delineating sections that were recorded at higher or lower frequencies.

For the qualitative data analysis, content analysis was performed [22]. First, the interview was audio-recorded and transcribed verbatim into Chinese. NVivo Pro 12 was used for data analysis. The researcher read through the transcript multiple times to become immersed in the data. Participants' experiences with the eResus app, challenges, and possible solutions were extracted and summarized into meaning units. Third, each meaning unit was condensed and labelled with codes. Fourth, subcategories were identified by comparing the similarities and differences between different codes. Finally, the latent meanings of the subcategories were sorted into themes.

Results

Quantitative Results

Tables 1 and 2 present the characteristics of the 5 domains of resuscitation documentation. Comparisons were made between the Pre-App Paper and Post-App Paper record sets. There were no significant differences in characteristics or documentation completion between the Pre-App Paper and Post-App Paper record sets (Table 3).

Table 1. Comparisons using the Mann-Whitney U test among the 3 resuscitation record sets in patient age; length of resuscitation; and total numbers of vital sign entries, procedures, investigations, and medications in the resuscitation documentation for patients requiring medical resuscitation (N=528).

5 domains	Pre-App Paper record set (n=176)		Post-App Paper record set (n=176)		Difference between Pre-App Paper and Post-App Paper record sets		Post-App Electronic record set (N=176)		Difference between Post-App Paper and Post-App Electronic record sets	
	Range	Mean (SD)	Range	Mean (SD)	*U*	*P* value	Range	Mean (SD)	*U*	*P* value

Total number of vital sign entries	1-58	10.9 (8.0)	2-47	11.1 (7.1)	15,089	.68	2-72	9.9 (7.6)	13,258	.02
Total number of procedures	0-7	1.83 (1.34)	0-8	1.76 (1.26)	15,050	.61	0-10	1.50 (1.12)	13,900	.06
Total number of investigations	0-11	5.72 (1.89)	0-11	5.49 (1.92)	15,091	.67	0-11	5.70 (1.91)	14,741	.42
Total number of medications	0-12	1.65 (2.07)	0-15	1.70 (2.31)	15,085	.66	0-19	1.68 (2.41)	15,288	.83

Table 2. Gender differences among the 3 groups of resuscitation records for patients requiring medical resuscitation (N=528), as assessed using the Chi-square test.

Gender	Pre-App Paper record set (n=176), n (%)	Post-App Paper record set (n=176), n (%)	Post-App Electronic record set (n=176), n (%)	Difference among the groups	
				χ^2 (df)	*P* value
Female	84 (47.7)	84 (47.7)	86 (48.9)	0.06 (2)	.97

Table 3. Differences in completion of the 5 domains of documentation between paper and electronic resuscitation records (N=528).

5 domains	Pre-App Paper record set (n=176), n (%)	Post-App Paper record set (n=176), n (%)	Post-App Electronic record set (n=176), n (%)	Differences among groups	
				χ^2 (df)	*P* value
Basic information	113 (64.2)	105 (59.7)	128 (72.7)	6.86 (2)	<.001
Vital sign	116 (65.9)	108 (61.4)	158 (89.8)	40.97 (2)	<.001
Procedures	123 (69.9)	127 (72.2)	176 (100)	63.50 (2)	<.001
Investigations	101 (57.4)	93 (52.8)	128 (72.7)	16.06 (2)	<.001
Medications	158 (89.8)	163 (92.6)	175 (99.4)	15.24 (2)	<.001

For the post-app comparison, there were no significant differences in the characteristics, except the number of vital sign entries, between the Post-App Paper and Post-App Electronic record sets (Tables 1 and 2). To answer research question 1, there was a significantly higher completion rate for all 5 domains in the Post-App Electronic record set than in Post-App Paper record set (Table 3).

Qualitative Results

Categories

The objective of the qualitative study was to explore nurses' perceptions of the use of eResus for documentation completeness. The main categories identified were "advantages of tablet-based documentation of resuscitation records," "challenges with tablet-based documentation of resuscitation records," and "areas for improvement of tablet-based resuscitation records" (Textbox 2).

Textbox 2. Summary of the categories and subcategories.

Advantages of tablet-based documentation of resuscitation records

- Structural guidance for documentation
- Easy to review and edit documentation
- Comparable mobility to paper and superior to desktop

Challenges with tablet-based documentation of resuscitation records

- System loading speed and stability
- Familiarization with the app layout

Areas for improvement of tablet-based resuscitation records

- Need for speedy documentation and automated documentation

Data saturation was achieved after conducting individual interviews with 12 nurses. The mean age of the participants was 26.9 (SD 2.68) years, and 9 participants were female. Participants' mean length of work experience was 4.46 (SD 2.20) years, with a range of 2.5 years to 8.5 years. Their mean length of work experience in AED was 3.3 (SD 1.87) years, with a range of 1.5 years to 8.5 years.

Advantages of Tablet-Based Documentation of Resuscitation Records

Structural Guidance for Documentation

The electronic app included an extensive database that encompassed the essential aspects of resuscitation documentation. The participants appreciated the app's preset data fields that prompted users to input essential data during documentation.

> *(During documentation of blood glucose,) the interface displayed all the data field such as time, result, performer. You definitely cannot forget to input.* [D168-169]
>
> *(After urinary catheter insertion) I may forget to write urinary output..., but eResus would prompt you if you did not enter.* [H 170-173]
>
> *The application made sure that you have 2 colleagues to countercheck the medication and documented their name before administration.* [C164-165]

The built-in logic set by emergency physicians and nurses provided clinical management support and guidance to users during documentation. Certain data fields were auto filled, saving more time for nursing care.

> *I found it convenient because the application would lead you how to input data in a step-by-step fashion.* [A49]
>
> *After inputting the systolic blood pressure, it would automatically divert you to the diastolic blood pressure.* [C70-71]
>
> *When asystole rhythm was chosen, the data field on blood pressure, pulse etc. would be prohibited from inputting...We no longer have to write "undetectable" over and over again.* [E47-52]

Furthermore, the electronic app reduced the need for verbal order prescriptions and allowed structured electronic prescriptions, which are less prone to error during documentation and administration.

> *Verbal order was prone to miscommunication, distraction, and error in administration.* [C146-147]
>
> *In the past, I would have to remember or write down physician's verbal order..., but now the drug name, dosage, infusion speed etc. would all be on the screen.* [K 41-47]

Easy to Review and Edit Documentation

Medical resuscitation documentation has to be done contemporaneously during resuscitation. Electronic documentation can ensure legibility compared with handwriting, and users were able to review specific aspects of the documentation for completeness using in-app features.

> *Colleagues' handwriting could be illegible; maybe everyone was in a hurry. And colleagues could misspell words, which could affect handover to ward colleagues.* [E22-24]
>
> *Someone may accidently splash alcohol onto the paper chart, and the word would become illegible.* [H209-210]
>
> *The application has a filter function which allows you to choose vital signs, allowing you to review vital sign inputs and trends or procedures, allowing you to review whether you have forgotten to document something.* [K123-125]

Fragmented information was conveyed to the documenter from various sources, in a random sequence. Not all users can correctly recall the exact sequence of medical resuscitation as they document. Electronic documentation allowed the users time to edit the sequence rather than having to rewrite the whole resuscitation event on a new paper resuscitation record.

> *If the handwriting was too ugly and the time sequence is too out of place, such as the medication administration time did not align to the corresponding row, then I would cross out the whole paper chart and rewrite it. But now, eResus can easily amend it.* [I 104-106]

Comparable Mobility to Paper and Superior to Desktop

Patients requiring medical resuscitation would often need to be transferred to another department for investigation or intervention. A tablet app can provide the mobility needed to document in various locations.

> *Let's say the patient has to be escorted to computed tomography (CT). I would take the table to the CT suite (to continue the document). When we returned to the resuscitation bay, I could use the Bluetooth keyboard to continue the document. It's better than desktop.* [L 169-171]
>
> *You can bring it (to CT) like paper...don't even need to bring pen, just use your fingers.* [J 179-180]

Challenges With Tablet-Based Documentation of Resuscitation Records

System Loading Speed and Stability

Participants embraced the transition to electronic documentation. However, participants reported technical challenges due to the internet connection or app coding issues when using the electronic app that could compromise documentation completeness. The fast pace of medical resuscitations and contemporaneous nature of the documentation exacerbated the problem.

> *It has some technical problems...there was a time when it kept crashing and could not input data.* [A58-60]
>
> *Sometimes, switching between different tab pages is rather slow.* [F60]
>
> *The patient was...in asystole, we were conducting chest compression, and administering medication, but the application was still loading.* [I 116-117]

Familiarization With the App Layout

Navigating through the various tab bars, interface, and data fields of the app was different from the paper resuscitation record that presented all the data fields on the same page. Users were required to tab multiple times to access the desired data fields on the tablet, which was more time-consuming. All participants received training prior to using the electronic app in clinical settings. They believed that being familiar with the design of the app takes time and practice:

> *I have to tab this and that before I could input data...if it was handwritten, it would be much quicker.* [H 53-57]
>
> *This application has different tabs and options, which require a bit of thinking...it is like using a phone.* [C33-43]
>
> *When you first encounter the application, you would need to spend time to learn the layout. But after you have become familiar with it, you would find the documentation process very smooth.* [D147-149]

Areas for Improvement of Tablet-Based Resuscitation Records

All participants reported that speed of documentation was an important aspect in resuscitation documentation. During medical resuscitations, the case nurse was required to perform patient care and document contemporaneously. These resuscitation events were highly demanding and required speedy documentation:

> *Sometime, the documentation with eResus could take up lots of time. There were cases when we needed to document lots of medication right at the beginning. The application may not be able to document events in real time.* [A63-64]
>
> *When you have many items pending documentation, you would be naturally prone to incomplete documentation.* [B76-77]

The multitasking nature of the nursing practice posed competing demands between managing patient care and documentation, which required the nurses to compromise. Nurses decreased the frequency of taking vital signs. One participant said:

> *When handling less critical cases...I would take vital signs every 5 minutes (instead of 3) so that I can be more at ease when managing both the patient and documentation.* [D113-117]

Users appreciated the auto retrieval of data from the Hospital Authority's network and the auto fill of relevant fields. Relevant data previously inputted into the app were prepopulated either automatically or after the user's approval:

> *It would auto-capture allergy status from CMS, an electronic health record system used in Hong Kong).* [G 102-103]
>
> *It can retrieve the previous (vital sign) data. Then, I can tab it and paste it onto the data field...such as Glasgow Coma Scale score, etc.* [H 44-46]

Faster documentation speed can improve documentation completeness and overall resuscitation quality. Participants believed that speed and improved care could be gained by automation:

> *If a multimonitor could automatically record vital signs and transfer data into the application, the user would spend less time inputting data and more time looking after the patient...or checking the (resuscitation) record for incompletion.* [D254-262]
>
> *(Automated vital sign recording) would be useful...But some factors could affect the reading's accuracy; it should allow health care workers to verify the readings prior to documenting.* [K 217-220]

Documentation speed can also be gained by flattening the user interface (UI). Participants found that, although organizing data fields into different categories and layers was logical, it made navigating through the layers inevitably slow. A more direct, intuitive UI is needed to improve the speed of data entry:

> *(The commonly used) items should be accessible with one tap.* [G194]

The commonly performed investigations...that has many data fields should be more easily accessible. [L 216-220]

Discussion

Principal Findings

This is the first study, particularly in Asia, to compare the completion rates of documentation between paper and tablet-based resuscitation records in the emergency room. Our results indicate that electronic documentation is promising, with a higher completion rate than with the paper format.

