Abstract

Mobile health (mHealth) with continuous real-time monitoring is leading the era of digital medical convergence. Wearable devices and smartphones optimized as personalized health management platforms enable disease prediction, prevention, diagnosis, and even treatment. Ubiquitous and accessible medical services offered through mHealth strengthen universal health coverage to facilitate service use without discrimination. This viewpoint investigates the latest trends in mHealth technology, which are comprehensive in terms of form factors and detection targets according to body attachment location and type. Insights and breakthroughs from the perspective of mHealth sensing through a new form factor and sensor-integrated display overcome the problems of existing mHealth by proposing a solution of smartphonization of wearable devices and the wearable deviceization of smartphones. This approach maximizes the infinite potential of stagnant mHealth technology and will present a new milestone leading to the popularization of mHealth. In the postpandemic era, innovative mHealth solutions through the smartphonization of wearable devices and the wearable deviceization of smartphones could become the standard for a new paradigm in the field of digital medicine.

KEYWORDS

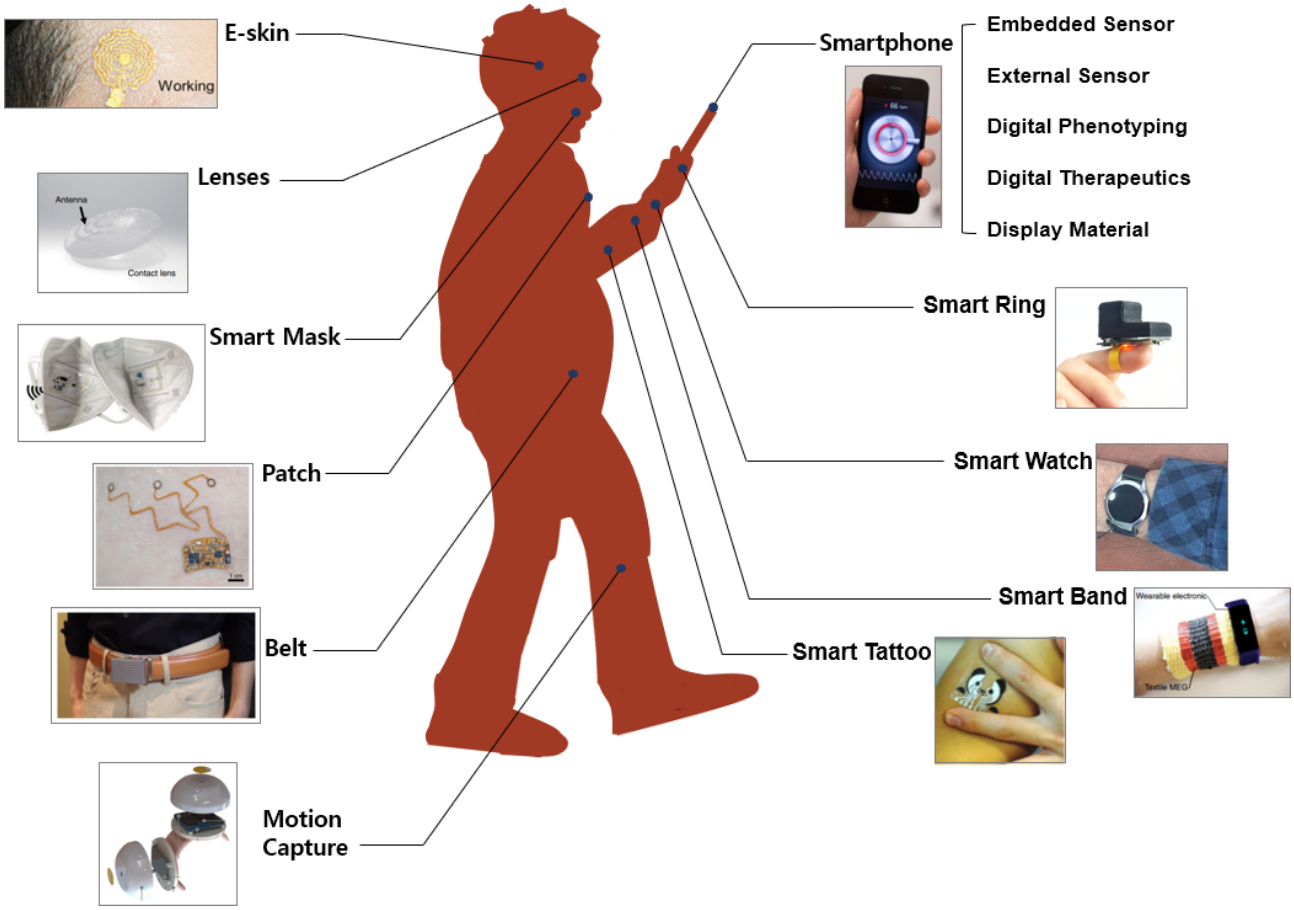
mobile health; mHealth; smartphonization; wearable deviceization; new form factor; sensor-integrated display

Background

In the postpandemic era, the significance of mobile health (mHealth) has been highlighted, and explosive growth in this area is expected to continue [1,2]. Cutting-edge technologies are converging with health care, and mHealth, based on hyperconnected intelligence, is leading the paradigm shift in medical care [3,4]. Many countries have already entered a superaged society, and the proportion of gross domestic product expenditures for medical care is increasing due to an upsurge in the number of people with chronic diseases. In addition, the excessive demand compared to the available supply, the lack of health care infrastructure, and the unbalanced distribution of medical staff are also problems. Therefore, prediction, prevention, and management through artificial intelligence (AI)–based medical big data analysis are required, and for this purpose, ubiquitous and accessible medical services using personalized devices must be provided [5]. mHealth is a strong candidate to make this possible, and the ultimate goal is to dramatically improve the standard and satisfaction of living by providing quality services at affordable prices [6,7].

Wearable electronics and smartphones are representative types of mobile systems optimized for personalized health care sensing. As shown in Figure 1 [8-19], wearable devices that cover the human body and smartphones, a necessity for modern people, enable comprehensive health management in real time.

Figure 1. Application and placement schematic illustration of wearable devices by body part and smartphone for mHealth management. The images were reprinted from Shin et al [8,19], Kim et al [9,19], Escobedo et al [10,19], Hwang et al [11], Nakamura et al [12,19], Hua et al [13,19], Moon et al [14,19], Zhao et al [15,19], Kim et al [16,19], Liu et al [17,19], and Chan et al [18,19]. e-Skin: electronic skin; mHealth: mobile health.



However, the pace of the development and popularization of mHealth technology is progressing more slowly than expected. From the perspective of a paradigm shift from the smartphonization of wearable devices and the wearable deviceization of smartphones, this viewpoint aimed to propose ways to unleash the potentiality of mHealth in the postpandemic era. The smartphonization of wearable devices and the wearable deviceization of smartphones do not simply mean that current smartphones become wearable devices and that current wearable devices maintain the functions of current smartphones. The smartphonization of wearable devices is to completely replace the smartphone function with a wearable device, while upgrading health care performance by embedding the current smartphone's computational power and sensor-integrated display, including large-area panels and user interaction, in the wearable system. In addition, the wearable deviceization of smartphones refers to a change in the form factor so that health care sensing can be performed by switching from the current rigid form to a form that can be attached to a curved skin surface. The new form factor, which features both wearable computer and smartphone functions, will improve detection performance through large-area sensing and increase the penetration rate.

This viewpoint investigated recent trends in health care sensing methods using wearable devices and smartphones, which are the central axis of mHealth. In the case of wearable devices, the form factor for each detailed location on the body and the corresponding detection target technology was described. In the case of smartphones, it covered the detection target and principles of health care according to the application of internal and external sensors, materials, and software. This viewpoint also analyzed the prospects of and current challenges in existing mHealth systems and considered new health care solutions using flexible displays for the convergence form factor of smartphones and wearables. The differentiating point was to consider the direction of mHealth from the perspective of a sensor-integrated and new form factor display. Ultimately, from a display perspective, solutions for the smartphonization of wearable devices and the wearable deviceization of smartphones will provide insight into the health care paradigm shift.

Recent Progress in the Development of Wearable Electronics for Health Care

The primary classification of wearable electronics based on the attachment position can be divided into the face, upper body, limbs, and whole body. Wearable clothes all over the body can also be classified separately.

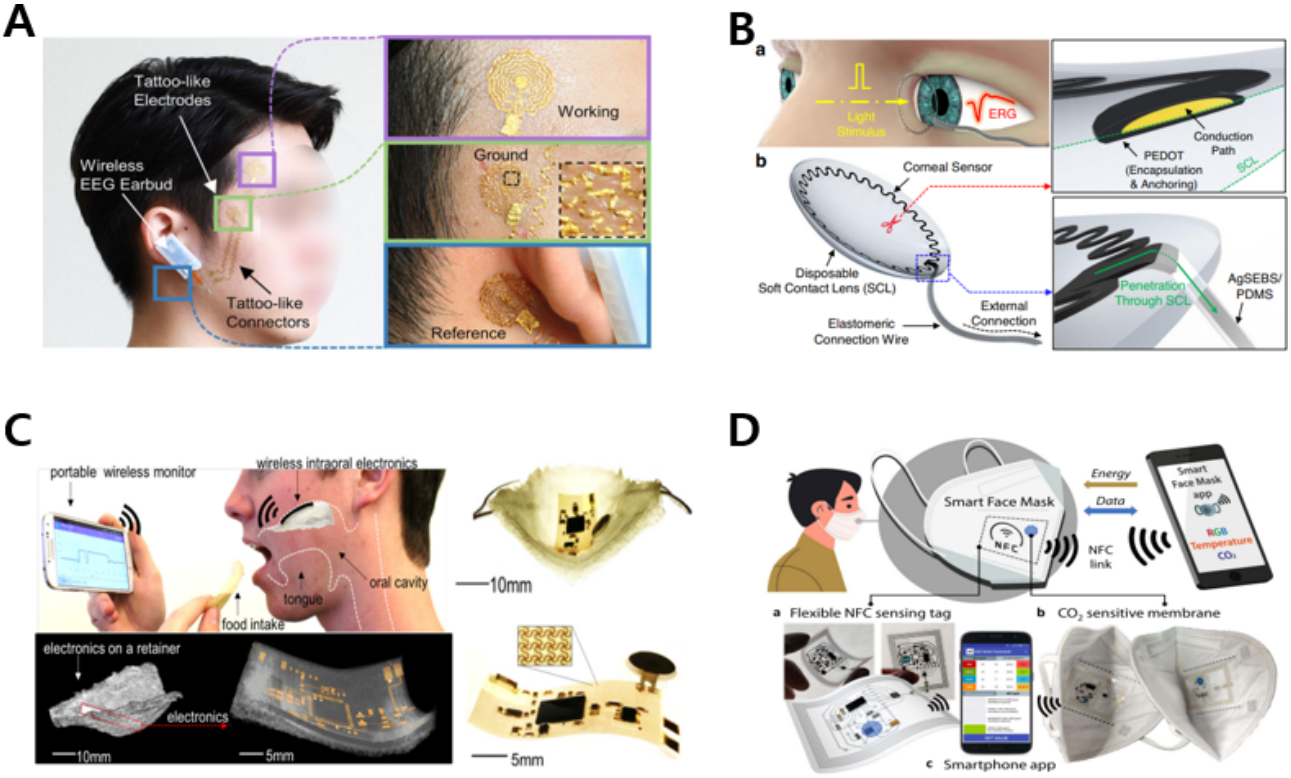
Face

Head

The face, which is closest to the brain, is significant from a sensory point of view because it is where the 5 senses are concentrated. Face-wearable devices with various form factors,

such as bands, caps, headsets, lenses, glasses, tattoos, mouthguards, and masks, may be distributed at each part of the head, eyes, nose, mouth, and ears to sense critical biosignals. In the case of the head, a wearable system that can analyze brain waves and psychological states can be applied [8,20,21]. Figure 2A [8] shows a wireless wearable electroencephalogram (EEG) measurement device based on a tattoo. AI can enhance decision-making by deep learning classification of received EEG data. Namely, it advances the decision performance of AI by feedback through brain waves. Additionally, it would be possible to grasp the degree of brain activation and mental condition of the frontal lobe and temporal lobe through the measurement of biosignals, such as brain waves.

Figure 2. Wearable devices attached to the face for mHealth. (A) Wearable EEG analysis platform with tattoo electrodes for EEG measurement and earbuds for wireless interaction. The images were reprinted from Shin et al [8,19]. (B) Stretchable corneal lenses for ocular electrodiagnosis. The images were reprinted from Kim et al [19,22]. (C) Intraoral electronics for sodium intake analysis through wireless remote control. The images were reprinted from Lee et al [23]. (D) Sensing platform for gaseous CO2 real-time determination inside filtering face piece 2 (FFP2) facemasks. The images were reprinted from Escobedo et al [10,19]. EEG: electroencephalogram; mHealth: mobile health.



Eyes and Nose

System form factors worn on the eye may be divided mainly into lenses and glasses. In the case of lenses, eye health factors, such as glucose, intraocular pressure, and electroretinographic measurements, can be determined using noninvasive methods [9,22,24-26]. For example, a corneal sensor embedded in a disposable soft contact lens can be deployed for electroretinography based on electrochemical anchoring, as shown in Figure 2B [22]. These corneal lenses are functional sensors tailored for ophthalmic electroretinographic testing in human eyes via a user-friendly interface and a design that can be deployed noninvasively. Glasses for health care are prescribed by doctors as an auxiliary tool for surgery and can also analyze the electrolyte and metabolite content of sweat flowing from the head [27-29]. In addition, a wearable system placed on the nose in the form of a nose pad on the glasses can sense the pulse wave, respiratory rate, and electrooculographic measurements [30,31].

Mouth and Ears

Wearable electronics related to the mouth take the form of mouth guards, tooth sensors, and masts and can analyze saliva and nutrients and monitor air quality [10,23,32-35]. For example, a small stretchable circuit and sensor that can be inserted into the human oral cavity may be integrated into a breathable, flexible microporous membrane for a tissue-friendly design, as shown in Figure 2C [23]. Such a device may be used in research to study the prevention of hypertension by facilitating continuous quantification analysis of sodium intake. Figure 2D [10] shows a sensing platform for detecting gaseous CO_2 inside a face mask via stable inorganic phosphors whose luminescence is controlled by a pH indicator. A mask combining a battery-free printed near-field communication (NFC) tag and a photochemical sensor for noninvasive CO_2 measurement was used to achieve detection performance with a resolution of 103 ppm. Practicality in physical activity has been increased through the compensation of the temperature noise and characterized analytical specifications of measurement systems. Moreover, health care wearable systems attached to the ears use earbuds to perform heart rate and sleep monitoring functions [36,37].

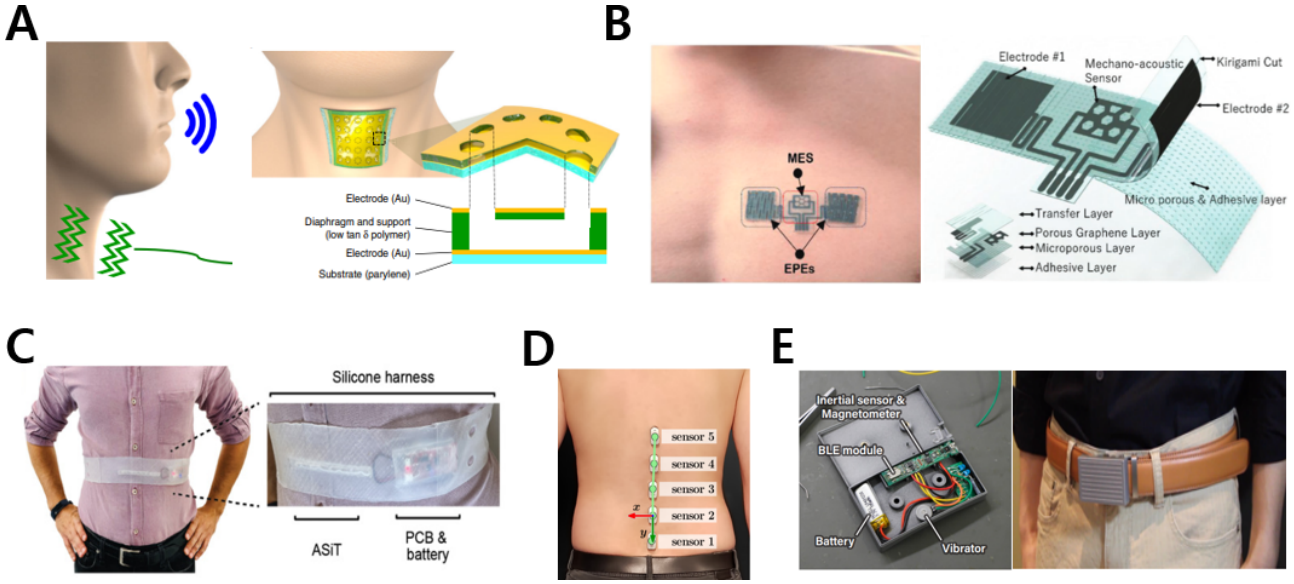
Upper Body

In addition to the face, wearable systems can be applied to the neck, chest, abdomen, internal organs, back, and waist to extract significant health values.

Neck

In the case of the neck, wearable devices with a necklace and patch form factor can record an electrocardiogram (ECG) and voice pressure and monitor the diet through an electroglottogram (EGG) using a neckband [38-40]. For example, a neck-attached wearable device incorporating a cross-linked polymer film and hole-patterned diaphragm structure detects and quantifies voice with an excellent sensitivity of 5.5 V Pa^{-1} over the voice frequency range, as shown in Figure 3A [39]. This device can be used for voice health management and security authentication by eliminating vibration distortions on the curved skin surface through excellent skin compatibility via using ultrathin profiles of ≥5 μm.

Figure 3. Wearable electronics mounted onto the upper body. (A) Vibration-responsive patch for sensing voice pressure. The images were reprinted from Lee et al [19,39]. (B) Epidermal cardiopulmonary patch based on laser fabrication. The images were reprinted from Rachim et al [41]. (C) Air-silicon composite transducer (ASiT) for breathing pattern monitoring. The images were reprinted from Nakamura et al [12,19]. EPE: electrophysiological electrode; MES: mechano-acoustic sensor; PCB: printed circuit board.



Thorax

Thorax-related wearable electronics, such as patches, chest belts, and brassieres, enable ECG recording, temperature measurement, sleep monitoring, posture analysis, and galvanic skin response (GSR) assessment [11,41,44-48]. Figure 3B [41] shows a sensor designed for continuous monitoring of the cardiopulmonary biosignal via a CO_2 laser–based manufacturing process. The epidermal patch consisting of a mechanoacoustic sensor and electrophysiological electrodes provides advanced functionality through a gas-permeable and biocompatible layer.

Abdomen

Abdomen-attached mHealth systems can sense glucose and breathing patterns through patches and straps [42,49]. For instance, an air-silicon composite transducer monitors respiratory activity by continuously measuring the force applied to the air channel embedded in the silicon-based elastomer, as shown in Figure 3C [42]. The system, which uses a pressure sensor and mixed-signal radio electronics, follows the principle of sensing the air pressure change inside the channel when breathing force is applied to the transducer surface. In particular, tactile sensing, including pressure sensing, is critical in health care. This is because tactile sensors attached to the skin detect physical stimuli, such as breathing patterns, heart rate, pulse, muscle activity, and body temperature, linked to biological signals. Skin, the most widely distributed organ among the five sense organs in the human body, is a tactile sensor with receptors that detect pressure, delicate movements, and temperature and is also an actuating organ that emits the same physical stimulation. Flexibility is a crucial element for the tactile sensor to be conformally attached to the skin to detect minute physical changes in detail and increase user convenience [50-52].

Furthermore, digestible pills check medication compliance. Management of medication adherence can prevent patients with severe mental illness from experiencing relapses and hospitalizations [53]. In addition, capsule endoscopy can monitor the colon health or bladder pressure state [54,55].

Back

A wearable system attached to the back can be used to analyze changes in the spine's shape during training. A spine tracker device shown in Figure 3D consists of 5 sensors, with each sensor attached to the lumbar spine, and can correct posture by providing real-time feedback [43].

Waist

In addition, a waist belt can be useful for obesity management [12,56]. The belt automatically measures waist circumference with high accuracy, with an F_1-score of 0.95, and monitors the daily lifestyle using a magnetometer, an accelerometer, and a gyroscope, as shown in Figure 3E [12].

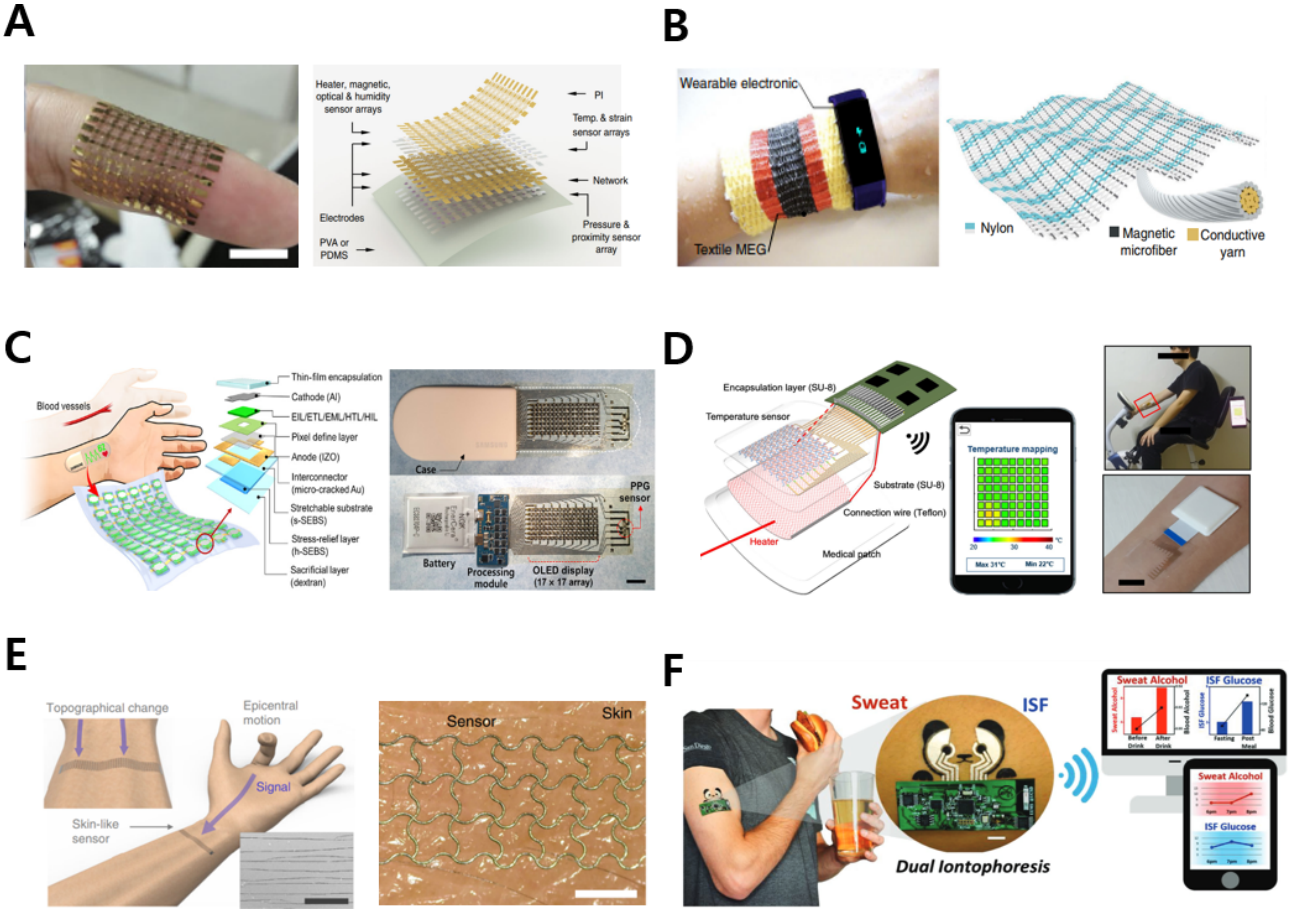
Limbs

In the case of the limbs, the main categories include the hands, arms, legs, and feet by attachment location.

Hands

The measurable health factors in a hand-related wearable device, such as a patch, ring, or glove, include rehabilitation evaluation analysis, ECG characteristics, oxygen saturation, dietary monitoring, pulse wave, and temperature [13,57-61]. For instance, a multisensory electronic skin integrated into a polyimide network simultaneously detects physical properties, such as temperature, strain, humidity, light, magnetic field, pressure, and proximity, in real time, as shown in Figure 4A [13]. It can also be used for rehabilitation evaluation using personalized intelligent prostheses.

Figure 4. Wearable devices attached to the hands and arms. (A) Stretchable and conformable electronic skin for multifunctional sensing. The images were reprinted from Hua et al [13,19]. (B) Power generation textile for wearable health care. The images were reprinted from Zhao et al [15,19]. (C) Stand-alone patch for health monitoring based on a stretchable organic optoelectronic system. The images were reprinted from Lee et al [62]. (D) Thermal patch for self-care treatment through temperature distribution sensing and thermotherapy based on wireless graphene. The images were reprinted from Kang et al [63]. (E) Sensor conformably attached to skin decoding epicentral human motions. The images were reprinted from Kim et al [19,64]. (F) A single wearable biosensor platform that simultaneously monitors sweat and interstitial fluid (ISF). The images were reprinted from Kim et al [16,19]. MEG: magnetoelastic generator; OLED: organic light-emitting diode; PDMS: polydimethylsiloxane; PI: polyimide; PPG: photoplethysmogram; PVA: polyvinyl alcohol; Temp.: temperature.



Arms

mHealth systems of various form factors related to the arm can also be useful for health management. Among them, wristwatches, bands, and bracelet devices can detect health factors, such as the heart rate, oxygen saturation, number of steps, blood pressure, ECG characteristics, glucose, blood sugar, and sweat metabolites [14,15,65-75]. Figure 4B [15] shows a magnetoelastic generator that provides the power to drive a wearable biosensor system. This generator can help measure cardiovascular parameters underwater without encapsulation for telemedicine and has excellent water vapor transmission characteristics.

A patch sensor attached to the arm can measure the pH, sweat rate, lactate, heart rate, temperature, electromyogram (EMG) and ECG characteristics, blood pressure, and water content and can also be applied for wound treatment and rehabilitation evaluation [62-64,76-85]. For instance, a stand-alone organic skin patch for health care with an organic light-emitting display with sufficient pixels reports the heart rate via a stretchable photoplethysmogram (PPG) sensor, as shown in Figure 4C [62]. An ultrathin patch of 15 µm is configured on a soft elastomer substrate and can operate stably at 30% strain using a combination of a stress relief layer and deformable microcracks. Figure 4D [63] shows a wireless graphene patch that simultaneously provides thermal sensing and thermotherapy capabilities. This thermal patch consists of a graphene-based capacitive sensor, a graphene thermal pad, and a flexible

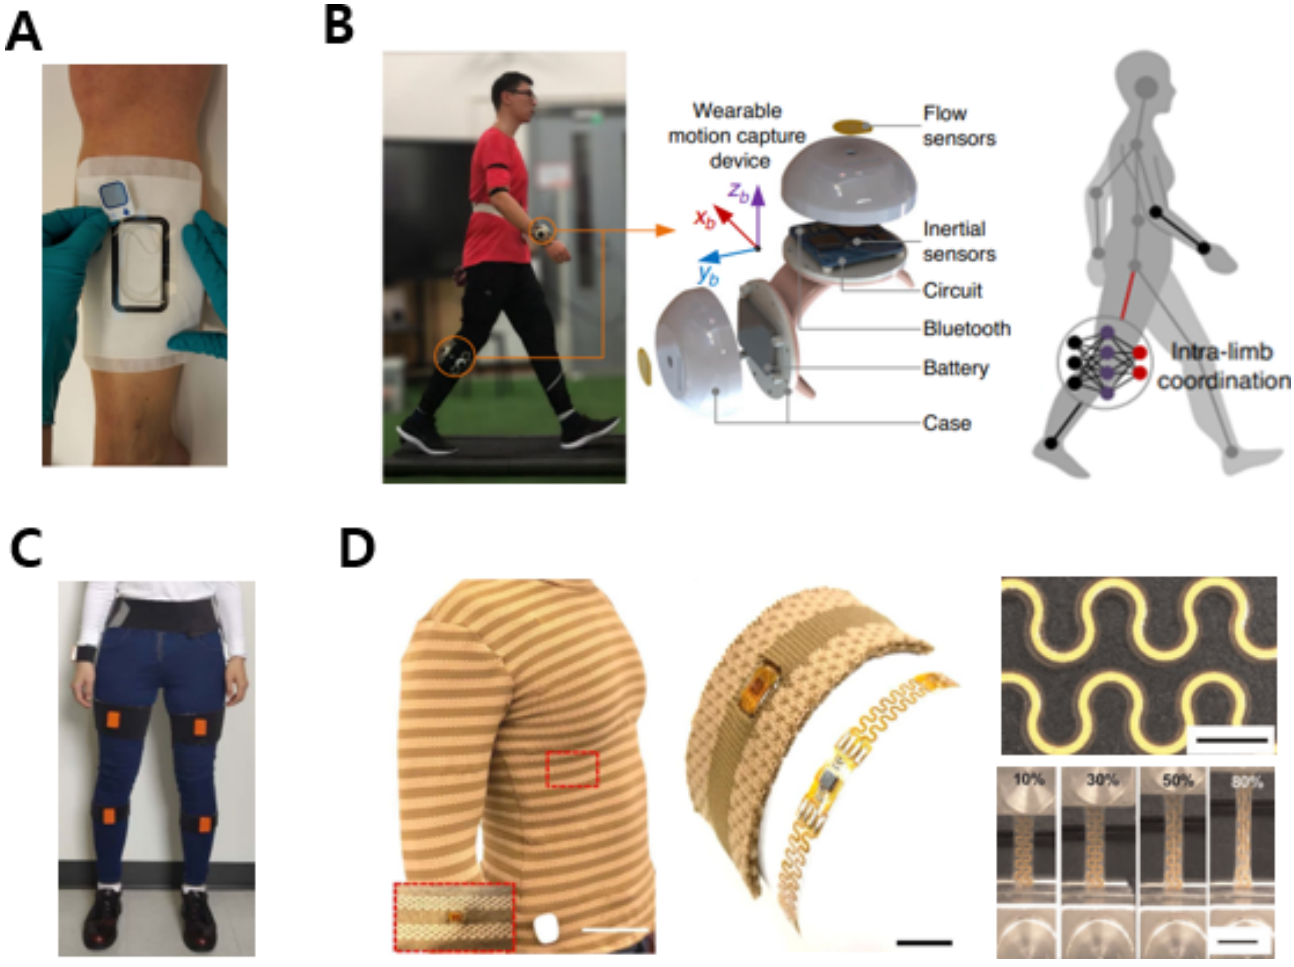
wireless communication module to continuously monitor temperature changes with high resolution and sensitivity and perform thermal treatment through a graphene-based heater. Beyond the existing complex multisensor structure, skin patches alone may decode movements of 5-finger gestures by detecting microdeformation using the laser-induced crack structure, as shown in Figure 4E [64]. Based on the same principle, it can be attached to various body parts to track physical movements.

Furthermore, ECG, EMG, temperature, sweat, and interstitial fluid analyses can be performed following health care monitoring through arm tattoos [16,86]. For instance, a noninvasive epidermal biosensing system includes physically separated electrochemical biosensors for the extraction of interstitial fluid at the cathode and sweat stimulus extraction at the anode, as shown in Figure 4F [16]. Namely, this biomarker monitoring system is a single wearable epidermal platform that simultaneously samples and analyses different biofluids.

Legs and Feet

Figure 5 describes a wearable health care device that may be applied to the legs, feet, or whole body. The mobile form factors applicable to the legs include patches, wearable robots, and straps, which perform moisture analysis at the wound area, gait analysis, ECG measurement, and rehabilitation evaluation [17,87-92]. For instance, appropriate dressing changes for exudative wounds are essential. Using a moisture sensor mounted on the bandage, as shown in Figure 5A [89], the change in the amount of dressing on the wound can be detected and the replacement time determined, increasing patient convenience. A motion capture device can accurately measure the movement of limbs during daily activities, strenuous exercise, and long-term exercise, as shown in Figure 5B [17]. Existing drift and instability problems are solved by integrating microtriaxis inertial and microtriaxis flow sensors. Additionally, it is possible to evaluate gait performance on irregular and uneven surfaces using a wearable sensor in the form of a strap with 6 inertial measurement units (IMUs) and an analysis algorithm, as shown in Figure 5C [92]. It is possible to implement edema measurement, gait analysis, and ulcer detection via plantar pressure analysis using wearable sensors attached to the shoes, socks, or soles of the feet [93-97].

Figure 5. mHealth apps for the legs and the whole body. (A) Moisture sensor for exudative wounds. The image was reprinted from Henricson et al [19,89]. (B) A motion capture device capable of detecting limb movements with high accuracy. The images were reprinted from Liu et al [17,19]. (C) Wearable strap sensor for gait analysis. The image was reprinted from Luo et al [19,92]. (D) An electronic textile conformable suit for distributed sensing wirelessly. The images were reprinted from Wicaksono et al [19,98]. mHealth: mobile health.



Whole Body

Furthermore, clothes worn on the whole body are also a type of wearable device. Figure 5D [98] shows a personalized and conformable suit of an electronics-based textile for multimodal health care sensing. The platform's elasticity ensures intimate contact between the electronic device and the skin, and it can detect the skin temperature, heart rate, and respiration with high accuracy and precision. The suit with electronic textiles can measure the body temperature, respiratory rate, heart rate, oxygen saturation, and EMG and ECG characteristics and can also perform phototherapy [98-103]. As described before, form factor and detection targets by body part on wearable devices are summarized in Tables 1-4.

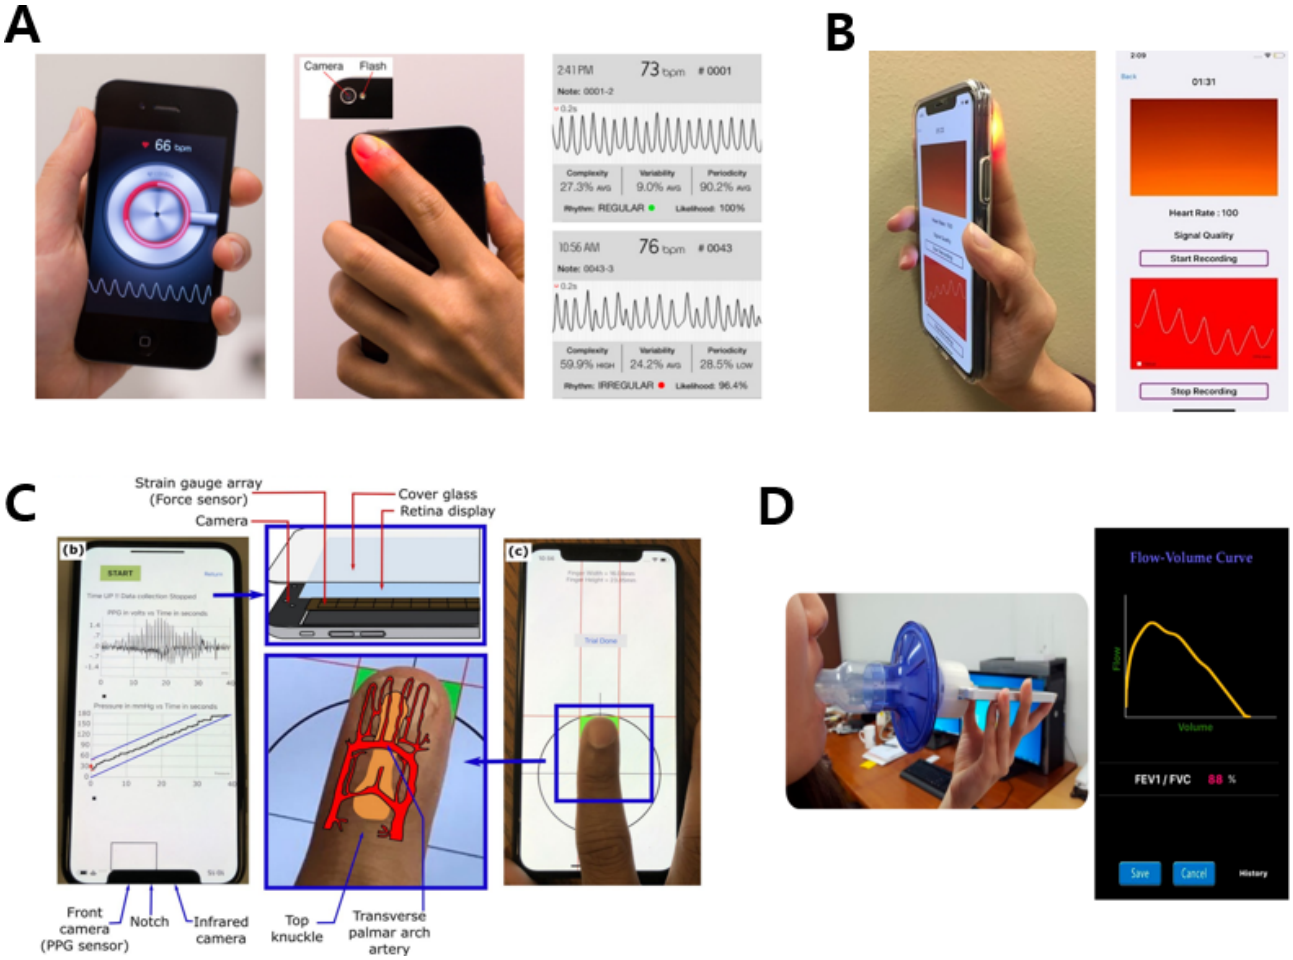
Recent Progress in the Development of Smartphone-Based Health Care Apps

In addition to wearable devices, health care delivery is also possible using smartphones through built-in sensors, smartphone-interlocked gadgets, display-related materials, and apps.

CMOS Only

Smartphones have built-in 20-30 sensors; in particular, complementary metal-oxide-semiconductor (CMOS) image sensors may be used to monitor heart, eye, and skin-related diseases [18,104-109]. As shown in Figure 6A [18], the atrial fibrillation screening ability using PPG pulse analysis based on a smartphone camera and a commercialized app showed a similar performance level to that of patches used for single-lead ECG monitoring. It has been proven that prodromal stroke symptoms can be detected using only a smartphone in a primary care setting. In addition, the fingertip motion signal and color intensity signal, both heterogeneous signals, are acquired and analyzed using a camera to remove finger movement and optical noise, as shown in Figure 6B [104]. In this way, a clean heart rhythm signal with high accuracy can be extracted via smartphone monitoring, while minimizing noise artifacts.

Figure 6. Health care apps using built-in smartphone sensors. (A) Smartphone built-in camera and app-based atrial fibrillation diagnosis. The images were reprinted from Chan et al [18,19]. (B) Heart rhythm analysis using CMOS image sensor. The images were reprinted from Tabei et al [19,104]. (C) Smartphone-based blood pressure measurement through the oscillometric finger-pressing method. The images were reprinted from Chandrasekhar et al [19,110]. (D) Set and acquisition graph of smartphone and 3D-printed mouthpiece adapter for spirometry. The images were reprinted from Thap et al [19,111]. CMOS: complementary metal-oxide-semiconductor; PPG: photoplethysmogram.



Hybrid Including CMOS

New functions, such as blood pressure measurement and temperature and dietary monitoring, can be established by combining pressure sensors, temperature sensors, and the phone microphone instead of CMOS alone [110,112-115]. For instance, as shown in Figure 6C [110], absolute blood pressure is measured via a blood flow oscillometric signal through finger pressure using a strain gauge on the front of the smartphone, in addition to CMOS. A light-emitting display may also be added to this, so it is possible to measure blood pressure ultimately with pure smartphone components.

IMU/Microphone/Ultrasonic Sensor

In addition, sleep position monitoring and treatment can be performed by detecting body movements through an IMU of the smartphone, and the gait of patients with Parkinson disease can also be analyzed [116-118]. The smartphone's built-in microphone sensor can also assess lung capacity and breathing sounds and monitor sleep [111,119-121]. Figure 6D [111] reports lung capacity and function parameter measurements following smartphone microphone–based, high-resolution time-frequency spectral analysis. A moisture-resistant ultrasonic sensor using polyvinylidene fluoride can be used for biometric authentication through fingerprinting [122].

Touch Sensor/Digitizer

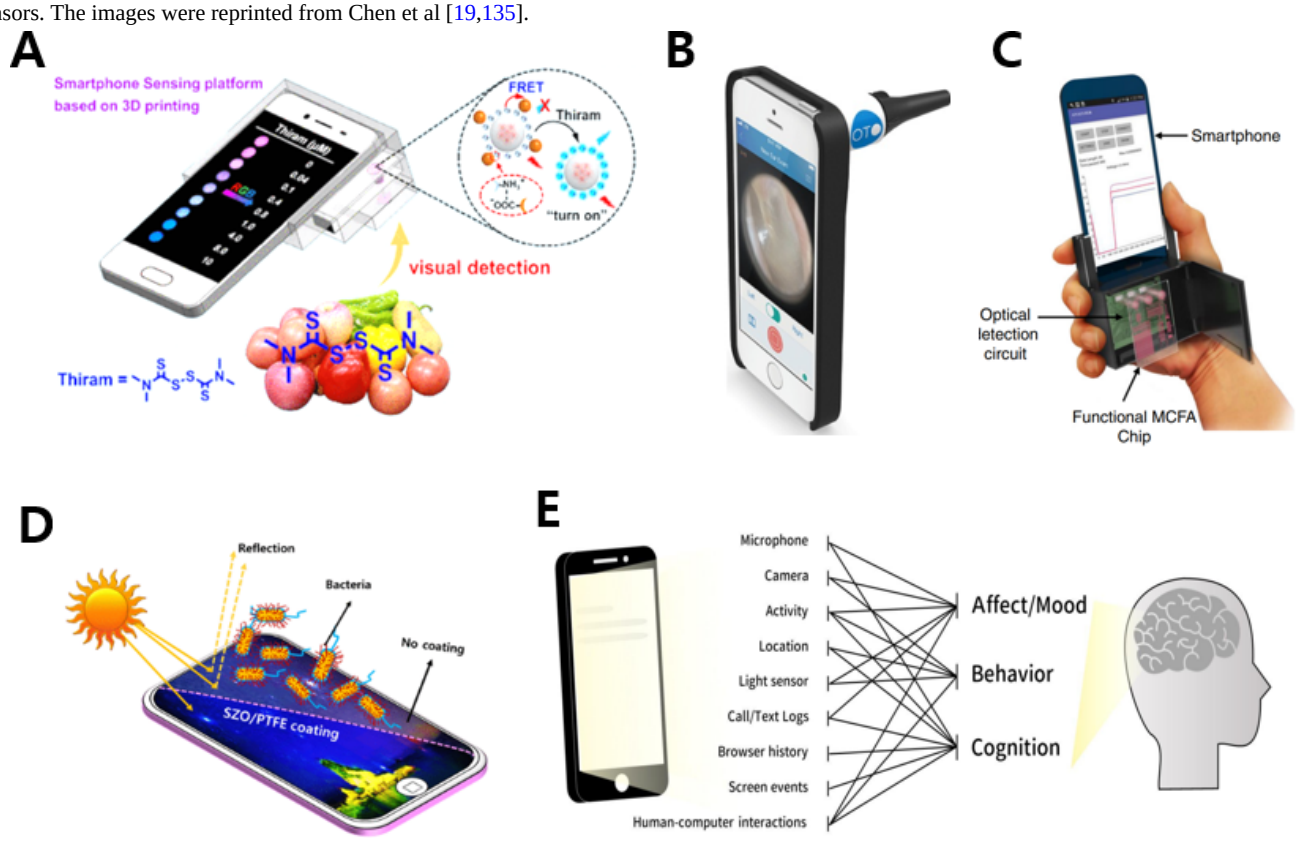
Moreover, general user interfaces, such as a touch sensor and digitizer, can also be used for health care purposes. For example, the heart rate can be checked by assessing capacitance changes according to the heartbeat with a capacitive touch sensor. The touch sensor is also helpful in diagnosing Parkinson disease through touch accuracy analysis [123,124]. In addition, a digitizer for writing can be applied to biometric authentication through handwritten signature recognition [125,126].

Interlocked Gadgets

There is a case of combining various mHealth sensing techniques, such as pesticide analysis, otitis media diagnosis, malaria infection detection, and ECG measurement, by adding a separate gadget rather than using just the smartphone itself [127-133]. The platform shown in Figure 7A [128] performs a visual, quantitative analysis of pesticides using an optical system that combines a dark cavity and an ultraviolet lamp with a smartphone. In other words, integrating a smartphone and a gadget-based paper strip enables real-time and on-site food evaluation. Additionally, it was confirmed that the diagnosis of acute otitis media is possible with the same level of accuracy as that attained with existing otoscopes through the combination of a commercialized optical system and a camera in a

smartphone, as shown in Figure 7B [130]. Figure 7C [132] shows a smartphone-based immunodiagnostic platform that performs a chemiluminescence-based enzyme-linked immunosorbent assay using a lyophilized chemiluminescence reagent. This hand-held point-of-care-testing analyzer can detect active malaria infections with a sensitivity of 8 ng/mL.

Figure 7. Health care apps using gadgets mounted on smartphones. (A) Smartphone platform for pesticide evaluation of food, integrated with an ultraviolet lamp and a dark cavity by 3D printing. The images were reprinted from Chu et al [128]. (B) Smartphone otoscope for diagnosis of acute otitis media. The images were reprinted from Mousseau et al [130]. (C) Smartphone-based immunodiagnosis using microfluidic assays. The images were reprinted from Ghosh et al [19,132]. (D) Antibacterial touchscreen for preventing contamination. The images were reprinted from Ippili et al [134]. (E) Digital biomarkers that reflect users' moods, behaviors, and cognitions using text logs, browser history, human-computer interactions, and various sensors. The images were reprinted from Chen et al [19,135].



Display Materials

Health care delivery can also be achieved through materials used in manufacturing smartphones, such as window coatings for antireflection and display processes. An ecofriendly antibacterial coating with Zn-doped silicon oxide thin films can prevent infectious diseases caused by microbial contamination of touch events, as shown in Figure 7D [134]. In addition, it is possible to reduce the deformation of retinal cells by decreasing the blue light of the display through the material development of organic light-emitting or color filters [136].

Apps

Furthermore, health care sensing is possible through apps incorporating digital phenotypes and digital therapeutics [135,137-140]. A digital phenotype refers to a disease or health condition that is unintentionally reflected in patterns of use of digital devices. Mobile apps can collect human-smartphone interaction data to monitor smartphone usage and construct long-term patterns and trend changes. As shown in Figure 7E [135], analyzing a digital biomarker that reflects human effects, moods, behaviors, and cognition can predict psychiatric conditions, such as depression and smartphone addiction. In addition, digital therapeutics delivered through games, education, coaching, and counselling are based on cognitive behavioral therapy and can treat insomnia, alcohol addiction, drug addiction, panic disorder, and attention deficit hyperactivity disorder. Additionally, it effectively improves physical diseases, such as obesity and high blood glucose. Table 5 summarizes the sensing methods and targets using smartphones.

Table . Summary of sensing methods and targets using smartphones.

Type and sensing methods	Target(s) of detection	Reference(s)
Built-in sensors

[d]ECG: electrocardiogram.

Prospects for mHealth

The industry of mHealth is expected to grow explosively in the future. In particular, the third generation of medicine and therapies that rely on novel solutions are emerging beyond the existing state of mHealth. Among them, bioelectronic medicine is a nonpharmacological treatment category that stimulates nerve functions with energy, such as electricity, light, and ultrasonic waves. This approach uses an electronic device that controls metabolic function to maintain homeostasis by regulating hormones [141]. To date, electroceuticals have been used for obesity, asthma, sleep apnea, brain tumors, epilepsy, and Parkinson disease and have shown substantial and significant therapeutic effects [142-144]. It is also one of the most innovative fields in medicine because it has significant advantages when considering the development time and cost of existing drugs.

Using digital therapeutics, also referred to as “software as a medical device,” it is possible to manage and treat not only physical diseases but also psychiatric conditions, such as posttraumatic stress disorder and schizophrenia [145,146]. It is

of great significance in terms of patient convenience that personal and sensitive mental health conditions can be diagnosed in real life, not in hospitals, through digital phenotypic analysis, such as smartphone usage patterns and uploaded social networking service (SNS) content.

From the point of view of the wearable form factor, since much of health care sensing is possible on the wrist, the smartwatch is currently playing a pivotal role in health care. The finger (as well as the wrist) is a body part to focus on as it can be used to assess health factors, such as the heart rate, oxygen saturation, ECG characteristics, blood pressure, blood sugar, biometric authentication, body temperature, and dietary monitoring. Therefore, it is expected that in the future, the ring type of device for health care will pair with the smartwatch as the 2 main pillars.

Challenges for mHealth

This viewpoint investigated comprehensive health care sensing technology using wearable electronics and smartphones. However, mHealth is less widely used than expected, unfortunately. Wearable devices are relatively more optimized for continuous and real-time health care sensing compared to smartphones [147,148]. However, the penetration rate compared to smartphones worldwide is sluggish [149-151]. A smartwatch, a representative wearable device, needs to be connected to a smartphone to operate, so users do not recognize the wearable device as an independent entity. Independent use is required to be fully positioned as a separate device. These devices lack effectiveness due to reduced user convenience because of their small screens, poor battery performance, low usage rate, clunky design, and high price. Wearable devices are recognized as a kind of subdevice rather than an essential and leading product because they do not have as much impact as smartphones. Therefore, in the case of wearable devices, innovative solutions are required to make them universal necessities for human beings, such as smartphones.

However, in the case of smartphones, the penetration rate is high worldwide, including low- and middle-income countries [152]. In the case of current smartphones, the fundamental value in terms of user experience as well as utility is high. However, it is not such a great solution from the perspective of health care. It is challenging to conduct biosignal sensing using a smartphone while being in close contact with human skin all day long, so it is challenging to implement continuous real-time big data–based predictive and preventive medical care using smartphones from the health care perspective. Smartphones desperately require a breakthrough that can allow them to monitor health in real time continuously, 24 hours a day, through a form more closely adherent to the skin, while maintaining the current phone function.

Breakthroughs for mHealth

The display is a crucial component of a health care system. In other words, smartphones and wearable devices, as central axes of the mHealth system, are inseparable from their displays. In addition, displays and sensors in mobile devices are closely related. To improve the convenience of user interaction, the proportion of the active area of mobile displays is increasing. However, the increase in the active area has a limitation that reduces the sensing performance, including sensitivity. To overcome this, the upper part of the sensor covers the display by lowering the resolution of the display to prevent the deterioration of the sensing transmittance. A typical example is under-panel camera (UPC) technology that covers the camera with the display by reducing the display resolution on the top of the CMOS image sensor to increase light transmittance.

Sensor-Integrated Display Solution

However, the ultimate and ideal method is a sensor-integrated display solution. A sensor-integrated display has many advantages from a health care sensing point of view. This is because (1) many mHealth sensors use an optical approach, (2) it is relatively easy to manufacture large-area sensors, and (3) the application of a new form factor display can lead to an increase in the body contact area.

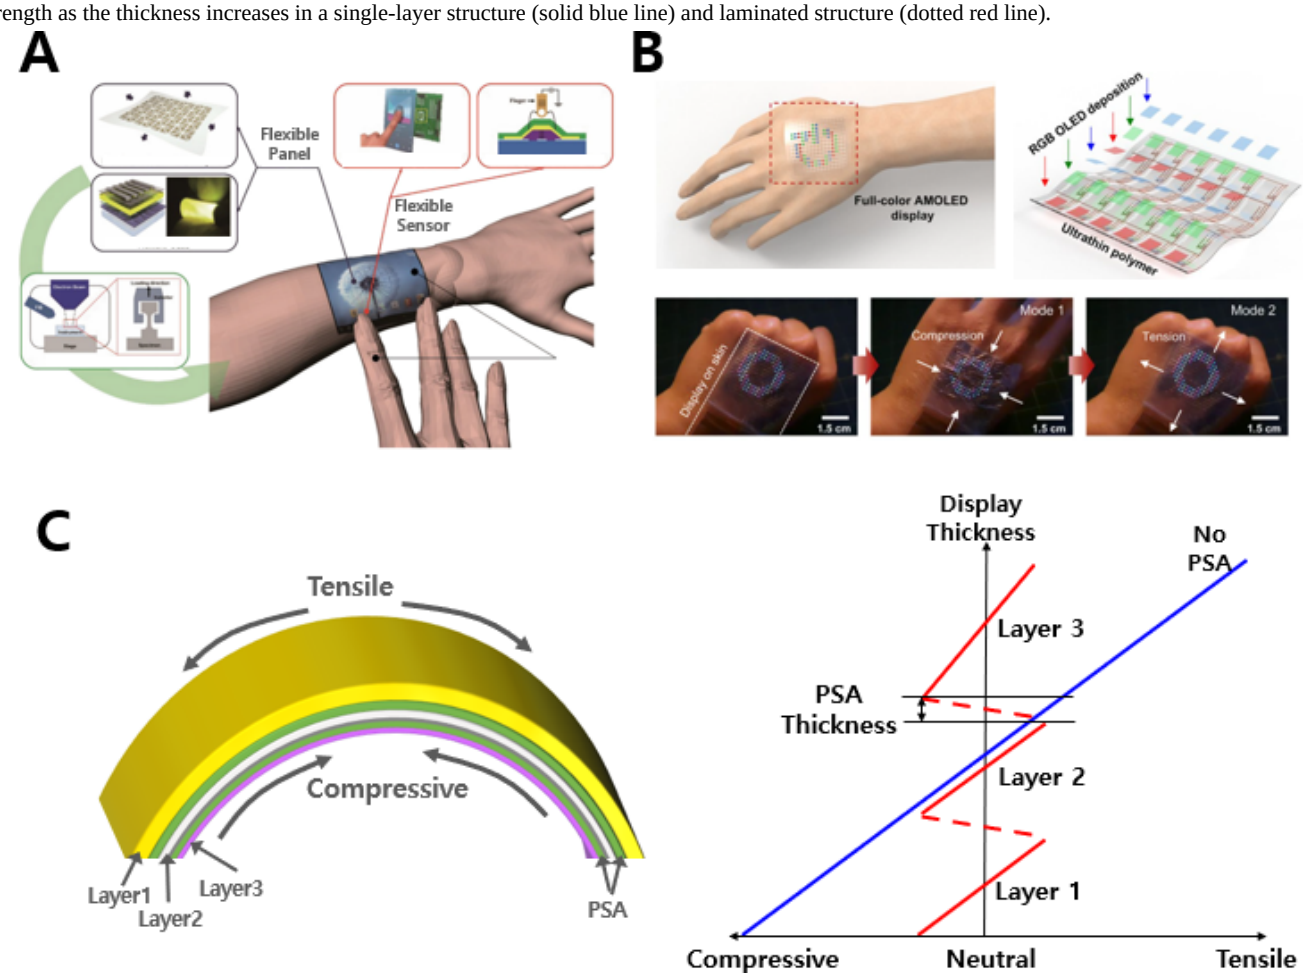
First, the majority of mHealth sensing approaches are optical methods. Various health care parameters, such as the heart rate, oxygen saturation, blood pressure, blood sugar, body temperature, environmental monitoring, and ECH characteristics, can be measured optically. A display is an optical system that already has the means to transmit light. Therefore, a sensor-integrated display could be an optimized health care solution. To implement health care devices using optical systems, in addition to optical transmitters, receiver systems must also be equipped. For advanced performance, the light-emitting wavelength band needs to be expanded and supplemented, including infrared as well as visible light, through the development of materials for the light-emitting layer.

Second, since the sensing area and detection performance are proportional, health care ability can be improved through a sensor embedded in a wide display area. It enables health care sensing in a large area over the entire display area when the built-in optical system is applied, considering design rules. In addition, it is more advantageous for wearability because of a reduction in volume due to the implementation of microlevel thickness because of the sensor-integrated display. Additionally, compared to the number of photomasks needed to manufacture a conventional display, the number of additional photomasks required to implement a display health care system with built-in sensors is far less. It can contribute to popularization due to the low manufacturing price according to the integral type. Ultrathin, low-cost health care devices with relatively simple processes have significant benefits over conventional, bulky, and expensive wearable computers.

Finally, the new form factor device, such as a stretchable sensor-integrated display, increases the area of contact with the body and improves detection capability through health care sensing in close contact with the skin. Flexible panels with user convenience could be applied to the human skin, considering ergonomic factors [153-159]. The flexibility of not only the active matrix backplane and core of the panel but also the touch sensor, fingerprint sensor, and pressure sensor must be ensured, as shown in Figure 8A [153]. In a complete sensor-integrated

display, the flexibility of the backplane allows the sensor part to gain flexibility naturally.

Figure 8. New form factor display and principle. (A) Wearable display with flexible and ultrathin active matrix backplane, touch screen panel, and fingerprint sensor components. The image was reprinted from Park et al [19,153]. (B) A flexible active matrix organic light-emitting diode (AMOLED) with large-area MoS2-based backplane for human skin display. The images were reprinted from Choi et al [154]. (C) A graph of compressive and tensile strength as the thickness increases in a single-layer structure (solid blue line) and laminated structure (dotted red line).



Furthermore, Figure 8B [154] shows a wearable full-color organic light-emitting diode (OLED) display using a 2D material–based backplane transistor suitable for complex skin shapes. The 18×18 thin-film transistor array was fabricated on ultrathin MoS_2 film and then transferred to Al_2O_3 (30 nm)/polyethene terephthalate (6 µm), providing mechanical flexibility beyond conventional OLED technology.

New Form Factor Display

The left picture of Figure 8C simulates a multilayered display, and when this display is bent, tensile strength is applied at the top and compressive strength is applied at the bottom. Assuming that it is formed with only a single layer of the same thickness rather than a laminated structure, extreme tensile and compressive forces occur on the upper and lower surfaces, resulting in cracks in the display, as shown by the solid blue line in the right graph. However, in the stacked structure, a pressure-sensitive adhesive (PSA) between the display layers continues to create new neutral planes, as shown by the dotted red line. In response, the magnitude of the tension and compression force at the top and bottom surfaces does not increase, even if the thickness of the display increases. In other words, using the PSA, it is possible to implement a flexible display without cracks.

No part of the human body is flat. When the health care system and the skin conformally adhere, sensing performance improves. Display technology based on PSA with the harmony of creep and recovery characteristics induces form changes in wearable devices and smartphones. A new form factor with flexibility based on PSA technology that creates a new neutral plane will facilitate a critical conversion of the mHealth system.

Standard of the Medical Paradigm in the Postpandemic Era

A new form factor display for health care with flexibility and display convergence technology using an optical method attaches a large-area health care system to the human skin conformally and continuously detects health care factors in real time, thereby providing a framework for collecting big data. As a result, the existing smartphone becomes a wearable device attached to the body, and the existing wearable device is equipped with smartphone functions suitable for user convenience. Namely, convergence health care technology with the sensor-integrated and new form factor display is an indispensable element that enables the smartphonization of a wearable device and the wearable deviceization of the

smartphone. Of course, health care systems with new form factors and sensor-integrated displays do not solve all mHealth problems. In other words, advances in big data AI software analysis and medical security should go hand in hand with the smartphonization of wearable devices and the wearable deviceization of smartphones. Furthermore, it will be necessary to supplement the medical system policy so that these benefits do not become the exclusive property of the upper class of the economy and so that people from lower social classes can also benefit. Advanced and popularized mHealth system technology could ensure universal health coverage so that everyone can use essential, high-quality medical services without discrimination. In other words, the authentic democratization of health care could become a reality, and a standard for a future health care paradigm in the post-pandemic era could arise.

Conclusion

Personalized platforms, such as wearable devices and smartphones, can be applied to AI-based disease prediction, prevention, and treatment. This viewpoint researched the latest technology trends in mHealth regarding form factors and detection targets according to body attachment location and type. In particular, the sensor convergence technology of the new form factor display provides a framework to analyze health factors in real time by conformally adhering a large-area system to the skin. Innovation in form factors in sensor-integrated displays and convergence health care solutions enable the smartphonization of wearable devices and the wearable deviceization of smartphones. In addition, the strategy for the smartphonization of wearable devices and the wearable deviceization of smartphones can accelerate the development of mHealth, realizing the democratization of medical care so that anyone can use essential services of high quality. Furthermore, it is expected to create a new milestone for the medical paradigm shift in the postpandemic era.

Abstract

Hospital-at-home has been gaining increased attention as a potential remedy for the current shortcomings of our health care system, allowing for essential health services to be provided to patients in the comfort of their own homes. The advent of digital technology has revolutionized the way we provide medical and health care, leading to the emergence of a "hospital without walls." The rapid adoption of novel digital health care technologies is revolutionizing remote health care provision, effectively dismantling the conventional boundary separating hospitals from the comfort of patients' homes. The Guangdong Second Provincial General Hospital has developed a 5G-powered Smart Home Ward (SHW) that extends medical care services to the home setting and is tailored to meet the needs and settings of each patient's household. The SHW was initially tested for its suitability for treating 4 specialized diseases, including cardiovascular disease, stroke, Parkinson disease, and Alzheimer disease. Understanding and addressing the potential challenges and risks associated with SHWs is essential for the successful implementation and maintenance of safe and effective home hospitalization.

The Future of Older Adult Care in China: Innovations in Health Care Delivery

China has emerged as a rapidly aging society. Aging contributes significantly to the health care burden in China due to the increased prevalence of chronic diseases and disabilities among older adults. The health care burden for the population of older individuals in China is further compounded by inadequate health care infrastructure and limited access to health care services in rural areas. The Chinese government has implemented various policies and initiatives to address these challenges, including expanding health care coverage, promoting preventative care, and increasing investment in health care infrastructure. Currently, the top-level design of China's older adult care model is "9073," which means that 90% of older people receive older adult care services at home, 7% of them receive short-term care in the community, and 3% of them receive institutional care. This implies that the age-friendly and livable environment at home affects 90% of the population of older adults.

Hospital-at-home, which seeks to provide essential health services to patients in the comfort of their own homes, has been gaining increasing attention as a feasible solution for at-home older adult care and medical services [1-3]. The COVID-19 pandemic has underscored the risks of overreliance on physical medical institutions, emphasizing the continued need to develop a decentralized medical service ecosystem that revolves around patients' families and communities. Hospital-at-home programs have been implemented in many high-income countries for years [4-7]; however, successful programs are limited [8]. Experience translating from high-income countries to low- and middle-income countries can be challenging, where medical resources are limited and public health literacy is low [2,3,9,10].

The Growth of Emerging Technologies for Home Hospitalization

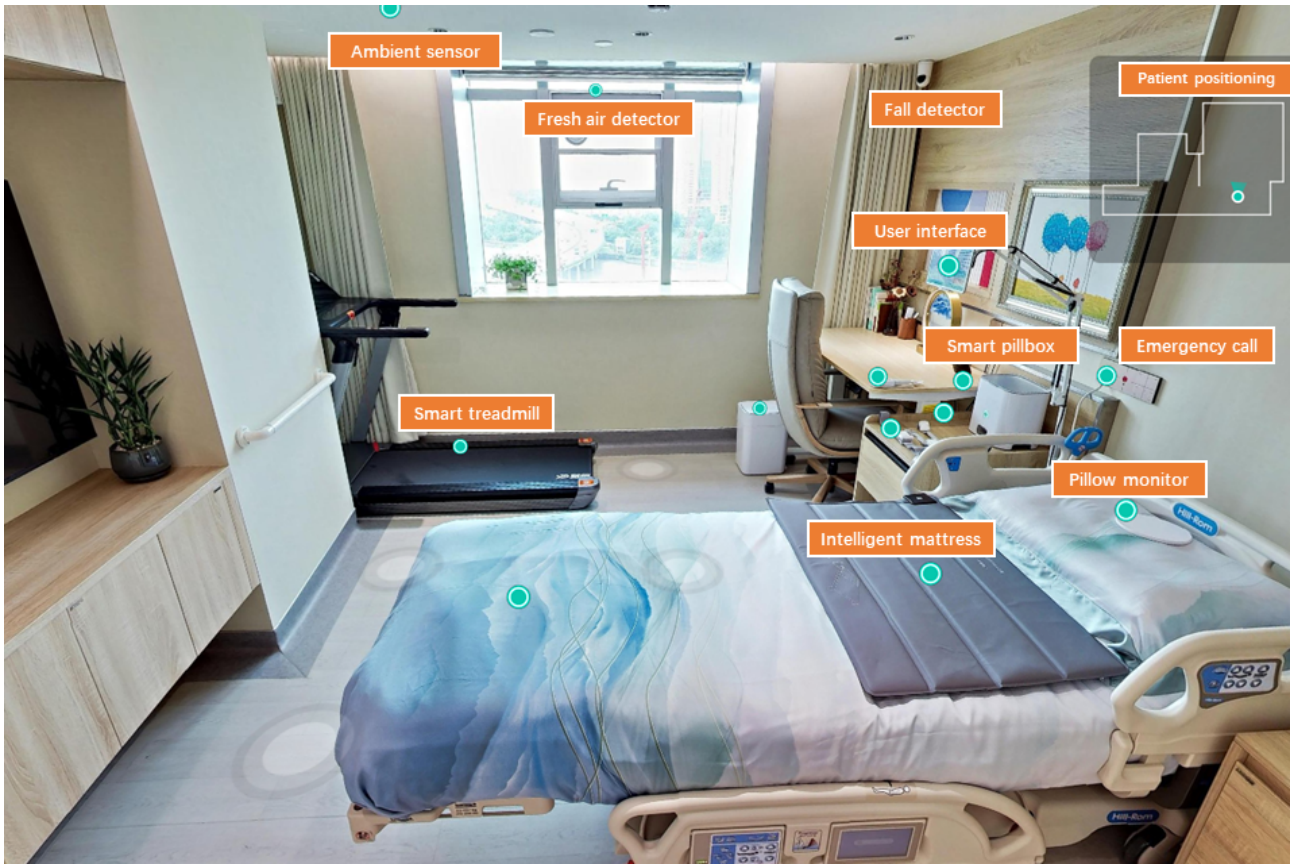
New digital health care technologies are being rapidly adopted for remote health care provision, which is breaking down the traditional barrier between the hospital and home. The emergence of 5G technology posed the potential to further enhance home hospitalization by enabling remote patient monitoring and real-time communication between health care providers and patients. The introduction of sensor-based wearables and devices has changed the way that clinical data are collected and stored, leading to groundbreaking advancements in how care is provided [11,12]. Digital biomarkers—a set of objectives, quantifiable measures of physiological and behavioral characteristics that are acquired via wearables, implants, and other devices—are becoming

increasingly essential in this process [13,14]. Home hospitalization can greatly benefit from the use of digital biomarkers, providing care teams with a more comprehensive understanding of a patient's health. These biomarkers enable the tracking of vital signs such as heart rate and respiration rate, as well as changes in sleep patterns, activity levels, and dietary habits [12,15,16].

Smart Home Ward for Hospital-at-Home Care

In 2021, Guangdong Second Provincial General Hospital developed the "Hospital Intelligent Twins," a 5G-powered smart hospital that integrates the Internet of Things (IoT), artificial intelligence (AI), cloud computing, and 5G applications to create all-scenario intelligence for health care and hospital management [17,18]. Leveraging this 5G smart hospital infrastructure, Guangdong Second Provincial General Hospital further explored the Smart Home Ward (SHW), which seeks to break through the "wall" of centralized hospital-based health care services by extending care services to the home setting (Figure 1). The SHW is a seamless hospital unit managed by health professionals in the hospital and is designed to provide patients with equivalent hospital-level services at home, including medical monitoring, ward rounds, consultation, and medical care, and so on. SHW can support 2 hospital-at-home models, early-supported discharge and admission avoidance, offering integrated health monitoring, medical care, and rehabilitation services all within the comfort of their homes [19,20].

Figure 1. Demonstration of the Smart Home Ward in the hospital.



The management of patients in the SHW is handled by an interdisciplinary care team overseen by responsible specialists from relevant clinical departments. At present, the Departments of Cardiology and Neurology are pilot testing SHWs for patients with cardiovascular conditions and those with cerebrovascular conditions, respectively. Each specialty establishes a dedicated home ward team comprising physicians from that department, along with nurses, pharmacists, physical therapists, occupational therapists, and social workers. For example, the post–coronary heart disease treatment team includes cardiologists, cardiac nurses, and rehabilitation therapists. Patients undergo an initial clinical assessment by their specialist physician to determine their suitability for remote home care. The inclusion and exclusion criteria for specific conditions such as coronary heart disease and stroke are provided in Multimedia Appendix 1. If deemed feasible based on the assessment and if the patient provides consent, the interprofessional SHW staff conduct a home environment evaluation. Necessary modifications are made and monitoring equipment or devices installed to safely support care at home with remote specialist oversight.

In the SHW, series of digital biomarkers are monitored, including blood pressure, heart rate, respiratory rate, blood oxygen saturation, body temperature, and electrocardiographic signals, with patients' daily activities, treatment compliance, and risk occurrences monitored via contact or contactless devices. These data can be leveraged to tailor treatments or notify care providers of any deviations from expected parameters.

Data generated from the SHW are transmitted securely to the hospital's electronic medical record (EMR) system in real time. The integration follows privacy and security guidelines set forth by our hospital's Health Insurance Portability and Accountability Act (HIPAA)–compliant policies. Only deidentified data points that are relevant for clinical care, such as vital signs, activity levels, and medication adherence data, are integrated into the EMR. Data transmission from the SHW to the EMR is one-way to ensure the security of sensitive hospital information. Authorized care team members, including attending physicians, nurses, pharmacists, physical therapists, and case managers, have access to consolidated patient data reports within the EMR system. This allows them to monitor trends, recognize any deviations from normal ranges, and act accordingly without needing to use separate systems.

The primary care team, led by the patient's attending physician, is responsible for reviewing the daily reports and contacting patients if follow-up care is needed, based on the remote patient monitoring data. Family members and caregivers participate in care conferences to stay updated on the patient's progress but do not have access to the EMR. We aim to expand access to aggregated reports to allow for greater caregiver involvement while maintaining privacy and security.

A pretraining ward has been established in the hospital to help patients transit from hospital to home living. Patients are trained on the use of smart home devices and receive guidance on remote rehabilitation training. In addition, the pretraining ward includes medical assessments to ensure that the patient is eligible for admission to SHW care and will benefit from the treatments provided at home. Specialized staff consisting of nurses, physical therapists, and occupational therapists are dedicated to supporting the SHW program. These clinicians provide personalized patient education, demonstrations, and skills training. They ensure that patients and caregivers are comfortable with the remote monitoring system and therapy program prior to discharge. The goal is to maximize treatment adherence and outcomes through empowering patients and families with knowledge. A dedicated tech support team is also available to assist families in successfully setting up the in-home system and addressing any technical issues that may arise post discharge. Readily available support from clinical and technical experts further enables safe and independent living at home with remote care and monitoring.

Characteristics of the SHW

The SHW constructed in this project not only integrates advanced medical IoT technology and products, but also involves the renovation of the environment to make it suitable for older adults and patients, extending homogeneous medical services provided in the hospital wards to patients' homes. Its characteristics are mainly reflected in the following 4 aspects.

First, the SHW has a multitude of functions including ambient sensing, medical monitoring, rehabilitation training, exercise and diet guidance, psychological counseling, and sleep management. To achieve these capabilities, a variety of cutting-edge technologies such as 5G or Wi-Fi 6, Internet of Medical Things (IoMT), smart wearable devices, smart home appliances, and health monitoring equipment have been deployed in the home setting. For instance, an intelligent closetool can detect urine levels and monitor heart rate, body fat, and the length of time spent on the toilet [21]. Additionally, an intelligent mattress and pillow monitor heart rate, respiration rate, and body movement frequency during sleep [22,23]. Applications such as those for fall detection in the bathroom and the amount of stillness in daily activities can trigger an automatic alarm for an emergency, which connects to the hospital [24].

Second, to facilitate hospital-at-home management, a platform was developed with the integration of cross-system and cross-ecological IoMT devices (Figure 2; see the screenshot of the SHW Medical Management Information System). Thus, IoMT devices and ambient sensors are interconnected, and data are generated, gathered, managed, and processed by various terminals, including data from a hospital and a SHW (including data for the home environment, daily activities, treatment, rehabilitation, etc). This enables interoperability for home ward management, allowing patients, health professionals, and caregivers to use mobile terminals such as tablets to view the patient's physiological data in real time and manage the home ward setting with ease. As medical teams have the capability to monitor a patient's health from a distance, fewer in-person visits are needed, thus decreasing the cost of care [25].

Figure 2. Screenshot of the Smart Home Ward Medical Management Information System.

Third, deployment of an SHW is tailored to cater the needs and settings of a patient's household. To promote patient autonomy in the home setting, the SHW undergoes various levels of renovations suitable for aging individuals, creating a barrier-free, safe, and secure living space. Furthermore, ambient sensors enable automatic configuration to ensure the comfort of the environment [26]. These sensors continuously detect the air, temperature, and humidity in the ward. Whenever the indoor concentrations of particulate matter of diameter ≤ 2.5 μm, formaldehyde, and carbon dioxide exceed standard levels, the SHW automatically adjusts its equipment to improve indoor air quality.

Fourth, the extension of hospital care services to the home setting is achieved through the integration of various technologies and resources. This challenge is addressed by the SHW through the deployment of advanced IoMT technology and products, which allow for the passive monitoring of patients' health and the implementation of timely medical interventions. Additionally, a comprehensive EMR system has been implemented, enabling seamless sharing of patients' medical records between the hospital and home health care systems. Furthermore, a robust 5G-based telemedicine infrastructure has been established, enabling real-time communication between patients and doctors, including digital consultations, remote monitoring, and telemedicine-enabled home visits, as well as providing on-demand home care services [27].

SHW Care Plans for Specialized Diseases

The SHW's feasibility of treating 4 specialized diseases, namely Parkinson disease, cardiovascular disease, stroke, and Alzheimer disease, is being tested. For each disease, corresponding care plans have been developed, and necessary monitoring and treatment facilities have been suggested.

In the case of Parkinson disease, exercise rehabilitation treatment is mainly used as the primary treatment modality in the home ward. Patients are guided by doctors remotely to implement various forms of internet-based rehabilitation exercise training, such as relaxation training, joint range of motion training, muscle training, breathing training, gait training, balance training, and cognitive training. During exercise, the patient's heart rate is monitored using a smart watch to prevent excessive exercise intensity. A smart lunch box is provided for daily monitoring of the frequency and amplitude of the patient's hand tremors while eating to evaluate the effectiveness of rehabilitation treatment [28].

For patients with cardiovascular disease, the home ward caters to those with ST-segment elevation myocardial infarction, non–ST-segment elevation acute coronary syndrome, stable angina pectoris, ischemic cardiomyopathy, chronic systolic heart failure, and sudden cardiac death syndrome. Cardiac rehabilitation exercise therapy is guided by health professionals from the hospital, which includes aerobic exercise, resistance training, and neuromuscular training. A treadmill with heart and lung function monitoring is set up as a rehabilitation tool at home, which records and monitors the patient's exercise status and heart rate, blood oxygen saturation, and calorie consumption. This allows doctors to adjust the program promptly [29].

For stroke, given that individuals who have experienced a stroke often face difficulties with mobility, the adaptation of living spaces to suit their needs is crucial to promote independent living and facilitate rehabilitation. To this end, we have implemented appropriate accessibility retrofits within the home

setting to establish a barrier-free environment for patients. Such efforts can contribute to not only increased mobility but also heightened patient confidence. To evaluate the efficacy of functional rehabilitation, regular assessments are conducted through both home visits and hospital evaluations.

In the case of Alzheimer disease, a comprehensive treatment approach is adopted, including cognitive training, task training, and music therapy. These treatments are supported by the augmented reality and virtual reality applications that allow doctors to simulate complex scenarios to stimulate patients' brain activities in a safe and controlled environment. Several physiological signals, such as heart rate variability, eye movements, and sleep patterns, are recorded and are used to train models for treatment evaluation. Furthermore, an AI-powered camera is installed in the home environment to monitor the patient's activity status, such as sitting and lying time. A smart watch with GPS positioning and communication functions is also used to prevent patients from getting lost [30].