Our study results support the hypothesis that tablet-based documentation of resuscitation records results in a higher documentation completion rate than paper formats in all 5 domains. Previous studies in AED settings have been conducted to compare the completion rates of key data elements for trauma resuscitation records between paper and electronic formats for adult [23] and pediatric [10] trauma cases. Both studies found areas for improvement and degradation in the key data elements. However, it is difficult to directly compare the studies since the outcome measures were different and none of the studies in AED settings used tablet-based devices. Nevertheless, our study results were consistent with those of previous studies that supported that, with electronic resuscitation records, documentation completion rates were higher, particularly of basic information such as case start time and disposal but not for serial vital signs [10,23]. Interestingly, although no difference was found in the completeness of documenting vital signs and interventions in these previous studies, our study showed improvement in the vital signs, procedures, investigations, and medication domains. This may be due to the differences in the inherent design of the EMRs and the use of a tablet-based device instead of desktops, as explained by interview participants. In addition, contrary to the concern of bias for improved documentation completeness caused by training [10], our study showed no statistically significant differences between the Pre-App Paper and Post-App Paper record sets. This indicates that missing data with the paper format could be consistent since the documentation format has not changed (such as using the same paper form).

Our qualitative results further explain the reasons why the tablet-based device could improve documentation completeness. The structural design of the tablet-based resuscitation record provided guidance that contributed to the completeness. This guidance provides support to the documenter via various clinical support features such as structured prescriptions, preset data fields, and preset documentation logic. This structural guidance was developed by consulting local emergency physicians and nurses working in the AED. The guidance mimicked the normal workflow and thus supported the documentation process. Similar results were found in a previous study in which nurses had higher confidence using the EMR when they perceived that their suggestions were used to customize the system [24]. This also implies that the tablet-based device will be considered useful if it is country, institution, and department-specific.

However, similar to other studies, our qualitative findings supported that nurses have to multitask during work, which has been shown to compromise documentation completeness [8]. Furthermore, documentation in an EMR was perceived to be more time-consuming and complex [25]. Our study participants also experienced similar concerns with slow app loading speeds and needing to navigate through various tabbed pages, which increases the complexity of documentation.

Our participants further suggested that future development of the app should include automation features that would spare the documenter from manually inputting individual data into the app. Automating data input can reduce the documenters' need to tab multiple times before finding the desired data field. This would be particularly useful for vital signs, which were the most frequently documented in this study. The UI should be flattened to facilitate input of other common data fields, which supports the concept that data fields that are more frequently recorded should be located in readily accessible spots [26]. With the automation of vital signs and an improved UI, the documenter would be able to spend more time on patient care and document in real time.

Implications for Emergency Room Nurses

Most emergency room nurses believed that the transition from paper to electronic charting can improve the quality of resuscitation documentation and patient safety. This study clearly demonstrates the potential of electronic charting to achieve that. During the transition period, the nurse documenters faced general problems with resuscitation documentation such as multitasking and unique challenges such as software updates and a subsequent need to become familiar with the app's layout. Therefore, systematic, periodic needs assessments of nurse documenters using tablet-based devices, followed by corresponding training, should be conducted. Emergency room nurses should also be actively involved in the development and implementation phases to ensure success in the transition and future development of electronic documentation. Automation functions should be considered during the development of future apps to improve documentation and redistribute more time for patient care.

Limitations

This study has some limitations. It was not able to demonstrate the effect on documentation accuracy, rates of medication errors, the quality of patient care, or the process of clinical decision-making. Furthermore, since the sample was obtained from 1 AED only, the study findings may not be generalizable to other AEDs or other acute ward settings where the staffing and workflow may be different. In addition, this study excluded trauma cases and cardiopulmonary resuscitation cases; thus, its findings cannot be generalized to all resuscitation room situations in the AED.

Conclusions

This study demonstrates that a statistically higher completion rate in 5 domains essential to resuscitation documentation was achieved with a tablet-based device than with the traditional paper resuscitation documentation. Refinement of the device should be ongoing and include consultation with the users. Further studies can expand the scope to involve all medical resuscitation cases across AEDs.

Acknowledgments

We acknowledge all the emergency room nurses who participated in the interviews in this study. This study did not receive any funding.

Abstract

Background: To cope with the rising number of patients with trauma in an already constrained Dutch health care system, Direct Discharge (DD) has been introduced in over 25 hospitals in the Netherlands since 2019. With DD, no routine follow-up appointments are scheduled after the emergency department (ED) visit, and patients are supported through information leaflets, a smartphone app, and a telephone helpline. DD reduces secondary health care use, with comparable patient satisfaction and primary health care use. Currently, little is known about the experiences of in-hospital health care professionals with DD.

Objective: The aim of this study was to explore the experiences of health care professionals with the DD protocol to enhance durable adoption and improve the protocol.

Methods: We conducted a mixed methods study parallel to the implementation of DD in 3 hospitals. Data were collected through a preimplementation survey, a postimplementation survey, and semistructured interviews. Quantitative data were reported descriptively, and qualitative data were reported using thematic analysis. Outcomes included the Bowen feasibility parameters: implementation, acceptability, preliminary efficacy, demand, and applicability. Preimplementation expectations were compared with postimplementation experiences. Health care professionals involved in the daily clinical care of patients with low-complex, stable injuries were eligible for this study.

Results: Of the 217 eligible health care professionals, 128 started the primary survey, 37 completed both surveys (response rate of 17%), and 15 participated in semistructured interviews. Health care professionals expressed satisfaction with the DD protocol (median 7.8, IQR 6.8-8.9) on a 10-point scale, with 82% (30/37) of participants noting improved information quality and uniformity and 73% (27/37) of patients perceiving reduced outpatient follow-up and imaging. DD was perceived as safe by 79% (28/37) of participants in its current form, but a feedback system to reassure health care professionals that patients had recovered adequately was suggested to improve DD. The introduction of DD had varying effects on workload and job satisfaction among different occupations. Health care professionals expressed intentions to continue using DD due to increased efficiency, patient empowerment, and self-management.

Conclusions: Health care professionals perceive DD as an acceptable, applicable, safe, and efficacious alternative to traditional treatment. A numerical in-app feedback system (eg, in-app communication tools or recovery scores) could alleviate health care professionals' concerns about adequate recovery and further improve DD protocols. DD can reduce health care use, which is

important in times of constrained resources. Nonetheless, both advantages and disadvantages should be considered while evaluating this type of treatment. In the future, clinicians and policy makers can use these insights to further optimize and implement DD in clinical practice and guidelines.

Introduction

The global increase in the number of patients with trauma presents a major challenge to the already strained health care systems [1,2]. To achieve more sustainable health care, digital alternatives to face-to-face outpatient follow-up have been introduced as a supported strategy [3-5]. These alternatives, also known as "eHealth," are defined by Eysenbach [6] as the intersection of medical informatics, public health, and business, referring to health services and information delivered or enhanced through the internet and related technologies. In a broader sense, the term characterizes not only a technical development but also a state of mind; a way of thinking; an attitude; and a commitment to networked, global thinking to improve health care locally, regionally, and worldwide by using information and communication technology.

Based on a British example, a Dutch teaching hospital implemented the Direct Discharge (DD) protocol to maintain the quality of care for patients with trauma in 2019 [7,8]. The DD protocol involves discharging patients from the emergency department (ED) without scheduled follow-up while providing patients with information through a self-care mobile eHealth app. DD significantly reduces secondary health care use (SHU) with similar levels of patient satisfaction and primary health care use (PHU) [9-11]. Based on these results and catalyzed by the COVID-19 pandemic, over 25 Dutch hospitals have implemented this protocol since 2019 [12].

The successful and sustainable adoption of digital health technology is complex and influenced by various factors at organizational, technological, and social levels [13,14]. This complexity is widely recognized in eHealth and eHealth evaluation frameworks [15-17]. The organizational and logistic benefits and patient satisfaction scores following DD have been well described in the literature [18-20]. However, the social aspects of the DD protocol for health care professionals remain underreported [21]. An in-depth exploration is warranted to better understand the adoption of the DD protocol within its social context, including insight into the experiences of stakeholders. The aim of this study was to explore the experiences of health care professionals with the DD protocol parallel to the implementation of this protocol in 3 Dutch hospitals to enhance durable adoption and improve the protocol.

Methods

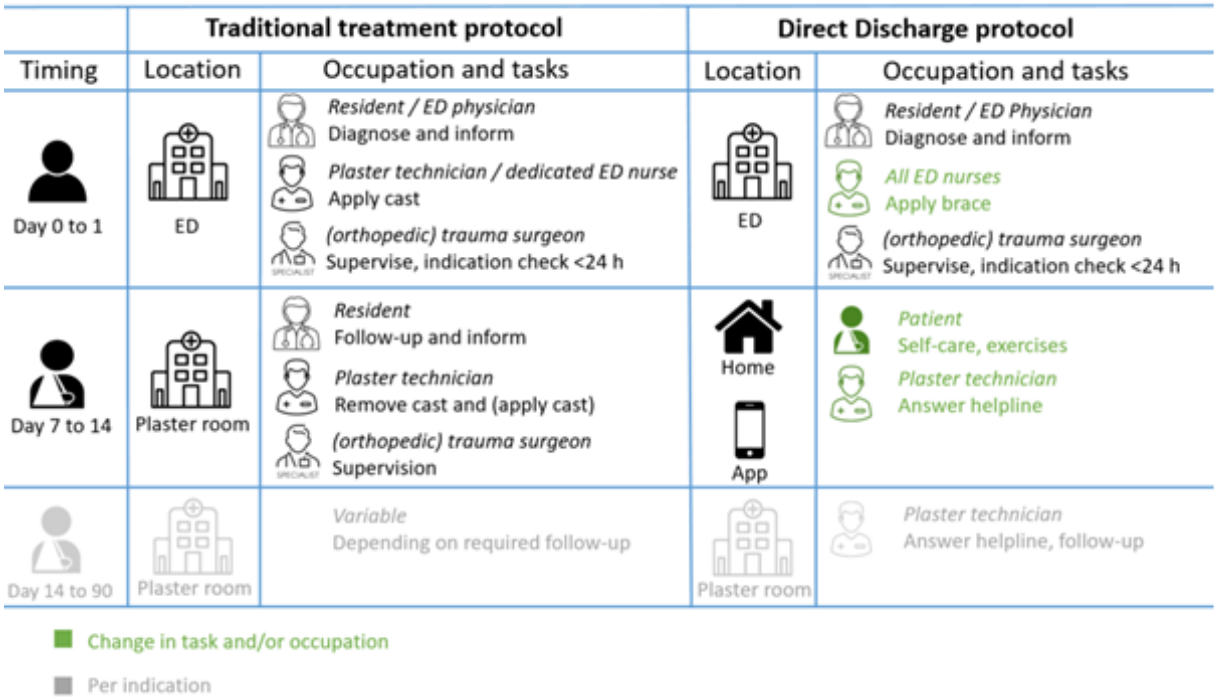
Design

An observational mixed methods study was conducted among health care professionals from August 2021 to June 2022, parallel to the implementation of DD in 3 hospitals. Both quantitative and qualitative data were collected and analyzed separately by a quantitative team (GW and JS) and a qualitative team (WDL and Elke Mathijssen). The Bowen feasibility framework was used to organize both data sources with the following parameters: implementation, acceptability, preliminary efficacy, demand, and applicability [22]. After separate analyses, quantitative and qualitative data were triangulated with the Pillar Integration Process [23]. This study was reported according to the Good Reporting on a Mixed Methods Study (GRAMMS) criteria (Multimedia Appendix 1) [24].

Context

The 3 participating centers were urban, level-2 trauma centers with up to 3 locations per hospital, treating between 1200 and 1800 patients with low-complex traumatic musculoskeletal injuries annually. Each center had a similar size and structure. All centers consisted of 3 locations, with 1 large location focusing on low-to-high complex traumatic injuries and having an ED with more rooms compared with the other locations. The 2 other locations were smaller and had no particular focus on patients with trauma, but they treated low-complex patients with trauma if they sought care at these locations. Per center, all 3 locations have 1 team taking care of all patients. These teams consisted of (orthopedic) trauma surgeons, residents, plaster technicians, ED physicians, and ED nurses. In total, 217 eligible health care professionals were exposed to DD based on data provided by participating hospitals. Changes in tasks per health care professional are described in Figure 1. These changes apply per center, including all 3 hospitals per center. The variance in the number of employees was correlated with the size of the hospital. The 2 centers implemented DD in September 2021 and 1 in March 2022.