Challenges for the Scale-Up of the SHW Care Program in China

The widespread adoption of SHWs has been faced with several challenges. First, authoritative guidelines for the implementation of medical service standards for home ward care and those for setting up technology-enabled digital wards in China are lacking. Second, a sustainable fee-based model for home ward care has yet to be established. Third, the effective operation of home ward care requires close collaboration among hospitals, community health service organizations, and family members. However, there are currently no unified regulations to delineate the responsibilities of various stakeholders involved in providing home ward care. Fourth, the popularity and reliability of the technology needs improvement. SHWs require specialized equipment and technologies, a secure and trust-based environment, and staffing competencies to ensure patient safety and privacy. A unique standard needs to be established to ensure the interconnectedness and interoperability of various devices. Meanwhile, potential problems associated with the cost of equipment, access to necessary data, and data privacy also exist.

Implications of Hospital-at-Home Care Using SHWs for Practitioners, Researchers, and Policy Makers

The implementation of SHWs has the potential to extend the quantity and quality of hospital care services in response to the increasing demand for medical care in China's aging society.

For health care practitioners, the integration of smart home digital health technologies can facilitate remote patient monitoring and management, enabling timely and effective care delivery in patients' homes. This approach can reduce the burden on hospitals and clinics, while improving patient outcomes and satisfaction. To enable the successful implementation of SHWs, new team structures with corresponding workflows must be created in clinical settings to optimize health care systems and patients' usage of this technology. Clinical physicians must work closely with technicians in developing workflows and integrated AI tools and in the process of care provision, such as remote monitoring.

For researchers, the implementation of SHWs presents a unique opportunity to study the impact of digital health technology on health care delivery, patient outcomes, and cost-effectiveness. However, ethical considerations must be navigated when accessing the vast amounts of data gathered at SHWs to ensure patient privacy and security [31]. All stakeholders must understand and adapt to these implications to fully harness their potential benefits while mitigating associated risks.

Policy makers can benefit from the use of SHW technologies, as they show promising potential in reducing health care costs and improving access to care, particularly for patients in rural or underserved areas. However, policy makers must establish regulations to safeguard patient privacy and security, ensure equitable access to technology, and enhance digital infrastructure for widespread adoption. With careful consideration of these factors, the implementation of SHW can revolutionize hospital-at-home care, improving the quality of care, reducing health care costs, and ultimately benefiting patients and the health care system as a whole.

In Summary

The advent of digital technology has revolutionized the way we provide medical and health care, leading to the emergence of "hospitals without walls." This SHW is an innovative care model that promises to bring a host of improvements to health care by providing convenient access to "boundless ambulatory care," as well as "boundless inpatient care." Despite the potential benefits, these digital projects are still faced with some challenges, such as public acceptance and adoption of the technology, willingness to pay for services, and encouraging medical insurance uptake. Therefore, it is essential for governments to promote public awareness of the advantages of digital technology and introduce incentives that motivate people to take up medical insurance in order for these services to be widely available.

Abstract

The integration of health and activity data from various wearable devices into research studies presents technical and operational challenges. The Awesome Data Acquisition Method (ADAM) is a versatile, web-based system that was designed for integrating data from various sources and managing a large-scale multiphase research study. As a data collecting system, ADAM allows real-time data collection from wearable devices through the device's application programmable interface and the mobile app's adaptive real-time questionnaires. As a clinical trial management system, ADAM integrates clinical trial management processes and efficiently supports recruitment, screening, randomization, data tracking, data reporting, and data analysis during the entire research study process. We used a behavioral weight-loss intervention study (SMARTER trial) as a test case to evaluate the ADAM system. SMARTER was a randomized controlled trial that screened 1741 participants and enrolled 502 adults. As a result, the ADAM system was efficiently and successfully deployed to organize and manage the SMARTER trial. Moreover, with its versatile integration capability, the ADAM system made the necessary switch to fully remote assessments and tracking that are performed seamlessly and promptly when the COVID-19 pandemic ceased in-person contact. The remote-native features afforded by the ADAM system minimized the effects of the COVID-19 lockdown on the SMARTER trial. The success of SMARTER proved the comprehensiveness and efficiency of the ADAM system. Moreover, ADAM was designed to be generalizable and scalable to fit other studies with minimal editing, redevelopment, and customization. The ADAM system can benefit various behavioral interventions and different populations.

Introduction

In recent years, the health care industry has focused a considerable amount of attention on wearable devices because of their capabilities in monitoring and collecting clinically relevant information such as heart rate (HR), blood pressure, respiratory rate, sleep, and physical activity [1]. One of the main drivers of this increased attention is the high level of adoption of wearable devices in the United States. Among all US adults, around 30% have experience with wearable devices and nearly half of those who use their wearable devices regularly are willing to share their data for research purposes [2]. Furthermore, there is an increase in the accuracy offered by these off-the-shelf wearables in providing health-related measurements. For example, several studies have been conducted on consumer wearable devices such as the Apple Watch, Samsung Gear, Fitbit, Huawei Band, and Xiaomi Mi Band, which reported high accuracy in measuring steps,

distance, and HR [3-6]. These trends and the maturity of consumer wearable technologies have led more researchers to use consumer wearable devices in their research studies.

However, this increasing use of wearable devices in research studies also presents challenges. Managing and analyzing the large amounts of data generated by wearable devices in research studies in real time is not a simple task, especially for research teams without dedicated specialized technical support in wearable data management and data engineering. For example, the Fitbit fitness band, one of the most widely used consumer wearable devices in research, has been used to track steps [4,5], physical activity [4-14], HR [15], and sleep patterns [16]. Among the publications we reviewed (n=15), many (n=6, 40%) of the studies using the Fitbit fitness band used a third-party, proprietary, web-based Fitbit data collection and visualization platform—Fitabase [6-9,11,17]; 3 (20%) studies reported that they manually checked and downloaded participants' data from participants' individual Fitbit account at the end of the study [5,12,17]; 1 (7%) study used the MySantéMobile system [13]; and the rest (n=5, 33%) did not report on the system they used for collecting and displaying data from the wearable devices [4,10,14-16]. At the time of writing, Fitabase is the most popular data collection system, having been used in more than 450 institutions and more than 1100 studies [18]. The advantage of using Fitabase is that it can automatically collect data for all participants in real time and provides a basic dashboard function for individual users. However, Fitabase can only access data from Fitbit-related products, and the dashboard cannot be adapted to study-specific needs. For example, although Nokia is one of the widely used personal weight scales in weight-related research studies [19-24], it is not supported by Fitabase. The lack of a data collection and management system that is useful across wearable technologies is a major barrier for researchers who would like to use multiple wearable devices in a study.

Mobile health (mHealth) methods use advanced interactive technologies for the assessment of behaviors and delivery of digital health interventions, an area of research that is growing rapidly. Typical mHealth systems [25-31] consist of a smartphone app for data collection and intervention delivery, sensors integration, and occasionally clinical or administrative portals. However, although mHealth approaches may be readily adopted in behavioral research, it does not encompass end-to-end research management functions such as participant recruitment, screening, randomization, and retention.

A comprehensive and integrated implementation of a clinical trial management system in addition to wearable and mHealth integrations would allow the tracking of the study based on its specified recruitment needs, guarantee that the study starts and ends on time, make sure the necessary action has been taken at participants' specialized milestones, and minimize study costs [32]. However, disjointed implementations and noninteroperable third-party systems have built inseparable barriers for researchers to take advantage of valuable data and track their study process efficiently. The three main barriers are as follows: (1) integrating data from various sources into 1 database poses difficulties [4-6,11,17]; (2) data are seldom ready to be processed for study-specific needs in real time, with previous attempts seeing varying degrees of success [12,14-17,19-24]; and (3) no end-to-end study management systems that address (1) and (2) are readily available on the market. Therefore, we designed and implemented the Awesome Data Acquisition Method (ADAM) system to address these barriers by providing a digital platform that enabled the management and collection of long-term health data from a variety of the Internet of Things (IoT) and wearable devices in an accurately and timely manner, thus allowing an accurate display of tailored and aggregated data in real time. The ADAM system significantly reduced data integration burdens, that is, (1) by having the most common third-party application programming interface (API) integration templates readily available and (2) saving costs in research management areas, such as recruitment, screening, enrollment, assessment scheduling, participant tracking, and recruitment reporting, by streamlining and digitalizing those processes, all of which support an efficient and rigorous study management experience.

General Design

The Iterative and Incremental Development model [33] was used in the development of ADAM. In implementing the Iterative and Incremental Development model, the development team devised a road map outlining core functionalities essential for supporting capabilities that will be mentioned later. Subsequent iterations were planned based on participants' and study coordinators' (end-users') feedback, as well as the latest technological advancements, with each iteration focusing on delivering a functional and deployable software increment. Criteria for transitioning from one increment to the next were determined by predefined milestones, including successful feature implementation, user experience enhancements, and adherence to performance metrics. End-user feedback played a pivotal role throughout the process, guiding feature enhancements and usability improvements, while rigorous testing procedures ensured the stability and reliability of each increment before release. This approach facilitated the creation of a responsive and user-centric software solution that continually evolved to meet user needs throughout the project.

The ADAM system was designed to support the entire management of research studies that include the use of commercial wearable devices and smartphone apps, including designing questionnaires and collecting the response data remotely, recruitment, screening, enrollment, data tracking, data monitoring, and data visualization. Those components were developed iteratively in each development cycle until the desired study flow was reached. The ADAM system consists of 3 main components: a mobile app, a portal, and a connection with the APIs of wearable devices.

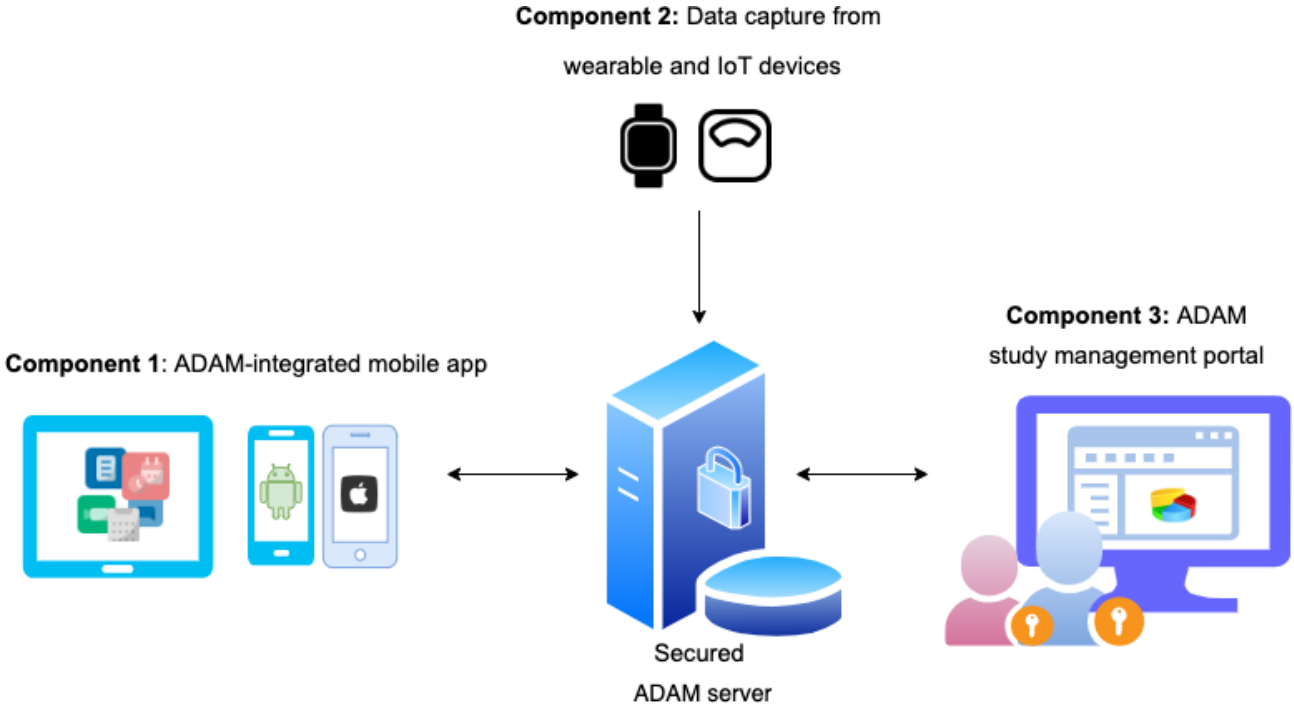
Architecture

The architecture for the ADAM system is illustrated in Figure 1. The 3 main components of ADAM include the ADAM-integrated mobile app, called the SMARTER app in the SMARTER trial, which is a cross-platform app that can run on Android and iOS devices (smartphones or tablets); a data capture component, which is used to capture and track the

study-related data from the wearable and IoT devices for all participants; and the study management portal, which allows study coordinators to collect data and manage the entire study process. These components are connected to a secured ADAM server. We designed the ADAM server to have 1-way data communication with wearable device APIs and 2-way data communication between the ADAM-related mobile app and the clinical portal.

Figure 1 illustrates the architecture of ADAM (the overall system will be referred to as simply ADAM or the ADAM system, to differentiate from its components), which consists of components for data capture from commercial digital wearables and IoT devices through APIs. Currently, ADAM has implemented integration with open APIs from Fitbit and Nokia. Participants' data were automatically collected from the wearable and IoT vendor's servers regularly, with a frequency that was customized to the study. The data transfer between wearable devices, servers, and ADAM was secured through a unique token. Furthermore, all data at transit were secured via Transfer Layer Security (TLS/HTTPS). A similar method of pulling data from other off-the-shelf wearable devices could be used beyond the 2 vendors, Fitbit and Nokia.

Figure 1. The architecture of the Awesome Data Acquisition Method (ADAM) system. IoT: Internet of Things.



We implemented ADAM as a system to support the SMARTER trial, which was conducted to evaluate the efficacy of 2 different approaches to a technology-supported (mHealth, wearable, and IoTs) behavioral intervention for weight loss [34-36]. The study used a randomized controlled trial design involving 502 adult participants who were randomized with equal allocation to 1 of 2 groups: the first group (n=250) received self-monitoring (SM) alone, while the second group (n=250) received remotely delivered feedback messages tailored to the recorded SM data. The main component of the SMARTER study intervention was personalized feedback messages via the ADAM-integrated SMARTER app, an investigator-developed mHealth app. The SMARTER app was connected to the ADAM portal through 2-way secure communications. Overall, ADAM, as a platform, was designed for the delivery of the study's feedback intervention that included secure real-time messaging, adaptive questionnaires that could be delivered promptly, and reminders. As a study tool, we designed the ADAM system to track participants' activities, such as the time when participants received or sent messages related to the study and the time when participants opened the app. All these data have been collected for future analysis.

Another component of the ADAM system was the ADAM portal, which includes a dashboard for study coordinators to review data and engage study participants. Study coordinators were able to get a bird's-eye view of all participants in the study, including a map of their geographical locations. The coordinator was also able to view the detailed data of individual participants, including questionnaire data, screening data, randomization status, and real-time wearable device data. The ADAM portal consists of 8 modules: a wearable device module for pulling data from the Fitbit and Nokia servers to the ADAM server; a questionnaire module for designing and collecting questionnaires; a screening and enrollment module for tracking participants' status in the study; a study phase–tracking module for providing a snapshot of the whole study process; a randomization module for study-customized randomization needs to help the interventionist performed the randomization at the baseline visit [34]; an assessment-scheduling module for remote or in-person assessment alerts and scheduling; a data-tracking and visualization module for reviewing participants' data; and a retention management module for follow-up assessment data collection and remuneration management. All features worked closely with each other throughout the study data flow.

Capabilities

Customized Questionnaire Design and Remote Assessment Collection

Questionnaire-based assessment is one of the most common methods of data collection in research settings. Therefore, the ADAM portal was designed around this need, from the process of questionnaire and assessment design to the remote delivery of questionnaires. Designing a questionnaire based on the study needs was made simpler for researchers with the inclusion of an easy-to-use, drag-and-drop interface and a library of frequently used question templates. The adaptive questionnaire feature in ADAM was designed to be used by study coordinators and investigators with no need to do programming, with a similar ease of use to that of proprietary solutions such as Qualtrics, but unlike most of these proprietary solutions, ADAM allowed integrations with an mHealth app. The ADAM portal also supported more advanced questionnaire features such as input-type validation, error messages, required field validation, and question branching. After a questionnaire was published in the ADAM portal, depending on the purpose, a public link or a participant-specific private link was generated for study use. Once the participant had answered and submitted this questionnaire via the given link, the ADAM portal automatically formatted the answers, placed time stamps, calculated scores, and triggered any necessary flags and status updates that could be immediately reviewed by the study coordinators. As the ADAM portal was designed to support multiphase study needs, questionnaires could be generated for each study phase while considering different restrictions for each phase, for example, adding certain filtering restrictions in the screening phase for certain criteria in the screening phase's questionnaire. This questionnaire module can also be adapted to fit the need for remote participant consent delivery, as the study consent form usually shares the same structure and data requirements as an assessment questionnaire.

Study Management and Multiphase Study Tracking

The ADAM portal also supported the management of other steps in the research study, which commonly included multiple phases or processes such as recruitment, enrollment, engagement, and retention. For the recruitment phase, the ADAM portal supported a multistep screening process. Each sequential screening step could be triggered by the answers or the calculated scores of the current step's screening or assessment questionnaire. It could also support manual evaluation by study coordinators. Once screening decisions had been made, the system automatically moved the eligible participants to the next phase in the ADAM system. This real-time process reduced the study coordinators' manual data review and data calculation workload. It also helped reduce the study cost by improving the overall recruitment process's efficiency.

For the enrollment and engagement phases, the ADAM portal has a built-in account management system that can assign a unique study-specific ID for each participant for efficient progress tracking while protecting their identifiable information. Furthermore, these IDs can also be used as common IDs linking data coming in from outside sources such as the Fitbit and Nokia APIs. With the benefit of the study-specific ID, the ADAM portal can easily record participants' digital footprints within the system and track the milestones and progress of all participants within the study. The portal also provides the study coordinator with access to aggregated data, such as that of important milestones or sorted by group, which is represented in a CONSORT (Consolidated Standards of Reporting Trials) flow diagram. Such a flow diagram is valuable for study management in 3 aspects: it allows the study coordinator to switch the recruitment effort to a specific group of people during recruitment in cases where a group has a less-than-optimal recruitment rate; it facilitates the adjustment of the speed of recruitment to help make sure the study can start and end on time; and it can monitor the screening process and rate of attrition, which may provide some hints for adjustments that may be needed in screening methods.

For the retention process, the ADAM portal provides a dashboard for showing study-related alerts or flags and participants' performance according to the data gathered from wearable devices, the digital scale, and the study app. Using this dashboard, the study coordinators have a near real-time report on whether participants are following the study protocol strictly, in other words, adhering to the study; as a result, they can intervene or take alleviating actions at a point closer to when participants began to show a trend toward lower adherence. This feature also helps to estimate the milestones for participants' assessments. Other features are study compensation and remuneration management, which were considered indispensable parts of the ADAM system. Study coordinators used the remuneration feature of the ADAM portal to record all payments made or planned at different time points in the study.

Data Synchronization With Wearable and IoT Devices

Data synchronization with wearable and IoT devices is one of the key features of the ADAM system. As more people rely on commercially available wearable and IoT devices to get their health data and track their fitness, a growing number of investigators have used this type of off-the-shelf wearable device as part of their studies. This trend indicates the need for a study management system that can integrate IoT and wearable data from multiple providers and vendors. Currently, the ADAM portal provides integration with Fitbit (wearable) and Nokia (IoT), since these companies have the largest market share, a secure authentication process, and stable open APIs. The steps to integrate data from wearables in ADAM from the users' (study coordinators') perspective are made simple. Study coordinators first need to create participant accounts in the ADAM portal and get participants' permission and authorization to collect their data from outside APIs. Once ADAM has been granted authorization, data synchronization for the given participant will be scheduled daily. The ADAM portal also supports subscription-based data integration, where any new data that become available in the wearable will trigger synchronization or a data import into the ADAM database in a real-time fashion, although we did not implement this feature in the SMARTER study.

Randomization

The ADAM system provided randomization by minimization, a more advanced randomization method, which was used to ensure the balance of prognostic factors between treatment groups and set equal treatment allocations [37].

Real-Time Data Analysis for Study-Related Apps

ADAM adopts Firebase Analytics libraries to anonymously monitor app use and statistics. This part of the data mainly describe the use of the app within a period. The study team can obtain a real-time visualization on the ADAM main page. This information can provide an overview of the app use among all study participants and additional background information for the efficiency of message delivery.

Evaluation of the ADAM Platform in the SMARTER Trial

Overview

An evaluation of the ADAM platform was conducted as part of a weight-loss clinical trial called the SMARTER trial [34]. This study was registered on ClinicalTrials.gov (NCT033677936) and approved by the Institutional Review Board of the University of Pittsburgh. The SMARTER trial was a randomized controlled trial that followed a single-site, 2-group design, with a 1-year study duration for both comparison and intervention groups [34]. In the SMARTER trial, participants were allocated equally to the 2 treatment conditions: SM only or SM with real-time tailored feedback messages (SM+feedback) [34]. The study provided all participants with a Fitbit Charge 2 and a Nokia Scale for physical activity and weight SM; participants used the Fitbit app for dietary SM. The SMARTER app generated 3 tailored messages per day responding to the SM data provided, for example, diet, physical activity, and weight. More details for the SMARTER trial design and screening criteria can be found in the study design paper [34].

Recruitment and Screening

The SMARTER trial's recruitment began in August 2018, and the trial itself was completed in March 2021. This study was designed to include a 3-phase screening process. The first 2 screenings were based on web-based questionnaires, where the ADAM portal provided autoscreening services based on the answers submitted by the participants. As shown in Figure 2, there were 3 steps for generating a questionnaire: Figure 2A lists all the questionnaires and consent forms from the SMARTER trial that were available on the ADAM portal; Figure 2B shows the straightforward drag-and-drop interface to design or edit a questionnaire; and Figure 2C shows that the ADAM portal could autocreate a specific questionnaire link for each participant on the user list page in the ADAM portal. In the SMARTER trial, phase-1 and phase-2 questionnaires were the study's basic screening surveys, and the ADAM portal provided automatic screening of the candidates based on preset criteria such as aged ≥18 years, BMI between 27-43 kg/m^2, smartphone user, general health history, lifestyle, and health and medical history. In phase 3, the ADAM portal still handled the display, submission, and scoring processes of the questionnaire but also gave the screening decisions back to the study coordinators. In this phase, participants were asked to complete a 5-day SM food diary using the Fitbit app. As illustrated in Figure 3, in our ADAM portal, the food diary data were automatically pulled from the Fitbit server for the study coordinators to review. Collecting data in one place relieved the pressure on study coordinators from switching back and forward between several different data management systems and tools.

Figure 2. Customized questionnaire module of the ADAM portal: (A) questionnaire list, (B) edit or create a questionnaire, and (C) personal link for the questionnaire. ADAM: Awesome Data Acquisition Method.

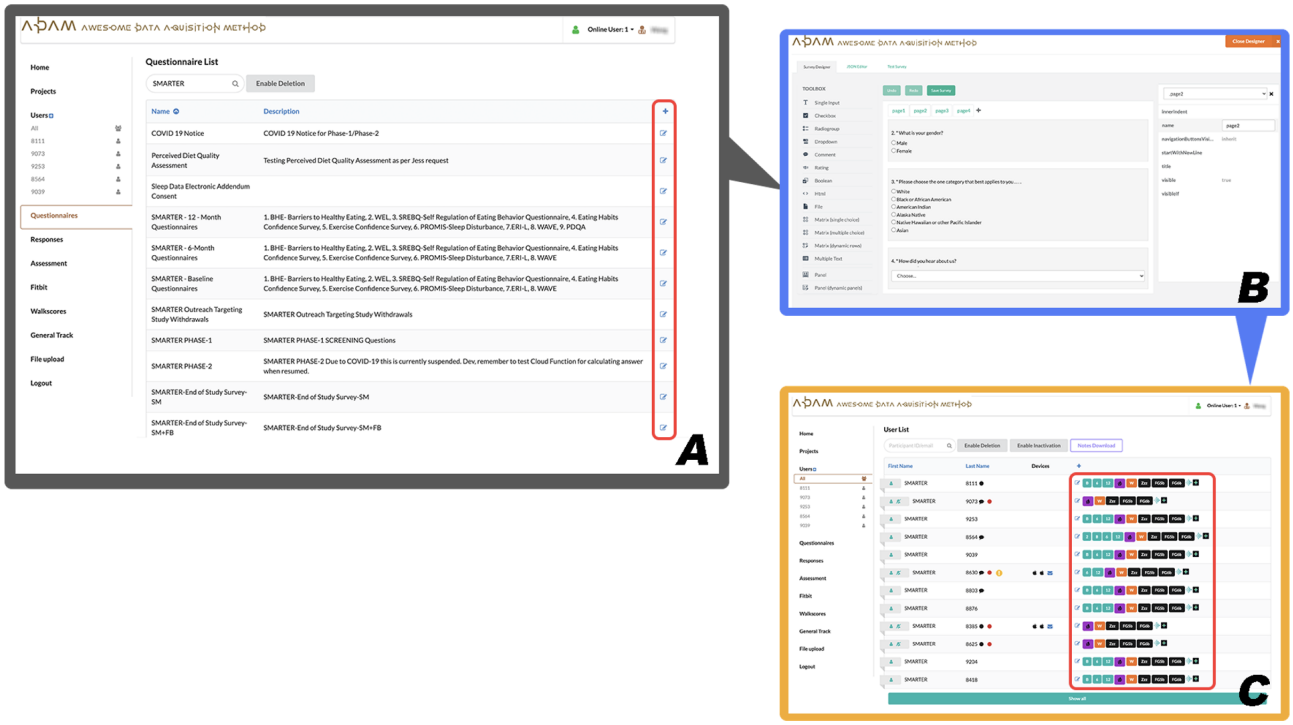


Figure 3. Food diary data collected from Fitbit. ADAM: Awesome Data Acquisition Method.

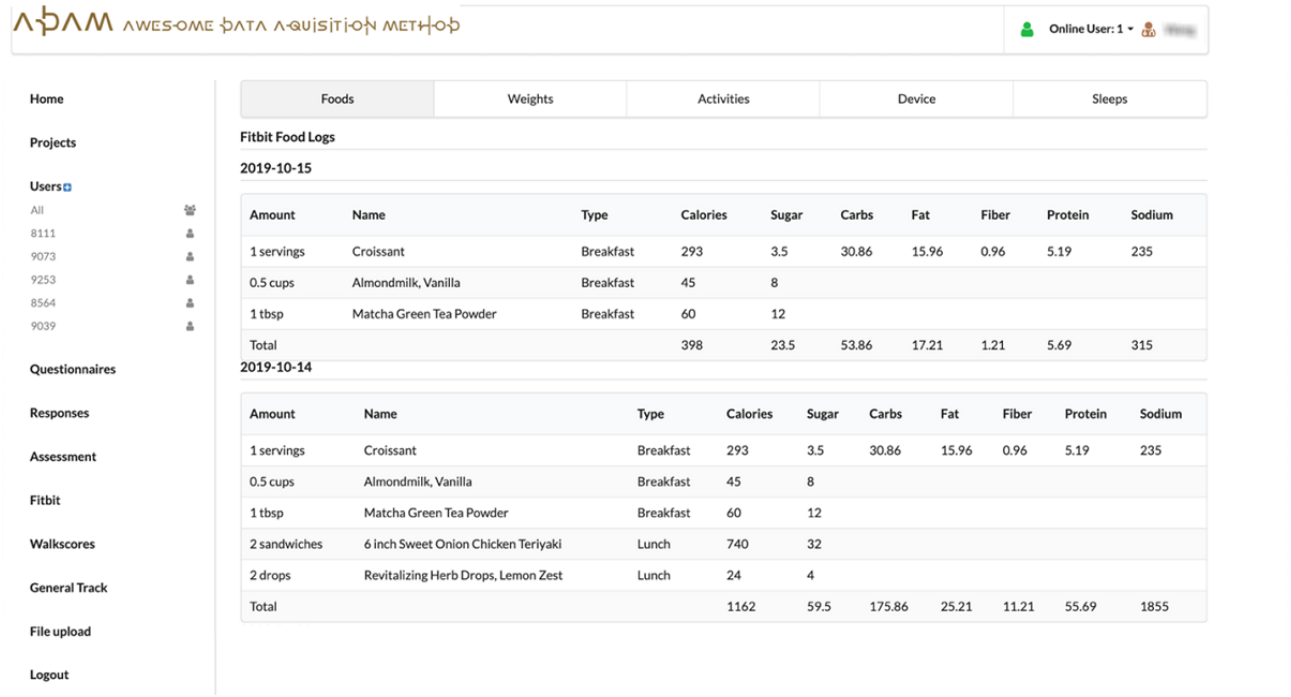
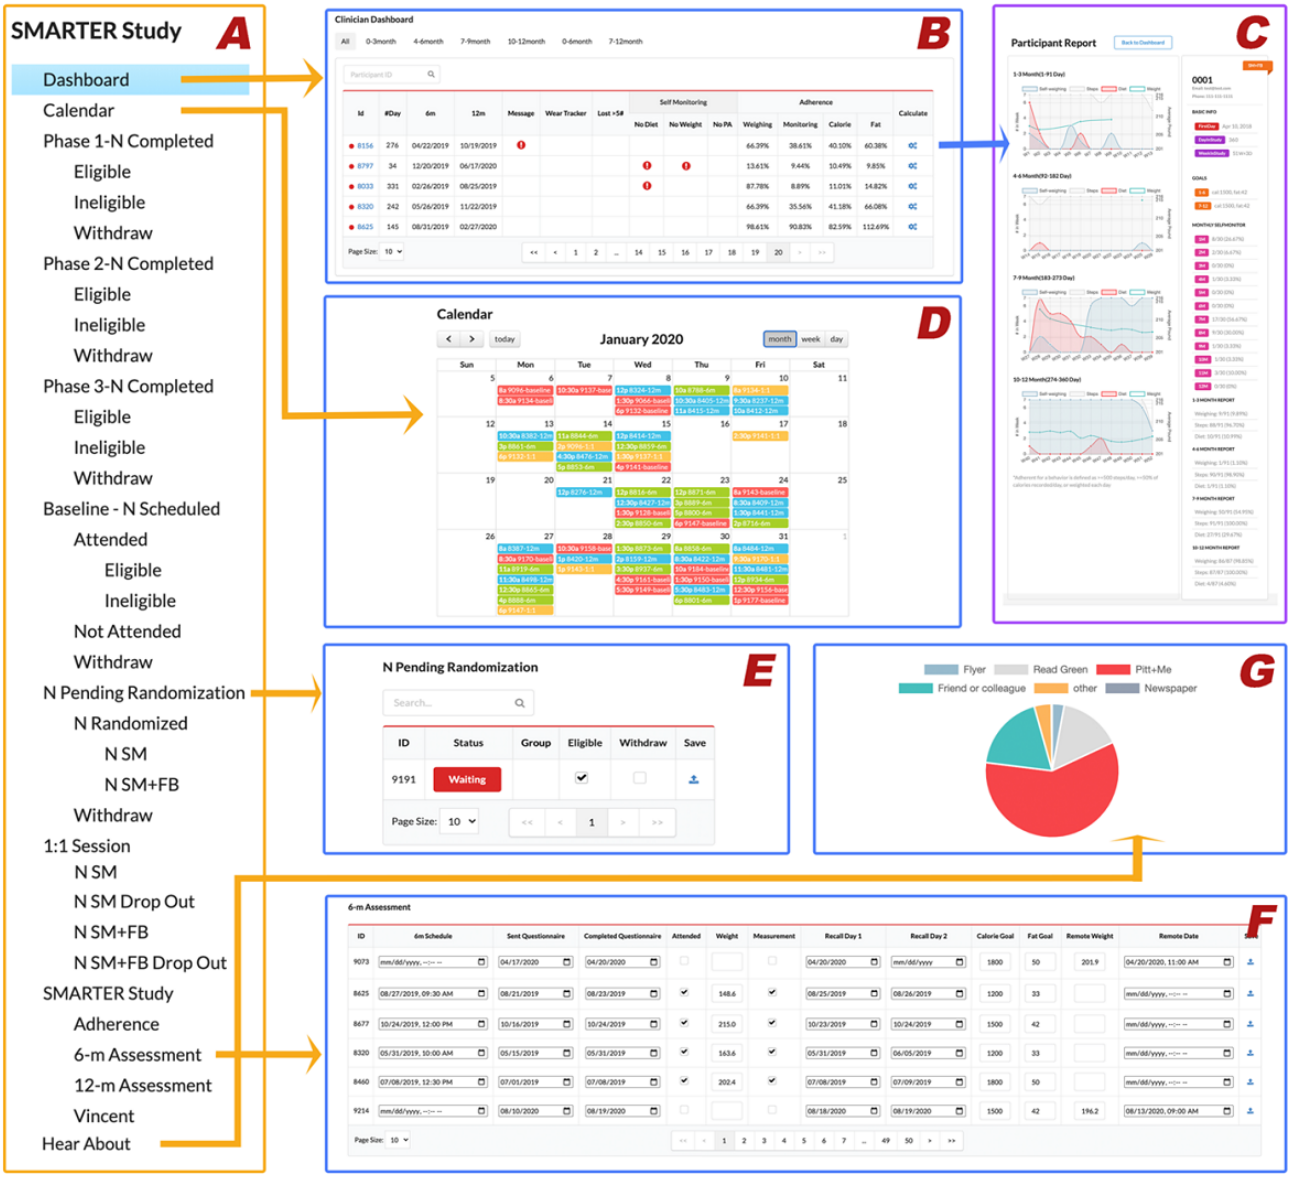


Randomization and Enrollment

As displayed in Figure 4A, all the SMARTER trial recruitment steps were visualized and cataloged in the ADAM system. By clicking on each recruitment step, study coordinators could review the current remaining number of participants in that phase and make decisions on moving them to the next phase of the study. Once participants were ready for the randomization step, they would be displayed on the randomization page, as shown in Figure 4E. The ADAM system provided a minimization randomization algorithm to support this randomization process. After randomization, participants' Fitbit and Nokia accounts were linked to our ADAM system by study coordinators; all the Fitbit-related and Nokia-related data including physical activity, food diary, and self-weighing data could then be collected by the ADAM system daily for the following 1-year intervention period.

Figure 4. The general data-tracking module for SMARTER trial management in the ADAM portal: (A) recruitment steps, (B) clinician dashboard, (C) participant report, (D) calendar, (E) randomization page, (F) 6-month assessment page, and (G) referral breakdown. ADAM: Awesome Data Acquisition Method.