Figure 1. Treatment protocols before and after implementation of DD and changes in location, involved stakeholders and tasks. DD: Direct Discharge; ED: emergency department.



Traditional Treatment

Before DD was implemented, patients were treated according to the local trauma protocols. These protocols consisted of immobilization or support with either a cast, sling, bandage, or splint and brief information about the injury at the ED. At least 1 outpatient follow-up appointment was scheduled at the plaster room or in the outpatient clinic within 2 weeks after the injury for review, extensive information, and definitive management planning.

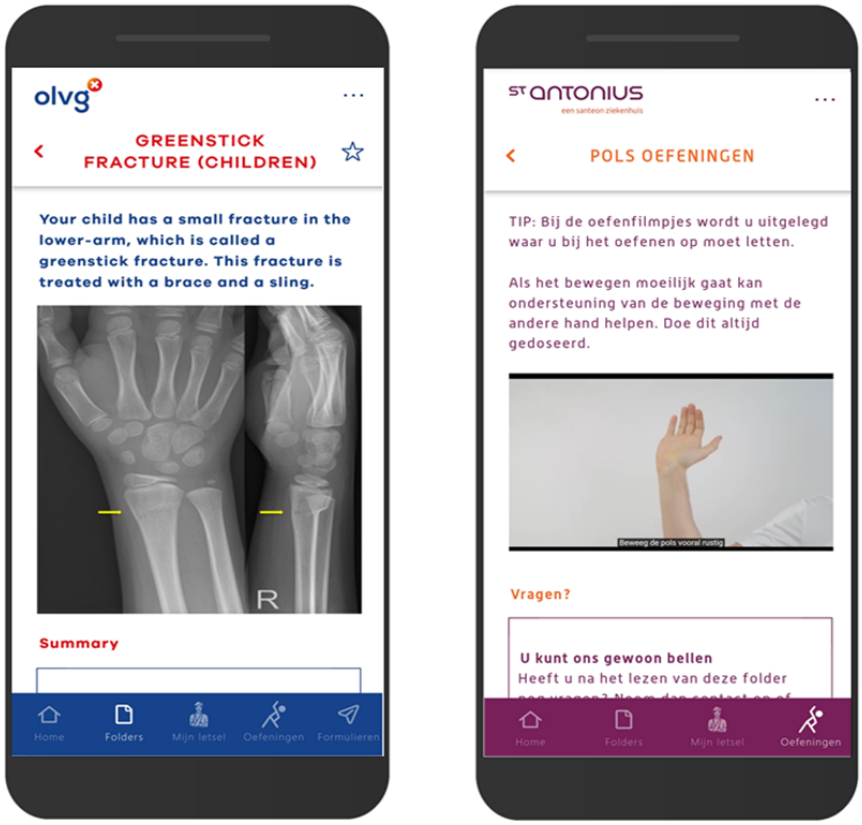
Direct Discharge Protocol

This protocol was derived from the British model of a Virtual Fracture Clinic (VFC) and adapted to the Dutch health care setting in 2019 [25]. In its Dutch adaptation, DD includes 11 treatment protocols for low-complex, stable traumatic orthopedic injuries with additional injury-related criteria (Multimedia Appendix 2) [25]. If patients met the injury-related inclusion criteria in Multimedia Appendix 2 and spoke Dutch or English fluently, they were included; no further predefined restrictions (eg, age or comorbidity) were used. Patients were excluded from the protocol at the ED if they had initial treatment in another hospital; follow-up in another hospital (eg, closer to home); multiple injuries; a reason for follow-up other than the injury (eg, social-care reasons); an eye-, motor-, or verbal-score <15 at presentation; or intoxication. With DD, patients were discharged directly from the ED without routine outpatient follow-up. They received a removable orthosis or a sling (eg, brace instead of a cast) and extensive information at the ED, summarized in a mobile self-care app (the VFC app). Patient eligibility for the protocol was re-evaluated on the next workday (within 24 hours) by a team consisting of an (orthopedic) trauma surgeon and a radiologist. If patients were incorrectly discharged directly based on the injury-related or social inclusion criteria during the second review the next day, then they were contacted by phone and scheduled for a face-to-face appointment. This re-evaluation was a standard procedure in both protocols and was used to check previous decisions of young doctors by a senior group of medical professionals based on the radiographs and electronic patient record.

The VFC App

The VFC app provides self-care assistance through information, videos, and a helpline and can be downloaded for free at the Google Play Store and iOS App Store (Figure 2). Injury-specific leaflets with recovery information, treatment rules, and red flags were included. Furthermore, frequently asked questions, audiovisual exercise, immobilization, and analgesic instructions were included to assist patients. If patients required human contact in addition to the information, a helpline by phone operated by a health care professional was available during working hours. The VFC app aimed to increase self-management and self-care during recovery and to substitute face-to-face follow-up.

Figure 2. English and Dutch in-app screenshots of the Virtual Fracture Clinic app used in the Direct Discharge protocol.



Implementation Tools and Materials

Interested centers contacted 1 of the trauma surgeons or the main email address of the initiating Onze Lieve Vrouwe Gasthuis (OLVG) Hospital, Amsterdam, the Netherlands. The OLVG Hospital created several tools to assist the implementation in other hospitals. The tools were created to streamline the implementation process as hospitals had similar questions during implementation and medical doctors struggled with the implementation of eHealth in their daily practice, partly due to inexperience with implementation and accompanying barriers and facilitators. These tools consisted of an email address that health care professionals could contact, an implementation guide, a digital PowerPoint presentation with an overview of the concept, and an information set with standardized information. This information set included posters, pocket cards, training guides, smart phrases for electronic patient records, standardized discharge letters, and a tool to personalize the layout of the VFC app. Participating centers started implementation preparations 3 months before the actual start of DD as the standard of care. Based on the experiences of the implementation in previous centers, 3 months was considered a sufficient amount of time to implement DD. There were minor differences between hospitals to optimize local fit (eg, the available hours of the staffed helpline).

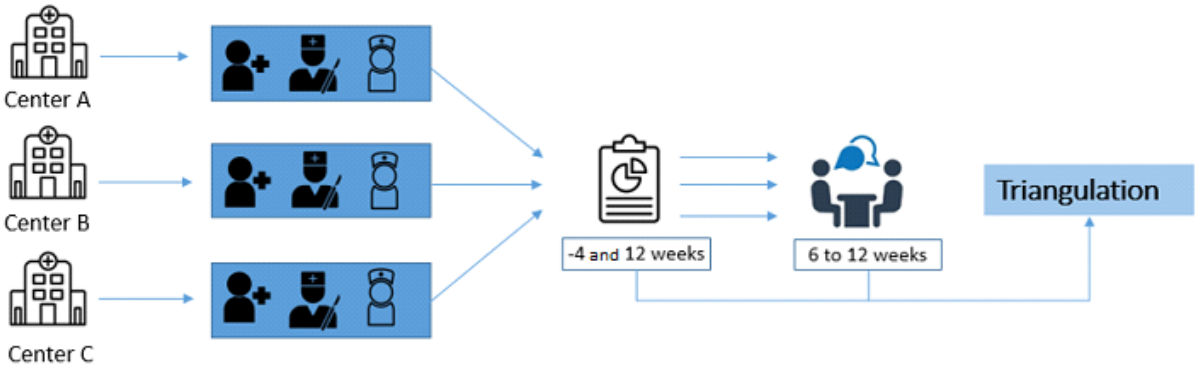
Study Population

Health care professionals involved in the in-hospital treatment of patients with eligible low-complex, stable traumatic orthopedic injuries on a daily basis were included in this study (Figure 1). Health care professionals were excluded from the final analysis if they did not provide the correct contact details or did not complete both surveys.

Sampling and Recruitment

A total of 4 weeks before the implementation of DD, the 217 potentially eligible health care professionals were asked to participate in the study through education moments, e-learnings, and by email. The health care professionals were given a survey distribution link by email to a preimplementation survey in Research Electronic Data Capture (REDCap; Vanderbilt University), a digital survey system [26]. Potentially eligible participants were remembered twice, 1 week after the initial email. Participants were excluded if they did not complete both surveys or if they did not provide any contact details to send the second survey to. Within the survey, consent for an additional semistructured interview was asked. Age, sex, occupation, medical specialty, and hospital were used to select a purposive sample among health care professionals who consented. During sample selection for the interviews, ED nurses and plaster technicians were underrepresented. Through an open call, nonresponders were recruited through email, after which the definitive sample was selected. Eligible health care professionals were contacted to schedule a web-based, semistructured interview. Health care professionals were reminded through email to complete the survey. The second survey was sent 3 months after the implementation of the DD protocol (Figure 3). We aimed to collect completed quantitative data from 100 health care professionals and qualitative data from 15 health care professionals.

Figure 3. Summary of hospitals, procedures, and models used to evaluate the Direct Discharge protocol among health care professionals. All centers consisted of 3 hospitals with similar teams and similar sizes.



Data Collection

Data were collected from surveys and semistructured interviews.

Surveys

A total of 2 surveys, a preimplementation survey and a postimplementation survey (Multimedia Appendix 3), with 46 questions, including close-ended questions, multiple-choice questions, 5-point Likert scales, visual analogue scales, and free-text questions, measured 5 Bowen feasibility parameters. As no golden standard for the evaluation of innovations exists, the surveys and topic list were developed by 4 researchers (JS, GW, BT, and TG) and checked by 2 experts on relevance: a professor in trauma surgery (CG) and an associate professor in process evaluations of health care innovations (Jaap Trappenburg). We pretested the survey with 5 health care professionals to improve clarity. After data collection, the preimplementation expectations were compared with the postimplementation experiences.

Semistructured Interviews

A total of 2 independent researchers from "The Healthcare Innovation Centre," not involved in daily clinical practice or the VFC research team, conducted digital semistructured interviews to minimize social-desirability bias. The web-based interviews were held at least 8-12 weeks after the implementation of DD to warrant an optimal recall. The interviews were guided by a topic list based on literature, including the previously mentioned Bowen feasibility parameters (Multimedia Appendix 4). The research team piloted the topic list for clarity and completeness and modified it during data collection. A pragmatic choice was made to interview 5 different types of health care professionals from each participating center, which was deemed sufficient to get a good understanding of the experiences of health care professionals and to reach saturation. No new themes were identified in the last step of the analysis, indicating that saturation was reached.

Data Analysis

Quantitative Data

Quantitative data were analyzed using SPSS (version 27; IBM Corporation) [27]. Baseline characteristics and outcomes were reported descriptively using numbers and proportions for categorical variables and mean (SD) or median (IQR) for continuous variables as appropriate. The normal distribution of continuous data was assessed with a visual analysis of boxplots. The paired 2-tailed *t* test or Mann-Whitney *U* test was used to determine the statistical significance of parametric variables for normally and nonnormally distributed data, respectively.

Qualitative Data

Qualitative data were analyzed using an inductive approach. Data analysis started after the first 5 interviews. Interviews were audiotaped, summarized, and analyzed using NVivo (version 12; QSR International) [28]. A total of 2 researchers (WDL and Elke Mathijssen) used inductive analysis with methods to ensure reliability and validity [29,30]. The data was independently analyzed by 1 researcher (WDL), and another researcher (Elke Mathijssen) reviewed the analysis. Discrepancies and remarks were discussed until they reached a consensus about the interpretations of the data. Memos were made to track research decisions during analysis. Code saturation was reached when no new categories or themes emerged from the new raw data [31]. We considered 15 interviews sufficient to reach saturation and get a good understanding of the experiences of professionals. Therefore, the number of interviews was limited by a pragmatic choice of available time. The final themes were used to describe the value and feasibility of DD from the perspective of involved health care professionals.