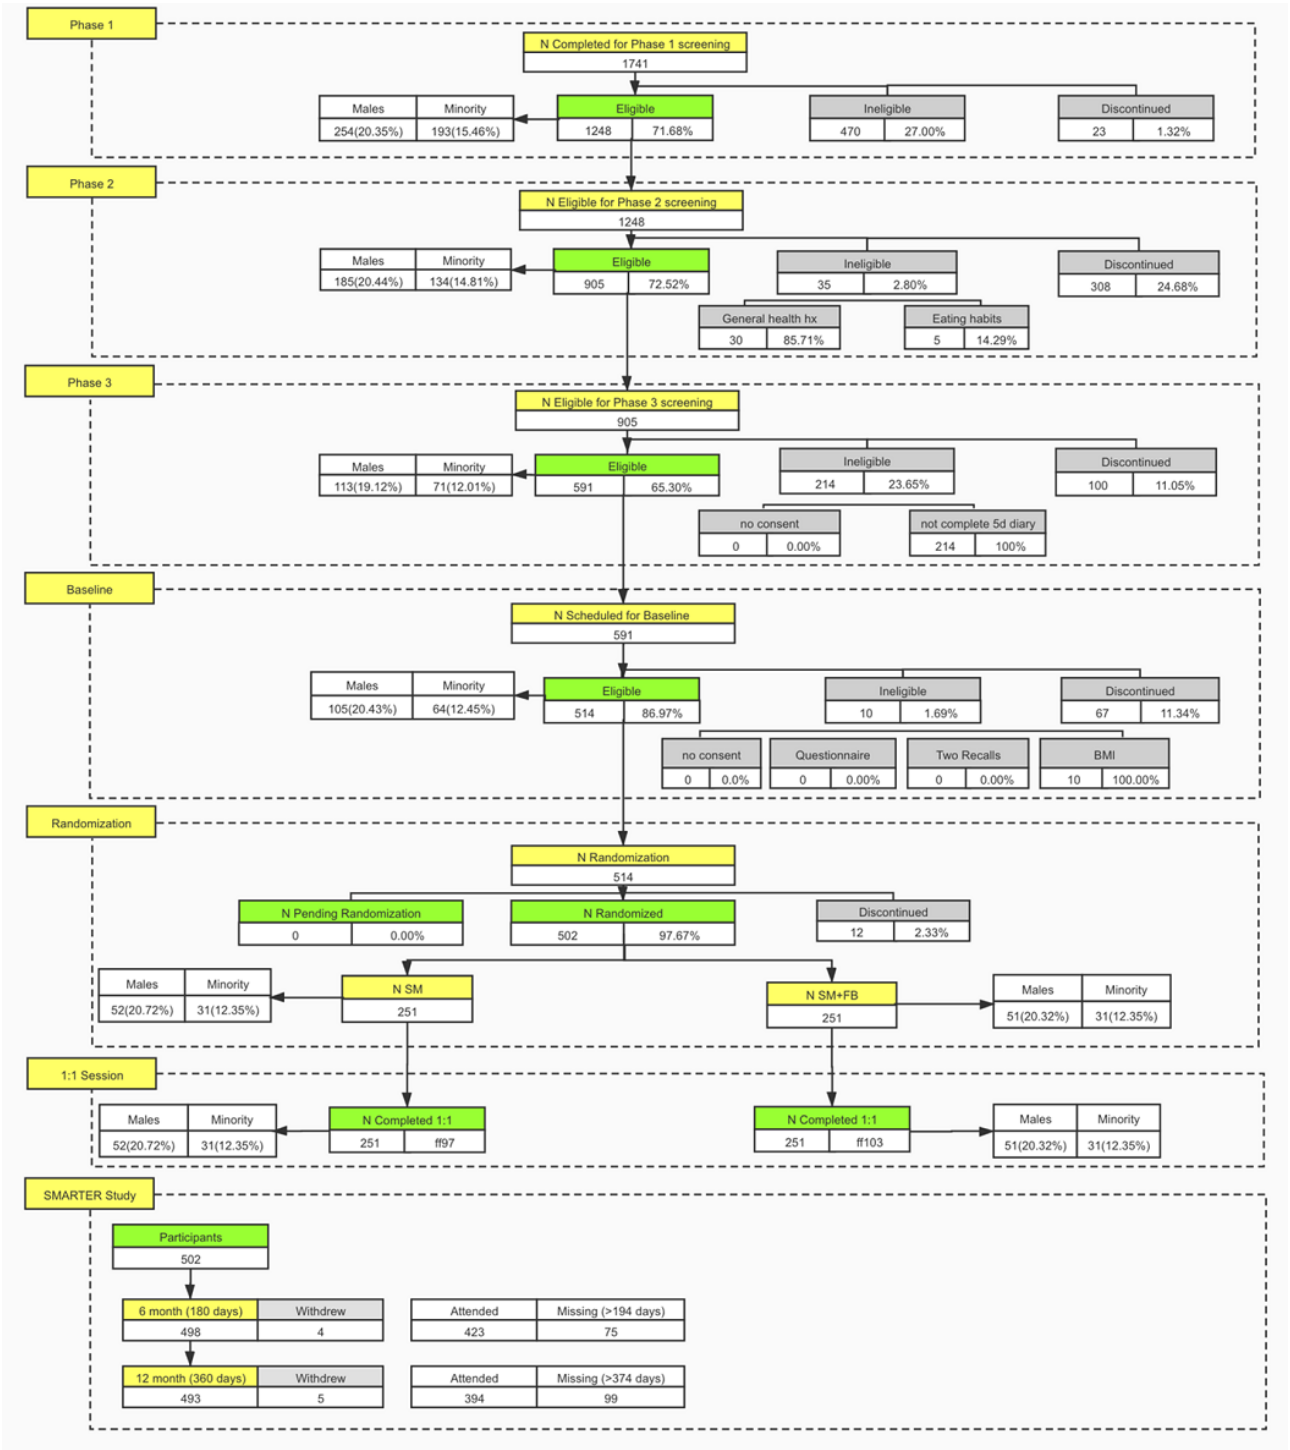
Engagement and Retention

After randomization, participants were asked to do daily SM during the 1-year study and complete 3 assessments at baseline, 6 months, and 12 months. During the 1-year study, participants were asked to adhere to the daily SM protocol by wearing a Fitbit tracker to record their daily physical activities, report food intake using the Fitbit app, and weigh themselves using a smart scale. All data were synchronized to the ADAM system and were displayed in a raw format, as shown in Figure 3, as well as a study-tailored precalculated report format, as shown in Figure 4B and C. The *clinical dashboard* in Figure 4B acts as a valuable resource for study coordinators to track participants' adherence to all SM protocols and to receive alerts if participants lose weight too rapidly (a precaution to prevent unwanted clinical effects) or have poor study adherence. Study coordinators used this page to mark withdrawals at any time during their study period. The ADAM portal then automatically recorded and marked the withdrawal date appropriately. The trial included 3 assessments that heavily used the ADAM portal as a method for appointment scheduling and web-based survey completion. Figure 4F represents an example of a 6-month assessment page, and Figure 4D is an all-in-one assessment calendar. Due to the COVID-19 pandemic, in-person assessments were no longer permitted as of March 2020. The study team made the decision to change all the assessments to be conducted remotely and to obtain the primary outcome of weight directly from participants' smart scales in their homes instead of the usual scale at the research center. Due to the remote-ready adaptive design of the ADAM system, this COVID-19–triggered transition was able to be performed quickly and with almost no interruption to the study flow.

The ADAM portal was also used for participants' compensation and reimbursement management. For example, once the payment was made, study coordinators recorded this on the Adam portal's remuneration page. Another example of a useful feature provided by the ADAM portal for the trial is a real-time flowchart (Figure 5). The flowchart provided an overview of

the entire study at any given time, which allowed for an adaptive recruitment strategy and effective adjustments to study resource allocation as needed. Furthermore, using the ADAM portal, the research staff coordinated activities with each other via a single platform remotely, since everything related to the study was accessible in real time and on the web.

Figure 5. Real-time study flowchart. FB: feedback; SM: self-monitoring.



SMARTER App

The SMARTER app is an ADAM-integrated app that was designed for the SMARTER trial. Only the intervention group had access to the app. Figure 6 shows the SMARTER app use data based on reports provided by Google's Firebase Analytics, which included aggregated data for the following aspects: number of daily active users, popular app versions, most common mobile devices among participants, and active users by city. This report worked as supporting information for the study team to track app use. As for the app's content, Figure 7 shows sample messages tailored and delivered by the SMARTER app. The ADAM system tracked and logged these messages' time stamps and status on whether the messages were delivered, opened, or missed—information for future data analysis that may provide auxiliary insight into the overall outcome of the trial.

Figure 6. SMARTER app use. ADAM: Awesome Data Acquisition Method.

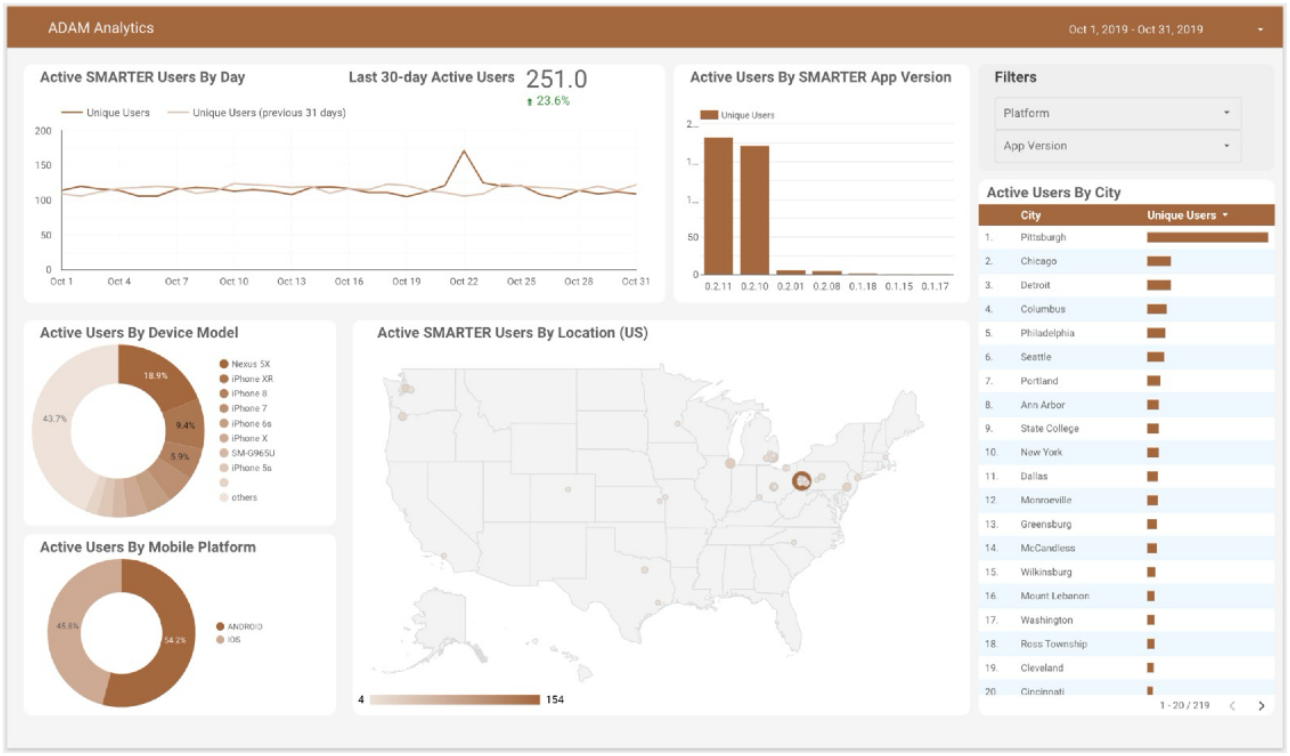


Figure 7. Screenshots of the SMARTER app.

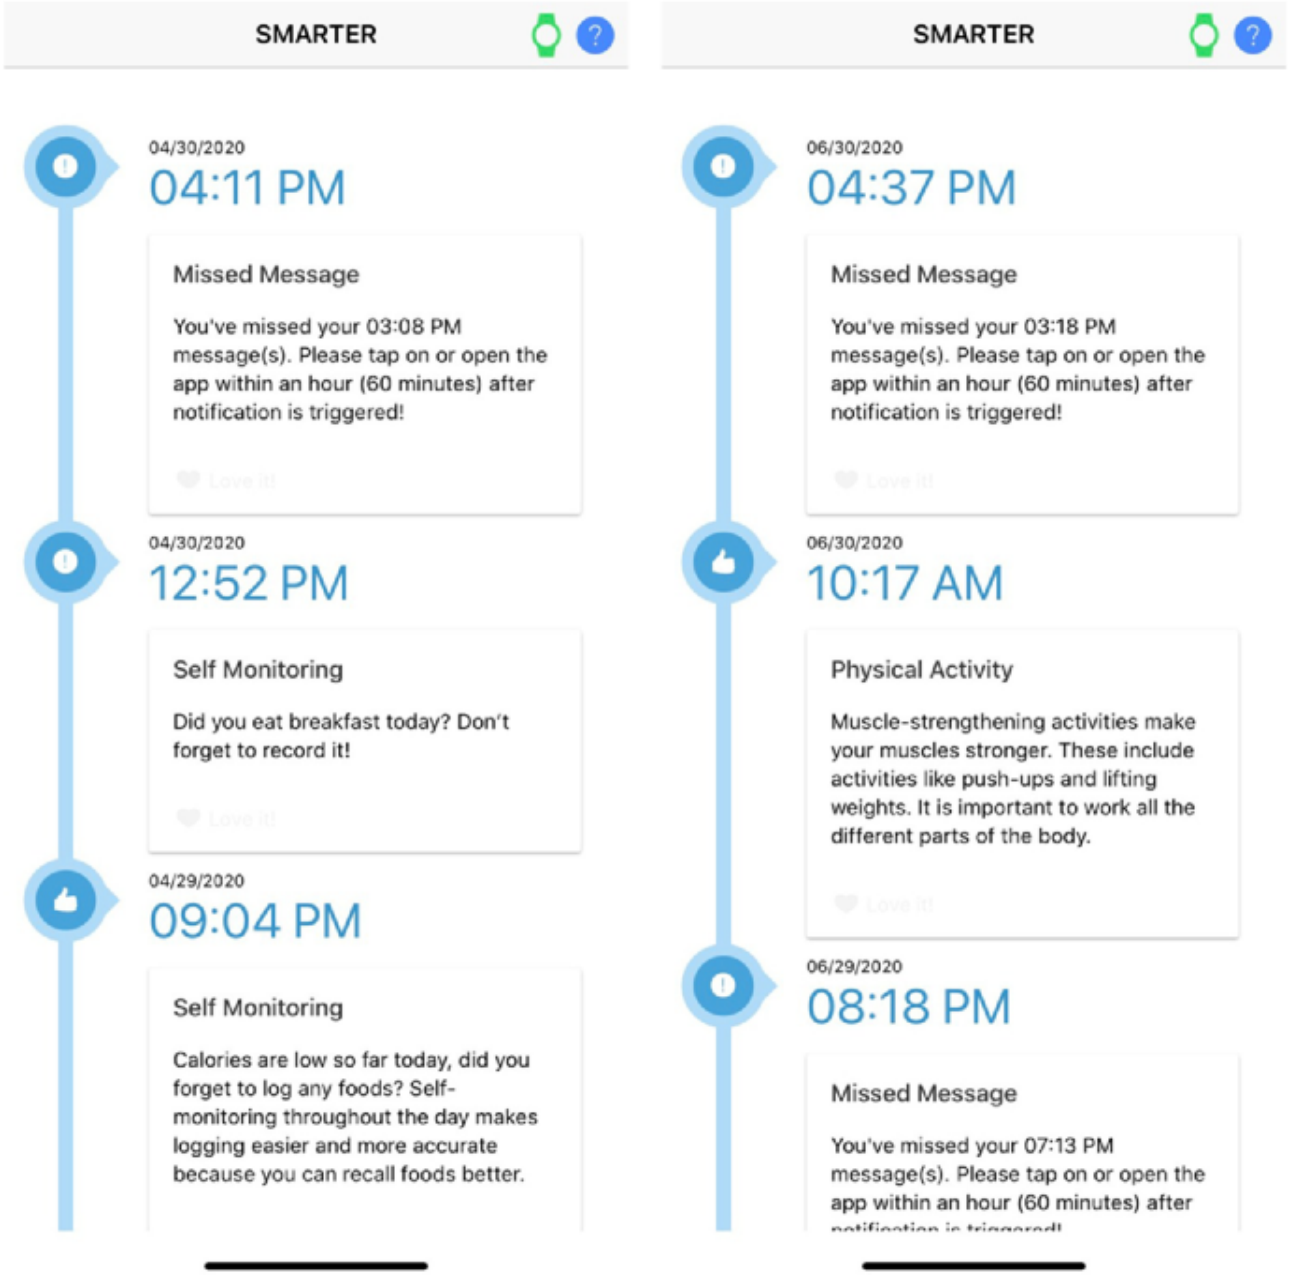

Data Validation and Integrity

The ADAM system incorporated 4 monitoring mechanisms to ensure the quality of collected data. First, as illustrated in Figure 4B on the clinical dashboard, ADAM can generate alerts. To guarantee data quality from various sources, the system sends automatic alerts for the following reasons: (1) if there are no food data recorded for 7 consecutive days; (2) if no weight data are recorded for 7 days or if there is a recorded weight change exceeding 5 lbs within a 7-day period; and (3) if there are no Fitbit tracker data received for 7 consecutive days. Second, the system performed automatic checks on API connections and promptly reported any issues to the study team. Third, to further ensure data integrity, study coordinators manually checked and reviewed selected records during the in-person assessments. Fourth, before data analysis, the research team also ran an algorithm to check for outliers in the collected data.

The SMARTER Trial Evaluation Results

In the SMARTER trial, 1741 unique individuals submitted their phase-1 survey through the ADAM portal; 1248 participants were eligible for the phase-2 screening; 905 participants were eligible for the phase-3 screening; and 591 participants were eligible for the baseline in-person assessment. After the baseline assessment, 502 eligible participants were randomized to 1 of the 2 treatment conditions. During the 12-month study period, 4 participants officially withdrew before their 6-month assessment, and 5 withdrew before the final 12-month assessment, all due to health issues. Even including the COVID-19 pandemic, the overall retention rate for the 6-month assessment was 84.93% (423/498) and for the 12-month assessment was 79.92% (394/493). The ADAM system efficiently coordinated study information and supported the study and study team, especially in a situation of limited human

resources and having to work fully remotely. It helped to recruit, screen, maintain, and track all individuals wishing to participate in the study; scheduled more than 1500 in-person assessments; and received 4131 questionnaire answers from the screening process to the study completion. Using the ADAM system allowed us to achieve every milestone in the study and minimize the disruptions by the COVID-19 pandemic.

Discussion

Principal Findings

We introduced the architecture and implementation of a data collecting and clinical trial management system called ADAM as a solution to current barriers in clinical or behavioral studies involving wearables, IoT, and mHealth. The ADAM system's adoption of the newest available interfaces in integration with multiple wearable devices makes it an attractive choice for behavioral and population-based health intervention studies. Using the ADAM system, the study team in the SMARTER trial no longer needed to switch between different systems or documents when working with study data from diverse sources and avoided most data missingness and data synchronization issues. ADAM's study management functions supported recruitment, screening, and randomization and helped maintain retention with a dashboard and flagging. In addition, it provided an efficient and manageable environment for study tracking and adjustment as necessary. ADAM's study flowchart was extensively used in the team's weekly meetings and contributed widely to decision-making during the entire study period.

Limitations

The system evaluations throughout the SMARTER trial indicated that the ADAM system was able to meet most of the data collection and study management demands. However, the ADAM system was not without limitations. The first limitation was not due to the ADAM system per se, but due to the limited availability of open APIs for third-party data collection sources also used in the study; therefore, the ADAM system had issues including all datasets for the study. For example, in the SMARTER trial, study participants needed to complete two 24-hour dietary recalls using the ASA24 system, a dietary assessment tool, at 3 assessment points. We could not directly synchronize the dietary recalls from the ASA24 system with the ADAM system due to the API limitations of the ASA24 platform. This limitation prevented study coordinators from receiving real-time data visualization and data analysis in the ADAM system for ASA24's data. Therefore, all the data from ASA24 needed to be manually downloaded and uploaded to the ADAM system. Although the ADAM system can integrate more datasets and be an all-in-one data solution for the study, we still need to consider approaches that may have API restrictions or the unavailability of such APIs by different companies and organizations that provide additional data required by the study.

The second limitation to consider is the data missingness and data synchronization issues with Fitbit or Nokia devices. Fitbit's open web API limits the number of API calls per hour for each participant or Fitbit account to 100. This stringent quota restricted the number of days that we could pull the data from the Fitbit server, as we needed to have at least a single call for each day of data. Furthermore, specifically for the SMARTER trial, we were restricted to pulling data only for the last 7 days. Since we were pulling data from several different areas of Fitbit's API, such as physical activity data, diary data, and sleep data, it quickly consumed the quota for the API calls. At the same time, from time to time, some Fitbit and Nokia devices experienced issues sending data to the Fitbit server when there were internet or Bluetooth connection problems or participants failed to open the Fitbit or HealthMate app for an extended amount of time. Those situations caused a data transfer delay and ultimately led to data missingness and failed data synchronization in the ADAM system.

Furthermore, the version of ADAM used in the SMARTER trial did not have the capabilities to send emails, SMS text messages, or push notifications. Therefore, the interventionists and study coordinators needed to use different modalities of communication and tools to send emails or SMS text messages to the participants. The next iteration of ADAM will include these capabilities to streamline communications and monitoring within one system, ADAM. This would increase the efficiency and the general ease of using the system in reaching participants as needed.

Finally, the ADAM system is more suitable for digital intervention studies using consumer technologies. If the study is highly dependent on in-clinic assessments using offline tools and closed or proprietary systems, the ADAM system provides a limited benefit since the data may be hard or even impossible to transmit to the ADAM system. In addition, studies that target recruitment groups who are unfamiliar with mobile technology or who have limited access to the internet could experience barriers to the adoption of the ADAM system technology. According to the questionnaires, these groups represent a small portion of potential study participants, but this is an important limitation to consider in future studies that may target these groups. This limitation was not an issue in the SMARTER trial, as the study was designed to exclude participants who were not smartphone users.

To address these limitations, first, we are considering supporting additional, widely used wearable devices. Second, we plan to generalize the study management components and make them easier to set up and adapt to distinct types of study design. However, overall, the ADAM system provides a solution to digitalizing a research study by providing and integrating multiple methods for collecting study data and ensuring an efficient and compliant study process.

Acknowledgments

The trial has been clinically registered at ClinicalTrials.gov with the identifier NCT03367936. This research was supported by grants from the National Institutes of Health (NIH): R01HL131583 (LEB), R01HL1311583S (LEB, JKK), F31HL156278 (JC), and T32HL098048 (JC). It was also supported by a grant from the University of Pittsburgh Clinical Translational Science Institute to Dr. S. Reis (UL1TR001857).

Abstract

Chronic pain is one of the most significant health issues in the United States, affecting more than 20% of the population. Despite its contribution to the increasing health crisis, reliable predictors of disease development, progression, or treatment outcomes are lacking. Self-report remains the most effective way to assess pain, but measures are often acquired in sparse settings over short time windows, limiting their predictive ability. In this paper, we present a new mobile health platform called SOMA*Science*. SOMA*Science* serves as an easy-to-use research tool for scientists and clinicians, enabling the collection of large-scale pain datasets in single- and multicenter studies by facilitating the acquisition, transfer, and analysis of longitudinal, multidimensional, self-report pain data. Data acquisition for SOMA*Science* is done through a user-friendly smartphone app, SOMA, that uses experience sampling methodology to capture momentary and daily assessments of pain intensity, unpleasantness, interference, location, mood, activities, and predictions about the next day that provide personal insights into daily pain dynamics. The visualization of data and its trends over time is meant to empower individual users' self-management of their pain. This paper outlines the scientific, clinical, technological, and user considerations involved in the development of SOMA*Science* and how it can be used in clinical studies or for pain self-management purposes. Our goal is for SOMA*Science* to provide a much-needed platform for individual users to gain insight into the multidimensional features of their pain while lowering the barrier for researchers and clinicians to obtain the type of pain data that will ultimately lead to improved prevention, diagnosis, and treatment of chronic pain.

Introduction

More of us are in chronic pain than you might think—20% of adults in the United States reported pain on most or several days in 2019 [1]. This presents a substantial burden on society, costing up to US $635 billion annually [2]. In 2016, chronic back and neck pain alone accounted for the highest amount of US health care spending across 154 conditions, including diabetes and heart disease [3]. Moreover, pain is the leading cause of health care use across all illnesses [4-6]. Against this backdrop, it has never been more important to develop accurate pain symptom assessment and prediction methods to help patients, caregivers, and other stakeholders make informed decisions about treatment and care.

Accurately measuring pain is crucial for predicting an individual's pain trajectory [7]. Methods to identify objective biomarkers of pain intensity [8-10] are still in their infancy and have yet to be proven effective in predicting future self-reported pain [11]. To date, the most common way to assess if someone is in pain is to simply ask them [12]. Typically, this is done using an 11-point pain intensity scale, where individuals are asked to rate their pain from 0 (no pain) to 10 (worst pain imaginable) [12-14]. Since the 1980s, this simple pain intensity scale has played a significant role in the clinical assessment of pain by enabling defined targets for pain management and the dosing of pain-relieving medications [15,16]. If a person consistently reports pain intensity as more than 3 out of 10 for more than 3 months, the scale becomes part of the diagnostic criteria for chronic pain [17]. For patients, self-reporting their pain on the scale can validate and quantify their pain experience, leading to improved shared decision-making and enhanced communication with health care providers [18].

Despite its ease of use, the pain intensity scale has not led to significant advancements in pain management or patient satisfaction [18-23]. When measured in medical settings, people tend to over- or underreport their pain intensity depending on difficulties with recall, expected treatments, care standards, or other subjective factors such as mood [24,25]. Additionally, regulatory approval for pharmaceutical companies to promote "titration to effect" practices, whereby physicians were encouraged to increase opioid doses to achieve continued reductions on the pain intensity scale, contributed to opioid overprescribing that fueled the opioid epidemic [23,25]. These limitations highlight the need for more nuanced self-report measures of pain.

In recent years, clinical approaches to pain have sought to better assess the multidimensional experience of pain from a biopsychosocial perspective [12,26]. Multidisciplinary and individualized assessment and treatment of pain with both pharmacologic and nonpharmacologic interventions is now considered the ideal way to treat both acute and chronic pain [27]. To overcome the limitations of the unidimensional pain intensity scale, expert panelists at the Food and Drug Administration (FDA) and National Institutes of Health (NIH) have established "core outcome sets" of multidimensional questionnaires for use in research studies [13,28,29]. Dimensions assessed include pain, unpleasantness, interference, and impacts on mood and activity [25,30]. However, completing multiple questionnaires is time-consuming, and therefore not ideal for daily longitudinal studies. As a result, a large barrier remains in the ability of researchers to collect comprehensive, multidisciplinary pain data sets [31]. It is therefore imperative in pain research to implement a reliable method for multidimensional pain measurements that accurately captures the most important dimensions of pain symptoms and treatments as they evolve over time in the context of people's daily lives.

A comprehensive approach to pain assessment necessitates the acquisition of both deep and wide pain data. Deep data involve in-depth evaluations of the multidimensional aspects of pain within individuals over extended periods, while wide data refer to data sets that encompass a large number of individuals across different demographic factors like age, geographic location, race, ethnicity, and socioeconomic status, as well as across different pain diagnoses (eg, arthritis, fibromyalgia, and postsurgical pain). The acquisition of deep data enables a deeper understanding of the mechanisms that trigger and sustain pain in individuals, while wide data provide the foundation for generalizing findings and developing biomarkers for pain persistence or recovery. Smartphone apps can provide large-scale platforms for data collection while also helping users track their daily symptom experience [32]. Such digital tools provide a promising solution for acquiring deep and wide data sets that enable new behavioral and scientific insights into the dynamics and evolution of pain.

Here, we introduce a novel mobile health (mHealth) platform for longitudinal pain assessment, called SOMA*Science*. This platform has been conceptualized to comprehensively capture multiple facets of pain through its smartphone app, SOMA. Unlike conventional pain assessment tools that focus primarily on daily pain intensity, SOMA offers an enriched multidimensional pain assessment. This includes factors like daily pain intensity, unpleasantness, interference, mood, expectations, and activities, based on experience sampling methodologies (ESMs) [33]. Our choice of measures is in accordance with the current Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials (IMMPACT) recommendations for pain assessment [28,34]. In addition, the design and validation of the SOMA app have been executed following the guidelines set forth by the American Psychiatric Association (APA) [35,36].

SOMA was designed with users in mind, offering a free and user-friendly tracking feature that facilitates real-time tracking of pain, medications, and treatment regimens. A "Trends" section distills the multidimensional data to visualize pain trends.

This feature aids users in self-managing their pain, recognizing patterns, and discerning between effective pain management and areas needing improvement. With these insights, users can communicate more efficiently with their health care providers, positioning SOMA as a valuable "companion" tool to be used alongside standard medical advice.

SOMA*Science* has been engineered to provide researchers with the ability to carry out independent single- and multicenter studies. Its pain assessments can be used as end points in research studies and within clinical practice. To support expansive research initiatives, the SOMA*Science* platform ensures seamless transfer of app-sourced data to researchers and affiliated institutions and offers open-source code to streamline data preprocessing.

Contemporary pain research standards underscore the significance of multidimensional pain assessments through established batteries of pain questionnaires [13,29]. However, we identified a scarcity of available tools that effectively capture such assessments in a format meaningful for researchers aiming to develop better measures of pain outcomes or symptom burden over time. While there are smartphone apps, like Manage My Pain and Pain Scale-Pain Tracker App, they primarily cater to users as self-management tools [37,38]. The foundational architecture of such apps and the nature of the data they procure do not typically align with the specifications researchers need for conducting or analyzing comprehensive, large-scale studies that meaningfully contribute to pain research. A further limitation is the proprietary nature of many of these apps, which can impede data quality, accessibility, and transparency.

To our knowledge, no other tools currently exist that are specifically designed to capture multidimensional and longitudinal pain metrics in compliance with the recommended standards and are simultaneously tailored for extensive open-source academic research. This distinctiveness sets SOMA*Science* apart as an unparalleled mHealth platform.

In this paper, we discuss the choices and technological considerations for the development of SOMA*Science* as well as the scientific rationale behind the selection of measures. Our aim is to outline how SOMA*Science* can be used by scientists and institutions to acquire large-scale, longitudinal, multidimensional pain data in single and multicenter studies in order to gain new insights into pain that will benefit patients.

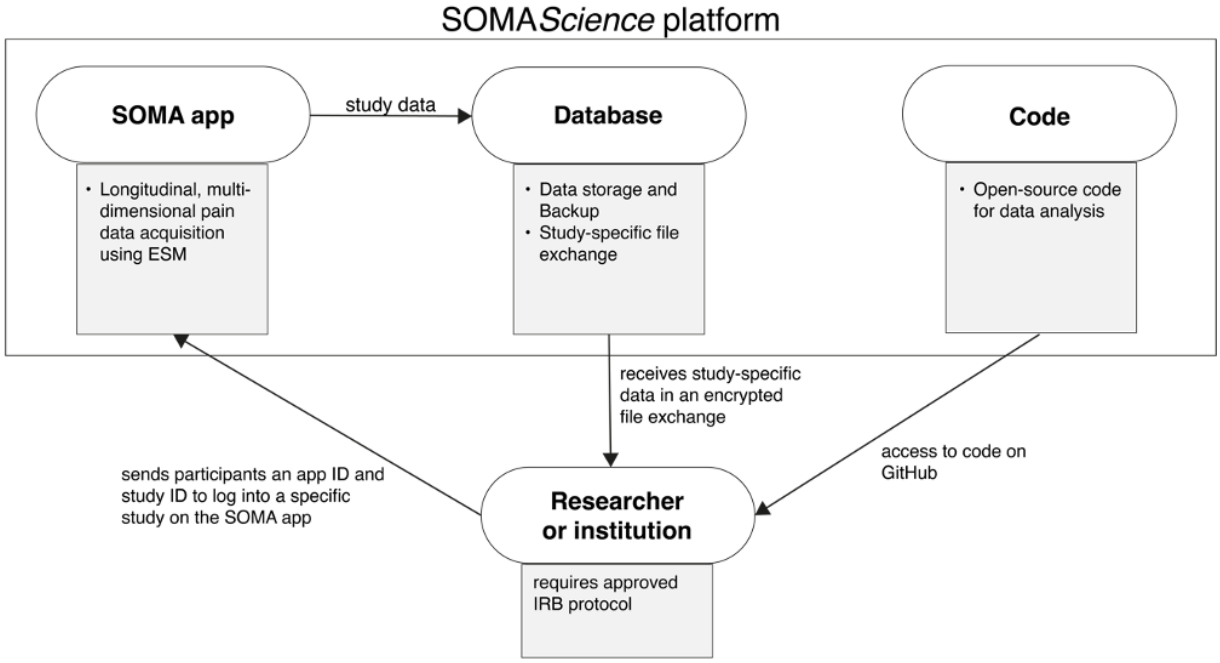
Section 1: SOMA*Science* Platform

Overview

SOMA*Science* aims to address the current shortage of platforms for acquiring both deep (multidimensional and longitudinal) and wide (cross-spectrum and large-scale) pain data to create novel insights into the dynamics and evolution of acute and chronic pain. The term SOMA stems from the Greek word σόμα (meaning body or entire person), signifying that it takes a holistic approach to pain.

SOMA*Science* represents the combination of 3 branches: the SOMA smartphone app used for data acquisition, an application programming interface for data transfer, and open-source analysis code distributed through GitHub [39] (Figure 1).

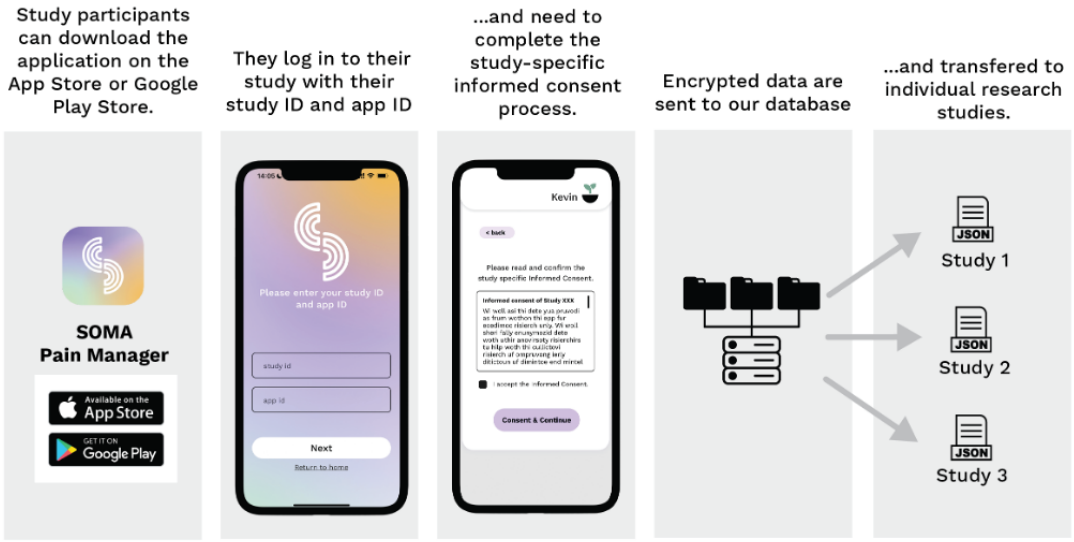
Figure 1. Schematic overview of the SOMA*Science* platform. Data will be acquired using the SOMA app, a user-friendly smartphone app available on Google Play and the Apple App Store. Encrypted data are sent to our application programming interface (currently located at Brown University) and shared in a study-specific manner with individual researchers and institutions. To facilitate data analysis, we created a GitHub repository where researchers can download, modify, or even create new versions of our template scripts for data preprocessing and certain analysis techniques through GitHub. ESM: experience sampling methodology; IRB: institutional review board.



To request to run a study through the platform, researchers need to submit a research inquiry detailing the study purpose on the SOMA website [40]. Data for SOMA*Science* are acquired through the SOMA app, which is freely available on Google

Play [41] and the Apple App Store [42] and can be found by searching for "SOMA Pain Manager." Anyone is able to download and use the app, regardless of whether they are participating in a research study. For associating people's app data with a specific study, the researcher will be assigned a unique study ID (1 per study) and a list of individual app IDs (1 per expected participant), which need to be sent to the study participants. Participants can then install and register on the SOMA app and enroll in a specific study using the study ID and unique app ID (instruction videos on [43]; Figure 2). This use of study and app IDs allows the assignment of individual participants' data to single and multicenter studies.

Figure 2. Schematic overview of study enrollment on the SOMA app. Study participants can download and register on the SOMA app directly using the links to Google Play or the Apple App Store or by searching for "SOMA Pain Manager." Inside the main menu of the app, they can sign into a specific research study using a pre-sent study ID and App ID. They are shown a copy of their institutional review board–approved study-specific informed consent form for their records. Encrypted research data on SOMA will be sent to our database and transferred to the researchers of each individual study.



Upon enrollment, participants will be sent regular reminders through the app to fill out short pain surveys (details about the ESM and data content are in the following sections). At the time of publication, assessments are restricted to the features listed below. Future releases may offer the option to request additional features and questions. After each assessment, encrypted data are transferred to our application programming interface, stored on an actively managed secure database (see "Maximizing Privacy and Security" in Multimedia Appendix 1), and then shared with researchers from individual studies (Figures 1 and 2).

Implementation of APA Guidelines in SOMA

The APA's app evaluation model stands as a notable benchmark for evaluating the suitability of health-related smartphone apps intended for patient populations [35]. It delineates 5 pivotal criteria to assess apps: accessibility, privacy and security, clinical foundation, engagement style, and therapeutic goal [44]. To keep pace with the rapidly advancing field of health apps, the system is regularly updated and refined [45]. Stemming from this APA model is a comprehensive database [46], which facilitates app evaluations across the 5 core domains [47]. Such initiatives are crucial in establishing public-facing, user-friendly standards for health apps and ensuring the development of safe and efficacious apps that benefit users [48-50].

In the development of SOMA*Science*, we have deeply integrated the cardinal principles of the APA model. Recognizing the emphasis that this model (and other akin evaluation frameworks) places on robust privacy, security, usability, and clinical foundations, we meticulously factored in specific technological elements during the app's creation [50]. For readers interested in the technological nuances and our dedicated approaches to privacy and security aligned with the APA guidelines, we direct you to Multimedia Appendix 1 [51-60].

Development of SOMA*Science*

A multidisciplinary team at the Psychiatry, Embodiment, and Computation Lab at Brown University, comprising academic neuroscientists, psychologists, pain physicians, software engineers, and designers, collaboratively conceptualized and initialized the early design and features of the SOMA app. The SOMA*Science* platform is supported by the Brainstorm program at the Carney Institute for Brain Science at Brown University, a new program to accelerate the translation of computational brain science into real-world applications that benefit patients, the scientific community, and society as a whole.

Incorporation of Patient and User Feedback

Any app meant for long-term use must provide a simple, user-friendly interface tailored to its target audience. With this in mind, we actively sought initial feedback from individuals experiencing chronic pain to shape our app's delivery structure. Through comprehensive one-on-one Zoom (Zoom Video Communications, Inc) discussions with a select patient group (n=4), representing a diverse pain spectrum including migraines, postsurgical musculoskeletal pain, cancer pain, and inflammatory bowel disease, we gleaned insights into our early app prototypes. These discussions involved a detailed

walkthrough of each interface, where patients aired their thoughts in a guided interview.

Drawing from this feedback, we refined the "Check-In" interface's design and flow. A common sentiment among initial users was the importance of daily tracking of pain and mood fluctuations in tandem with daily activities. To accommodate this, we introduced the "Trends" screen, a visual tool designed not only to foster self-management and a deeper understanding of pain dynamics but also to facilitate effective communication with health care providers. To further enhance the app's utility, we incorporated screens to monitor various treatment modalities and transitioned the mood and emotion tracking interfaces to use intuitive visual analog scales (VASs) in lieu of a 2D rating system.

Responding to the patient's desire for a more personalized experience, we introduced an interactive chatbot during the onboarding phase. This chatbot briefly engages users, gathering foundational demographic details and an introductory snapshot of their pain experiences. Existing studies vouch for the efficacy of chatbots in extending support to people with chronic pain [61], making this an evolving component with forthcoming features in SOMA that focus on pain interventions.

Our iterative refinement strategy incorporated a beta-testing phase. Initially, 30 internal testers actively engaged with the app daily across a gamut of devices and operating platforms, enabling us to identify and correct technical glitches and enhance the user experience, especially regarding the "Trends" data visualization. To expand our feedback, SOMA was then shared with a larger patient interest group (over 250 people with chronic pain), leading to critical refinements and the inclusion of user-suggested enhancements. This ongoing feedback mechanism ensures the continuous improvement and evolution of SOMA.

Section 2: Pain Data Acquisition Through SOMA*Science*

Deep Data Acquisition Using ESMs

Overview

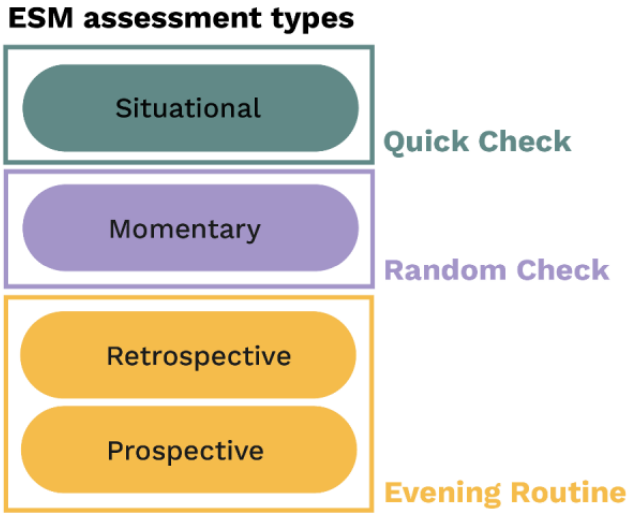
The SOMA app uses ESMs to gather multidimensional and longitudinal pain data for SOMA*Science*. ESMs, also known as ecological momentary assessments, provide real-time, self-report data about individuals' thoughts, feelings, and experiences (eg, "How do you feel right now?") in the context of people's daily lives [33]. Previous ESM studies on pain have shown high completion rates (>85%) and demonstrated the feasibility of using these daily self-reports for pain [62], in line with findings about the high completion rates of mobile-delivered ESM studies in general [63].

ESMs have several benefits over traditional self-report measures. First, they offer real-time data that are less prone to recall bias, allowing for the capture of critical experiences that might be missed by retrospective long-term self-report measures [64-67]. Second, ESMs can capture contextual information about an individual's thoughts and experiences, such as knowing what activities a person engaged in when they experienced pain [68]. Thus, they provide insight into the longitudinal dynamics of multidimensional aspects of pain in people's natural ecological environments across time and context [69,70]. This enables the generation of rich data sets that could be used to identify candidate behavioral "biomarkers" or "assays" that predict transitions in disease states based on self-report alone [68,71]. For example, there is preliminary evidence that longitudinal measures of pain can predict acute pain state transitions after surgery [72] and identify treatment response time courses in patients with chronic pain [73].

*Momentary, Situational, Retrospective, and Prospective Assessments in SOMA*Science*

One limitation of existing ESM studies is that they typically solicit several short, momentary reports throughout the day [74]. While this approach reduces bias in pain reports resulting from memory recall or pain beliefs, it may still miss important short-term pain dynamics, such as flare-ups, and fail to assess the role of expectations in the development and treatment of pain [75]. To address this limitation, SOMA*Science* uses a multifaceted approach, which includes 4 daily assessment types on the SOMA app: momentary assessments (called random check-ins), voluntary self-initiated entries (called quick check-ins), and both retrospective and prospective assessments or coverage assessments [75] (which are both part of an evening routine at the end of the day; Figure 3).

Figure 3. ESM assessment types in SOMA*Science*. Users complete 3 main types of daily check-ins per day (Quick Check, Random Check, and Evening Routine) that assess different domains of their daily experiences. ESM: experience sampling methodology.



Random and quick check-ins capture various aspects of mood, activities, pain, and pain location and can be completed in less than 30 seconds. Quick check-ins can be performed at any time, for example, during or shortly after a flare-up. Random check-ins reflect classical ESM assessments and only occur during randomly selected moments within a specific time window (eg, 3 checks per day between 8 AM and 6 PM). Users receive notifications on their phone when the random check-in is available and have the option to snooze the notification for a predefined time window (eg, a maximum of 60 minutes).

The evening routine assesses recall of pain, mood, activities, and any pain-related treatments over the past day (retrospective), as well as predictions of pain, mood, and activities for the next day (prospective). This routine is available during a prolonged, preset, but fixed time window at night (eg, 6 PM-11 PM) to promote habit formation that increases the likelihood of long-term app use. It takes less than 3 minutes to complete.

Longitudinal Assessments with SOMAScience

Pain is inherently dynamic, fluctuating not just daily but hourly and even on a minute-to-minute scale, even without changes in physiological markers [18,47,62]. Traditional methods, which measure pain intensity sporadically during clinical trials or medical visits, might not capture a patient's holistic pain experience due to their limited assessment windows.

While some studies aim for more granular pain assessments, they often focus on brief periods. A systematic review found the median duration for ESM studies in pain to be 14 days and a mere 7 days for general mHealth ESM studies [40,61]. Such short durations can overlook pivotal phases, like the transition from acute to chronic pain over 3-6 months. Consequently, the role of self-reported pain dynamics in acute pain recovery or its evolution to chronic pain remains ambiguous.

The SOMA app is designed to bridge this gap. Its check-ins are concise, using straightforward design principles for ease of use. The chosen metrics cater to diverse pain experiences, facilitating collaboration and data sharing among researchers. Moreover, the app's "Trends" feature empowers users to track their pain, treatments, activities, and mood over diverse timeframes (ie, weekly, monthly, and annually). This aids in providing users with a deeper understanding of their pain journey, ultimately supporting more effective self-management.

Wide Data Acquisition Using Smartphones

While large data sets on repeated multidimensional pain ratings beyond intensity alone are still few and far between, smartphones offer a unique opportunity to expand data acquisition beyond classical experimental settings [74]. Smartphone access has increased tremendously in the past decade (84% of US households reported owning at least 1 smartphone) [76]. Data acquired remotely through smartphone apps facilitate large-scale, real-world studies without the constraints of traditional laboratory studies. The results of such pragmatic studies are more generalizable than highly selective traditional randomized controlled trials [77-79]. SOMA*Science* was built to allow remote monitoring of longitudinal symptoms and treatments to maximize high-quality data in large-scale pragmatic studies. To further facilitate a much wider array of user input, the SOMA app is compatible with both Android and iOS devices, meaning anyone in the United States with a smartphone can use it.

Smartphone-based pain assessments offer a solution to the limited geographic, economic, and cultural diversity in traditional pain studies. Smartphones are pervasive, even in low-resource [80] or rural areas [72,81], where almost half of the world's smartphone owners live [82]. They are also widely used by older adults [83], who are often left out of laboratory-based pain studies. Additionally, there is a need to consider how pain and its treatment vary across racial, ethnic, and cultural backgrounds for comprehensive care. Even within a specific culture, there are important differences in how pain is experienced and treated across different racial and ethnic backgrounds that need to be accounted for to deliver the best pain care [84-86]. Upcoming translations of the app into languages like Spanish and German, in collaboration with experts familiar with the culture, will further diversify data and

insights. Translation into other languages will follow, and collaboration to translate the app is welcomed.

Section 3: Data Content

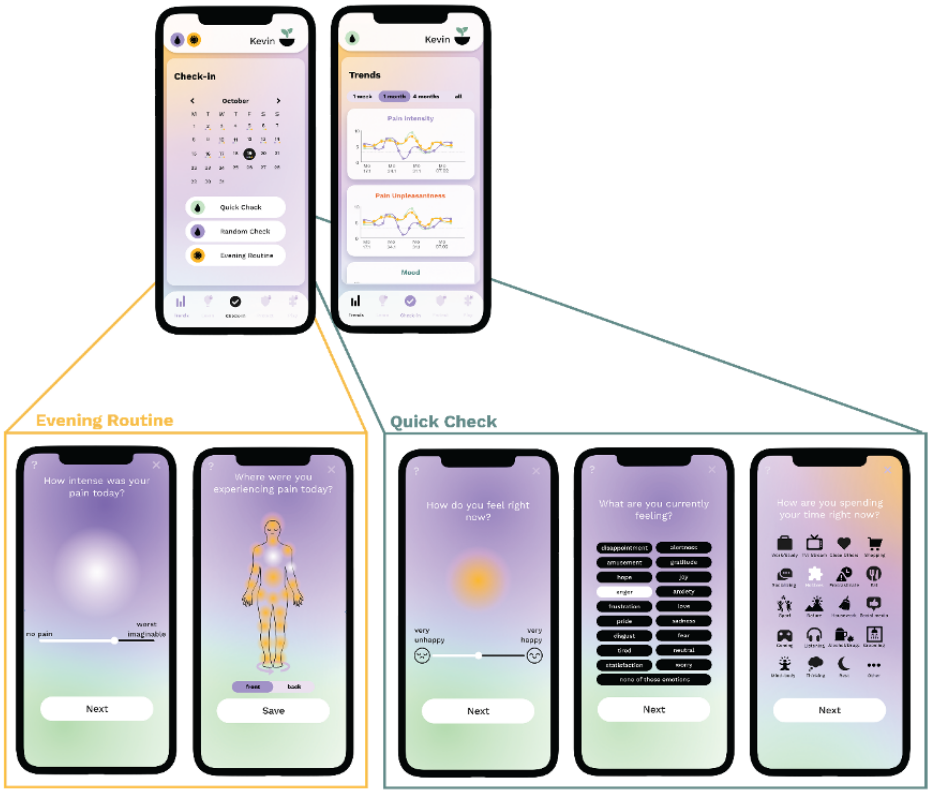
Overview

With the rising number of health-focused smartphone apps, there is also a growing need for transparency in the selection of measures for the app. Here we briefly detail the process of selection for each measure in SOMA*Science* as assessed through the SOMA app, its basis in the scientific and clinical literature, and what gaps it was chosen to address. The goal is to provide transparency in the design and selection process to facilitate the development of research studies using SOMA*Science*. Specific measures may be refined over time with user feedback and as scientific studies using SOMA*Science* identify areas for improvement.

Measuring Pain Intensity, Unpleasantness, and Interference

Multidimensional pain assessment is a crucial aspect of clinical practice as it helps determine the effectiveness of treatment and recovery. The SOMA app assesses the pain intensity scale in addition to pain interference and pain unpleasantness to provide a more holistic measure of daily pain symptom load [87]. Participants are asked to rate each pain question on a sliding VAS, providing a simple and comparable assessment of daily pain experience (Figure 4). This operationalizes a practice advocated in the International Statistical Classification of Diseases and Related Health Problems for providers to use a composite rating of pain intensity, distress, and interference of pain to determine overall burden [88]. The composite pain score provides a multidimensional solution that balances the limitations of the unidimensional pain scale while still being easily quantifiable. The ability to analyze the 3 measures individually and as a composite score helps identify meaningful individual variability, enabling specific predictions between individuals. For example, pain unpleasantness could be more predictive of future pain in individual A, while pain interference may be more important for individual B's long-term outcomes.

Figure 4. Upper panel: example screens on the SOMA app for check-ins and trends. Lower panel: example screens on the SOMA app from Quick Check, Random Check, and Evening Routine. From left to right: assessing pain on a visual analog scale (VAS), indicating pain location, assessing mood on a VAS, emotion selection, and activity selection.



Importantly, SOMA's 3 pain questions were chosen because they are directly comparable to results from established pain questionnaires, such as the Brief Pain Inventory [89] or the McGill Pain Inventory [90]. They also satisfy the standards set by major scientific and regulatory bodies, such as the IMMPACT recommendations, the NIH Helping to End Addiction Long-term initiative, and the FDA guidelines for assessing multidimensional components of pain [13,28,29,87]. In this way, SOMA's multidimensional pain assessment of intensity, unpleasantness, and interference can provide important supplemental measures that are directly comparable to established clinical benchmarks and standards of care. This is

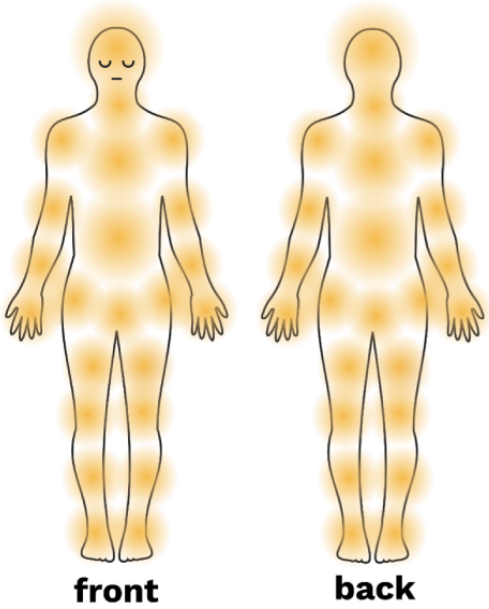
critical for researchers looking to establish and validate novel pain biomarkers or end points.

Measuring Pain Locations

Pain localization is an important aspect of pain assessment. Conventional methods of measuring pain location in medical appointments and research studies involve having individuals indicate it on a body map, such as the Brief Pain Inventory [89], the McGill Pain Questionnaire [91], or the Michigan Body Map [92]. This approach can pinpoint differences in peripheral and central pain pathology based on the localization and stability of pain representation over time. For instance, nociceptive or inflammatory pain is usually precisely localized somatically and does not change much over time, while neuropathic or chronic primary pain is often experienced in multiple bodily locations, radiates, or changes over time [93].

More recent methods of digital quantification, like the ones used on the SOMA app, have established the reliability and validity of body maps for pain assessments [94,95]. Interactive body maps delivered through digital or tablet apps are more effective than traditional paper or laptop assessments [92,96]. Yet a review of smartphone apps that use the body map for tracking pain found that few actually quantified the location ratings or provided any summary feedback [97]. The SOMA app's interactive body map offers 46 different discrete location options on the front and back of the body that participants indicate in every daily check-in (Figure 5 and Multimedia Appendix 1). The use of discrete points ensures uniformity across devices and accounts for differences in participants' finger size or dexterity. The "Trends" section of the SOMA app displays the body map with the percentage of times a location has been selected, enabling users to visualize the frequency of pain at a given location. For participants who experience nonspecific, difficult-to-localize, or widespread pain, such as fibromyalgia, there is an additional option to indicate "My pain is everywhere" on the body map.

Figure 5. Pain map included on the SOMA app covering 46 discrete pain locations.



Measuring Interventions

The treatment of pain has been incredibly difficult to get right. The newest clinical guidelines advocate the use of multimodal, multidisciplinary approaches [27,98,99]. Such approaches emphasize a combination of pain treatments that include medications, restorative therapies (eg, physical therapy), interventional procedures (eg, epidural injections), behavioral interventions (eg, cognitive behavioral interventions), and complementary and integrative medicine (eg, acupuncture). Combinations of these therapies have been associated with the best long-term pain outcomes [100,101] and satisfy a biopsychosocial approach to pain [102].

It can be challenging for individuals and providers to determine which treatments are most effective for them, as the effects of many treatments for pain may not become apparent for weeks or even months (eg, cognitive and physical interventions, certain medications, and surgery) [103,104]. In determining how to measure treatments through the SOMA app, we followed the recommendations of the 2019 Department of Health and Human Services Pain Strategy [27].

In the case of medications, many different pathophysiologic mechanisms are targeted with different classes of medications. The use of different medications often changes over time, so we designed the medication screen on the SOMA app to be able to capture such changes. We, therefore, included 20 options across the main classes of pain medications for both acute and chronic pain on the SOMA app, detailed further in Multimedia Appendix 1.

A second treatment screen includes the recommended nonpharmacologic approaches to pain. Combinations of these treatments are often used by a single person over time to target different pain mechanisms [105]. SOMA*Science* currently provides the ability for people to track up to 20 different nonpharmacologic therapies across these 4 major classes, detailed in Multimedia Appendix 1. SOMA*Science*'s broad treatment tracking capabilities therefore facilitate the type of

wide data needed to understand differences in treatment use across users.

Measuring Emotions

Emotion and pain are fundamentally related. Definitions of pain acknowledge that pain is partially an emotional experience [106,107], yet few researchers would reduce pain down to just another emotional state such as sadness or happiness. The complexity of the pain-emotion relationship is highlighted by reviews of the neural circuits of each construct, showing both shared and functionally dissociable brain regions [108,109]. Unfortunately, the theoretical and empirical understanding of how emotion and pain are connected is limited, as much previous research only focuses on cross-sectional correlations between the 2 constructs [110,111].

Despite the renaissance of emotion research since the 1960s [112], emotion researchers continue to disagree on what constitutes an appropriate emotion measure [113]. The discrete emotion perspectives suggest that specific emotions such as anger, fear, happiness, sadness, disgust, and surprise are special kinds of biologically distinct responses associated with unique behavioral, physiological, and experiential correlates [114,115]. The dimensional perspectives consider emotions to be organized along a set of common dimensions such as valence (unpleasantness) and arousal (intensity) that are combined with cognitive and cultural knowledge to form emotional states.

When designing an emotion list for the SOMA app, we wanted a set of emotions that are commonly experienced, had a balance of positive and negative emotions, and were relevant to pain experiences (eg, worry). We started by selecting emotions experienced more than 5% of the time from a large-scale ecological momentary assessment study [116], removing rare emotions such as contempt or awe. Next, we balanced the remaining emotion set by using positive and negative emotions from the clinically relevant scale (Positive and Negative Affect Schedule) [117]. Lastly, we allowed participants to indicate no emotion (neutral) or emotion not listed (other).

A complementary method from a dimensional perspective is to assess general mood through a single-dimensional VAS of valence ranging from very unpleasant to very pleasant. Although there are other dimensional scales that could also be assessed, such as arousal [118,119] or goal congruence [120], valence is known to capture the majority of variance between emotion states [121], as self-reports of emotions tend to be highly correlated within a positive or negative valence [122]. Accordingly, on the SOMA app, we ask users to evaluate their current, past, or future mood on this VAS, ranging from unpleasant (0) to very pleasant (100). One major benefit of this measure is that we can quantify daily emotional experiences even if the participant does not self-report any discrete emotions from our finite list, reducing the need to interpolate or remove missing data from our analysis of the dynamics of emotion and pain (Figure 4).

Measuring Activities

People's experiences of both pain and emotion are intrinsically tied to the activities they are engaging in each day. There have been many large-scale studies investigating the relationship between emotions and behavior, showing that physical exercise is meaningfully associated with reduced mental health difficulties [123] and that people's choice of activities is motivated by minimizing negative affect and maximizing positive affect [124,125]. In particular, people seem to engage in mood-elevating activities (eg, socializing) when they are feeling down and mood-depressing activities (eg, work and chores) when they are feeling up. At the same time, being in pain affects both mood and daily activities.

Most people intuitively reduce their activities when they experience new-onset pain. Acute pain generally functions as an alarm bell in the brain to signal tissue damage, with the urge to rest considered a protective mechanism to prevent further injury and promote healing [126]. However, outside of the initial acute phase, a lack of activity can hinder long-term recovery and may signal underlying changes in affective and motivational brain circuits that have been causally linked to the transition from subacute to chronic low back pain [126,127]. The synergistic impact of activity engagement on mood, pain, and physical function is why activity engagement is promoted by pain self-management and rehabilitation programs alike [128]. While many people assume that patients with chronic pain move less than those not in pain, objective actigraphy data do not differ between patients with chronic pain and no-pain controls [129,130]. What has been less studied is the types and range of daily activities and how they change between acute and chronic pain stages. While people may recognize changes in their daily activities as a result of pain (eg, no longer walking as much), they may not have insight into the relationship between pain, mood, emotion, and activities (ie, which activities increase or decrease pain in the short vs long term). It remains unclear whether certain patterns of activity engagement at different stages of pain experience are important for long-term outcomes.

For this reason, we added an activities-tracking feature alongside mood and pain tracking. The activities screen on the SOMA app contains 20 activities that are known to have a dynamic relationship with mood based on large-scale, longitudinal data sets [125] or to be common among patients with pain (eg, medical visits). Specific activities selected are detailed in Multimedia Appendix 1. In addition to having the person report either momentary or daily activities, we also have participants reflect on how each activity they completed made them feel that day and how much it affected their pain. Taken together, these measurements provide a full picture of participants' daily activities and help understand the potential bidirectional relationships between emotion, pain, and behavior. Users are also able to visualize their ratings of how much a given activity affected their pain and mood over time in the dedicated trends screen, which may help people develop insight into how certain activities help or hinder their recovery.

Measuring Predictions

Expectations play an undeniably large role in pain perception. In artificial laboratory settings where healthy participants receive painful stimulation, a wealth of findings show that expectations about pain can increase the pain experience (nocebo effect) or conversely decrease it (placebo effect) [131,132]. This has important implications for the experience of pathological pain

[133,134], where expectations about pain treatment are reliable predictors of treatment response [135]. These studies suggest that an ongoing cognitive modulation of pain is an important determinant of ongoing pain perception [136]. Expectations for pain relief most likely shift over time, the longer someone has experienced pain the more difficult the pain is to control [137,138]. Subtle longitudinal changes in expectations are believed to occur as pain becomes chronic, but capturing these changes in research studies is challenging. For this reason, we included an assessment of daily predictions about pain, mood, and activities on the SOMA app to capture how predictions vary over time within the same person or between different types of users (eg, patients with acute vs chronic pain).

We decided to assess expectations on the SOMA app by asking users to predict their expected levels of pain intensity, unpleasantness, interference, mood, and activities for the next day using the same scales used to capture their actual rating for that day. This allows the assessment of the bilateral influence of pain and mood expectations on actual experiences of pain, mood, and activities that are entered the following day.

Discussion

There is a great need for easy-to-use tools that help those in pain, their medical providers, and the larger health care system identify risk factors and predict the onset of chronic pain. Pain management is a rapidly evolving field that increasingly relies on assessments and treatments that are multimodal and multidisciplinary. Traditional, unidimensional assessments of self-reported pain fail to capture the nuances of pain experience and multimodal pain management. Therefore, there is an urgent need for research tools that have been specifically designed to capture this complexity.

To address this gap, we built the SOMA*Science* platform. Briefly, the platform uses the smartphone app SOMA to collect longitudinal, multidimensional, ESM-based pain data that capture daily pain intensity, unpleasantness, inference, mood, activities, and predictions. The SOMA app provides a simple and pleasing user interface that can promote pain self-management through visualization of pain trends over time, helping encourage individual insight into factors that exacerbate or alleviate pain. The visualizations provided can also be used to improve communication of multidimensional pain burdens to health care providers. At the same time, the larger SOMA*Science* platform enables user data to be included in registered single and multicenter studies.

In this paper, we have detailed the clinical and technological considerations taken into account in developing SOMA*Science* and the scientific rationale behind its measurements. We believe this platform is capable of meeting the requirement for tools to acquire deep and wide-ranging pain data over time, which has been largely absent from existing pain data sets. As such, SOMA*Science* can be used to answer a broad range of research questions, such as the correlation between initial pain dynamics and the eventual development of chronic pain (ie, predicting the transition from acute to chronic pain), evaluating both short-term and long-term effects of various treatments on pain experiences, or identifying distinct symptom clusters (ie, pain phenotypes). Moreover, the data available are sufficient to calculate more detailed multidimensional and longitudinal clinical trial or observational study end points.

The primary focus of this paper was to introduce SOMA*Science* as a platform for scientific studies. In the long term, we also plan to build platforms with a more clinical focus that facilitate integration with medical care (SOMA*Clinic*) and the support of treatments (SOMA*Therapeutics*). This will involve connecting the SOMA app to electronic medical records and including interfaces to health trackers (eg, daily actigraphy, heart rate, or sleep data from health kits or wearables). The intention is to have a significant positive impact, both in terms of advancing research on pain and improving the lives of people with pain.

Acknowledgments

This work was supported by the Brainstorm program at the Robert J & Nancy D Carney Institute for Brain Science (FHP), the COBRE Center for Nervous System Function (grant NIGMS 5P20GM103645; FHP), and conducted with the help of research staff at the Center for Computation and Visualization at Brown University and volunteers from the Rhode Island School of Design. CZG has been awarded an individual research grant that covered her effort on this paper from the National Center for Complementary and Integrative Health (grant F30AT012306). We want to thank everyone who has supported the development of SOMA*Science* and the SOMA app over the past years, including but not limited to Benjamin Andrew, Rashi Dhar, Louis Rakovich, and Isabel Restrepo.

Abstract

Wearable monitors continue to play a critical role in scientific assessments of physical activity. Recently, research-grade monitors have begun providing raw data from photoplethysmography (PPG) alongside standard raw data from inertial sensors (accelerometers and gyroscopes). Raw PPG enables granular and transparent estimation of cardiovascular parameters such as heart rate, thus presenting a valuable alternative to standard PPG methodologies (most of which rely on consumer-grade monitors that provide only coarse output from proprietary algorithms). The implications for physical activity assessment are tremendous, since it is now feasible to monitor granular and concurrent trends in both movement and cardiovascular physiology using a single noninvasive device. However, new users must also be aware of challenges and limitations that accompany the use of raw PPG data. This viewpoint paper therefore orients new users to the opportunities and challenges of raw PPG data by presenting its mechanics, pitfalls, and availability, as well as its parallels and synergies with inertial sensors. This includes discussion of specific applications to the prediction of energy expenditure, activity type, and 24-hour movement behaviors, with an emphasis on areas in which raw PPG data may help resolve known issues with inertial sensing (eg, measurement during cycling activities). We also discuss how the impact of raw PPG data can be maximized through the use of open-source tools when developing and disseminating new methods, similar to current standards for raw accelerometer and gyroscope data. Collectively, our comments show the strong potential of raw PPG data to enhance the use of research-grade wearable activity monitors in science over the coming years.

Introduction

Wearable monitors are increasingly used to measure physical activity in research, and new tools and techniques are continually emerging [1]. Recent innovations have improved the cost, size, and technical capability of various monitors [2], but accuracy has not increased at a commensurate pace [3-6]. Thus, there is a need for further innovation. Successful innovation will likely entail novel measurement paradigms, rather than incremental improvements on current techniques [6]. One of the most promising and underexplored paradigms is to integrate data from multiple types of sensors, rather than the traditional use of only accelerometer sensors [7,8].

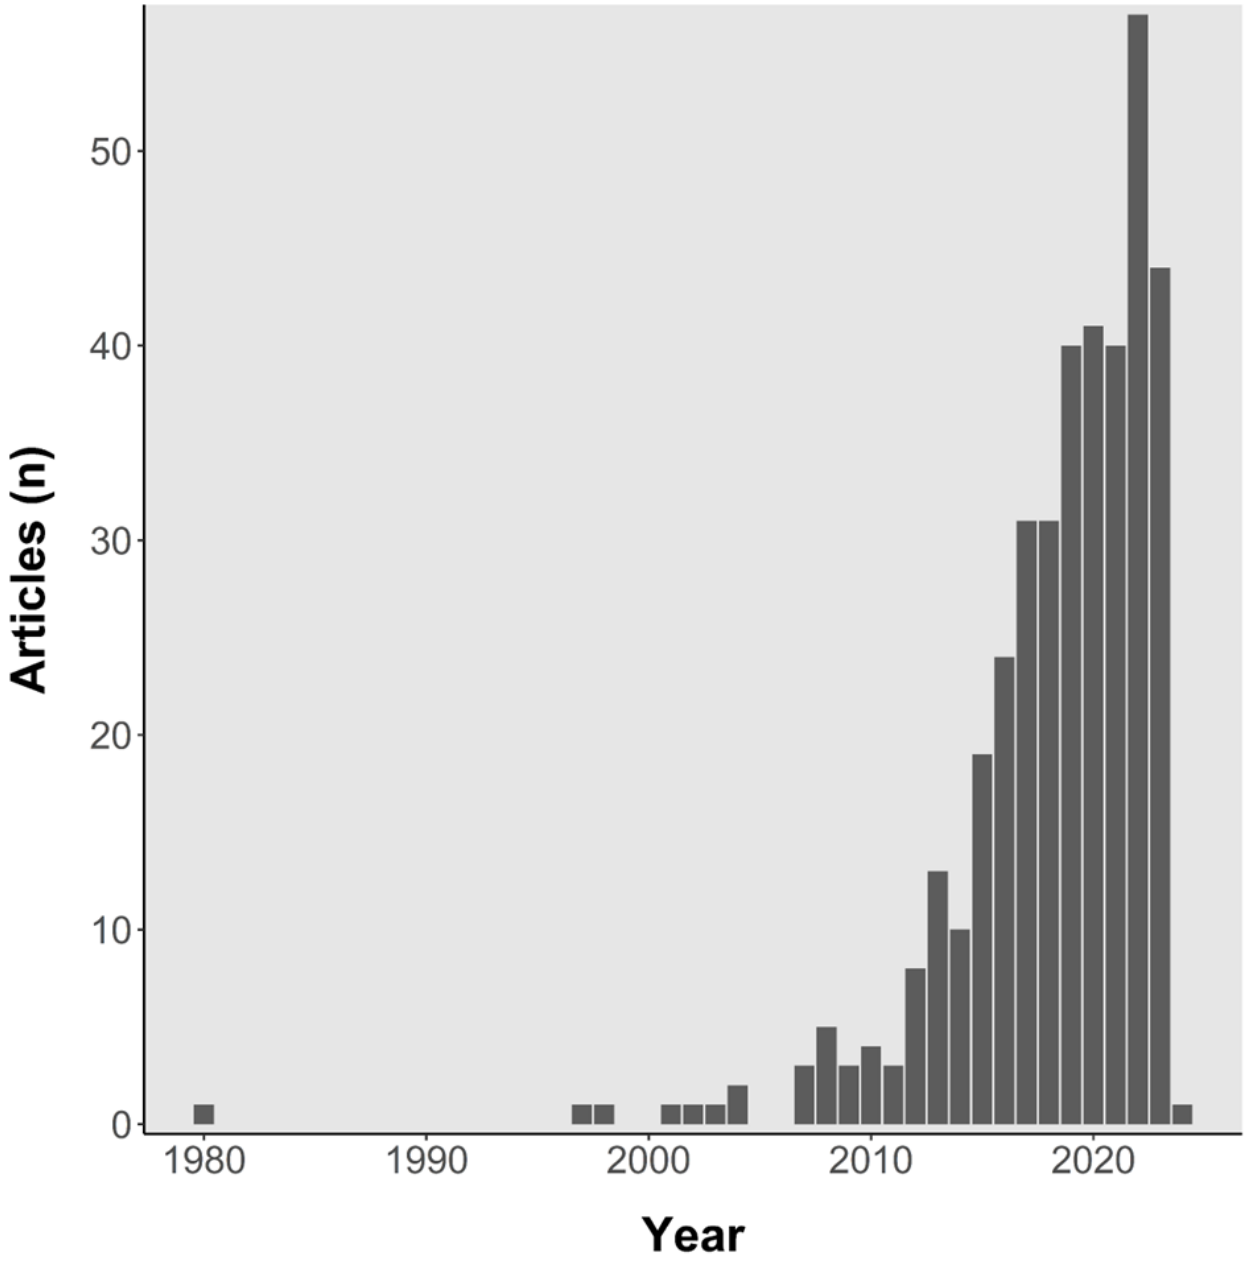
Photoplethysmography (PPG) is an optical technology that may have potential to enhance physical activity measurement when combined with established inertial sensors (accelerometers and gyroscopes) [9]. Although PPG was first described nearly 90 years ago, it has only recently gained a high level of visibility for physical activity assessment [10-12]. This growth is reflected in Figure 1, which shows the results of a Scopus search for

documents addressing physical activity and PPG. Roughly half of the identified studies (183/385, 48%) were published in 2020 or later, and roughly three-quarters (285/385, 74%) were published in 2017 or later.

To date, most applications of PPG for physical activity assessment have involved consumer-grade smartwatches [13-16]. A wealth of developmental research has also been reported in the engineering literature [17-20], but commercial products for research have rarely incorporated PPG sensors and even more rarely given access to raw PPG data (ie, the data recorded by the sensor itself, without any preprocessing applied) [21]. This is beginning to change, and as it does, there is a need to raise awareness of PPG and its potential contribution to monitor-based physical activity assessment. In particular, awareness is needed for *raw* PPG data since it provides an avenue for device-agnostic measurement and iterative, open-source refinement, similar to the standard for inertial sensing [22].

In this viewpoint paper, we present raw PPG as a new frontier in monitor-based methodology. To do this, we first provide an overview of the fundamentals of PPG for physical activity assessment, after which we describe the importance and availability of raw PPG data, as well as specific applications where it holds the most potential. Throughout, we highlight ways that raw PPG data can synergize with raw data from inertial sensors to overcome long-standing challenges (eg, measurement during cycling).

Figure 1. Annual publication counts over time, drawn from a Scopus.com search for "TITLE-ABS-KEY (physical AND activity AND photoplethysmography OR ppg)," conducted on December 6, 2023.



Fundamentals of PPG for Physical Activity Assessment

Technology, Techniques, and Theory

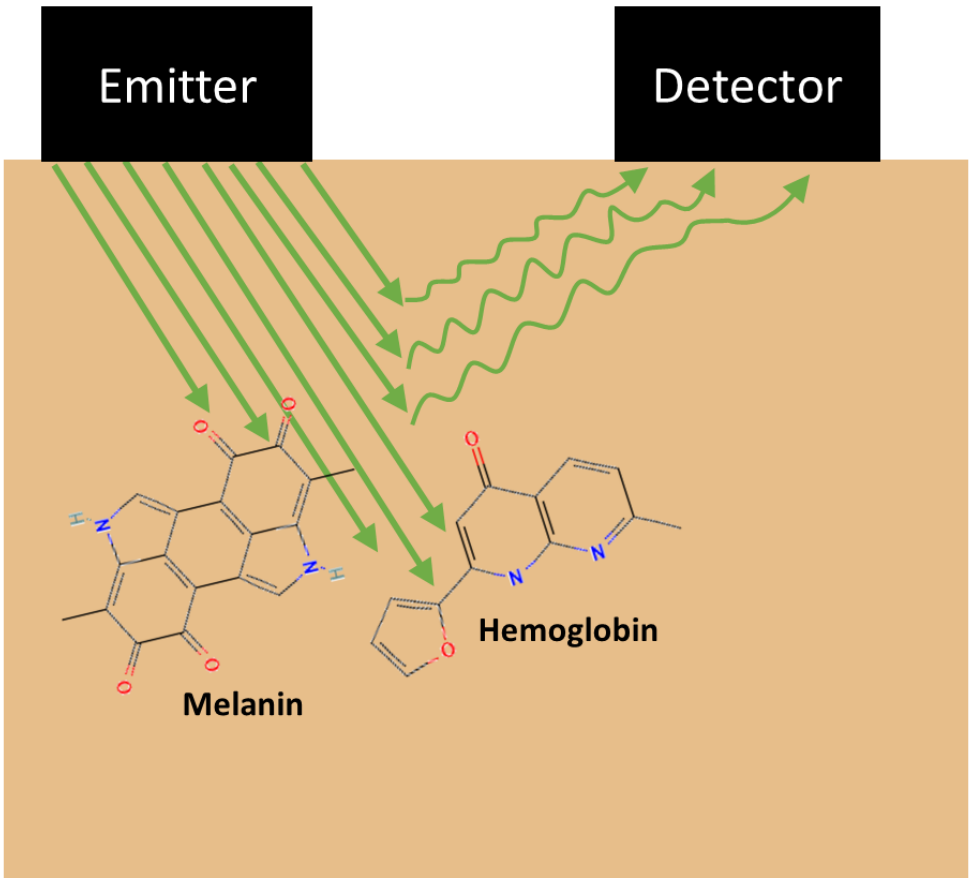
There are 2 types of PPG, namely, transmission and reflectance [23]. Transmission PPG is common in clinical settings where it is used for pulse oximetry [12]. It typically involves red and near-infrared lights, which are shone into one side of a tissue (commonly a finger or an earlobe) and measured upon exiting the other side [10,24,25]. In physical activity assessments, transmission PPG has limited use compared with reflectance PPG. Therefore, we do not provide further comments on transmission PPG.

Reflectance PPG has been investigated using both "wearable" and "remote" instruments, the latter referring to cameras that do not touch the skin. Similar to transmission PPG, remote applications of reflectance PPG have minimal relevance for physical activity assessment, and thus we forgo additional comments on them. Instead, we focus our comments on wearable applications of reflectance PPG, particularly those embedded in wrist-worn devices. Hereafter, we use the term "PPG" to refer exclusively to such applications.

As noted by Mannheimer [26], the term "reflectance" is a misnomer, since there are no mirrors in the skin. Instead, light is scattered by various components of the tissue, and portions of the scattered light return to the surface where they can be measured by a photodetector. Thus, the defining characteristic of this PPG technique is that emission and measurement of light occur on the same side of the tissue [27].

There is some debate around what exactly PPG captures, but the prevailing theory is that it detects pulsatile changes in blood volume [28-30]. Figure 2 depicts the mechanics of this proposed process, with light being shone into the skin while cyclical fluctuations in scatter are monitored. These fluctuations occur because blood concentration is increased when a pulse wave passes under the light, resulting in more light absorption in accordance with the Beer-Lambert law [26,31]. Consequently, a waveform emerges in the PPG signal, which can be analyzed to detect pulse waves and calculate related parameters such as heart rate [9,10,23]. Green light is typically used because it offers shallower penetration and greater robustness against motion artifacts and other noise [17,19,32-35].

Figure 2. Basic representation of PPG technology. An emitter shines light into the skin. The light is absorbed by some components—mainly hemoglobin and melanin—and scattered by others toward a photodetector. Pulse waves cause increases in local blood concentration, leading the balance of absorption and scatter to shift in favor of more absorption. The photodetector signal thus diminishes as the pulse wave passes, creating a waveform that can be analyzed to predict cardiovascular parameters such as heart rate and blood pressure. Public domain icons from PubChem are shown for melanin (CID 6325610) and (deoxy)hemoglobin (CID 135310457).



Common Difficulties and Sources of Error

It is important to understand not only the theoretical workings of PPG but also practical issues that affect its operation. Fine et al [36] have grouped such issues into 3 categories (individual differences, physiology, and external factors), while Bent et al [37] have highlighted the unique importance of one overarching individual factor (skin type) and 2 external factors (motion artifact and signal crossover). In this section, we provide a brief overview of these latter 3 factors and their potential implications for physical activity research, with additional comments on broader sources of error for general applications of PPG.

Skin type encompasses adiposity, pigmentation, and other factors that influence tissue composition (see the study by Fine et al [36] for a detailed listing). Differences in tissue composition can affect optical scattering and absorption in ways that are difficult to predict. Accordingly, prior work has shown the accuracy of PPG-based estimates to vary depending on age, sex, obesity status, and skin tone [13,20,38-40]. The latter is an especially important variable to consider because melanin is one of the skin's main absorbers of light at various wavelengths [41,42]. When using PPG for the measurement of physical activity, there is thus a clear need to ensure that new methods have consistent accuracy across diverse skin types. This is especially important given the implications for equity in health research.