Triangulation

After the separate quantitative and qualitative analyses, the findings were triangulated with a simplified approach of the Pillar Integration Process technique [23]. This approach uses a transparent and rigorous 4-stage technique for integrating and presenting qualitative and quantitative findings in a joint display (Microsoft Excel, 2018; Microsoft Corporation) [32]. A researcher (JS) presented the quantitative findings per study parameter, and another presented the qualitative findings (WDL). Dissimilarities and self-contained themes were objectified. These themes were merged by 1 of the researchers (Elke Mathijssen) into a meaningful narrative (the pillar), which was reviewed by 2 researchers (JS and WDL).

Patient and Public Involvement

Patients or health care professionals were not involved in the design, intervention, research question, or outcome measures of this study.

Ethical Considerations

This study, including the process analysis, was reviewed and approved by the Medical Ethical Committee of Utrecht, Netherlands (W21.261).

Patients provided consent for participation in the research, and could opt out at any time after request by e-mail. The original consent or IRB approval covers secondary analysis without additional consent. Data is de-identified. A data key is stored at the local hospitals in a secured map and coded file. This is only accessible to JS and GW. The accessible data has been de-identified as far as possible (e.g., age in years instead of date of birth). Patients received no compensation to participate in this research.

Results

Demographics

Of the 217 estimated eligible health care professionals, 128 started the primary survey, 42 did not complete the primary survey, and 49 did not complete both surveys (Figure 4). Of the 37 included health care professionals (response rate of 17%), 23 (62%) were female, and the median age was 38 (IQR 32-45) years. Current occupations were medical specialists (14/37, 38%), residents (14/37, 38%), plaster technicians (7/37, 19%), and ED nurses (2/37, 5%; Table 1). The baseline characteristics of health care professionals who solely filled out the primary surveys did not vary statistically significantly in age (P=.98) or sex (P=.28) as compared to those who filled out both surveys. A total of 15 health care professionals, 5 per hospital, participated in the web-based, semistructured interviews, of which 60% (9/15) were female.

Figure 4. Flow diagram of the included health care professionals in the evaluation of the Direct Discharge (DD) protocol.

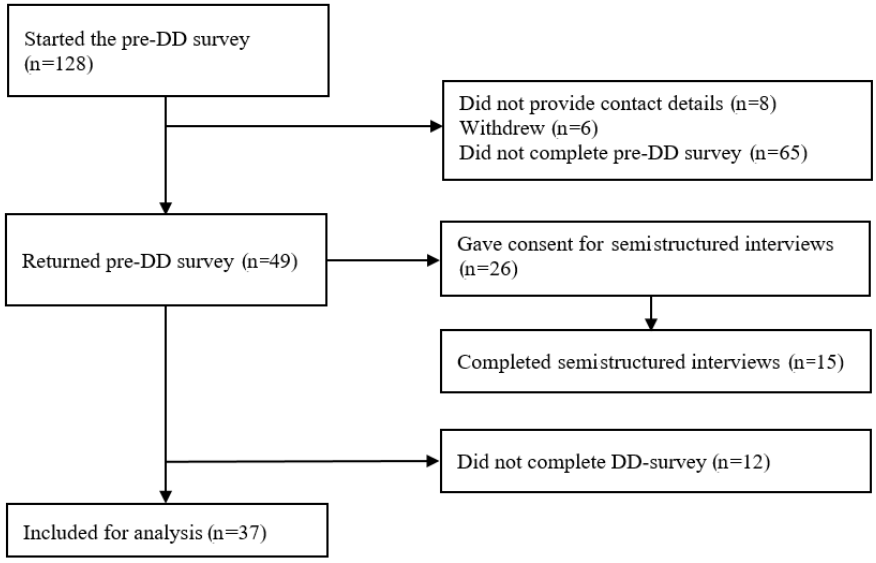


Table 1. Baseline characteristics of health care professionals included in a mixed methods evaluation of Direct Discharge.

Characteristics	Survey (n=37)	Interview (n=15)
Female, n (%)	23 (62)	9 (60)
Age (years), median (IQR)	38 (32-45)	40 (32-44)
Hospital, n (%)		
Hospital A	19 (51)	5 (33)
Hospital B	11 (30)	5 (33)
Hospital C	7 (19)	5 (33)
Current function, n (%)		
Trauma surgeon	5 (13)	3 (20)
Orthopedic surgeon	1 (3)	0 (0)
Emergency physician	8 (22)	2 (13)
Surgery resident in training	8 (22)	3 (20)
Surgery resident not in training	6 (16)	1 (7)
Plaster technician	7 (19)	3 (20)
ED[a] nurse	2 (5)	3 (20)
Total	37 (100)	16 (100)

[a]ED: emergency department.

Implementation

Qualitative data showed that the implementation strategy varied between hospitals and was adjusted to improve the local fit (eg, available hours of the helpline or brace brands). Changes in tasks, immobilization material, and the number of follow-up appointments influenced the implementation experience the most. Some nurses reported that coworkers had difficulties applying the braces, sometimes because their schooling during implementation was suboptimal or delayed, for example, because someone was ill (quote 1 in Table 2). Health care professionals reported that adequate schooling and involvement of the previous responsible health care professional in the implementation process were essential to executing the DD protocol adequately. Mainly because the ED nurse, now responsible for applying the braces, had less experience immobilizing fractures than the plaster technician.

Table 2. Health care professionals' quotes and associated feasibility parameters.

Theme and quote number	Quote	Health care professional
Implementation of Direct Discharge among health care professionals		
1	Some of my colleagues have difficulty with the materials. How does it work and what goes where? It takes a bit longer for some of them to get the hang of it. Having to learn so many new things sometimes causes resistance.	ED[a] nurse
Acceptability of the Direct Discharge among health care professionals		
2	This is a significant improvement for patients and appeals to their autonomy and control, as well as their own influence on the healing process. I believe it is motivating and in line with the current times.	ED nurse
3	I no longer have to do these routine outpatient clinical check-ups. I could only provide limited contributions besides providing information, allowing me to have more peace and tranquility in the clinic. I can use that time for other patients to add more value.	Trauma surgeon
4	Both among doctors and nurses, DD has been widely embraced and well implemented, but for both professions, it requires valuable extra minutes due to additional explanation. Currently, the workload is very high.	Resident
5	But if that care is taken away from us, I do believe that we have a responsibility towards the patients to ensure the proper transition of that care.	Plaster technician
Preliminary efficacy of the Direct Discharge among health care professionals		
6	We now have a tool in our hands to change healthcare without it deteriorating, which convinces people who tended towards over-treatment.	ED physician
7	The quality is not affected, assuming the doctor was already good. It is mainly more efficient. Information provision has improved. It has become more modern. I think DD is not worse, but we're not certain yet.	Trauma surgeon
8	We are sometimes called about 2-3 times per day on the fracture line. I don't think that's a bad score.	Plaster technician
Demand for Direct Discharge among health care professionals		
9	I was already familiar with DD because I was looking for good and reliable information on injuries during my training as an ED nurse. I came across the article published by OLVG and started using the app in my work.	ED nurse
10	Every day, a few patients are treated through the app. I am starting to notice the reduction in daily practice!	Trauma surgeon
11	In my work, it has changed that we see less patients, but new things have also been added. However, we no longer see minor injuries. The easier type of care has decreased a bit.	Plaster technician
Applicability of the Direct Discharge among health care professionals		
12	I see the advantage of a brace instead of a cast, a great improvement. I would also prefer DD myself.	Resident
13	The walking boot is difficult to fit, which poses a risk of misuse. This results in most complications being caused by misuse. What does that do to the recovery process?	ED physician

[a]ED: emergency department.

Acceptability

Overview

Quantitative data showed a median satisfaction with treatment of 7.8 (IQR 6.8-8.9) on a 10-point scale. This finding complemented qualitative data, as most health care professionals were satisfied with DD (quote 2 in Table 2). Health care professionals suggested that in-app patient feedback, such as pain scores or patient-reported outcome measures, could further increase health care professional satisfaction levels and address health care professionals' possible concerns about adequate recovery. Some health care professionals were hesitant about DD due to its novelty, limited education during implementation, changes in work activities, and concerns about the short- and long-term outcomes of certain injuries.

VFC App Acceptability

The introduction of the VFC app at the ED yielded both advantages and disadvantages. Both qualitative and quantitative data showed that introducing the VFC app and treatment information in the ED required more time than the traditional treatment (19/37, 52%; Multimedia Appendix 5). Qualitative data showed that this time decreased once DD was fully implemented but remained longer than traditional treatment. Despite the increased time to inform patients, the perceived reduction in logistics at the outpatient clinic was perceived as more valuable (quotes 3 and 4 in Table 2). Both data sources underline the benefits of the app in terms of uniform, on-demand, and adequate information for patients after discharge. The downsides of the VFC app include less personal health care and the current limited language availability (Dutch and English).

Workload and Job Satisfaction

Qualitative data showed that workload and job satisfaction decreased slightly after the introduction of DD. Quantitative data did not support this, as no statistically significant differences between expectations and experiences were found regarding workload (P=.37) and increased job satisfaction (P=.42). Plaster technicians reported that the introduction of DD has led to losing a "fun" part of their job. Some reported they could provide less service for patients and felt responsible for educating ED nurses who had less experience with the immobilization of fractures compared with them (quote 5 in Table 2).

Preliminary Efficacy

Quality of Care

Quantitative data showed that the quality of care with the DD protocol is perceived as comparable to traditional treatment (25/37, 67%). Health care professionals reported an improvement in the quality of information and uniformity (30/37, 82%; Multimedia Appendix 6). No statistically significant differences were found between expectations and experiences of quality of care (P=.86), quality of information (P=.42), and quantity of information (P=.18). Qualitative data supported these findings, highlighting the benefits of uniform, injury-specific information (quotes 6 and 7 in Table 2). In both the survey and interviews, most (27/37, 73%) health care professionals reported a reduction in outpatient follow-up and injury-related imaging. Qualitative data showed that (orthopedic) trauma surgeons experienced the reduction as beneficial, whereas some plaster technicians experienced the reduction as a disadvantage. Most residents and ED physicians reported that the logistical benefits at the outpatient clinic outweighed the slight increase in time at the ED.

Perceived Safety

Both data sources showed that most (29/37, 79%) health care professionals perceived DD as safe and that sufficient scientific evidence exists to treat patients safely. Health care professionals assumed that patients had fully recovered if they did not contact the hospital again. Nevertheless, they proposed a numerical feedback system in the VFC app to ensure adequate recovery and alleviate concerns about the poor long-term functional outcomes of their patients. The frequency of helpline use was low (≤5 times per week; quote 8 in Table 2). Some residents reported that the introduction of DD decreased their exposure to low-complex traumatic injuries, which might influence their learning curve in the future. Furthermore, the lack of follow-up introduced the tendency for some residents to be more explanatory at the ED. However, some residents stated that during crowding at the ED, they limited their explanation to downloading the VFC app with minimal instructions. The frequency of calling varied per injury, with patients with a greenstick fracture rarely requiring contact. Reasons to call the helpline were similar among the 3 centers. Patient questions were related to a poor recall of the ED visit, suboptimal information provision at the ED, doubts about their recovery, or insufficient reading of the app's content. The daily multidisciplinary radiologic evaluation and helpline were considered effective safety nets.

Demand

Qualitative analysis revealed that some health care professionals had previous knowledge or experience with the DD protocol (quote 9 in Table 2). The COVID-19 pandemic positively influenced their perceptions of digitally assisted care. Some health care professionals reported that it fits the general demand to develop more efficient outpatient follow-up models and that the DD protocol is an example of "tomorrow's health care." Reduced outpatient follow-up, hospital use (eg, treatment rooms or parking lots), and staff were mentioned as benefits. Health care professionals expected the DD protocol to stay and intended to continue using it. Health care professionals reported that the DD protocol could improve patient empowerment and enhance self-management and independence, especially among younger patients. Health care professionals had different experiences integrating the DD protocol into their daily activities. Orthopedic trauma surgeons perceived a decrease in patients at the outpatient clinic following DD implementation and stated that their workload was starting to decrease due to DD (quote 10 in Table 2). Plaster technicians also reported a decrease in patients. However, they perceived this sometimes as a disadvantage as they no longer treated these low-complex injuries, which is considered a loss of a fun part of their job. No reduction in workload was perceived among plaster technicians due to additional tasks and an increase in a patient population with more complex injuries (quote 11 in Table 2).