Motion artifact is movement-induced noise in the PPG signal, which can occur due to both mechanical and physiological aspects of the movement [43]. Efforts to address motion artifact often rely on frequency-domain analyses, since it is expected that the rhythmicity of the pulse will create a sharper contrast between signal and noise in that domain [44]. Increasingly, these analyses involve cross-referencing PPG against data from concurrently worn accelerometer and gyroscope sensors to aid in differentiating between inertial and cardiovascular signal [45]. Thus, when using PPG for physical activity assessments, future studies may benefit from using devices that provide access to raw data from both PPG and inertial sensors.

Signal crossover is closely related to motion artifact and refers to confusion between rhythmic motions of the monitor itself (eg, during locomotion) and the inherent rhythmicity of the cardiovascular signal from PPG [37]. Specifically, cardiovascular signal is expected to have dominant frequencies between roughly 1.0 Hz and 3.5 Hz (corresponding to heart rates between 60 and 210 beats per minute), and human movements can generate considerable amplitude in the same range [46-48]. Thus, it is likely that some motions will result in overlap of inertial and pulsatile signal components, making it hard to tell which is which. This is one reason that PPG-based devices have frequently been shown to have lower accuracy during physical activity than during other behaviors [37,49,50]. Signal crossover is uniquely important to highlight because it suggests that device accuracy may vary based on not only the amount of movement but also the type of movement. This could have major implications for physical activity assessments, making it crucial to address in future work.

Apart from skin type, motion artifact, and signal crossover, Fine et al [36] have highlighted difficulties posed by physiological factors (respiration, venous pulsations, attachment site of the device, and body temperature) and additional external factors (ambient light and pressure of the sensor on the skin). These difficulties are important to acknowledge and address, but their implications may not be substantively different for physical activity research than what has been described for other disciplines.

Many of the difficulties with raw PPG resemble what is already faced when dealing with inertial data from accelerometers and gyroscopes [51]. The latter sensors have enhanced the measurement of physical activity despite their limitations [52], and thus PPG may have similar potential. Furthermore, the impact of device limitations may diminish over time through ongoing innovation in technology and analytics. Thus, the difficult aspects of PPG can be viewed as opportunities for refinement rather than insurmountable barriers.

Importance and Availability of Raw PPG Data

To understand the revolutionary potential of raw PPG data for physical activity assessment, it is helpful to consider a similar revolution that has already taken place with accelerometer data [53-55]. Historically, accelerometer-based devices provided only proprietary "activity counts" as their output, which led to intermonitor differences and a lack of flexibility to innovate with new data processing techniques [56-58]. Over time, raw acceleration data became commonplace, opening doors for standardization and innovation in physical activity research [2]. An especially noticeable result was that many researchers began to focus on techniques that combined research-grade products with open-source tools for data processing and analysis, thereby promoting streamlined and coordinated progress in the field [59-64].

The potential parallels for PPG data are striking. To date, most research with PPG has relied on proprietary outputs from consumer-grade devices, which have been used to track heart rate, atrial fibrillation, blood pressure, and more [65-76]. Intermonitor differences and lack of flexibility are thus limitations of current standards for PPG, in much the same way as they once were for accelerometry. Furthermore, concerns have frequently been raised about unannounced algorithm and firmware updates that can make consumer-grade technology undesirable in certain research contexts [77-81]. The advent of raw PPG data therefore offers many of the same benefits that have already been derived from raw accelerometer data, especially when pairing research-grade devices with open-source resources. But the full potential of raw PPG for physical activity research cannot be realized unless the market provides devices that are scalable for use in large studies.

Existing research involving raw PPG data has generally involved small-scale devices (sometimes custom-made) [19,21,27,30,82], specialized tools for hospital use [83-86], or smartphone technology [87-89]. While these studies have shown strong proof-of-concept, they have only sometimes been oriented toward physical activity research, and the availability of suitable devices for large assessments remains an issue. The best-known

research-grade devices are likely the E4 and EmbracePlus from Empatica Inc, the Shimmer3+ GSR from Shimmer Sensing, and the LEAP from ActiGraph LLC. Each device has strengths and limitations, with major points of comparison being cost, comfort, and access to raw data. The Shimmer3+ GSR is the most affordable option and provides access to fully raw data from both PPG and inertial sensors. However, a potential limitation is its reliance on physical components (eg, wired probes that wrap around the fingers) that may be unappealing or uncomfortable for some participants. The EmbracePlus is the most expensive device and is a replacement for the E4. It is designed like a standard smartwatch and is therefore very comfortable, but it does not provide truly raw PPG data (nor did the E4 [21]). Specifically, the EmbracePlus preprocesses PPG data using a proprietary algorithm that produces a blood volume pulse waveform, which resembles but does not replace raw data as it would appear in a direct recording from the photodetector. The LEAP device falls between the other 2 in terms of cost and comfort but does provide access to fully raw data from PPG and inertial sensors.

As new and upgraded devices continue to emerge and provide access to raw PPG data, a key objective will be to apply, extend, and standardize the techniques from earlier proof-of-concept studies for use in large-scale physical activity assessments for research. The following section outlines several specific areas in which there may be greatest warrant for these efforts.

Potential Applications of Raw PPG in Assessments of Physical Activity

The most obvious application of raw PPG for physical activity assessment is heart rate monitoring, where a notable contrast exists between the wrist-based optical approach and standard electrode-based approaches involving chest-worn monitors (eg, heart rate straps and Holter monitors). The latter tend to have greater accuracy than the former [90,91] and yet can also be uncomfortable to wear, especially over long periods [92]. Conversely, wrist-based PPG devices can be comfortably worn over long periods and yet have lower accuracy than chest-worn monitors. One implication is that raw PPG may encourage participant compliance in long assessment protocols (eg, lasting a week or more, which is common in physical activity research). This could be especially valuable for interventions that assess change over time, since responsiveness is generally a greater concern than accuracy in those contexts. Moreover, the diminished accuracy compared with chest-worn monitors may be less of an issue in cases where the key outcome is categorical intensity rather than continuous heart rate (eg, if assessing time in heart rate zones, where measurement error would be a concern only at the boundaries between zones, rather than across the spectrum of continuous heart rates). Nevertheless, there is a definite trade-off between accuracy and comfort, and neither chest-worn nor wrist-worn monitors are the optimal choice for every research question. This makes the accuracy-comfort trade-off a critical consideration when selecting a monitor for research. With continued innovation and refinement, the accuracy gap may narrow between chest- and wrist-worn devices, and trade-off–related considerations may change accordingly. But it is unlikely that the issue will ever disappear completely.

While heart rate monitoring is an obvious application for raw PPG, it may not be the most impactful one. Rather, there may be greater promise when combining raw data from PPG and inertial sensors to predict other physical activity–related outcomes such as energy expenditure. This multimodal approach not only allows for robust correction of motion artifact in the PPG signal (as described previously) but also enables concurrent analysis of movement and cardiovascular data. While this is not an entirely new concept, the ability to carry it out using purely raw data from a single wrist-worn device is quite recent. Thus far, the primary multimodal methods have relied on either separately worn movement and cardiovascular monitors [93-95] or the chest-worn Actiheart device (CamNtech Ltd) [96-99] when predicting energy expenditure. These approaches have shown clear synergy between movement and cardiovascular data but have ultimately had limited uptake compared with the widespread use of wrist-worn monitors in field-based research. Furthermore, heart rate has been the only cardiovascular parameter emphasized with the earlier methods, whereas raw PPG can potentially lead to enhanced predictions through the capture of additional aspects of cardiovascular response to activity (eg, pulse wave parameters and variability). This highlights the warrant for translating and extending earlier concepts of multimodal assessment to the use of raw PPG and inertial data from wrist-worn devices.

The combination of raw PPG and inertial data may also help overcome known limitations of movement-only techniques in the prediction of energy expenditure. For example, wrist-worn monitors are generally unable to register any motion during cycling despite the level of lower-limb exertion, resulting in poor measurement validity [100]. In contrast, PPG may still detect exertion during cycling because it relies on optical and physiological signal rather than inertial signal. This advantage reflects the known benefit of using not only multiple sensors but multiple types of sensors [51,56]. Similar benefits may also arise for other activities where the body's inertial profile is altered, such as when carrying an external load or pushing a stroller [101,102]. The potential to overcome these limitations with virtually no change in participant burden highlights the strong potential of raw PPG to improve physical activity research, especially in the area of energy expenditure prediction.

Combining raw PPG and inertial data may also be beneficial for activity recognition, promoting greater understanding about certain elements of activity context [103]. Activity recognition is also important as a precursor to energy expenditure prediction, since it is much easier to predict energy expenditure if the type of activity is first known [104-106]. This is the basis for several prior models of energy expenditure, including well-known 2-regression models [107-114]. The utility of raw PPG for activity recognition was recently highlighted by Hnoohom et al [115], who calibrated models using data from 3 open-access datasets [116-118]. The parent studies used devices from Shimmer, Empatica, and Maxim Integrated (Analog Devices Inc), and the models were calibrated using deep learning and different combinations of accelerometer, PPG, and electrocardiographic data. When combining accelerometer and

PPG data, the dataset-specific models each achieved near-perfect accuracy during 10-fold cross-validation. However, external validations are needed to confirm the effectiveness of the models and apply them with scalable devices, as described previously.

Outside of energy expenditure and activity recognition, raw PPG may have use for measuring a range of other physical activity–related variables as well, from specific hemodynamic parameters related to exertion (eg, pulse transit time [119]) to consequences of physical activity such as fatigue and recovery [120]. Steps warrant mention as well, given their status as a well-known output of most wearable activity monitors. Raw PPG could potentially enhance or refine the measurement of steps and related variables (eg, cadence), including during periods where the inertial movement profile is altered, as described previously for energy expenditure. The combination of raw data from PPG and inertial sensors could also enable automated measurement of highly specialized outcomes in free-living settings, such as cardiac-locomotor coupling (ie, synchrony of footfalls with systole or diastole) [121].

Finally, although our focus has been on physical activity–related applications of raw PPG, it is important to acknowledge potential contributions in the broader context of 24-hour measurement as well. This refers to the growing emphasis on interrelationships between physical activity, sedentary behavior, and sleep as part of a daily composite [122,123]. The importance of the concept is reflected in the release of 24-hour movement guidelines from numerous governments and the World Health Organization over the last few years [124-129], and there are at least 2 key contributions raw PPG can make to 24-hour assessments. One is to differentiate between nonwear, sedentary behavior, and sleep, all of which produce minimal accelerometer and gyroscope signal and are therefore hard to tell apart using only inertial data. Raw PPG may exhibit richer variation across the categories, thereby assisting with disambiguation. Some proof-of-concept already exists in this area as well, given the amount of prior work using PPG for sleep measurement [130]. The other benefit may be to assist with classifying posture (seated or lying vs upright) [131], which is essential for differentiating sedentary behavior from light-intensity physical activity [132]. These possibilities highlight the strong potential and exceptional flexibility of raw PPG, which will be an asset for a broad range of movement-oriented research in the coming years.

Discussion and Conclusion

In this viewpoint paper, we have introduced raw PPG and highlighted its potential benefits for physical activity assessments. Our specific focus on raw PPG data (as opposed to preprocessed or aggregated data) was critical and timely, given the recent emergence of mainstream devices that provide access to them. A key strength of raw PPG is that its optical basis complements the inertial basis of familiar accelerometer and gyroscope sensors. Furthermore, raw PPG can be used to assess not only heart rate but also broader aspects of cardiovascular physiology. These are the driving forces behind the potential we laid out in the prior sections.

Going forward, it will be critical to obtain raw data from both PPG and inertial sensors, not only to facilitate merging them but also to make new algorithms both transparent and device agnostic (ie, applicable to data from any PPG-inclusive device). These characteristics help combat the “black box” phenomenon of closed-source devices [133]. Device agnosticism also plays an important role in “future proofing” new methods by reducing dependence on individual monitors that can leave the market at any time (eg, as seen with the SenseWear Armband, Phillips Actiwatch, Empatica E4, and ActiGraph GT9X). The use of raw PPG can be further advanced by using open-source channels when developing and disseminating of new resources, consistent with growing standards for existing wearable devices in physical activity assessment [59-64].

This viewpoint paper was among the first to suggest the value of integrating raw PPG data into large-scale assessments of physical activity, where the importance of raw accelerometer and gyroscope data has already been established. In doing so, the viewpoint paper serves to orient new users to the wealth of prior work on PPG from other research areas, where critical reference points have been provided that can spur a paradigm shift in physical activity research. A noteworthy limitation of the viewpoint paper was that it was not a systematic review. As such, it did not fully summarize the available literature, whether in general or focused specifically on physical activity assessment. Nevertheless, our overall conclusion is that there is warrant for vigorous exploration of raw PPG going forward.

Acknowledgments

This study was not supported by a specific award. PRH led the literature review and drafted the manuscript. MK provided support for the review and edited the manuscript.

Conflicts of Interest

PRH has received funding from ActiGraph LLC, who recently released a photoplethysmography-inclusive monitor to the market. ActiGraph had no role in the preparation of this paper.

Abstract

This paper proposes an approach to assess digital health readiness in clinical settings to understand how prepared, experienced, and equipped individual people are to participate in digital health activities. Existing digital health literacy and telehealth prediction tools exist but do not assess technological aptitude for particular tasks or incorporate available electronic health record data to improve efficiency and efficacy. As such, we propose a multidomain digital health readiness assessment that incorporates a person's stated goals and motivations for use of digital health, a focused digital health literacy assessment, passively collected data from the electronic health record, and a focused aptitude assessment for critical skills needed to achieve a person's goals. This combination of elements should allow for easy integration into clinical workflows and make the assessment as actionable as possible for health care providers and in-clinic digital health navigators. Digital health readiness profiles could be used to match individuals with support interventions to promote the use of digital tools like telehealth, mobile apps, and remote monitoring, especially for those who are motivated but do not have adequate experience. Moreover, while effective and holistic digital health readiness assessments could contribute to increased use and greater equity in digital health engagement, they must also be designed with inclusivity in mind to avoid worsening known disparities in digital health care.

Introduction

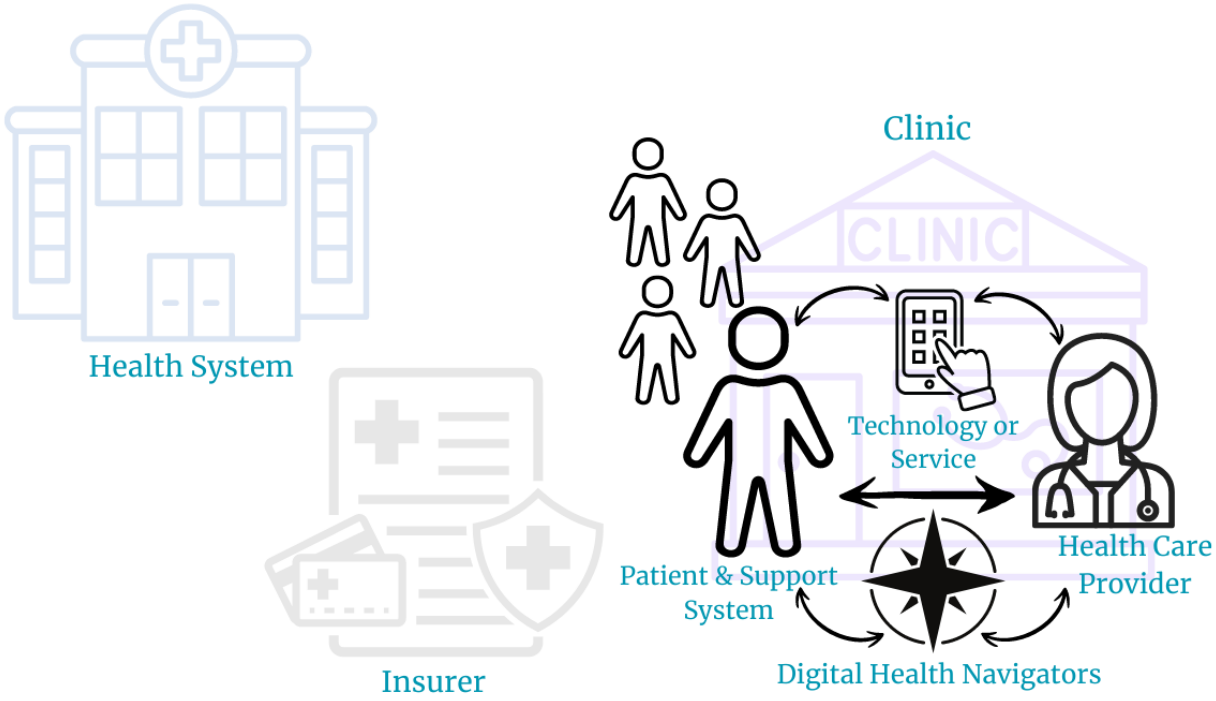
The use of digital tools for health care—including video visits, patient portals, mobile apps, and remote monitors—has risen exponentially over the last decade and become more essential for care access during and after the COVID-19 pandemic [1,2]. Patients using digital health tools have been shown to have better outcomes in managing many outpatient health conditions, including diabetes [3,4], anxiety and mood disorders [5], hypertension [6], and chronic pain [7]. Still, despite their growing incorporation into health care and potential to improve health outcomes, many who could benefit from these tools are not using them [1,2,8,9]. If health systems can develop approaches to close this gap with innovative and tailored pathways to digital health care, they could improve access, inclusivity, and outcomes.

Prior approaches to increase digital health engagement focused on several domains, including such logistical factors as broadband internet access [10], access to smartphones, and the ability of individuals to use technology to participate in health care and understand their health (ie, digital health literacy) [11]. Initial assessments of digital health literacy in the mid-2000s focused on the ability to use the internet, but they have since expanded to encompass smartphones, mobile apps, and social media [12,13]. As a construct, digital health literacy has also grown to reflect multiple domains of health technology use, including personal aspects like prior experiences, digital self-efficacy, motivation to use digital health, and access to technology [14]. The evolution of these assessments reflects changes in the technological environment but also demonstrates the multifaceted nature of digital health literacy overall. Future approaches to facilitating further equitable growth of digital health could consider the ecosystem of factors that drive engagement with these tools. General health literacy is increasingly understood as a relational concept in which patients and health care providers (HCPs) balance their skills and abilities against the demands of health care systems [15,16]. Digital health readiness for individual patients exists within similar contexts and is impacted by the technological tools themselves (particularly the demands that they place on patients), the HCPs prescribing and monitoring their use, the clinics and digital health navigation services where technological instruction occurs, the health systems and their approach toward digital health implementation, and the insurers that control coverage of these services and tools (Figure 1). In this paper, we review current digital health literacy measures to assess and predict a person's ability to engage with digital health, discuss their relative strengths and weaknesses, and describe our holistic vision for health care systems to assess digital health readiness efficiently with health record data.

Multidomain digital health readiness assessments could create a phenotype for each patient representing how prepared, experienced, and equipped they are to use a particular digital health tool at a certain point in time [17]. Prior studies have established approaches to understand readiness within health systems (ie, how prepared and experienced a system is for digital care implementation) [18], within individual health care facilities [19], and among health professionals themselves [20]. Approaches for comprehensively defining and assessing individual-level digital health readiness could become central to health system and payor operations, as signaled by the Center for Medicare and Medicaid Services (CMS) mandate that Medicare Advantage organizations offer "digital health education" for telehealth to their members [21].

Creating effective and holistic digital health readiness assessments could contribute to increased use of and access to these tools among patients and their families. In this paper, we focus only on assessing individual, patient-level digital health readiness, but we acknowledge that this construct can be applied to any node within the digital health readiness ecosystem, as noted above and in Figure 1.

Figure 1. Health care system components of a proposed digital health readiness ecosystem. These are the possible health care nodes of a digital health readiness ecosystem—all of which impact digital health use—including the technology or service, patients and their support system, health care providers, digital health navigators, insurers, and clinics and health systems.



Strengths and Weaknesses of Current Digital Health Readiness Measures

Current methods to assess digital health readiness have several strengths and weaknesses.

One strength of these measures is that they assess relevant aspects of digital health participation and are often short enough to be incorporated into clinical practice; however, these measures assess personal attitudes alone without considering technological aptitude. For example, the eHealth Literacy Scale (eHEALS) is the most cited digital health literacy measure and focuses on assessing a person's attitudes, confidence, and subjective skill level in using internet search engines and evaluating online information, yet it does not assess the experience needed for smartphones and wearable monitors or address such structural factors as device access (either through personal ownership or sharing) [13]. Newer measures such as the Digital Health Care Literacy Scale do capture skills for using and troubleshooting mobile apps and videoconferencing apps in a brief manner that is primed for clinical settings, but they also do not assess technical aptitude or device access [22]. For digital health readiness assessments to be useful in the clinical operations of health systems, they should have an aptitude assessment to stratify individuals into levels with matched support interventions. Additionally, research will be needed on what demonstrated skills are most important for a particular care modality (like a video visit versus wearing a remote monitor).

More thorough digital health readiness assessments cover many relevant aspects of the digital health care experience; however, they may be logistically challenging to administer in clinical settings. For instance, the recent Digital Health Readiness Questionnaire (from 2023) gathers a more detailed assessment of a person's experiences with digital health by asking about their skills, digital literacy, digital health literacy, device use, and learnability, but its 20 items might be cumbersome to administer in a busy primary care setting, do not assess actual aptitude, and do not include questions about device or internet access [23]. Even more robust assessments, including the eHealth Assessment Toolkit [17] and eHealth Literacy Questionnaire [24], are validated and available, though their comprehensiveness also likely makes them unwieldy for application in clinical settings. For example, the eHealth Assessment Toolkit [17] has 44 questions encompassing 7 different tools for digital health care.

One strength of contemporary digital health readiness measures is that they are grounded in updated theoretical constructs of digital health equity that aim to improve engagement with populations facing health disparities and reflect our current technological environment.

The framework for digital health equity augmented the National Institute on Minority Health and Health Disparities research framework by adding individual, interpersonal, community, and societal aspects of the digital environment and patient experience [14]. Previously elaborated digital health readiness research strategies like those from Lyles et al [25] and Jaworski et al [26] were built on components such as "access, motivation and trust, and digital health literacy" that are also fundamental for boosting digital health engagement. Despite being published relatively recently, these frameworks are widely cited and are being incorporated into wide-ranging fields, including behavioral health research, addiction medicine, and cardiovascular medicine—among others [27,28]. While these updated

constructs reflect the current experiences of being a digital health care user, they will also likely need to be updated over time to match the dynamic nature of digital health innovation and remain relevant in the frantic pace of clinical care. Moreover, as seen in the following scenario, approaches to digital health readiness will need to be agile and adaptable to meet the unique needs of each individual.

Scenario 1: Digital Health Readiness and Wearable Health Monitors

This hypothetical patient scenario (Textbox 1) reflects the challenges of applying individual digital health readiness assessments and how clinical teams could be responsive to each person's unique needs.

Ms T's case demonstrates the importance of aptitude testing (eg, prompting a user to show an instructor how they might use a phone app) and how a care team might adjust a digital health care modality to best meet the needs of a patient.

Another weakness of current digital health literacy and readiness measures is that they do not integrate passively collected data from the electronic health record to improve efficiency and efficacy. Using available metrics—such as a visualized breakdown of previous in-person care, completed video visits, completed phone visits, and patient portal use— can increase the efficiency of digital health readiness assessments and portray a person's actual care use compared with their stated goals. Examples include the Telemedicine ImPACT Score [29] and EpicCare Video Visit Technical Risk Score [30], which use data on the number of prior completed video visits and portal messages sent to forecast future digital engagement without the need to administer a questionnaire. These data seamlessly contribute information about an individual's digital determinants of health—that is, the larger social, personal, and structural barriers that impact digital health engagement [14,31]—and could focus on particular factors that are most predictive of certain tasks (like completing a video visit) [32-34]. Looking at a person's health record data in a digital health readiness profile, in-clinic technology navigators may find that a person has no broadband access or internet experience and recommend in-person care over virtual care until these factors are addressed. Passive health record data could refine in-person and digital care delivery so that patients are accessing resources in a way that matches their personal situations.

The essential elements needed for comprehensive and practical digital health readiness assessments will include aptitude testing, in addition to evaluating attitudes toward technology, customizing skill assessment to address emerging technologies, and incorporating passively collected health system data. Existing digital health literacy screening metrics and digital health prediction tools each have strengths that could create a more comprehensive profile of a person's prior technological experience and could be adapted to the use of new technologies over time.

Textbox 1. Hypothetical patient scenario 1.

Ms T is a woman aged 63 years with a laptop computer and a smartphone who regularly searches for health information on the internet. Ms T qualifies for a continuous glucose monitor (CGM) to track her blood sugars; however, the device typically downloads data to a smartphone for users to view their trends. She has nerve damage from diabetes that limits her ability to navigate smartphone screens, but she is able to use computer keyboards without issue. Once the CGM is ordered, the diabetes education team asks her to bring whichever devices she most commonly uses to her CGM training session. During her visit, the diabetes nurse educator evaluates her for digital health literacy using the 3-item Digital Health Care Literacy Scale and feels that she is prepared to use the CGM interface. After the educator downloads the CGM app on her smartphone, Ms T is prompted to sign in and create an account. Immediately, the staff notices that she has issues navigating the smartphone interface. Pivoting to make the technology more usable for her, they set up the CGM application on her laptop so that she can view her blood sugar trends more easily.

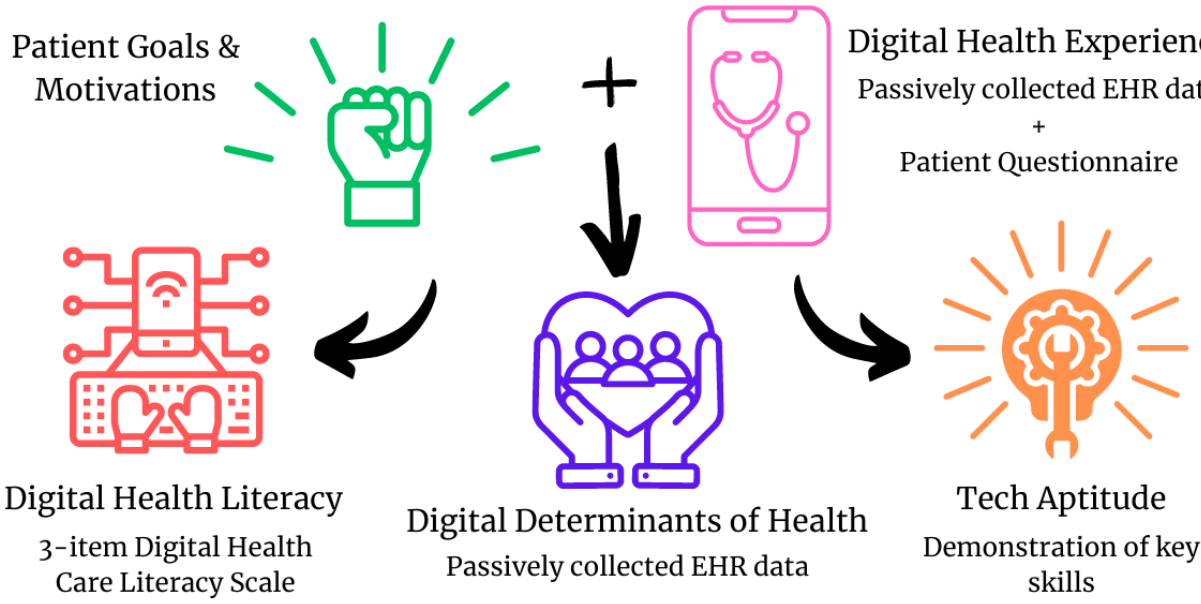
Making Digital Health Readiness Assessments Practical and Efficient for Clinical Settings

We envision a holistic digital heath readiness assessment that will enable health systems to deliver targeted support to those who need it most and close gaps in use. Similar to the Conversational Health Literacy Assessment Tool (CHAT), which is designed to assess multiple dimensions of a person's health literacy in health care settings, digital health readiness assessments could be designed to provide a more comprehensive and pragmatic picture of a patient's digital health strengths and obstacles [35]. In particular, the Health Promotion Barriers and Support, Health Information Access and Comprehension, and Current Health Behaviors domains from the CHAT could be adapted to a digital health context. Digital health readiness assessments could begin with questions about personal goals for health technology use and prior digital health experience, followed by focused aptitude testing for a particular digital health tool or goal, a brief digital health literacy assessment, and visualization of that person's health systems data to probe into their digital determinants of health. Figure 2 reflects the proposed elements of an individual digital health readiness profile that would allow HCPs and care navigators to understand a person's digital phenotype and act to meet their unique needs. The components of Figure 2 [14] represent our thoughts on ways to address the strengths and weaknesses outlined above and were informed by the framework for digital health equity [14]. This multi-domain approach would incorporate patient-reported data with passive data from health systems and payors to make responses more relevant and able to be added to busy clinical workflows. The key difference from existing digital health literacy assessments is the incorporation of a focused aptitude test assessment (such as having a patient show how they use a mobile app for 1-2 minutes) and the integration of passively collected clinical data. These aspects would make digital health readiness phenotyping more efficient, systematic, and, hopefully, effective for clinical settings.

As technology evolves and alters the required skills to participate in modern health care, digital health readiness assessments will

need to grow in kind to reflect these skills. Ideally, the collection of inputs will differ for specific tasks. For example, completing a video visit may involve downloading a mobile app, registering an account, checking in online, and signing in to the appointment. In contrast, registering for a patient portal may involve only some of these steps. Domain-specific digital health readiness assessments could make the assessment most relevant to patients and their goals. The following fictional vignette shows how digital health readiness assessments could be tailored to help patients complete a specific task—such as how to log on to and complete a video visit.

Figure 2. The proposed components of a holistic digital health readiness assessment based on the thoughts of the authors and the digital health equity framework of Richardson et al [14].



Scenario 2: Digital Health Readiness and Telehealth

The hypothetical patient scenario shown in Textbox 2 reflects how passively collected data could link patients with digital health navigation services to improve digital health care outcomes.

Looking at Mr P's case, he is a person who has ostensibly high digital health readiness through demonstrated skills, access to a network, and use of a health system app; however, he has also consistently had issues logging in for video visits, which adversely impacted his digital health care use and increased his risk of hospital readmissions. In this scenario, an automated alert based on previous patterns of digital health care use from electronic health record data triggered help with navigating video visits from a digital health navigator, which many health systems offer [36-38]. That alert could have triggered office staff to arrange an in-person appointment or home visit to assess his ability to use telehealth and provide help if he could not.

Having systematic processes in place to assess who is most appropriate for in-person versus remote or asynchronous care could guide efficient service delivery and use of resources. With their abundance of claims data and the opportunity to trial different variations of digital support pathways, integrated delivery and finance systems represent a unique setting where digital health readiness measures could be deployed, tested, and refined.

Digital health readiness assessments could be a key step toward making digital health implementation more systematic for all people, leading to greater equity and effectiveness. In many clinics, the process of selecting in-person care versus telemedicine could be tied to the nature of the medical issue, the judgment of scheduling and treating team members, and personal preferences (ie, a subset of patients who always want in-person care). Adding more specificity to digital health implementation through the creation of care delivery phenotypes—that is, providing navigation support for patients who are motivated to use digital health but are inexperienced—would optimize this care. It is likely that many opportunities for digital engagement and adoption of new tools are missed simply because health systems do not have robust ways to screen for who is best equipped and motivated for digital health but has not used it. Rather than limiting digital health to those patients who are already confident with technology, streamlined and methodical digital onboarding guided by a digital health readiness assessment could expand the reach of these tools to more patients. In turn, this could provide greater efficiency and, in some cases, reduced costs [39] for patients in scenarios where similar treatment outcomes have been achieved with video versus in-person visits [40]. Differentiating those who can complete a telemedicine appointment on their own from those who might need additional support would further expand digital health as a standard of care and improve the service experience for all patients.

To fully assess digital health readiness, we should also consider how a person's situation may change over time as well as how personal and community resources could help them succeed.

With an aging and increasingly medically complex population, digital health readiness phenotypes will likely be dynamic and may need to be repeated in certain circumstances, such as a major health event, functional decline, cognitive impairment, financial insecurity, or loss of family support [17]. In the event that a person can no longer use a particular tool, a support person may be best suited to provide digital health support in a convenient environment like a health center–affiliated or community-embedded internet clinic [41]. Furthermore, studies have shown that patients with limited technology experience are often able to complete a telehealth visit with the help of a family member, friend, or caregiver—thereby providing an opportunity to engage those with lower digital health readiness from the onset [42,43]. Partnering with patients, families, and communities could help to personalize digital care delivery pathways even further and improve engagement.

Textbox 2. Hypothetical patient scenario 2.

Mr P is a man aged 75 years who has been hospitalized 5 times in the past year for decompensated heart failure. He has a smartphone that enables him to message his primary care provider and heart failure specialist via his health system's patient portal. As he transitioned between hospitals, skilled nursing facilities, and home, he missed multiple follow-ups. His primary care office proactively contacts him at home and sets up a video visit to reestablish care. When the time for the appointment arrives, his primary care provider begins the visit but Mr P cannot log in. After he spends 10 minutes of the 30-minute appointment trying to use the videoconferencing platform, his doctor switches to a phone visit. At the end of the visit, his doctor receives an automated alert from the electronic health record noting that prior scheduled video visits have been converted to phone visits. Looking deeper into the situation, the doctor notices that recurrent telehealth platform issues have taken time away from health care providers to discuss all aspects of his health issues in prior visits—especially dietary counseling (a key reason for his hospitalizations). After the visit, Mr P is referred for an in-person digital health navigation session where he is instructed on ways to troubleshoot the telehealth platform and demonstrate that he can use the videoconferencing service independently.

Challenges of Implementing Digital Health Readiness Assessments

While digital health readiness assessments apply to individual patients, health systems will also need to build infrastructure to respond to the results of these assessments in a meaningful way to realize their full potential. There are established standards to promote organizational health literacy within health systems that could be applied to digital health implementation—including fostering a culture among employees that promotes communication and engagement with patients and families using technology [44,45].

Moreover, HCPs and team members also have varying levels of digital health readiness that affect the implementation of digital health readiness assessments. Similar to medication prescribing, HCPs often serve as gatekeepers for recommending and promoting digital health tools. HCPs' awareness and perceptions of the benefits of digital tools have been identified as determinants of mobile app uptake for chronic disease management [46]. While one might assume that HCPs would have more than adequate digital health readiness and literacy, some studies of hospitals in resource-limited settings worldwide (including one from Ethiopia during the COVID-19 pandemic) have found that less than half of HCPs had high digital health literacy [47]. Health care systems must consider the levels of technological awareness, comfort, and competence among their HCPs when considering more equitable digital health implementation.

There are also potential risks and ethical concerns involved in digital health implementation. With studies showing that digital health engagement is lower among older people, those who require an interpreter, and those who live in more deprived areas [48], efforts to shift more and more health care to digital platforms could exacerbate gaps in care. Furthermore, while the aforementioned evaluation frameworks for digital health tools do consider inclusivity and equity for diverse populations, studies have suggested that only 58% of mobile app evaluation frameworks do so, meaning that vital perspectives on technological tools may still be left behind [49]. Tying back to digital health literacy and health literacy, patients could experience delays in care if they were to choose telehealth or a patient portal message for a condition that warrants in-person evaluation. Personal health data collection and security are also important considerations for making sure that participating in digital health care is safe for all users.

A challenge of aptitude- and analytics-based digital health readiness assessment approaches is that they could amplify societal inequities if not designed carefully and evaluated among minoritized populations. Assessments based solely on aptitude may be biased against other-abled individuals with visual or hearing impairments or people whose primary language is not English. Moreover, given the complex array of factors that impact digital health engagement, digital health readiness assessments cannot be perfectly comprehensive. Digital health literacy is a single digital determinant of health that incorporates a person's underlying literacy, numeracy, and general health literacy—each of which could not be measured or acted upon in a single clinic visit. Using passively collected data carries the risk of perpetuating systemic biases through algorithmic determinism (eg, the perpetuation of systemic bias through algorithms trained on biased data) [50,51] and underrepresentation of marginalized groups in data overall [52], which could further contribute to the digital health divide [21]. It will be important to test and validate digital health readiness assessments among diverse patients. If the evidence for these assessments has not yet been established among certain groups, this should be noted in the electronic health record and factored into how they are deployed and understood.

Conclusion

Assessing and supporting individual patient-level digital health readiness is a crucial step toward maximizing benefits from digital health care and could provide a path toward greater digital health equity. More systematic approaches to support patients with low digital health readiness could ensure that

assessments are actionable for clinicians, payors, and health systems. If we can work to increase the reach of health technology to keep up with the evolution of the consumer electronics market, more patients could be empowered to enter the digital health care age and benefit from these new tools.

Abstract

Background: The use of smart technology in the management of all forms of diabetes mellitus has grown significantly in the past 10 years. Technologies such as the smartwatch have been proposed as a method of assisting in the monitoring of blood glucose levels as well as other alert prompts such as medication adherence and daily physical activity targets. These important outcomes reach across all forms of diabetes and have the potential to increase compliance of self-monitoring with the aim of improving long-term outcomes such as hemoglobin A_{1c} (HbA_{1c}).

Objective: This systematic review aims to explore the literature for evidence of smartwatch technology in type 1, 2, and gestational diabetes.

Methods: A systematic review was undertaken by searching Ovid MEDLINE and CINAHL databases. A second search using all identified keywords and index terms was performed on Ovid MEDLINE (January 1966 to August 2023), Embase (January 1980 to August 2023), Cochrane Central Register of Controlled Trials (CENTRAL, the Cochrane Library, latest issue), CINAHL (from 1982), IEEE Xplore, ACM Digital Libraries, and Web of Science databases. Type 1, type 2, and gestational diabetes were eligible for inclusion. Quantitative studies such as prospective cohort or randomized clinical trials that explored the feasibility, usability, or effect of smartwatch technology in people with diabetes were eligible. Outcomes of interest were changes in blood glucose or HbA_{1c}, physical activity levels, medication adherence, and feasibility or usability scores.