Residents reported that extensive information has changed from the ED and outpatient clinic to solely the ED. The ED nurses reported applying fewer casts and more orthoses, such as braces or walking boots.

Applicability

Before implementation, some health care professionals expressed concerns about the incorrect use of immobilization materials. However, after implementation, the types of immobilization materials were perceived as adequate, with 74% (27/37) of health care professionals finding the braces easy to use for patients (Multimedia Appendix 7). The braces were less immobilizing than a cast, which was perceived as a benefit (quote 12 in Table 2). The less immobilizing treatment regimens could result in an earlier return to full function. However, some were concerned that the braces could lead to inferior long-term functional outcomes, even though the scientific evidence for these concerns was lacking (quote 13 in Table 2).

Discussion

Principal Findings

Dutch health care professionals considered the DD protocol a safe and satisfactory alternative to traditional treatment, leading to a perceived decrease in SHU. Although providing information with DD required more (explanation) time for residents and physicians at the ED, the logistical benefits (ie, reduced number of follow-up appointments) outweighed the slight increase in time. Before and after implementation, no statistically significant differences were found regarding workload or job satisfaction.

However, qualitative data reported benefits in workload and job satisfaction for trauma surgeons and residents, and disadvantages for some plaster technicians in terms of job satisfaction and workload. Furthermore, health care professionals reported increased quality of information and comparable quality of care. Almost all health care professionals would like to continue using DD after implementation. To improve DD, several new app functionalities were suggested, and the earlier involvement of stakeholders who performed new tasks was suggested.

Comparison With Existing Literature

The study results show that DD is an acceptable alternative to traditional follow-up for health care professionals. Health care professionals reported similar, high satisfaction scores with treatment as previously reported patient satisfaction scores for similar protocols [18,33]. To further improve health care professionals' satisfaction scores, health care professionals in this study suggested a short numerical feedback system to monitor injury recovery remotely (eg, recovery questions after 3 months). In the literature, health care professionals have also mentioned this as an important feature of eHealth developed for patients with musculoskeletal injuries [34,35]. A challenge to incorporating this is that these functions would require a more enhanced app that complies with current laws and regulations for data storage and requires substantial financial investment. In addition, this request might also be a sign of early-stage adoption, where health care professionals feel a bit uncertain about the patients they would normally see for follow-up but who are now out of sight. As time progresses, it seems likely they will feel more comfortable not seeing these patients anymore, as this is then considered standard of care.

Preliminary efficacy was partly in line with the literature [18,20,33]. Most health care professionals considered DD a safe alternative to face-to-face follow-up, leading to a perceived reduction of SHU. This finding is consistent with previous articles, which concluded that DD is safe based on low, comparable complication numbers, with significantly reduced SHU compared to traditional treatment [9,18,33]. The perceived reduction in SHU varied among stakeholders. The reduction was perceived as most beneficial in qualitative data regarding workload for (orthopedic) trauma surgeons and least beneficial for plaster technicians, as they enjoyed this particular part of their workload. This study has been unable to demonstrate statistically significant differences regarding workload and job satisfaction before and after implementation. Even though the introduction of DD at the ED increased valuable treatment time for some stakeholders, which decreased but remained longer after implementation, almost all reported that the benefits of less SHU outweighed this downside. These findings are interesting, as the increase in time has been reported as one of the most important personal barriers to implementing and adopting eHealth but was not reported as an important disadvantage in this study [14,35].

Similar quality of care and increased quality of information after the introduction of DD are in accordance with earlier findings [11,20,36]. Particular advantages of DD were uniform, injury-specific, and on-demand information, consistent with a study pointing out the current heterogeneity in treatments for these injuries and the demand for uniform treatment [37]. The disadvantages of DD were the care being less personal, the loss of care activities for several stakeholders, and the inability to monitor recovery. A previous study described that VFCs might influence learning curves as residents become less experienced with the follow-up and full recovery of these injuries [38]. This was not supported by our results. However, a lack of follow-up has led to a tendency for some (often inexperienced) residents to be more explanatory at the ED to ensure the patient had received all information during the only contact moment. To reassure themselves and identify the small group of patients with persistent complaints, some health care professionals suggested a feedback system to ensure they had recovered adequately. Such a system should not increase workload but only filter patients with remaining questions, pain, or complications. This should be developed with patients and health care professionals and could contain anchor-based questions or patient-reported outcome measures with predefined cut-off values.

Health care professionals report that DD fits the public demand to develop more efficient (outpatient) care, and digital assistance could help deal with constrained resources. This partly aligns with the literature, as attitudes toward the usefulness of eHealth vary [39-41]. Almost all health care professionals would like to continue using DD after its implementation. This finding complements current literature showing the widespread implementation of DD protocols and VFCs in the United Kingdom, Australia, New Zealand, and India [8,33,42,43]. This further strengthens the idea of at least adequate acceptance and the general applicability of this concept in different countries. The applicability of DD varied among stakeholders and was influenced by the increase or loss of tasks after implementation of the protocol and their experience with that particular increase or loss of tasks. Even though evaluation of applicability for health care professionals and health care professional satisfaction with the protocol seems vital to determining feasibility, it has not been reported previously for DD protocols, despite the many centers that have implemented similar protocols. Health care professionals reported that early stakeholder involvement during implementation could be beneficial to cope with the changes in tasks and transfer of knowledge, which aligned with the results of Logishetty [21] reporting the importance of early stakeholder involvement during VFC implementation in a quality improvement approach. The lack of early involvement of stakeholders and limited feasibility among health care professionals are known risks for nonadoption or abandonment [3,44,45].

Strengths and Limitations

This study has several strengths. To date, this is the first study to explore the in-depth views of several stakeholders involved in DD protocols and VFCs. The COVID-19 pandemic has accelerated the implementation of DD in the Netherlands, emphasizing the demand for a shift in patient care, where eHealth alternatives have become the new standard [46]. The views and perceptions of health care professionals about different eHealth services are valuable to further tailor these services to their needs and preferences. A second strength of

this study is the multidisciplinary involvement of the research team during evaluation and analysis. This approach ensured that the data were analyzed from all possible angles. A third strength is a mixed methods approach to evaluating DD because the separate collection of both data sources combined with the triangulation increased the likelihood of our results being a realistic representation of the daily clinical activities of the involved health care professionals. The fourth strength is the use of a validated framework to evaluate DD, which allowed for a structured insight into each feasibility parameter. The fifth strength was the heterogeneity in the sizes and locations of the three study sites. This allowed us to investigate the applicability within different types of hospitals.

This study also has limitations that need to be addressed. The first limitation is the small quantitative sample size and low response rate. Even though the response rate among health care professionals is 10% to 15% lower compared to patient studies, the quantitative sample size remains limited [47]. Nevertheless, for almost all parameters, quantitative and qualitative data were similar, indicating a realistic response from most health care professionals. A third limitation is that ED nurses were not involved in the initial design of this study and did not provide quantitative data. Nevertheless, they have been included in the qualitative data to strengthen the study results.

Implications for Clinicians and Policy Makers and Future Perspectives

DD protocols reduce SHU without negatively influencing PHU, satisfaction, complications, or functional outcomes [17]. By assisting patients through the VFC app, they can receive care at home, potentially reducing health care costs [9]. Health care costs in the Netherlands have increased drastically, particularly due to specialized in-hospital care. In addition, there is a growing shortage of personnel. Digitally assisted solutions are suggested to cope with the rise of these costs and limited personnel, but implementation remains difficult [14]. The technical (eg, compliance and complication numbers) and logistic outcomes of this concept are well explored, but the social and cultural elements of DDs have not been explored. These findings help optimize future implementation strategies for eHealth in orthopedic and trauma surgery by providing preconditions and learning lessons such as early stakeholder involvement. These findings might be generalizable for other short treatment processes in other (surgical) departments with high volumes of relatively low-complex surgical patients (eg, low-complex dermatology or otorhinolaryngology).

As DD is introduced rapidly to cope with constrained financial and human resources and health care professionals expect DD to stay, a thorough evaluation of caregivers and patients is essential to ensuring sustainable adoption. Results of this study have improved our DD protocol and have led to 2 corresponding major points of improvement among all stakeholders and many points of improvement, such as ideas for illustrations, adjusted language (levels), and adjustable font size from 1 or more health care professionals. Future studies should focus on co-designing numerical feedback with patients and health care professionals. Furthermore, a thorough evaluation of patient perspectives should be performed to gain insight into the end users' perspective on this innovation. Particularly to investigate the potential link between different levels of literacy (health literacy, digital literacy, and literacy) and health equity, as suggested in previous studies [48,49].

Conclusion

Health care professionals perceive DD as an acceptable, applicable, safe, and efficacious alternative to traditional treatment. A short numerical feedback system could alleviate concerns about a full recovery and further improve DD protocols. DD can reduce SHU, which is important in times of constrained resources. Nonetheless, both advantages and disadvantages should be considered while evaluating this type of protocol. In the future, clinicians and policy makers can use these insights to further optimize and implement DD and VFC in clinical practice and guidelines.

Conflicts of Interest

The institutions of the authors affiliated with St Antonius Hospital and Onze Lieve Vrouwe Gasthuis (OLVG) Hospital have received funding to support this work through an unrestricted grant from the Dutch organization for health care sciences and health care innovation, ZonMw, the Hague, Netherlands (516012524).

Abstract

Background: Obsessive-compulsive disorder (OCD) is a disabling disorder associated with high interference in people's lives. However, patients with OCD either do not seek help or delay seeking help. Research suggests that this could be explained by poor mental health literacy about the disorder and the associated stigma.

Objective: This study aims to evaluate the feasibility, acceptability, and preliminary effectiveness of a mental health mobile app, esTOCma, developed to improve knowledge about OCD and its treatment, increase help-seeking intention, and reduce stigmatizing attitudes and social distance associated with OCD.

Methods: We used preintervention, postintervention, and 3-month follow-up assessments in this single-arm pilot intervention. Overall, 90 participants were recruited from the community using the snowball sampling method. We used esTOCma to defeat the "stigma monster" over the course of 10 missions. The participants completed the sociodemographic information and Obsessive-Compulsive Inventory–Revised at preassessment and an acceptability questionnaire at postassessment. All other measures were completed at the preassessment, postassessment, and 3-month follow-up (ie, the Spanish Mental Illness Stigma Attribution Questionnaire–27, the General Help-Seeking Questionnaire, the Social Distance Scale, and the Mental Health Literacy Questionnaire).

Results: Of the 90 participants from the community that were assessed for eligibility, 86% (n=78) were allocated to intervention. Of these 78 participants, 79% (n=62) completed the game and answered the postintervention assessment (completer group). Overall, 69% (43/62) of the participants also completed the 3-month follow-up assessment. The participants completing the study were older (P=.003) and had a higher baseline knowledge of OCD (P=.05). The participants took an average of 13.64 (SD 10.50) days to complete the intervention, including the pre- and postassessments. The participants spent an average of 4.56 (SD 3.33) days completing the 10 missions included in the app. Each mission took a mean of between 2 (SD 3.01) and 9.35 (SD 3.06) minutes. The app was rated as useful or very useful by the vast majority of participants 90% (56/62). Moreover, 90% (56/62) of the participants reported that they had learned or learned a lot, and 98% (61/62) of the participants reported that they would recommend the app to a friend. Repeated measures ANOVA (43/62, 69%) showed that after the intervention participants showed an increased knowledge of mental health and intention to seek help as well as fewer stigmatizing attitudes and less social distance.

Conclusions: Preliminary data show that esTOCma is a feasible and acceptable app, and after completing its 10 missions, there is an increase in the understanding of OCD and help-seeking intention along with a decrease in the social stigma and social distance associated with OCD that lasts for at least 3 months. The results support the potential of technology-based interventions to increase the intention to seek help and reduce the stigma associated with OCD. A larger, community-controlled study is also recommended.

Introduction

Background

Obsessive-compulsive disorder (OCD) is a clinically heterogeneous condition characterized by obsessions, compulsions or both that cause clinically significant levels of distress or functional impairment [1,2]. At present, effective treatments exist for OCD [3,4]; however, many people delay seeking treatment [5,6], and this may contribute to its chronic course [7,8]. Research suggests that this delay in seeking treatment by patients with OCD may be explained by social stigma and poor mental health literacy (MHL) about the disorder [5,9,10].

To date, many interventions have proved to be effective in reducing stigma associated with mental disorders, producing knowledge, and achieving attitudinal improvements [11-13]. Data show that contact and education strategies produce small-to-medium short-term reductions in stigmatizing attitudes, and there is limited evidence on long-term effectiveness [14,15]. A few of these interventions have benefited from the advantages of new technologies (eg, video games and electronic contact with patients), showing medium effects on reducing social stigma and suggesting that new technologies are a useful tool to decrease stigmatizing attitudes toward mental disorders, at least in the young population (the mean age of participants ranged between 15.7 and 24 years) [16]. However, none of these studies have examined the benefits of using app-based interventions. Furthermore, most of these interventions have focused on reducing the stigma of mental disorders such as schizophrenia [17-19], depression [20-22] or bipolar disorder [23,24].

In the case of OCD, programs are scarce, and most proposals have studied the impact of the educational mechanism [25-28], showing a reduction in stigmatizing attitudes and an improvement in participants' MHL. Furthermore, a proposal has reported a significant reduction in social stigma and social distance using an indirect contact strategy through a video of a patient with OCD and a family member talking about their experience with the problem [29]. However, none of these interventions are based on innovative technologies, and only 1 of them includes >1 intervention strategy (ie, contact and education) [29]. In this context, as a response to the limited interventions focused on OCD and the need to bridge the gap between the onset of symptoms and seeking help, a gamified mental health app named esTOCma has been developed [30] (refer to the Methods section). In this way, the intervention will take advantage of mobile mental health interventions as low-cost tools that are available 24 hours a day for a large number of people [31,32], in addition to including gaming benefits such as providing immediate feedback, motivating users to achieve goals, and being easy to use [33].

Objective and Hypothesis

The aim of this study is to explore the feasibility, acceptability, and preliminary effectiveness of the beta version of the eHealth mobile app esTOCma. Regarding the effectiveness, and based on the reviewed literature on interventions to reduce stigma and increase knowledge of OCD [25-29] and other mental disorders [11,14,16], we hypothesize that the esTOCma intervention will (1) improve knowledge associated with OCD and its treatment, (2) decrease stigmatizing attitudes and social distance, and (3) increase intention to seek help. Moreover, we hypothesize that changes will be maintained at the 3-month follow-up assessment.

Methods

Study Design

This study was a single-arm pilot intervention with 3 measures at the pretest, posttest, and 3-month follow-up. Data were collected from people residing in Spain.

Participants and Procedure

Data were collected from a convenience sample. Participants were recruited from the general community and university setting by snowball sampling after providing relevant information via face-to-face classes and inviting the participants to share information about the study with their acquaintances. The inclusion criteria for this study were as follows: (1) being aged >18 years, (2) residing in Spain, (3) owning a smartphone, and (4) self-reporting not having an OCD diagnosis. Interested participants were invited to participate in a study consisting of downloading an app (esTOCma) in an Android Package Kit file format, playing with it, and completing a set of questionnaires before and after using the app. The participants performed all the tasks individually at home and at their own pace at the time they deemed most convenient. Furthermore, they chose the rate at which they completed the game, although the app recommends completing 1 mission a day.

The participants signing the informed consent form were given an identification number automatically generated by the app. The data from the questionnaires and the game were matched with the personal player ID. The participants were randomized by the app using a sampling without replacement method to 1 of 6 vignettes describing a person with obsessive-compulsive (OC) symptoms from 1 out of 6 types of content (ie, aggression or harm; sexual; religious, blasphemous, or immoral; contamination or washing; doubts or checking; or superstition, symmetry, or order). The vignettes consisted of descriptions of patients presenting with OC symptoms, with similar severity. Furthermore, interference and impairment in quality of life were described. The descriptions were based on real clinical cases [34]. All of them meet the diagnosis criteria following the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, and the labels of obsessions or compulsions were avoided. All the described patients were referred to as A; sex

was not specified, and they were middle aged. Furthermore, all descriptions included between 166 and 175 words.

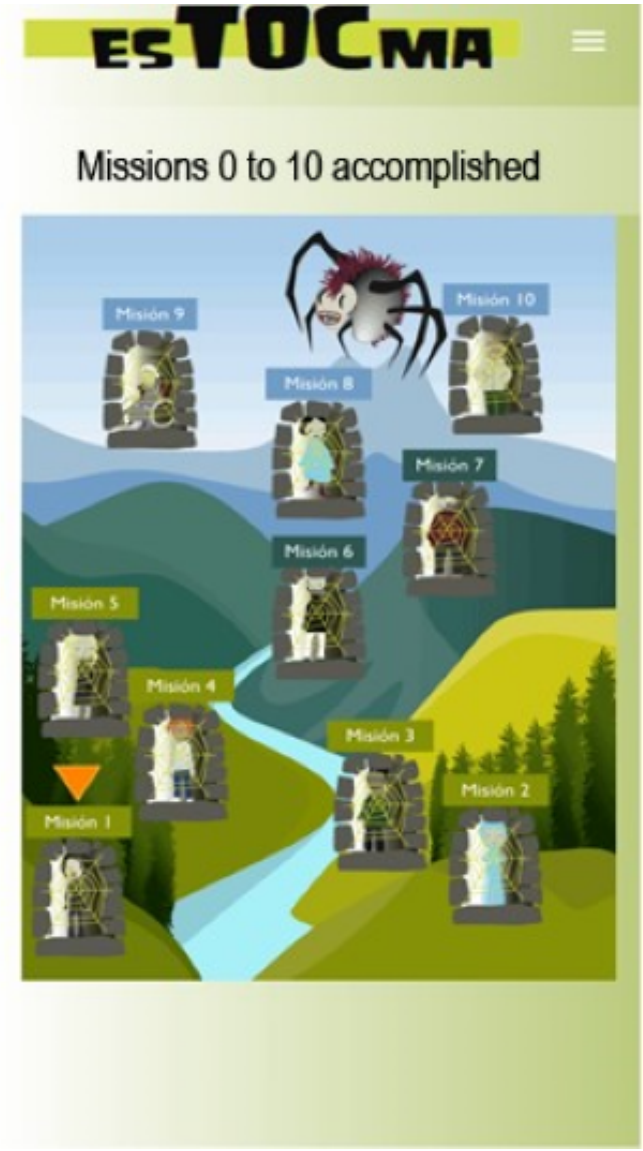
After reading the assigned vignette, the participants were asked by the app to complete the preintervention measures. Most of them (ie, Spanish Mental Illness Stigma Attribution Questionnaire–27 [AQ-27-E)], General Help-Seeking Questionnaire [GHSQ], Social Distance Scale [SDS], and MHL questionnaire) were answered in reference to the assigned vignette. Only after completing the preassessment were the participants able to begin playing. The participants who completed the 10 missions and finished the game were asked through the app to complete the postintervention assessment and the 3-month follow-up assessment. To encourage the participants to complete the game, they were given entries to a prize draw for a voucher to spend on the web.

Intervention Program

The esTOCma beta version is a serious game whose content and videos were developed by Doctor of Philosophy–level clinical psychologists who are experts on OCD, together with a usability expert. A professional designer developed the graphic elements, and a computer engineer developed the app. After testing multiple prototypes, this version was developed (Multimedia Appendix 1).

During the game, participants are asked to fight against the OCD "stigma monster" with their knowledge by accomplishing 10 missions and freeing the 10 characters who are affected by the esTOCma monster, a creature that feeds on false beliefs and misinformation in society [35] (Figure 1). The participants are guided through the game by a woman who describes herself as an OCD expert.

Figure 1. The missions, set along a mountain road.



The game is organized into three different intervention mechanisms: (1) psychoeducation (general information about OCD, OCD heterogeneity, OCD dimensionality, OCD cognitive model, evidence-based treatments, and options for seeking help in OCD), which includes 5 missions, and 1 of them—mission 3—includes a video explaining the OCD cognitive model (1 min); (2) indirect contact (including 6 videos of approximately 2 to 3 minutes of 3 patients diagnosed with OCD who talk about their own experience with OCD: symptom description, interference, how long it took them to seek help, their experience

in disclosing that they had a disorder, and experience with psychotherapy), which is organized into 2 missions; and (3) cognitive restructuring to replace dysfunctional beliefs related to rejection toward people with OCD, variables involved in OCD development, and treatment options and effectiveness, which includes 3 missions.

The missions are organized as follows: (1) the expert describes the objective of the mission and introduces the character to be freed, (2) the expert presents activities associated with the mission (between 6 and 8 activities, mostly consisting of reading a text and answering questions about it), and (3) the freed character appears. During the game, users receive basic internet-based rewards (ie, a key to free the character), together with a message of reinforcement and a video of the character actually being freed from esTOCma. At the end of the game, there is new visual reinforcement through a video in which all the characters are freed from the monster. Moreover, users receive reinforcement through a diploma that certifies them as OCD experts. A further description of the game can be found in the study by Chaves et al [35].

Measures

The participants completed the sociodemographic information and Obsessive-Compulsive Inventory–Revised at preassessment and an acceptability questionnaire at postassessment. All other measures were completed at the preassessment, postassessment, and 3-month follow-up assessment.

Sociodemographic Variables

The sociodemographic variables include gender, age, educational level, level of information and communications technology (ICT) knowledge (from 1 *little or none* to 5 *expert level*), and the question of whether they have an OCD diagnosis.

Acceptability Questionnaire

It consisted of 3 questions developed ad hoc to assess the acceptability of the esTOCma app. The survey included 2 questions related to usefulness (ie, “Did you find the app useful?” [from *very useful* to *not useful at all*] and “Did you learn from the app?” [from *I learned a lot* to *I learned nothing*]) and 1 question related to satisfaction with the app (ie, “Would you recommend this app to a friend?” [from *a lot* to *not at all*]). The questions were multiple-choice questions with 4 alternatives.

AQ-27-E Measures

This measures the social stigma associated with a vignette describing a person showing OC symptoms through 27 items rated on a Likert-type scale ranging from 1 to 9 [36,37]. It includes 9 subscales with 3 items: responsibility, pity, anger, dangerousness, fear, no help, coercion, segregation, and avoidance. Higher scores indicate higher social stigma. In this study, the AQ-27-E scales showed acceptable to excellent internal consistency across subscales (from 0.70 [anger, 3-month follow-up] to 91 [fear, 3-month follow-up]), except for responsibility (ranging from 0.40 [postassessment] to 0.63 [preassessment]) and pity (ranging from 0.36 [preassessment] to 0.52 [3-month follow-up]).

GHSQ Measures

This measures the intention to seek help from 10 different sources with regard to the specific content described in a vignette describing a person showing OC symptoms [38,39]. Participants rated 10 items regarding their help-seeking intentions if they were experiencing from symptoms similar to those described in the vignette on a 7-point Likert-type scale ranging from 1 (*extremely unlikely*) to 7 (*extremely likely*). Scores were calculated by summing up the items and dividing by 10. Higher scores indicate a higher intention to seek help. In this, the GHSQ showed acceptable internal consistency at the different assessment points (Cronbach α ranging from 0.68 [preassessment] to 0.75 [postassessment]).