Results: Of the 8558 titles and abstracts screened, 5 studies were included for qualitative synthesis in this review. A total of 322 participants with either type 1 or type 2 diabetes mellitus were included in the review. A total of 4 studies focused on the feasibility and usability of smartwatch technology in diabetes management. One study conducted a proof-of-concept randomized clinical trial including smartwatch technology for exercise time prescriptions for participants with type 2 diabetes mellitus. Adherence of participants to smartwatch technology varied between included studies, with one reporting input submissions of 58% and another reporting that participants logged 50% more entries than they were required to. One study reported significantly improved glycemic control with integrated smartwatch technology, with increased exercise prescriptions; however, this study was not powered and required a longer observational period.

Conclusions: This systematic review has highlighted the lack of robust randomized clinical trials that explore the efficacy of smartwatch technology in the management of patients with type 1, type 2, and gestational diabetes. Further research is required to establish the role of integrated smartwatch technology in important outcomes such as glycemic control, exercise participation, drug adherence, and diet monitoring in people with all forms of diabetes mellitus.

Introduction

Background

Mobile health (mHealth) solutions, which include mobile apps, have rapidly gained popularity as part of the overall management of chronic diseases and have further created opportunities and potential to enhance the ability for self-management in patients with diabetes mellitus (DM) and reduce long-term and irreversible health complications [1-3]. More recently, the introduction of smartwatch technology has opened up the opportunity for the increased use of these wearable devices for health and wellness [4], as well as for the management of chronic medical conditions, such as monitoring chronic obstructive pulmonary disease [5], and health outcomes, such as physical activity monitoring in the older adult population [6]. Smartwatch technology has also seen increasing adoption for use in common chronic conditions such as atrial fibrillation [7] and other cardiac arrhythmias. Most of the early smartwatch intervention research has focused on the accelerometer smartwatch data as a surrogate measure of exercise; however, as innovation in smartwatch technology evolves, more sources of data input become available [8].

Companies manufacturing smartwatches have focused on developing applications that address a broader range of general health and lifestyle interventions such as weight, diets, and exercise. Examples of popular applications include Sugar Sense, Grab Manager, and Diabetes Tracker; however, none have been evaluated for their effects on clinical endpoints. Traditionally, technological companies developing glucose monitoring devices have subsequently launched proprietary applications such as Freestyle Libre Link App and Dexcom Clarity for either personal computers or mobile devices. Henriksen et al [9] showed that research into the area of wrist-worn fitness wearable devices has been accelerating, and technology giants include companies such as Fitbit, Garmin, Misfit, Apple, and Polar, with possible applications in patient diagnostics and treatment. The lack of glucose monitoring technology in smartwatches has served as a real barrier to their broader usefulness in patients with diabetes. This has somewhat been addressed by mobile phones that can integrate data from stand-alone glucose monitoring devices, most recently continuous glucose monitoring (CGM), and other minimally invasive devices such as flash glucose monitoring (FGM). However, early attempts to develop technology such as the GlucoWatch G2 biographer, which was designed to detect trends and track patterns in glucose levels, had setbacks in commercial development [10].

The ability of smartwatch technology to display goals visually and offer motivational graphics upon completion of these goals should not be underestimated. These devices deliver behavioral influences that encourage patients to set specific daily, weekly, or monthly targets and achieve them. Wearable devices can also be wirelessly connected in real time to smartphones that record important outcome data, such as blood glucose levels, which are then automatically synchronized with a freely available and password-protected cloud network. This network is accessible live at any time and anywhere by the patient, family members, and clinicians, allowing potential multidisciplinary clinical decisions to be made in a much more integrated, informed, and prompt manner [11].

The aim of this systematic review is to explore the evidence for the effect and provision of smartwatch technology in patients with type 2 DM (T2DM). This review will also include studies exploring the use of this technology in type 1 DM (T1DM) and gestational DM (GDM).

Research Questions

The following were our research questions:

1. What role can wearable smartwatch-based technology play in the provision of care and improvement of behavioral and clinical outcomes for patients with T1DM, T2DM, or GDM?
2. What is the acceptability and usability of smartwatch-based technology in the care of patients with DM?

Methods

This review was registered with the PROSPERO (International Prospective Register of Systematic Reviews) database for systematic reviews (CRD42019136825).

Search Strategy

The following databases were searched: PubMed, Ovid MEDLINE, Ovid Embase, Cochrane Library, Scopus, Web of Science (Social Sciences Citation Index and Science Citation Index Expanded), IEEEXplore, and CINAHL in August 2023. The search strategy was developed using keywords from systematic reviews that focus on smartwatch technology, mHealth, or mobile app–based interventions in patients with either T1DM, T2DM, or GDM. The OVID search strategy has been provided in Multimedia Appendix 1.

No restrictions were placed on the dates of articles or type of articles during the initial search. Specific search terms were adopted to reflect the requirements of each database. Thesaurus or MeSH (Medical Subject Headings) terms and truncation appropriate to each database were used. Furthermore, ProQuest Dissertations and Theses Global (plus full-text 1997-present)

were searched for relevant dissertations. Theses and conference proceedings were searched via Scopus to capture any additional pertinent research in this emerging field. Reference lists of included studies, as well as the reference lists of related systematic reviews and meta-analyses, were searched to identify any relevant studies. If potential eligible articles were not in English, they were to be translated; however, this was not required.

Types of Studies to Be Included

To capture the full extent of the research literature, any relevant quantitative research addressing the use of smartwatch technology in the treatment of DM was considered. Eligible study designs included randomized controlled trials (including randomized crossover studies and cluster randomized trials), quasi-experimental studies (including interrupted time series studies), controlled before and after studies and observational studies (cohort, case-control, and observational studies (cohort, case-control, and cross-sectional studies). Partially published work (eg, conference abstracts) was eligible only if the full-text reports could be identified.

Participants/population

Participants of any age with a current or previous diagnosis of T1DM, T2DM, and GDM were included.

Intervention(s) and Exposure(s)

Studies using smartwatch technology as an intervention for patients with T1DM, T2DM, or GDM were included. Both wrist-worn and clip-on smartwatches were included; however, they must be "smart devices" (Bluetooth or Wi-Fi enabled to allow synchronizing with a mobile phone app or website) and must be commercially available.

Comparator(s)/control

Potential studies were not specifically excluded if they did not include a control group. Should studies include a comparator group, they may include alternative mHealth interventions, non–smartwatch app-based interventions, or standard-of-care or placebo interventions.

Exclusion Criteria

The rationale for including nonrandomized studies and extension to studies including T1DM and GDM, beyond T2DM, was pragmatic, as a limited number of randomized clinical trials (RCTs) evaluating the use of smartwatch technology in the management of DM were identified. Studies evaluating patients only with prediabetes were excluded.

Outcomes of Interest

Primary Outcomes

The primary outcomes were as follows:

1. Glycemic control: including measures of hemoglobin A_{1c} (HbA_{1c}), CGM parameters using subcutaneous CGM or interstitial FGM, or measures of diabetic complications (eg, fetal or maternal outcomes in GDM).
2. Lifestyle and medication: at least one measure of either objective or subjective record of physical activity, dietary records, or medication adherence.

Secondary Outcomes

The secondary outcomes were acceptance, usability, and acceptability of the smartwatch as an intervention in patients with T1DM, T2DM, or GDM. This included study retention rates, how often patients wore the smartwatch, and any comments/qualitative data on the patient's perception of the watch.

Data Extraction

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses; Checklist 1) guidelines were used in the identification of eligible studies. Of the studies retrieved from the initial search, titles and abstracts were screened by the authors (AF and DS) using Covidence software. Full texts of potential eligible studies were then screened by two independent authors (AF and DS) to identify eligible studies, with discrepancies resolved by a third reviewer (SDA) if required. The review assessed and discussed the effect of missing data and the degree of its effect on the overall synthesized results.

Data were extracted using a standardized form including the following parameters: publication details (authors, year, and country of study), participant characteristics (number of participants, baseline characteristics, inclusion and exclusion criteria, and type of diabetes), methods (study design, baseline measure, time points [when data were collected: at baseline and the end of the study], and study setting [location, year, and environment]), intervention duration and description including manufacturer/brand of smartwatch used, outcome measures used to identify the effects of the smartwatch intervention, smartwatch-related process evaluation outcomes (usability, acceptability, adherence, and interaction), measures of glycemic clinical outcomes and diabetic complications; and limitations of the study.

Risk of Bias Assessment

The Downs and Black (1998) methodological quality assessment checklist was used as different types of study were anticipated [12]. Two independent authors (DS and AF) assessed the risk of bias, with discrepancies in checklist items resolved by the team; if resolution was not achieved, an arbitrator (AC) was nominated. This was never required.

After analysis, study outcomes were reported using summarized descriptive analysis, focusing on the types of study participants, types of interventions, types of smartwatches, length of follow-up, clinical and behavioral outcomes, and smartwatch-related results.

The overall quality of evidence for an outcome was assessed using a Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) approach, which uses the summary of the risk of bias of the outcome across studies to assess the robustness of the evidence [13]. The GRADE approach uses assessments across 5 domains—study limitations, consistency of results, directness of the evidence, precision of the results, and publication/reporting bias—to categorize the levels of quality as high, moderate, low, and very low [13].

Ethical Considerations

This study did not include human subjects research (no human subjects experimentation or intervention was conducted) and so did not require institutional review board approval.

Results

Overview

A total of 11,470 articles were retrieved from the database searches, of which 2912 were immediately removed as duplicates. Overall, 8558 articles were screened by the two independent reviewers; ultimately 30 studies were considered as potentially eligible, and full-text articles were retrieved. In general, 12 studies were excluded, as they did not incorporate smartwatch technology [14-25]. In total, 5 studies were systematic or literature reviews [26-30]. The reference lists of these reviews were screened for potentially eligible papers, but none were identified. There were 4 studies that were excluded, as they were conference abstracts only and a full-text paper was not available for adequate data extraction [31-34]. Among these studies, 3 studies were the wrong study designs, meaning they did not investigate the use of smartwatches or digital technology [35-37]. Finally, 1 study was excluded, as the intervention was not eligible for inclusion [38]. Multimedia Appendix 2 provides a list of excluded studies and the reasons for their exclusion. A total of 5 studies met the inclusion and exclusion criteria listed and were included for analysis in this review [11,39-42]. Figure 1 depicts the full PRISMA flow diagram and Table 1 provides the table of characteristics of included studies.

To date, 5 studies [11,39-42] have evaluated the integration of smartwatch technology in patients with a diagnosis of DM. Each included study's results have been separately provided below due to the heterogeneous nature of methods and reporting.

Figure 1. Depicts a Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram that was generated in Covidence software during the screening phases of this systematic review.

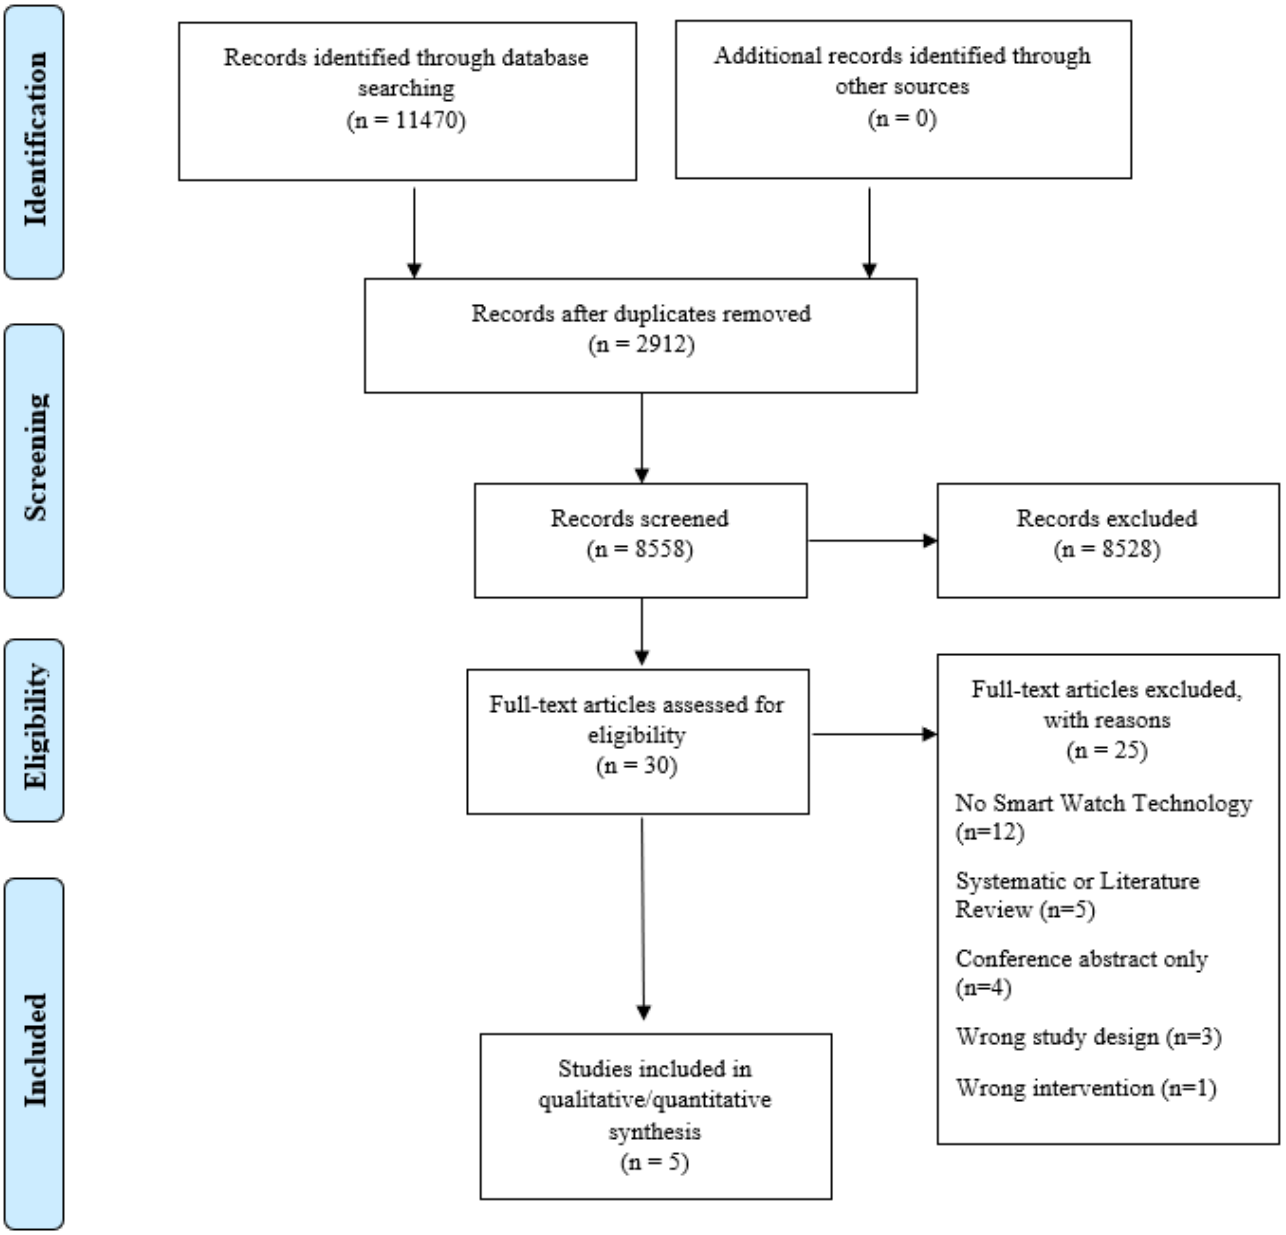

Table . Characteristics of included studies.

Study	Population/sample/context	Aim/objectives	Technologies	Study design	Outcome measures	Results	Limitations
Årsand et al [11]	4 Participants with type 1 diabetes mellitus. Motol University Hospital, Prague.	Feasibility study to test the usability and acceptability of smartwatch technology in patients with type 1 diabetes mellitus.	Pebbles smartwatch on android+ Diabetes Diary App	A novel 6-participant cohort study designed to give the research group feedback on smartwatch technology.	Outcome measures focused on participant feedback on the technology as well as usability of the smartwatch and Diabetes Diary App	Authors concluded that overall users reported positive usability. Participants provided good feedback such as the user interface and being able to input measurements quickly and accessing them. Participants did suggest areas of improvement such as battery usage not able to delete inputs if added accidentally.	Limited sample size with no control group as study was novel and exploratory only. Short observation period.
Kim et al [39]	29 adults with type 2 diabetes mellitus. Seoul National University Hospital, South Korea.	Test the feasibility of HbA_{1c}[a] reduction using a patient-centered, smartphone-based, diabetes care system.	(1) Android-based application with four modules: glucose; diet; physical activity; and social network system (2) Bluetooth glucometer (3) Bluetooth activity tracker	12-week feasibility pilot study. One-arm group.	HbA_{1c}, fasting plasma glucose, body weight, blood pressure, various cholesterol measures. Summary of diabetes self-care activities (SDSCA) was used to evaluate the overall self-management activities for diabetes	After 12 weeks, participants had significantly decreased HbA_{1c} and FPG[b]. Reduction in HbA_{1c} was correlated with the number of daily glucometer inputs. Inputs were generally higher in older patients. Body weight and cholesterol measures were not statistically significant after 12 weeks.	Pilot study. No control group. Short observation time. Small sample size.
Shaw et al [40]	60 adults with type 2 diabetes mellitus. South Eastern United States.	To determine feasibility and acceptability of using multiple mHealth technologies in patients with type 2 diabetes mellitus.	(1) Glucometer – “iHealth” (2) Fitbit (3) Self-report mobile SMS text messaging (4) Cellular enabled Scale by Body Trace	6-month cohort prospective study.	(1) Blood glucose (2) Physical activity – daily steps, distance travelled, and activity intensity (3) Medication adherence (4) Weight	mHealth interventions not used as to improve outcomes listed. Most used technology was the Fitbit. Participants who were younger, had higher HbA_{1c}, and identified as Black were less likely to be engaged with their mHealth devices.	Only observational study. Did not use control group for interventional impact. Small sample size.

Study	Population/sample/context	Aim/objectives	Technologies	Study design	Outcome measures	Results	Limitations
Zahedani et al [41]	665 participants: healthy (448); prediabetic (25); type 2 diabetics (192)	Investigate combined use of continuous glucose monitoring and mobile app (Sugar AI) on glucose tracing, heart rate, and physical activity.	(1) Abbott Freestyle Libre (2) MiBand 3 or Garmin watch (3) Sugar Artificial intelligence app	10-day observational study.	(1) Blood glucose, measured as TIR[c]: 54 - 140 mg/dL for healthy and prediabetes, and 54 - 180 mg/dL for type 2 diabetes mellitus	Authors concluded that a subgroup of those showing poor TIR (combined type 2 diabetes mellitus and prediabetic participants) demonstrated an average of 22.7% improvement in TIR. 62.9% of diabetic participants who showed improved TIR had greater improvement in their daily variation.	Only observation study. Not randomized clinical trial. Short follow-up. Limited results provided on use of Garmin watch or MiBand 3 to improve outcome measures such as blood glucose levels or heart rate, etc.
Chang et al [42]	35 adults with type 2 diabetes mellitus. New South Wales, Australia.	To test the feasibility of prescribing an individualized daily exercise time.	(1) Abbott Freestyle Libre 2 (2) Accelerometer smartwatch (ActiGraph Bluetooth Smart wGT3X-BT	Two-week observational period.	(1) Exercise adherence–feasibility. Proportion of participants completing more than 15 minutes of physical activity (moderate to high intensity) (2) Continuous glucose monitoring (3) Dietary intake	Authors found that participants increased their daily physical activity by an average of 10 minutes per day. However, authors did report adherence issues with a participants not conducting physical activity in the prescribed time.	Proof-of-concept randomized clinical trial. Small sample size. Short observational period.

[a]HbA_{1c}: hemoglobin A_{1c}.

[b]FPG: fasting plasma glucose.

[c]TIR: time in range.

Årsand et al 2015

The “Pebble” smartwatch was tested on 4 participants with T1DM ranging from ages 20 to 46 years. Usability scores for this study averaged 4.4/5, with 5 being the best score. The highest scoring question was that all values were clearly shown on the smartwatch (4.8/5) and the lowest was the ability to make a new registration with the “Pebble” app (4.3/5). Qualitative feedback for appreciated features included the ability to see the last values and user interface while nonappreciated feedback included battery usage, not being able to delete entries from the watch, and the possibility of entering wrong values. A total of 2 of the 4 participants preferred to use their phone to input data as they found it more convenient [11].

Kim et al 2016

An “LG LifeGram” activity tracker combined with a mobile-centered mobile app was tested on 29 participants with T2DM over 12 weeks. The intervention focused on delivering information on glucose control, diet, exercise, and finally a social support network for motivation. After 12 weeks, participants experienced a statistically significant reduction in HbA_{1c} (P=<.0001 with a decrease of 0.6%) and fasting plasma glucose (P=.0088 with a decrease of 20.8 mg/dL) levels. No changes were observed in body weight and cholesterol levels. Authors reported high input scores that correlated with the amount of change in HbA_{1c} levels (P=.0013) [39].

Shaw et al 2020

A total of 60 adults with T2DM were observed for 6 months while using the “Fitbit Alta” (Google Fitbit), which is a reliable and valid accelerometer used for tracking physical activity. This smartwatch was paired with the participant’s smartphone app. A total of 87.45% of daily physical activity submissions for the “Fitbit Alta” were completed by participants, which was the highest achieving outcome for input completions. Other outcomes such as glucose monitoring (60.99%), drug adherence (71.19%), and weight (53.83%) did not score as high as physical activity and, interestingly, were not tracked using smartwatch technology. Technical support was also monitored during this study in which authors reported that 35/60 (58%) participants

required assistance due to devices not syncing or logging-in problems [40].

Zahedani et al 2021

The "Sugar AI" app was used in conjunction with a "MiBand 3" or "Garmin" in 192 participants with T2DM. It is noted that this study also involved healthy individuals and participants with self-diagnosed "prediabetes." The primary outcome in this study was time in range that was defined as individuals with T2DM to be between 3 and 10 mmol/L. The authors reported that 58.3% (112/192) of participants with T2DM and a poor time in range showed an average improvement of 22.7%. Authors did not report adherence, feasibility, or adherence to the intervention [41].

Chang et Al 2023

In this double-blinded proof-of-concept study, 35 participants with physician-diagnosed T2DM were issued a Freestyle Libre 2 (Abbott) and an "ActiGraph Bluetooth Smart wGT3X-BT." These technologies were used and worn for a 14-day baseline period followed by a 14-day interventional period with the purpose of testing the feasibility of prescribing an exercise time to target peak hyperglycemia. The participants were further randomized into the "ExPeak" group, which aimed at conducting physical activity for 30 minutes before peak hyperglycemia, or the "NonPeak" group, which conducted physical activity for 90 minutes after peak hyperglycemia. Adherence to prescribed exercise times showed that only 29% (10/35) of participants adhered to their prescribed times. Overall, 66% (23/35) of participants completed their exercises but not during the times recommended to target peak hyperglycemia. the authors concluded that participation in moderate physical activity increased by 26% during the intervention period versus the baseline period but was not statistically significant between groups (P=.26). There was no statistically significant difference in the intensity of physical activity between groups (P=.77). Authors did not provide specific data on the usability of the smartwatch technology used in this study.

Data extraction revealed the heterogeneous nature of the studies included in this review. This extended to the risk of bias assessment, with results presented in Table 2. Only one study attempted to blind participants to their intervention and randomized this process with robust methods [42].

Table . Risk of bias of included studies.

Discussion

Principal Findings

This systematic review found that among the current literature, only 5 studies have explored the use of smartwatch technology in people with DM (T1DM, T2DM, and GDM). A total of 4 of the 5 included studies recruited participants with T2DM, while no studies included participants with GDM. This review also provides evidence of the paucity of robust RCTs that evaluate the effect of smartwatch technology in the management of patients diagnosed with DM. Recent research developments have evaluated transcutaneous noninvasive sampling technology such as noninvasive optical glucose monitoring, based on optical glucose monitoring, and noninvasive fluid sampling, based on fluid sample glucose estimation, but these are in their infancy [43]. These technologies aim to reduce the need for patients with diabetes to use the more traditional finger-prick method of measuring their blood glucose levels, which can be painful, more time-consuming, and reduce compliance [44]. It may be an additional impetus for technology development if smartwatches are able to harness these technologies to monitor patients' glucose effectively and noninvasively. T1DM is the area that is most suitable for the development of smartwatch technology for the management of diabetes. Patients with T1DM tend to be younger and thus often have more agile technological literacy and are often early adopters of technological developments. T1DM is also a condition prone to hypoglycemia and thus an important area for technologies that may reduce the risk of developing serious complications that may arise due to hypoglycemia unawareness, which may be where smartwatch technology can most appropriately intercept in patients that exhibit a lack of warning symptoms [45]. The same could also be said for patients with hyperglycemia and life-threatening diabetic ketoacidosis. The carers of patients with T1DM also value the ability to use technology for distant monitoring of children and adolescents with T1DM. Emerging evidence on smartwatch technology may be available soon, with Sehgal et al [46] recently publishing a protocol that will assess the safety and efficacy of the addition of smartwatch technology to usual CGM in adults with T1DM. The authors have stated the primary endpoint will be glucose time in range expressed as a percentage time interstitial glucose between 3.9 and 10 mmol/L. Other outcomes will include quality of life, distress, and sleep quality [46]. Finally, Corbett et al [47] published data on the use of smartwatch gesture–based meal reminders using a proprietary app that picks up "eating motions" by using the smartwatch and uses this to remind patients with T1DM to inject insulin if appropriate.

DM is a heterogenous condition and there is provision for future research in the use of smartwatch technology in all types of diabetes. There is an opportunity for this technology to combine with others like the FreeStyle Libre 2 to prompt regular blood glucose level monitoring, improve time in range and variability, and reduce the risk of serious complications such as

hypoglycemia. Moreover, as more evidence emerges on other subtypes of DM such as diabetes of the exocrine pancreas (type 3c), the provision for evidence-based technologies to monitor and improve outcomes increases [48]. Detailed usability and acceptability trials followed by robust long-term clinical trials should be conducted to test these emerging smart technologies prior to their introduction into the management of patients with diabetes.

Limitations of the Study

This review does not include quantitative analyses or meta-analyses due to a lack of homogenous RCTs. Most papers included were feasibility, usability, and/or acceptability studies and did not include a comparator group. The quality of the papers included was sound. Improvements in blinding of participants and team members to intervention groups need to be considered in future research as well as the sampling of patients selected for studies to promote generalizability of results. This is an area that is rapidly developing and even though an attempt has been made to encompass all contemporaneous literature available, there may be new evidence that will inform the topic. Technology is rapidly developing within the commercial and proprietary arena, making it unavailable for systematic review.

Conclusion

This systematic review highlights the current paucity of evidence supporting the use of smartwatch technology in the management of patients with all types of DM. As smartwatch usage increases with greater affordability and comfort with the technology grows, so does the potential for their significant role in the management of DM. This would especially be the case if wearable technology seamlessly interfaces with glucose monitoring devices or can serve to monitor glucose directly through innovative developments in noninvasive glucose monitoring. Smartwatches would allow patients the ability to check their glucose level frequently and discretely if they are linked to a CGM device. Nutrition and physical activity are cornerstones of diabetes management. Mobile technologies, such as smartphones and wearables, have the potential to educate, motivate, and prompt individuals to optimize lifestyle interventions and thereby favorably affect health.

Authors' Contributions

SDA, AF, and AC conceptualized the research question and methodology. AF and D Sculley screened the titles and abstracts. AF and D Santos assessed the risk of bias. All authors were responsible for drafting the manuscript and ultimately approving the final paper for publication submission.

Conflicts of Interest

None declared.

Abstract

Background: Mobile health (mHealth) interventions have immense potential to support disease self-management for people with complex medical conditions following treatment regimens that involve taking medicine and other self-management activities. However, there is no consensus on what discrete behavior change techniques (BCTs) should be used in an effective adherence and self-management–promoting mHealth solution for any chronic illness. Reviewing the extant literature to identify effective, cross-cutting BCTs in mHealth interventions for adherence and self-management promotion could help accelerate the development, evaluation, and dissemination of behavior change interventions with potential generalizability across complex medical conditions.

Objective: This study aimed to identify cross-cutting, mHealth-based BCTs to incorporate into effective mHealth adherence and self-management interventions for people with complex medical conditions, by systematically reviewing the literature across chronic medical conditions with similar adherence and self-management demands.

Methods: A registered systematic review was conducted to identify published evaluations of mHealth adherence and self-management interventions for chronic medical conditions with complex adherence and self-management demands. The methodological characteristics and BCTs in each study were extracted using a standard data collection form.

Results: A total of 122 studies were reviewed; the majority involved people with type 2 diabetes (28/122, 23%), asthma (27/122, 22%), and type 1 diabetes (19/122, 16%). mHealth interventions rated as having a positive outcome on adherence and self-management used more BCTs (mean 4.95, SD 2.56) than interventions with no impact on outcomes (mean 3.57, SD 1.95) or those that used >1 outcome measure or analytic approach (mean 3.90, SD 1.93; *P*=.02). The following BCTs were associated with positive outcomes: self-monitoring outcomes of behavior (39/59, 66%), feedback on outcomes of behavior (34/59, 58%), self-monitoring of behavior (34/59, 58%), feedback on behavior (29/59, 49%), credible source (24/59, 41%), and goal setting (behavior; 14/59, 24%). In adult-only samples, prompts and cues were associated with positive outcomes (34/45, 76%). In adolescent and young adult samples, information about health consequences (1/4, 25%), problem-solving (1/4, 25%), and material reward (behavior; 2/4, 50%) were associated with positive outcomes. In interventions explicitly targeting medicine taking, prompts and cues (25/33, 76%) and credible source (13/33, 39%) were associated with positive outcomes. In interventions focused on self-management and other adherence targets, instruction on how to perform the behavior (8/26, 31%), goal setting (behavior; 8/26, 31%), and action planning (5/26, 19%) were associated with positive outcomes.

Conclusions: To support adherence and self-management in people with complex medical conditions, mHealth tools should purposefully incorporate effective and developmentally appropriate BCTs. A cross-cutting approach to BCT selection could accelerate the development of much-needed mHealth interventions for target populations, although mHealth intervention developers should continue to consider the unique needs of the target population when designing these tools.

Introduction

Ever-advancing mobile health (mHealth) technologies hold immense potential to deliver behavior change techniques (BCTs) to diverse audiences, including people with complex medical conditions that involve treatment adherence and other self-management activities. mHealth refers to "medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants, and other wireless devices" [1]. Common examples include sending smartphone notifications as medication reminders or recording in an app when treatments are completed. Prior mHealth reviews have broadly summarized mHealth interventions as "reminders, education, or behavioral" [2], which included a wide range of study outcomes beyond adherence or self-management [3] or limited the outcome to medication taking [4,5]. Therefore, existing reviews have a limited impact on exactly how mHealth can most effectively support adherence and disease self-management or can be adapted and tailored for chronic illnesses with complex regimens beyond simply taking medicine.

The BCT Taxonomy [6] was created to define discrete, cross-cutting techniques (or approaches) to changing behavior to facilitate the design and evaluation of behavior change interventions, as well as the comparison of BCTs across interventions to identify which BCTs are the most efficacious. The BCT Taxonomy is disease agnostic such that BCTs found to effectively improve treatment adherence and self-management in one complex medical condition should, in theory, generalize to other complex medical conditions with similar adherence and self-management demands. Reviewing mHealth interventions of diseases with complex adherence and self-management demands using BCT Taxonomy could accelerate the design of mHealth solutions by identifying "essential elements" of effective mHealth interventions. Unfortunately, there is no consensus on what essential features should be included in an adherence or self-management mHealth solution for any chronic medical condition.

Our group's interest in cross-cutting BCTs for adherence and self-management stems from our work with the cystic fibrosis (CF) community. CF is a rare, multisystemic medical condition affecting an estimated 162,428 people worldwide [7]. CF self-management is complex and typically involves a combination of daily oral medications, inhaled treatment, high calorie diet, chest physiotherapy, airway clearance, and exercise [8]. Not surprisingly, people with CF have demonstrated high rates of nonadherence across various aspects of the multicomponent treatment regimen, including low medication adherence (48%-68%) [9,10], nonadherence to caloric goals (24%-40%) [11], and low adherence to airway clearance therapy (28%) [12]. Effective behavioral interventions are needed to promote CF self-management and, in turn, support health outcomes and quality of life. However, rare diseases with complex regimens are rarely the target population for technology developers, and for almost a decade, people with CF have expressed interest in an app but noted that existing apps do not provide the necessary functionality to address their CF management needs [13-15]. A recent search of the Google Play Store (Android) and Apple App Store (iOS) for health-related apps found that only 29 (1.3%) out of 2272 apps address a rare disease population [16], including CF, with none having empirical evidence of their efficacy.

Recognizing that there is a dearth of empirical research on mHealth solutions for treatment adherence and self-management of CF and other rare diseases, we aimed to learn from the BCTs used in effective mHealth interventions for other chronic medical conditions with complex treatment adherence and self-management demands. We, therefore, purposefully designed our systematic review to include people with complex diseases and regimens with overlapping characteristics to CF. Our research questions were (1) Which BCTs have been used in mHealth interventions? and (2) Which BCTs have a positive impact on adherence and self-management behaviors? Differences in BCTs in adult-only studies compared to adolescent and young adult studies were examined, as well as interventions explicitly targeting medicine taking compared to studies targeting broader self-management and other areas of treatment adherence. A systematic review was used because heterogeneity in measuring adherence and self-management outcomes across studies precludes a meta-analysis [17-19] (in contrast to a systematic review, a meta-analysis involves statistically summarizing results across reviewed studies using effect sizes [20]). Our overarching goal was to identify the essential, cross-cutting BCTs delivered via mHealth to effectively facilitate long-term adherence and self-management for people with complex medical regimens, thereby accelerating intervention development, evaluation, and dissemination.

Methods

Overview

Standardized search strategies, eligibility evaluations, and data extraction procedures were used (detailed below and in Multimedia Appendix 1). This review was registered with the International Prospective Register of Systematic Reviews (PROSPERO CRD42021224407), in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines (Checklist 1).

Ethical Considerations

As this was a systematic review, institutional review board approval was not required.

Search Strategy

A literature search in the PubMed, Scopus, Embase, CENTRAL, Web of Science, and PsycINFO databases identified potentially relevant articles published from 2015 through 2020, to enhance relevance to current technology. Given our group's focus on CF, 2 categories of search terms were used: "CF-specific" and "other chronic conditions," which included conditions identified by the study authors as having similar adherence and self-management characteristics to CF (eg, conditions with complex daily medical regimens and diseases often diagnosed in childhood, thus involving caregivers in self-management tasks).

Eligibility Criteria

Peer-reviewed, English language articles published between 2015 and 2020 reporting original empirical findings of mHealth interventions for selected medical conditions and targeting adherence and self-management were included. The mHealth interventions must be accessed on a mobile device (smartphones, cell phones, or tablets, including internet browser programs) and used by a person managing a medical condition or their caregiver.

Post Hoc Exclusions

After executing the search strategy, 3 post hoc exclusion criteria were added. People with chronic obstructive pulmonary disease or engaging in pulmonary rehabilitation were excluded, as it was decided that the former population was too different from people with CF and the latter included medical conditions. Reminder-only text messaging and exclusively synchronous telephone or web videoconferencing interventions were excluded, as our interest was in automated BCTs beyond simple reminders and interventions requiring real-time human interaction. Investigations conducted in low- to middle-income countries were excluded due to potential technology access limitations (unreliable internet or cellular service) that would likely affect the types of interventions tested.

Selection Process

Study records were compiled in a database; duplicates were removed based on DOI number or title. Reviewers (CKE, E McWilliams, DY, TS, and Brandi Blackshear) evaluated each study record (title and citation; blinded double review) for eligibility criteria. The reviewers screened studies for final inclusion and data abstraction using a REDCap (Research Electronic Data Capture; Vanderbilt University) [21,22] form developed for this study.

Data Collection

Overview

A reviewer independently abstracted the study data. A second reviewer read the article, reviewed the initial data abstraction, and identified items of disagreement. Discrepancies were discussed and resolved with all team members. Study characteristics were abstracted for each study in the final review (publication year, study location, study design, sample size, medical condition, age group, and theoretically derived intervention). Missing study details were noted.

Key Definitions

The adherence and self-management measurement method was abstracted. Reviewers categorized adherence and self-management measurement as (1) objective behavior (eg, electronic medication monitoring), (2) subjective behavior (eg, patient-reported medication adherence), (3) psychosocial outcome (eg, disease knowledge and adherence self-efficacy), (4) objective health outcome (eg, hemoglobin A_{1c} and viral load), or (5) subjective health outcome (eg, patient-reported asthma control level). Health outcomes were included if the authors conceptualized them as adherence and self-management indicators.

mHealth tools (eg, app and text messaging) and targets of intervention (eg, taking a specific medicine, airway clearance therapy, diabetes self-management activities, dietary recommendations, exercise and physical activity, managing disease activity and symptoms, etc) were abstracted. mHealth intervention results were categorized based on authors' conclusion of the results as follows:

- Positive: intervention was associated with improved adherence and self-management.
- Negative: intervention was associated with worse adherence and self-management.
- No impact: intervention had no effect on adherence and self-management.
- Mixed: intervention had different effects (positive effect, negative effect, or no impact) on adherence and self-management due to multiple outcome measures and analytic approaches.

The abstracter used information in the manuscript and the BCT Taxonomy to assign discrete BCTs to each intervention component.