SDS Measures

This assesses an individual’s willingness to interact with an individual with a mental disorder described in a vignette across 7 different situations on a 4-point Likert scale from 0 (*definitely willing*) to 3 (*definitely unwilling*) [40]. The total score has been calculated by adding the scores and dividing by the 7 items, with higher scores indicating a greater preference for social distance. In this, the SDS showed between good and excellent internal consistency at all assessment points; Cronbach α ranged from 0.86 at postassessment to 0.93 at the 3-month follow-up.

MHL Questionnaire

This is an instrument developed for this study based on previous studies [25,41] and assesses 1 of the components defined by Kutcher et al [42] as MHL but only referring to OCD: the understanding of OCD and its treatment. Part 1 has 4 multiple-choice questions including between 2 and 7 alternative answers, only 1 of which is correct. The questions refer to the assigned vignette (person A) and evaluate the following dimensions: (1) problem recognition (ie, “What happens to A is cause for concern?”; response alternatives: yes and no), (2) OCD identification (ie, “What do you think might be happening to A?” This question includes 7 response alternatives: family problems, adjustment problems, anxiety disorder, generalized anxiety disorder, schizophrenia, OCD, and depression), (3) perception of causality, and (4) effective treatment option. Part 2 has four multiple-choice questions with 3 alternative answers, only 1 of which is correct, and refers to participants’ general knowledge of OCD: (1) identification of OCD as a mental disorder (ie, OCD is [a] a learning disorder, [b] a mental disorder, or [c] a set of manias); (2) definition of obsession; (3) definition of a compulsion; and (4) role played by compulsions and other control strategies in the maintenance of obsessions. A total score has been calculated as the sum of the correct answers, thus ranging from 0 to 8.

Obsessive-Compulsive Inventory–Revised Measures

This is an 18-item self-report questionnaire assessing distress caused by OC symptoms and rated on a 5-point Likert scale ranging from 0 (not at all) to 4 (extremely) [43,44]. A total score was calculated. The total score of the Obsessive-Compulsive Inventory-Revised showed excellent internal consistency at all assessment points in this study (Cronbach α ranging from 0.89 [postassessment] to 0.90 [preassessment]).

Statistical Analysis

Descriptive statistics (eg, means, SD, and frequencies or percentages) were used to analyze demographic data, study variables, and app use patterns. Chi-square and 1-tailed *t* tests were used to test whether the groups (completers vs noncompleters) had preexisting differences. The change in study variables over time was determined by a repeated measures ANOVA. Partial eta–squared was used to report the effect size of the intervention on the dependent measures. A mixed model was used to determine whether the pattern of use of the app affected its effectiveness. The within-participants factor was time, and the between-participants factor was whether the user followed the 1 mission per day recommendation. The statistical significance level was set at *P*=.05. SPSS Statistics (version 26; IBM Corp) was used for statistical analysis.

Ethical Considerations

All procedures described in the study have been approved by the Human Research Ethics Committee of the University of Valencia, Spain (1276901). All study participants provided informed consent before study enrollment.

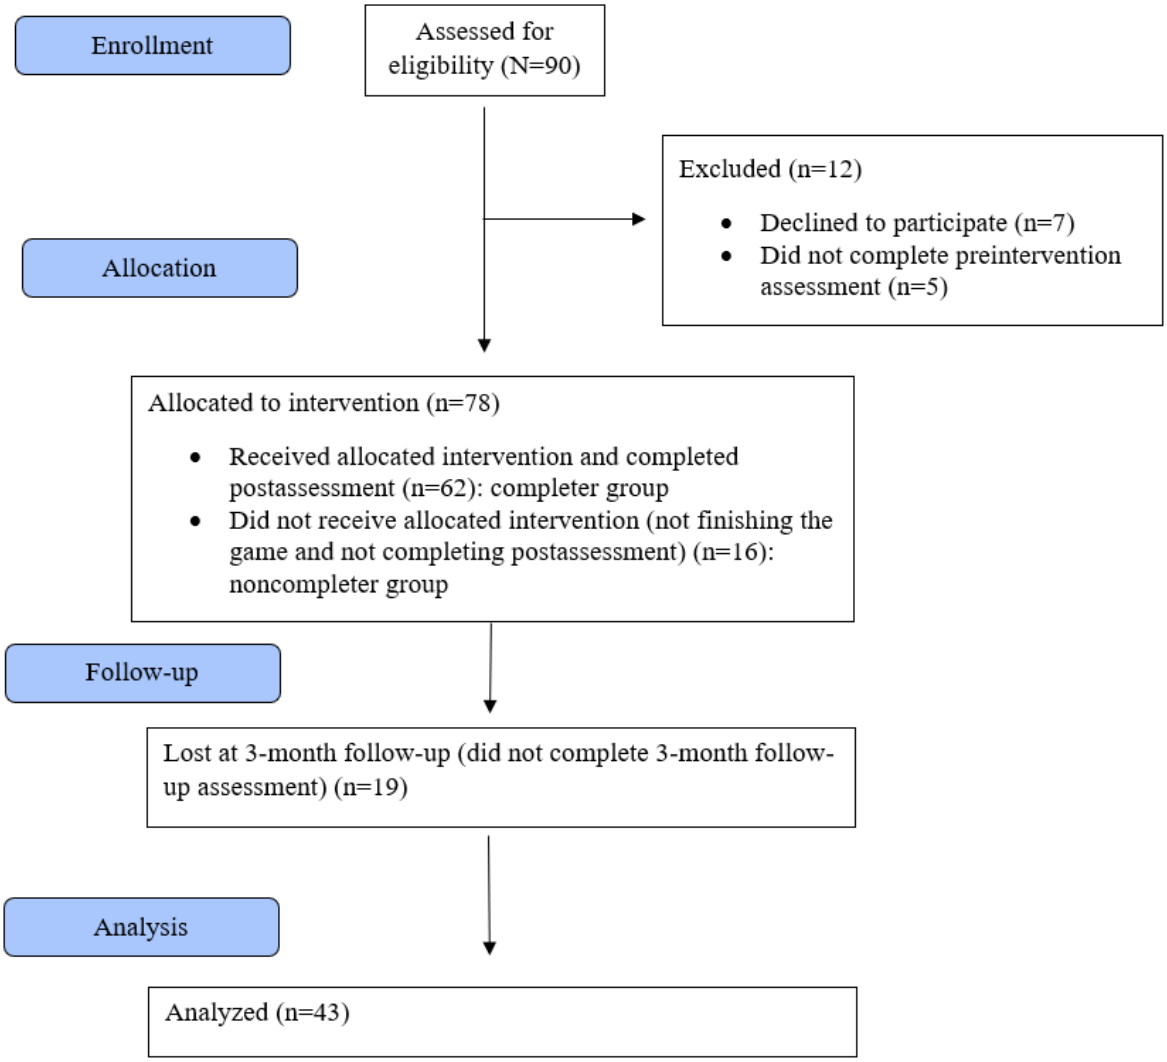
Results

Feasibility

Recruitment

A total of 90 participants were enrolled in the study; they downloaded the app and met the inclusion criteria. Of these 90 participants, 86% (78/90) were allocated to intervention and 13% (12/90) were excluded as they did not provide informed consent or did not complete the preassessment intervention (Figure 2). Of these 78 participants, 20% (16/78) did not complete the game or the postassessment (noncompleter group) and 79% (62/78) completed the game and answered the postintervention assessment (completer group). In the completer group, 69% (43/62) of the participants completed the 3-month follow-up assessment, and the remaining 30% (19/43) of the participants were lost at the 3-month follow-up.

Figure 2. Participants' flowchart.



Participants' Characteristics

The completer group had a mean age of 36.74 years, ranging from 18 to 71 years; were mostly women; and had university studies and moderate ICT knowledge. Differences in sociodemographic characteristics and preintervention assessment (baseline) between the completer group and the noncompleter group were calculated (Table 1).

Table 1. Differences between the completers and noncompleters on demographic and study variables (N=90).

Variable or measure	Completers (n=62)	Noncompleters (n=16)	Chi-square (*df*)	*t* test (*df*)	*P* value

[h]Total score ranging from 0 to 3.

[i]GHSQ: General Help-Seeking Questionnaire.

[j]Total scoring from 1 to 7.

[k]OCI-R: Obsessive-Compulsive Inventory–Revised.

[l]Total scoring from 0 to 72.

Statistically significant differences were only observed in age, with the completer group being older, and MHL scores, which were higher in the completer group. In addition, in the completer group, we explored the differences between the participants who completed the 3-month assessment (43/62, 69%) and those who did not (19/62, 31%). The only discernible difference observed was in age (t_{60}=2.167; *P*=.01), with participants who completed the follow-up assessment being older.

Of the 43 participants included in the effectiveness analyses, most were women (n=28, 65%) with a mean age of 39.30 (SD 14.58; range 21-71) years, with university-level education (n=35, 81%), and with ICT knowledge between moderate (n=23, 54%) and advanced (n=15, 35%; only 3 (7%) participants described having between little or none and low ICT knowledge level).

App Use Pattern

An analysis of the app use pattern was conducted with the completer group. First, we explored the number of days that elapsed from the preassessment to the postassessment. The participants took a mean of 13.64 (SD 10.50; range 1-44) days to complete the app (which includes having done the preassessment, the 10 missions and the postassessment), with a mode of 1, that is, the most frequent pattern was conducting the pre- and postassessments and missions of the app in 1 day. Second, we analyzed the number of days the person spent performing the missions. The participants spent between 1 and

10 days performing the missions, with a mean of 4.56 (SD 3.33) days and a mode of 1. In total, 30% (19/62) of the participants completed the 10 missions in 1 day, whereas another 21% (13/62) of the participants spent between 9 and 10 days completing the app, that is, approximately 1 session per day.

Finally, we explored the minutes spent performing each mission, first excluding the participants who stayed on 1 mission for >20 minutes, as we assumed that they left the app open without using it. The data on the participants completing the missions in <20 minutes is presented in Table 2.

Table 2. Time (in min) spent in completing each of the 10 missions for participants who complete the mission in <20 minutes.

	Participants, n (%)[a]	Time (min), mean (SD; range)	Mode (min)
Mission 1	58 (94)	3.93 (1.02; 1-6)	4
Mission 2	54 (87)	4.44 (1.90; 2-10)	4
Mission 3	35 (56)	3.80 (1.37; 1-8)	3
Mission 4	35 (56)	2.06 (1.64; 0-10)	2
Mission 5	35 (56)	5 (3.11; 2-20)	4
Mission 6	56 (96)	8.71 (1.78; 7-20)	8
Mission 7	29 (47)	9.35 (3.06; 7-20)	8
Mission 8	33 (53)	3.85 (1.48; 2-8)	3
Mission 9	58 (94)	2 (3.01; 0-19)	0
Mission 10	56 (90)	2.09 (2.26; 0-9)	0

[a]n (%) of participants completing the mission in ≤20 minutes.

The data are displayed in minutes.

Between the participants who completed missions in ≤20 minutes, and considering the mode, missions included in module 1 (ie, missions 1 to 5) took between 2 and 4 minutes, in module 2 (ie, missions 6 to 7) took 8 minutes, and in module 3 (ie, missions 8 to 10) took between <1 minute and 3 minutes.

Acceptability

After completing the app until the end of the game, most participants (56/62, 90%) perceived the app as useful or very useful. Moreover, 90% (56/62) of the participants indicated that they had learned or learned a lot, and 98% (61/62) of the participants indicated that they would recommend the app to a friend.

Preliminary Effectiveness: Differences Between Pre- and Postintervention Assessments and 3-Month Follow-Up

Repeated measures ANOVA was conducted to examine differences between pre- and postintervention and the 3-month follow-up on knowledge of OCD and its treatments (MHL questionnaire), stigmatizing attitudes (AQ-27-E), social distance (SDS), and intention to seek help (GHSQ) associated with OCD (Table 3). The results showed statistically significant differences (P≤.05) in all variables with medium-to-large effect sizes, except for the second part of the MHL questionnaire and the pity and coercion subscales (AQ-27-E). In general, the results show that using esTOCma until the end of the game results in an increase in MHL and intention to seek treatment (GHSQ) and a decrease in stigmatizing attitudes (AQ-27-E) and social distance desire (SDS). Post hoc pairwise comparisons showed statistically significant differences between preintervention and the other 2 assessment points (postintervention and 3-month follow-up). No significant differences were observed between postintervention and the 3-month follow-up in the variables assessed, except for the MHL total score, in which follow-up scores did not differ from pre- to postintervention.

Table 3. Means (SDs) and repeated measures ANOVA on pre-, post-, and 3-month follow-up intervention scores (n=43).

Variable or measure	Pretreatment, mean (SD)	Posttreatment, mean (SD)	3 month follow-up, mean (SD)	*F* test (*df*)[a]	*P* value	ηp^{2b}
MHL[c]						
Part 1[d]	3.32 (0.80)[e]	3.72 (0.54)[e]	3.62 (0.61)[e]	6.523 (1.566, 65.769)	.005	0.134

[c]MHL: Mental Health Literacy Questionnaire, total score ranging from 0 to 8.

[d]Part 1 scoring from 0 to 4.

[e]Significant differences among groups ($P \leq .05$).

[f]Part 2 scoring from 0 to 4.

[g]AQ-27-E: Spanish Mental Illness Stigma Attribution Questionnaire–27; subscales ranging from 3 to 27.

[h]SDS: Social Distance Scale, ranging from 0 to 3.

[i]GHSQ: General Help-Seeking Questionnaire, scoring from 1 to 7.

Finally, we examined whether the pattern of use of the app influenced the effectiveness of the intervention with a 2 (group: individuals who follow the recommendation of 1 mission per day [ie, 9/10, % days] [12/N, %; percentile 75] vs individuals who did it in another way [31/N, %])×3 (time: pre-, post-, and follow-up assessments) repeated measures mixed ANOVA. The results show that there was no significant group×time interaction ($F_{26,16}$=0.838; P=.67). Univariate follow-up analyses also indicated no significant group×time effect for any of the measured variables (P>.05).

Discussion

Principal Findings

This study is the first to investigate the feasibility, acceptability, and effectiveness of a mobile health app designed to enhance several variables related to OCD, which were identified by Kutcher et al [42] as components of MHL: understanding OCD and its treatments, decreasing stigma associated with OCD, and enhancing help-seeking effectiveness. Our findings show that esTOCma was feasible and acceptable and that after using it until game completion, there was a positive change in the variables of interest, which lasted for at least 3 months.

Of the participants allocated to the intervention, approximately 80% (78/90) completed the app, and of the who completed the intervention, approximately 70% (62/78) completed the follow-up assessment. This adherence rate is similar to or higher than that reported in other internet-based studies with self-help interventions, with dropouts being one of the main challenges of interventions with mental health apps [45-47].

The participants who completed the study were older and had higher knowledge of OCD than those who began the study but did not complete it. However, there were no differences in participants' knowledge of new technologies, which suggests that the app is easy to use and does not require a significant amount of knowledge to become involved in its use, although >50% (35/62) of the participants described themselves as having

moderate ICT knowledge. Regarding the pattern of use, although it was recommended that participants complete 1 mission per day and participants were reminded of this recommendation after finishing each mission, the most common pattern of use was to complete the app, including pre- and postevaluations, in 1 day. In fact, only 21% (13/62) of the participants completing the intervention followed the recommendation to perform 1 mission per day. It seems that it is more comfortable for participants to perform more missions per day; otherwise, they forget to complete the mission the following day. In fact, the participants completed their participation in the study within a range of 1 to 44 days.

Regarding the time invested in each mission, although missions were quick to complete and always took <10 minutes, the participants often left missions midway and continued later the same day or days later. Furthermore, certain missions were abandoned in the middle more frequently, suggesting that they could be reformulated to make them more "attractive." This was the case for mission 7, which was interrupted by >50% (31/62) of the participants, as well as for missions 3, 4, 5, and 8. The pattern of use and interruptions does not seem to be associated with the intervention mechanism on which the mission is based but perhaps with the content or the duration of the mission. If we analyze missions 1, 2, 6, 9, and 10, those that were carried out without interruption, we see that missions 1 and 2 are the initial ones and deal with content describing obsessions and compulsions; mission 6 includes the first videos that also describe symptomatology and interference, without additional theoretical content to read; and missions 9 and 10 (cognitive restructuring) are characterized by being very brief and with less theoretical content than missions 1 to 5 (psychoeducation). It seems that the description of symptomatology, as well as more dynamic and shorter missions, result in more attractive missions or at least in missions that capture participants' attention to a greater extent.

In general, the participants seemed satisfied with the app, as approximately 100% (62/62) would recommend it to a friend and >90% (56/62) consider it useful and that they have learned about OCD.

Regarding the effectiveness of the app, the results show an increase in OCD knowledge. Our data match those of the previous interventions that have found increases in general knowledge of OCD after offering written information about the disorder [25,26]. The data are also consistent with other technology interventions that have increased MHL levels on different mental health problems [48-50]. However, the differences were not statistically significant in those questions that asked about OCD in general (eg, the definition of an obsession), that is, not referring to the description of a person showing OC symptoms. This could be due to a ceiling effect, as the scores were already high in the preassessment evaluation. In fact, they were higher among those participants who played with the app until the game was over in comparison with those who did not finish the game. In this sense, our first hypothesis was only partially supported.

Regarding the hypothesized decrease in stigmatizing attitudes, the results support our hypothesis, as they suggest that after completing the 10 missions of the app, there was a decrease in some stereotypes or public attitudes, such as the perception of OC symptoms as dangerous; emotional reactions of anger or fear toward people showing OC symptoms; discriminating behaviors such as the intention of not helping, segregating, or avoiding people showing OC symptoms; or the desire to maintain social distance. Although a video-based intervention decreased social distance desire [29] and 2 interventions centered on reading the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition diagnostic criteria for OCD decreased negative attitudes about violent and sexual thoughts [28,51], other interventions consisting of reading information on OCD (psychoeducation) showed small changes in stigmatizing attitudes [25]. The results suggest that the esTOCma intervention, which includes psychoeducation but also incorporates components such as contact, seems to change stigmatizing attitudes to a greater extent, with medium-to-large effect sizes.

Our data are also consistent with previous research also using new technologies to reduce stigma associated with other mental disorders that have reported a decrease in dangerousness, anger, fear, segregation, and avoidance [15,52,53]; a decrease in stigma as a general measure [53-55]; an increase in the help factor [52]; or a decrease in social distance [52,56]. This is a remarkable result, as traditional antistigma interventions not using innovative technologies often report small-to-medium effect sizes [14,52]. Moreover, the results are based on a community sample with an average age higher than those used in studies reporting interventions using innovative technologies [16], suggesting that these types of interventions could also be useful for older people.

In addition to the changes in stigmatizing attitudes after using esTOCma, there were no significant changes in 2 of the social stigma dimensions measured by the AQ-27-E: pity and coercion. Previous studies have also reported a lack of changes in pity [57]. In fact, it has been suggested that pity should be considered, at least in some contexts, not to be a factor of stigma but rather a reflection of compassion and the capacity to empathize with people with mental health problems [58], and research has shown associations between pity and the tendency to help [37]. Regarding coercion, there is no significant change after the intervention in the belief that people with OCD should receive treatment, even if they refuse it (coercion). This is consistent with previous interventions in the OCD field [25].

Finally, the results also support our third hypothesis, as there was a large effect size improvement in the intention to seek help when experiencing symptoms similar to those represented in the different vignettes. Thus, increasing knowledge of OCD and its treatment could have acted as a help-seeking facilitator [59,60]. To the best of our knowledge, there are no interventions to improve help seeking associated with OCD, and thus, our results are of great relevance, as research shows that early help seeking is associated with a better treatment response, earlier remission of symptoms, and recovery from the disorder [9,61]. The data are consistent with other studies that, through mental health apps [62] and other technology-based interventions, have improved the intention to seek help for other mental health problems [63].

Moreover, our study showed a maintained effect in the study variables at the 3-month follow-up assessment. This is especially relevant as most of the interventions do not include a follow-up assessment [16,50,63,64], and only 1 intervention on OCD has included a follow-up assessment [29].

Limitations and Recommendations

This study has limitations. As a pilot study, the study sample was small and did not include a control group. There was also a considerable dropout rate that could be associated with the fact that participants forgot to complete the app (to do all 10 missions) as well as the large number of assessment questionnaires included. Furthermore, considering that OCD is a heterogeneous disorder and that there are differences in stigma and OCD recognition between different types of content [41,64,65], we decided to randomize participants to 6 vignettes that represent OCD heterogeneity. However, this decision could be considered as a limitation of the design of this study that could affect the effectiveness of the data.

Despite these limitations, our results provide valuable information for a broader implementation of the app. First, as future lines of work, we propose making an effort to motivate participants, given that higher adherence was associated with initial knowledge of OCD or sensitivity toward mental health problems. Second, a potential strategy to attract a younger audience, as adherence was also associated with older age, could involve transforming the app into a serious game, aligning esTOCma with the immersive experience of video games. Actively engaging participants through gamification elements could further contribute to increasing adherence. Looking ahead, evolving esTOCma into a serious game with an adventure game theme holds promise for future developments and for addressing the stigma associated with OCD. Third, pop-ups and emails to remind participants to “play” could be incorporated, as those participants who completed the participation took up to 44 days to finish an app recommended to be conducted in 10 days. Fourth, given that the number of missions per day seems not to influence the effectiveness of the app, the recommendation to play 1 mission per day could be omitted, as this is not the preferred pattern of use of participants. Finally, given that some missions were completed with interruptions by approximately half of the participants, it would be recommended to inform users of how long each mission will last. Furthermore, missions 3 to 5, 7, and 8 should be revised, as although they were quick to complete (between 3 and 8 min), the participants often left them midway and continued later. They could perhaps be shortened or made more dynamic.

Future Research

The results suggest the potential for the use of this intervention app and provide the basis for developing a larger randomized controlled study to validate the use of esTOCma (version 1.0), as has been proposed [35]. Importantly, we will also explore differences in OCD types of content through a controlled study, as research shows that there are differences in OCD recognition and stigma considering the different OCD types of content [41,64,65]. Furthermore, it will be of interest to explore the effectiveness of each intervention mechanism (ie, psychoeducation, indirect contact, and cognitive restructuring) to understand whether there are differences between them. This analysis would allow us to develop a new app that would eliminate those mechanisms that are less effective or improve them. Future studies should also examine the usefulness of this app in OCD cohorts, especially in the first stages of diagnosis, and their families. Through esTOCma, people with OCD could receive (or reinforce) cognitive-behavioral psychoeducation and be assisted in their search for empirical-based treatments. Furthermore, esTOCma could eliminate self-stigma, improving their quality of life. In terms of family involvement, esTOCma could assist them in comprehending and managing OCD symptoms as well as support their relatives with OCD in seeking effective treatment.

Conclusions

Our findings show that esTOCma is a feasible and acceptable app and that after completing its 10 missions, there is an increase in the understanding of OCD and help-seeking intention as well as a decrease in the social stigma and social distance associated with OCD that lasts for at least 3 months. These changes might result in less delay in seeking help and a better treatment response to the problem and prognosis. Moreover, providing mental health knowledge to the community population as to the nature and universality of intrusive thoughts may protect and prevent the general population from developing OCD and, furthermore, reduce the economic and personal costs associated with OCD.

Acknowledgments

Funding for this study (RTI2018-098349-B-I00 and PID2021-124409OB-I00) was provided by the Ministry of Science and Innovation—State Research Agency of Spain and by the European Union European Regional Development Fund: “A way of making Europe.” None of the funders had any role in the design, preparation, review, or approval of the manuscript or in the decision to submit the manuscript for publication.

Authors' Contributions

The work was conceptualized by AC and GG-S. The methodology and research, and the writing of the original draft were carried out by AC, GG-S and SA. Formal analyses were developed by SA. The final manuscript was reviewed and edited by GG-S.

Conflicts of Interest

None declared.