Risk of Bias

The Revised Cochrane Risk-of-Bias tool (RoB 2) [23] for randomized controlled trials (RCTs) and the Risk of Bias in Non-randomized Studies-of Interventions (ROBINS-I) [24] tool for nonrandomized studies (excluding qualitative studies) were used to assess risk of bias, certainty, and quality of evidence among the studies reviewed. Blinded double assessments were conducted by 2 independent reviewers (RG, IK, E McWilliams, DY, and AD). The RoB-2 assessed risk of bias due to the randomization process, deviations from intended interventions, missing outcome data, measurement of outcome, and selection of the reported result. The ROBINS-I assessed risk of bias due to confounding, deviations from intended interventions, missing data, bias in measurement of outcomes, and bias in selection of the reported result. Discrepancies in ratings were identified and resolved. If multiple outcomes were assessed, an average risk score was calculated to derive a single rating.

Synthesis

Statistical analyses were conducted in Stata 15 software (StataCorp LLC). Abstracted data were summarized using

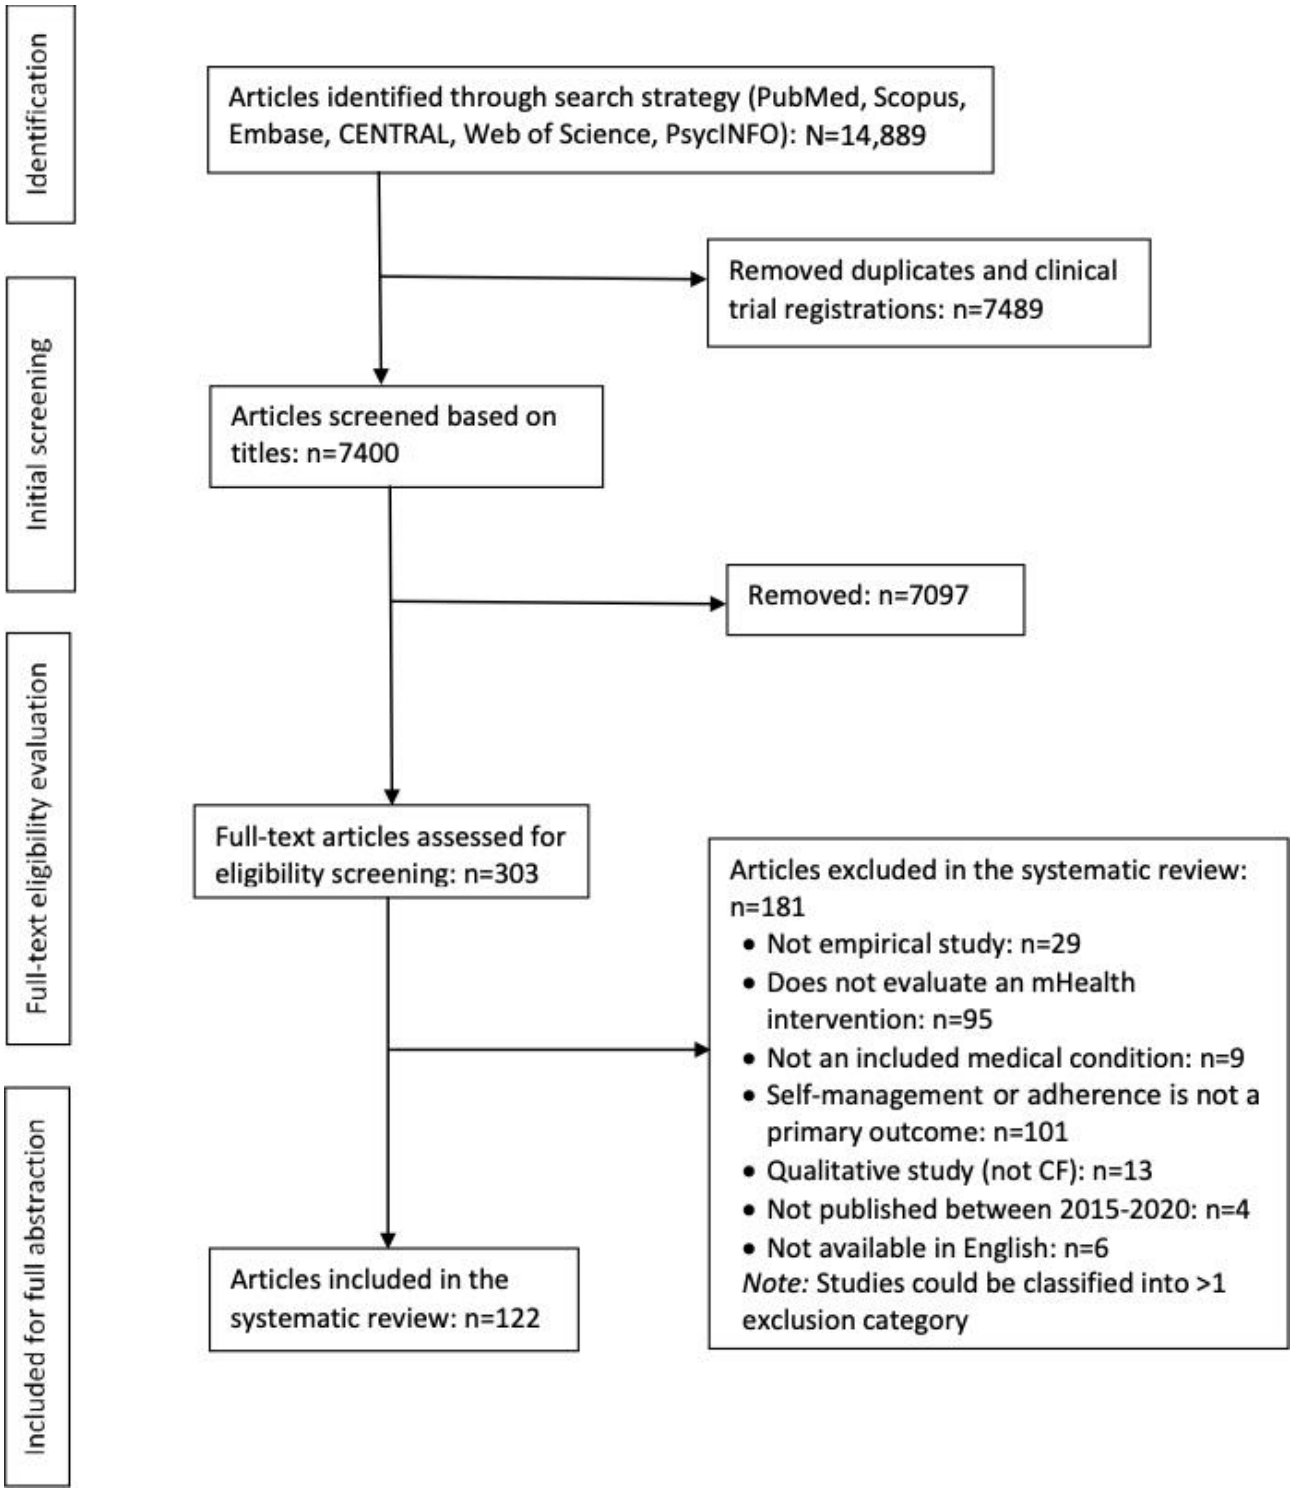
frequencies and percentages. Subgroup analyses examined differences in study characteristics, including BCTs used, age group (adult only [≥18 years and older] vs adolescent and young adult [11-25 years or sample characterized by authors as "adolescents and young adults"]), study design (RCT vs non-RCT), and whether the intervention was theoretically derived. We also conducted an exploratory subgroup analysis to examine which BCTs appeared the most often in interventions explicitly focusing on medicine taking compared to interventions focusing on self-management and other adherence targets. The results highlight BCTs (1) appearing in ≥5% of studies and (2) with a difference of >10% between positive effects versus no impact on adherence and self-management outcomes. This does not mean that rarely used BCTs are ineffective or that 10% is a verified benchmark of clinically meaningful difference. This pragmatic decision supported the interpretation of a large number of BCTs and comparisons. Statistically significant (P<.05) differences in the number of BCTs based on the direction of results were tested using 1-way ANOVA. No effect measures, missing summary statistics or data conversions, or meta-regression were used for this systematic review.

Results

Screening Process

Figure 1 presents this review's PRISMA diagram. The initial search returned 14,889 articles. After removing duplicates and clinical trial registrations, 7400 titles were screened for initial eligibility, 303 articles were potentially eligible, and 122 manuscripts met the criteria for data extraction (see Table S1 in Multimedia Appendix 1 for all included studies and characteristics).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) diagram. CF: cystic fibrosis; mHealth: mobile health.



Study Characteristics

The most represented medical conditions were type 1 or 2 diabetes and asthma (Table 1). Only 6 (4.9%) out of 122 studies involved people with CF. Most studies were published in 2020 (32/122, 26.2%), were conducted outside of the United States (64/122, 52.5%), and used an RCT design (75/122, 61.5%). Nonrandomized study designs were primarily observational pre-post (23/122, 18.9%), observational without pre-post measurement (6/122, 4.9%), or mixed methods (6/122, 4.9%) studies. Study sample sizes ranged from 10 to 14,085 (median 92, IQR 44-179) participants. Most studies involved adult-only (81/122, 66.4%) or adolescent and young adult–only samples (22/122, 18%), followed by child, adolescent, young adult (11/122, 9%); child, adolescent, young adult, and adult (6/122, 4.9%); and child-only (2/122, 1.6%) samples.

Table . Study characteristics in all studies included for final abstraction (overall) and by direction of primary study results[a].

Study characteristic		Overall (N=122), n (%)	Positive (n=59), n (%)	No impact (n=23), n (%)	Mixed (n=40), n (%)
Study design					
	Randomized controlled trial	75 (61)	26 (44)	21 (91)	28 (70)
	Nonrandomized study	47 (39)	33 (56)	2 (9)	12 (30)
Use of theory in intervention design					
	Yes, theory guided intervention design	22 (18)	12 (20)	5 (22)	5 (13)

	Rheumatoid arthritis	1 (1)	1 (2)	0 (0)	0 (0)

[a]Medical conditions are listed from most frequently to least frequently observed in the overall study sample.

Adherence and self-management outcomes were typically evaluated with objective health outcomes or subjective behavior measures (61/122, 50% for each; Table S2 in Multimedia Appendix 1). mHealth interventions were delivered via app (75/122, 61.5%), SMS text messaging (34/122, 27.9%), or website (30/122, 24.6%). Nearly all studies presented mHealth tools used by patients (118/122, 96.7%), but many included health care providers (48/122, 39.3%) or caregivers (21/122, 17.2%). Only 22 (18%) interventions were clearly informed by scientific theory. mHealth interventions most often targeted taking medication (68/122, 55.7%), diabetes self-management activities (46/122, 37.7%), dietary recommendations (32/122, 26.2%), exercise and physical activity (27/122, 22.1%), asthma self-management activities (13/122, 10.7%), managing disease activity and symptoms (11/122, 9%), and general "self-care" behaviors (5/122, 4.1%). One (0.8%) study targeted airway clearance therapy.

Study results were characterized as having a positive effect on the outcome or outcomes (59/122, 48.4%), followed by mixed results (40/122, 32.8%) or no impact (23/122, 18.9%). No studies were characterized as having negative effects (Table 1). Comparing studies reporting positive effects to no impact, 34% (20/59) of the positive studies used objective behavior adherence measures compared to 13% (3/23) of no-impact studies (Table S2 in Multimedia Appendix 1).

BCTs Used

Across all reviewed studies, 32 different BCTs were used (mean 4.30, SD 2.32). Table S3 in Multimedia Appendix 1 provides

the frequencies, definitions, and examples of BCTs appearing in ≥5% of reviewed studies.

BCTs by Intervention Effect on Outcomes

Overview

Interventions with positive effects contained significantly more BCTs (mean 4.95, SD 2.56) than interventions with mixed effects (mean 3.90, SD 1.93) or no impact (mean 3.57, SD 1.95; *P*=.02). BCTs used in >10% of studies with positive results versus no impact (Multimedia Appendix 2) were self-monitoring of behavior, self-monitoring of outcomes of behavior, feedback on outcomes of behavior, feedback on behavior, credible source, and goal setting (behavior).

Subgroup Analysis: Age

Table S3 in Multimedia Appendix 1 includes the 15 most common BCTs used in adult-only and adolescent and young adult–only studies. Among adult-only studies (n=81), interventions with positive effects contained significantly more BCTs (mean 5.02, SD 2.13) than studies with mixed effects (mean 4.28, SD 2.27) or no impact (mean 3.28, SD 1.96; *P*=.02). BCTs used in >10% of studies with positive results compared to no impact included prompts and cues, self-monitoring of outcomes of behavior, feedback on outcomes of behavior, self-monitoring of behavior, feedback on behavior, credible source, and goal setting (behavior; Multimedia Appendix 3).

In adolescent and young adult–only studies (n=22), interventions with positive effects contained significantly more BCTs (mean 7.75, SD 5.91) than studies with mixed effects (mean 3.50, SD 1.67) or no impact (mean 5.00, SD 1.41; *P*=.04). BCTs used in >10% of studies with positive results compared to no impact included self-monitoring of behavior, feedback on behavior, goal setting (behavior), information about health consequences, problem-solving, and material reward (behavior; Multimedia Appendix 4).

Subgroup Analysis: Study Design and Theory

Non-RCT studies tended to report positive results (33/59, 56%), whereas RCT designs more commonly reported no impact (21/23, 91%) or mixed results (28/40, 70%). Theory rarely guided intervention design; a small proportion (12/59, 20%) of theory-informed interventions were shown to have a positive effect (Table 1).

Subgroup Analysis: Intervention Target

Table S4 in Multimedia Appendix 1 includes the 16 most common BCTs used in studies targeting medicine taking versus self-management and other adherence targets (appeared in >5% of studies). A total of 62% (42/68) of studies targeting medicine taking included people with diabetes (21/68, 31%) or asthma (21/68, 31%). A total of 80% (43/54) of studies targeting self-management and other adherence targets included people with diabetes (37/54, 69%) or asthma (6/54, 11%). There were no significant differences in the number of BCTs used in interventions targeting medicine taking (mean 4.07, SD 1.94) compared to interventions targeting self-management and other adherence targets (mean 4.69, SD 2.70; *P*=.16).

Within interventions explicitly targeting medicine taking (n=68), BCTs used in >10% of studies with positive results compared to no impact included prompts and cues, self-monitoring outcomes of behavior, self-monitoring of behavior, feedback on behavior, feedback on outcomes of behavior, and credible source (Multimedia Appendix 5). There were no significant differences in the number of BCTs used based on the direction of results (*P*=.06).

Within interventions focused on self-management and other adherence targets (n=54), BCTs used in >10% of studies with positive results compared to no impact included self-monitoring outcomes of behavior, feedback on outcomes of behavior, self-monitoring of behavior, feedback on behavior, instruction on how to perform the behavior, goal setting (behavior), and action planning (Multimedia Appendix 6). There were no significant differences in the number of BCTs used based on the direction of results (*P*=.21).

Risk of Bias

Table S1 in Multimedia Appendix 1 reports each study's risk of bias rating. No study was excluded due to bias rating. For RCTs, 57% (43/75) received an overall risk of bias rating of "Some concerns," 39% (29/75) had "High" concerns, and only 4% (3/75) had "Low" concerns. "High" concern ratings were generally due to deviations from the intended interventions (18/29, 62%), the randomization process (11/29, 38%), or missing outcome data (11/29, 38%). For nonrandomized studies, 82% (36/44) received an overall risk of bias rating of "Serious" concerns, 9% (4/44) had "Critical" concerns, and 2% (1/44) had "Moderate" concerns. No nonrandomized study had "Low" risk of bias. "Serious" or "Critical" ratings were generally due to confounding (38/40, 95%) or deviations from intended interventions (13/40, 33%).

Discussion

Principal Findings

Our literature review of mHealth adherence and self-management interventions returned 122 studies, from which we identified discrete behavioral strategies using the BCT Taxonomy [6] with promise to promote adherence and self-management for people living with medical conditions requiring complex, daily self-management activities. The BCT Taxonomy provides, to date, the most rigorously tested, standardized method to identify cross-cutting BCTs with potential applicability across chronic medical conditions with overlapping adherence and self-management demands. The BCT Taxonomy also helps compare mHealth interventions and provides a shared language about BCTs for clinicians, researchers, mHealth innovators, and other key stakeholders such as patients and caregivers. As technological advances can quickly outdate mHealth, focusing on BCT principles, rather than the technology to deliver them, enhances the research's relevance and potential generalizability to a range of complex medical conditions, including rare diseases (an area of focus for our group), which often have significant need for such tools in contrast to the finite resources available to conduct large-scale, multistep mHealth design and evaluation studies.

Consistent with prior research [25,26], using more BCTs was associated with improved adherence and self-management. However, 6 BCTs appear particularly promising: self-monitoring of behavior, self-monitoring of outcomes of behavior, feedback on behavior, feedback on outcomes of behavior, credible source, and goal setting. *Self-monitoring of behavior* and *outcomes of behavior* involve tracking health behavior engagement (eg, logging in an app when medicine is taken) or outcomes of behavior (eg, using a Bluetooth-enabled glucometer to monitor blood glucose levels), whereas *feedback on behavior* and *outcomes of behavior* involve providing users with a summarized interpretation of the tracked data (eg, providing in-app graphical representations of one's daily step count over the past month). Consistent with our results, a prior meta-analysis showed that monitoring medication adherence and providing feedback improve medication adherence [27]. These strategies may build awareness for when the mHealth user engages in a health behavior, provide opportunity to reflect on successes and challenges, and ultimately help the user make informed behavior changes. *Credible source* involves providing expert-generated information about managing the user's medical condition (eg, the app contains information about etiology, symptoms, and treatment), which presents users with knowledge to understand the condition and its management. *Goal setting (behavior*) involves setting measurable and attainable goals for a target health behavior (eg, set a goal for number of days to exercise in a month), which can help the mHealth user focus on key health behavior and build self-efficacy as goals are met.

Developmental differences emerged between adult samples and adolescents and young adult samples. In adult-only studies, *prompts and cues* (reminders) were associated with positive outcomes, consistent with reviews showing that reminders are associated with a 2- to 3-fold increase in adherence [28,29], but they were less effective in adolescent and young adult studies. Indeed, a pre-post study of children and adolescents with CF found that adherence did not change after delivering reminders only (therefore excluded from this review) for 6 months [30]. Adolescents and young adults may benefit from improving knowledge (*information about health consequences*), improving skills (*problem-solving*), and building motivation (*material reward* [*behavior*]). Given the small number of adolescent and young adult studies, these results and interpretations should be seen as hypothesis generating.

Differences emerged between interventions explicitly targeting medicine taking versus those focused on disease self-management and other adherence targets. In interventions targeting medicine taking, *prompts and cues* and *credible source* were associated with positive outcomes. Reminders and expert information may be the most effective when focused on discrete, clearly defined behaviors rather than complex, multicomponent self-management activities. In interventions focused on self-management and other adherence targets, *instruction on how to perform the behavior, goal setting (behavior)*, and *action planning* were associated with positive outcomes. Over three-quarters (43/54, 80%) of studies focused on self-management and other adherence targets involved people with diabetes or asthma, which are relatively common yet complex medical conditions involving self-management behaviors that extend beyond simply taking medicine. Skills training, behavioral goals, and assistance with creating a detailed plan for managing a complex medical condition may be the most effective for multicomponent self-management activities that may involve monitoring and intervening upon changes in disease activity (eg, managing fluctuations in blood glucose levels for people with diabetes or managing asthma exacerbations) and self-managing lifestyle and environmental considerations (eg, diet in diabetes and environmental triggers in asthma). Careful consideration of the intervention target will likely help to further guide appropriate BCT selection from the BCTs found to be associated with improved adherence and self-management in our review.

This review has limitations. A meta-analysis was not conducted due to heterogeneous outcomes [17-19], thus we could not conclude which BCTs were statistically the most effective. Our risk-of-bias assessment highlighted methodological concerns across the studies reviewed. No-impact studies were more likely to be RCTs, and positive studies were more likely to be nonrandomized, raising concerns about publication bias toward positive results irrespective of study quality. We excluded reminder-only interventions; thus, most studies incorporated more than 1 BCT. Our reported average number of BCTs is likely higher than that of all adherence-promoting mHealth interventions. Although we identified some BCTs that may be effective, others may be as or more effective in supporting disease self-management but were rarely used in the reviewed studies. Moreover, no BCT was found to do harm. Thus, mHealth innovators should continue to integrate and evaluate how a wide variety of technology-delivered BCTs may support people living with chronic diseases, including rare diseases such as CF. An inherent limitation of conducting literature reviews is that a cutoff date must be selected, yet scientific literature is constantly being published; there may be utility in conducting an updated systematic review of this topic in the future. We only included studies that were published in peer-reviewed journals to focus on interventions with clear evidence of scientific evaluation; however, expanding our review to "gray literature" may have provided more insight into the most current interventions and reduced publication bias. Our review characterized mHealth BCTs generally. Other metrics including digital literacy and socioeconomic barriers to mHealth were not evaluated. Future researchers should evaluate these factors to support sustained mHealth use among diverse audiences. Additionally, BCTs were analyzed across the included chronic medical conditions given the disproportionate number of studies in diabetes and asthma compared to other medical conditions. Although the BCTs are disease agnostic, intervention developers and researchers should carefully consider the applicability of the BCT to the target patient population.

Future Directions

Our review identified discrete BCTs that may have broad cross-cutting applicability across chronic diseases with complex medical regimens, including people with CF, the community with which our group primarily works with. We consider our systematic review approach to be a model for gathering key findings from the extant scientific literature to inform the development of multicomponent behavioral mHealth

interventions tailored for a patient population that may be smaller and with less existing research, yet has significant self-management needs warranting further research, such as CF [9,10,31,32]. Research involving people with chronic medical conditions following complex treatment regimens should prioritize the design and evaluation of mHealth interventions incorporating cross-cutting, evidence-based, and age-appropriate BCTs to promote adherence and self-management. Such an approach could help accelerate mHealth intervention design and evaluation to create effective products that may be efficiently disseminated to communities with significant need for such tools.

Accelerating mHealth design and evaluation by taking a cross-cutting approach to BCT selection would also help answer remaining "unknowns" about mHealth BCTs and strengthen mHealth intervention quality. For example, although interventions including more BCTs appear to have greater benefit, the optimal number, type, and combination of BCTs to include in mHealth interventions have not been determined. For BCTs demonstrating potential to promote adherence or self-management, the ideal delivery method must be determined (eg, should the BCT *self-monitoring of behavior* be delivered via manual data entry of treatment completion or using an electronic monitoring device to automatically track data?). An overrepresentation of certain BCTs (eg, *prompts and cues* and *self-monitoring of outcomes of behavior*) and underuse of other, potentially more effective techniques (eg, *feedback on behavior* and *goal setting* [*behavior*]) highlight mHealth's focus on simpler technologies at the expense of innovation and efficacy. Collaborations between behavioral scientists, care teams, patients, caregivers, and industry could answer these questions and produce mHealth solutions that are transformative and effective.

When incorporating BCTs that are expected to effectively and appropriately generalize to a range of complex medical conditions and associated regimens, mHealth intervention developers must still consider the unique needs of the target population. In CF, for example, highly effect CF transmembrane conductance regulator modulator therapies have the potential to simplify the regimen and reduce treatment burden [33,34]. The implementation of key BCTs may need to be adapted as new therapies roll out, although the core theory behind the BCT itself is not expected to change. It is critical to build the scientific evidence base for effective adherence and self-management mHealth interventions that maintain pace with rapidly advancing medical management across complex medical conditions.

Abstract

Background: In the past few years, a burgeoning interest has emerged in applying gamification to promote desired health behaviors. However, little is known about the effectiveness of such applications in the HIV prevention and care continuum among men who have sex with men (MSM).

Objective: This study aims to summarize and evaluate research on the effectiveness of gamification on the HIV prevention and care continuum, including HIV-testing promotion; condomless anal sex (CAS) reduction; and uptake of and adherence to pre-exposure prophylaxis (PrEP), postexposure prophylaxis (PEP), and antiretroviral therapy (ART).

Methods: We comprehensively searched PubMed, Embase, the Cochrane Library, Web of Science, Scopus, and the *Journal of Medical Internet Research* and its sister journals for studies published in English and Chinese from inception to January 2024. Eligible studies were included when they used gamified interventions with an active or inactive control group and assessed at least one of the following outcomes: HIV testing; CAS; and uptake of and adherence to PrEP, PEP, and ART. During the meta-analysis, a random-effects model was applied. Two reviewers independently assessed the quality and risk of bias of each included study.

Results: The systematic review identified 26 studies, including 10 randomized controlled trials (RCTs). The results indicated that gamified digital interventions had been applied to various HIV outcomes, such as HIV testing, CAS, PrEP uptake and adherence, PEP uptake, and ART adherence. Most of the studies were conducted in the United States (n=19, 73%). The most frequently used game component was gaining points, followed by challenges. The meta-analysis showed gamification interventions could reduce the number of CAS acts at the 3-month follow-up (n=2 RCTs; incidence rate ratio 0.62, 95% CI 0.44-0.88). The meta-analysis also suggested an effective but nonstatistically significant effect of PrEP adherence at the 3-month follow-up (n=3 RCTs; risk ratio 1.16, 95% CI 0.96-1.38) and 6-month follow-up (n=4 RCTs; risk ratio 1.28, 95% CI 0.89-1.84). Only 1 pilot RCT was designed to evaluate the effectiveness of a gamified app in promoting HIV testing and PrEP uptake. No RCT was conducted to evaluate the effect of the gamified digital intervention on PEP uptake and adherence, and ART initiation among MSM.

Conclusions: Our findings suggest the short-term effect of gamified digital interventions on lowering the number of CAS acts in MSM. Further well-powered studies are still needed to evaluate the effect of the gamified digital intervention on HIV testing, PrEP uptake, PEP initiation and adherence, and ART initiation in MSM.

Introduction

Background

The HIV epidemic among men who have sex with men (MSM) has become a global concern [1]. Current evidence suggests that MSM accounted for two-thirds of all new HIV infections in the United States in 2019 [2], and systematic reviews showed that the HIV prevalence in MSM in China increased from 1.4% in 2001 to 8% in 2015 [3,4]. Given the burden of HIV, substantial efforts have been made to address the unmet needs of MSM. For instance, there is overwhelming scientific evidence of the efficacy and safety of pre-exposure prophylaxis (PrEP) and postexposure prophylaxis (PEP) to prevent HIV infection in MSM. However, studies indicate that uptake of PrEP and PEP has been suboptimal in these risk groups, especially among racial or ethnic minorities [5]. In a recent systematic review and meta-analysis, the PEP uptake was only between 4% and 6% in MSM; major obstacles included insufficient knowledge, underestimated risk of exposure to HIV, and social stigma [6]. Interventions that improve effective HIV prevention adoption among MSM are urgently needed to maximize HIV prevention benefits.

Nearly universal mobile phone ownership provides MSM an opportunity to move away from traditional ways of meeting partners to seeking sexual partners through geo–social networking applications [7]. The widespread use of smartphones also creates a unique opportunity to design innovative internet-based digital interventions for diverse MSM in a scalable manner. Internet-based digital interventions, defined as using internet-based information and communication technology (eg, mobile apps, websites, and social media) to support health [8], benefit from being implemented at a large scale with low costs and can deliver health services at the time and place chosen by users [9]. However, previous research showed that user engagement in digital interventions is suboptimal (due to, for example, high participant attrition) [10], resulting in a significant gap in intervention efficacy.

Gamification, which first emerged in 2008 and gained popularity since the 2010s, refers to applying game components such as leaderboards, points, and badges into nongame contexts [11]. Unlike serious games, which refer to full-fledged video games for health purposes, gamification is relatively open to varying situational engagement models [12]. Previous studies have been widely conducted on the use of gamification as a means to increase the initiation of desired health behaviors [13,14]. Given its increasing use in public health, gamification might also be useful for interventions to promote HIV prevention and control services. To our knowledge, two previous reviews explored how gamification was used during the HIV prevention and care continuum; the first review was conducted in 2017 and only summarized studies published between January 2016 and March 2017 [15], and the second review searched studies published in the *Journal of Medical Internet Research* and its sister journals [16], both of which would result in an incomplete study search. Moreover, to our knowledge, no meta-analysis has hitherto examined the effectiveness of gamification applied to HIV prevention and control. Therefore, it is essential to conduct an in-depth review and provide a meta-analysis combining evidence on the effectiveness of gamified HIV digital prevention interventions. Findings from this review may have important implications for HIV digital health prevention development and future research.

Objectives

This study was divided into two parts. The first part was a systematic review of HIV prevention and control gamification with the following aims: to describe the characteristics of included studies that applied gamification, describe the various gamification elements that are commonly applied, and evaluate the methodological quality of included studies. The second part is a meta-analysis of the effectiveness of gamification applied to HIV prevention and control to assess the impact of gamification on HIV testing; condomless anal sex (CAS) reduction; and uptake of and adherence to PrEP, nonoccupational PEP (nPEP), and antiretroviral therapy (ART). It was hypothesized that MSM participating in the gamified intervention would display higher levels of HIV prevention and care than those in the control groups.

Methods

We conducted this systematic review and meta-analysis according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guideline [17]. The PRISMA checklist is listed in Checklist 1, and the study was registered in PROSPERO on January 27, 2023 (CRD42023392193).

Search Strategy and Identification of Studies

The electronic databases PubMed/MEDLINE, Embase, the Cochrane Library, Web of Science, Scopus, and the *Journal of Medical Internet Research* and its sister journals were searched for scientific articles published from their inception until January 15, 2024, using a combination of Medical Subject Headings (MeSH) terms and text words: *Men who have sex with men* AND *HIV/AIDS* AND *gamification/game-based learning* AND *telemedicine*. The search strategy used for each database is listed in Multimedia Appendix 1 .

Study Selection

The full review screening was conducted by two independent reviewers who independently checked the titles and abstracts for inclusion in the review. Full-text articles were obtained for closer inspection when an article met the inclusion criteria. In addition, reference lists of retrieved articles, existing relevant systematic reviews, and all articles citing the included studies on Google Scholar were manually searched to allocate studies not identified in the database searches. Any disagreement on study selection was resolved by discussion with a third reviewer.

To be eligible for inclusion, studies were required to describe or evaluate gamified interventions for HIV prevention and control in MSM. For the systematic review, the inclusion criteria were peer-reviewed original articles that explicitly addressed the use of game elements or gamification; the intervention described involved a task specifically designed for HIV prevention and control, and at least one game element was

involved in the task; the task was delivered via a digital device (eg, smartphones, tablets, or laptops); the study population should be exclusively MSM or more than 50% of the participants should be MSM; and the primary outcome should contain at least one of the following outcomes related to HIV prevention and control, namely, HIV testing, CAS, and uptake of and adherence to PrEP, nPEP, and ART for MSM living with HIV. Given the limited number of published randomized controlled trials (RCTs), we included a heterogeneous range of study designs, including controlled pre-post studies, quasi-randomized studies, cohort studies, and case-control studies. If a study included both a protocol and efficacy study, we only included the efficacy study; otherwise, we included the study protocol. The studies included in the meta-analysis represented a subset of studies in the systematic review. An additional inclusion criterion for the meta-analysis was that the study design should be an RCT. The definition of gamification by Deterding et al [18] was adopted for this review, which considers gamification as an umbrella term for using game elements (rather than full-fledged games) to improve user experience and user engagement in nongame services and applications. Studies were excluded if they were not peer-reviewed articles including letters, commentary, conference abstracts, etc; were not written in English or Chinese; were systematic reviews or meta-analyses; the full text was not available in published form; did not include a well-described intervention; exclusively used text-based technology; or involved serious or full-fledged games.

Study Quality Assessment

Two reviewers independently assessed the quality and risk of bias of each included RCT using the revised Cochrane Risk of Bias Tool (RoB2) [19,20], which contains 5 domains, namely, bias arising from the randomization process, bias due to deviations from the intended intervention, bias due to missing outcome data, bias in outcome measurement, and bias in the selection of the reported result. The risk of bias in each domain was judged as *low risk*, *some concerns*, or *high risk*. We used the Risk of Bias in Nonrandomized Studies of Interventions (ROBINS-I) tool to assess the risk of bias in nonrandomized studies of interventions (cohort studies, case-control studies, controlled pre-post studies, and quasi-randomized studies), which contains 7 domains, and the risk of bias in each domain was judged as *low risk*, *moderate risk*, *serious risk*, *critical risk*, or *no information* [21]. Any disputes between the two reviewers were resolved through discussion with a third author. We summarized the quality evaluation results with a risk-of-bias plot by *robvis* [22]. The average score between the two authors was calculated for each study, and the weighted Cohen κ coefficient was measured to test the interrater reliability.

Data Extraction

A structured data extraction form was developed and revised by the authors. The extracted data comprised study characteristics, participants, intervention characteristics, comparison activity, and outcomes. The study characteristics included first author, publication year, country, study design, and study setting. Participant characteristics included participant recruitment method, recruitment period, sample size, follow-up times, mean and SD of participants' age, and HIV status. For intervention characteristics, we extracted intervention developers, intervention names if available, the number of modules in each intervention, intervention delivery modality, game components used in each intervention, and theories used to apply gamification. The primary outcomes were CAS reduction; HIV testing; and uptake of and adherence to PrEP, nPEP, and ART. Authors of the initial publications were contacted when additional information was needed. Because of multiple classifications proposed for the term gamification, the components in each digital gamified intervention were analyzed through the lens of the Octalysis gamification framework [23], which comprises 8 core drives into which various gamification elements can be placed, namely, epic meaning and calling, development and accomplishment, empowerment creativity and feedback, ownership and possession, social influence and relatedness, scarcity and impatience, unpredictability and curiosity, and loss and avoidance (Table S3-2 in Multimedia Appendix 2 [13,24-48]). Laine et al [49] mapped their interview results from schoolchildren to the Octalysis framework to better establish a digital gamification-based intervention for promoting active school transport.

Data Synthesis and Analysis

First, data were synthesized and summarized in a narrative form assessing the characters of included studies and game components in each intervention. This qualitative review consolidated all studies that met the eligibility criteria, including those for which we could not extract data. Second, a meta-analysis was conducted to evaluate the effectiveness of gamification applied to HIV prevention and care, and variables that mediated these relationships. For each trial, we estimated the risk ratio (RR) of HIV testing; CAS; and uptake of and adherence to PrEP, PEP, and ART, comparing the intervention group and the control group together with the SE of the log RR. Random-effects summary effect estimates were obtained from DerSimonian and Laird's [50] random-effects meta-analyses of (log) RRs and 95% CIs from each study. When studies included more than one intervention group with gamification features, they were first combined into one group following the recommendation by the Cochrane Handbook. Studies with multiple control groups were integrated into different subgroup analyses if they compared their gamified interventions to inactive and active control groups. For studies reporting outcomes at more than 1 time point, we abstracted data in each time point after randomization. Higgins I^2 and 95% CI were estimated to measure between-study heterogeneity (low heterogeneity: <25%; moderate heterogeneity: 25%-75%; large heterogeneity: >75%) [51]. When heterogeneity was detected by I^2 (P<.05), a subgroup analysis was performed to investigate the possible source of heterogeneity: study designs, type of control group, selected samples (eg, participants with different risk levels) versus unselected samples, intervention duration, and outcome diagnosis (clinical diagnosis vs self-reporting). A meta-regression analysis was conducted if the number of RCTs for each outcome of interest was >10 [52]. Potential publication bias was explored by the Egger test and contour-enhanced funnel plots. If publication bias was present, nonparametric trim-and-fill analysis was performed to explore its impact on the

meta-analysis results. All *P* values were 2-sided, and *P*<.05 was considered statistically significant. All analyses were conducted using Stata 15 (Stata Corp) using “metan” commands.

Role of Funding Source

The study funder had no role in the study design, data collection, data analysis, and result interpretation. The corresponding author had full access to all study data and held the final responsibility for the decision to submit the manuscript for publication.

Ethics Approval

This study was approved by the medical ethics board of Binzhou Medical University (#2021-007).

Results

Search Results

Figure 1 illustrates the literature search and the screening process. A total of 348 records were initially retrieved by the database search. After removing 74 duplicates, the remaining 274 records underwent screening based on their title and abstract. Among these, 218 records were determined to be irrelevant and excluded. Next, the eligibility of 56 full-text records was assessed, yielding 25 records meeting the inclusion criteria and being included in the study. In addition, a secondary reference search was performed, yielding 1 more relevant record. Consequently, a total of 26 articles were included in the qualitative analysis [13,24-48]. Furthermore, of the 26 articles, 6 RCTs were chosen for the meta-analysis [24,29,30,32,33,39].

Study Characteristics

The features of each included paper regarding study information, interventions, and outcomes are listed in Multimedia Appendix 2. As shown in Table 1 and Table S3-1 in Multimedia Appendix 2, the included studies were published between 2013 and 2023, with the majority published after 2018, which indicated that research on adopting gamification during the HIV prevention and care continuum among MSM is an emerging field. A total of 73% (n=19) of studies were conducted in the United States. As for study designs, most adopted an RCT design (n=10, 38%). In terms of sample sizes, the studies had a range of participants from 5 to 901. When considering all the studies included in the review, a total of 4436 participants were involved. The mean age of participants reported in the studies ranged from 16.2 to 42.7 years. Concerning primary outcomes, most studies explored the effects of gamified intervention on PrEP adherence (n=9), followed by HIV-testing promotion (n=7), changes in CAS (n=6), ART adherence (n=5), PrEP uptake (n=4), and PEP uptake (n=2).

Gamified Digital Intervention Characteristics

As for intervention characteristics (Table S3-3 in Multimedia Appendix 2), the number of intervention modules ranged from 3 to 13. Of the 26 studies, 22 (85%) included members of the target population (MSM) during the developmental phase of the intervention. Gamification was delivered mostly by mobile apps (n=18, 69%), followed by the internet (n=5, 19%). The duration of study follow-ups ranged from 2 weeks to 15 months. Of the 26 studies, 88% (n=23) used theories for gamified intervention development. Information-motivation-behavioral skills (IMB) were used in 42% (n=11) of studies, social cognitive theory in 19% (n=5), motivational interviewing in 4% (n=1), integrated behavioral model in 4% (n=1), Information System Research Framework in 4% (n=1), social learning theory in 4% (n=1), principle of self-learning in 4% (n=1), dyadic HIV care engagement in 4% (n=1), and Levesque framework in 4% (n=1). Studies included in the systematic review used a range of game core drives and game components (Table 2 and Table S3-3 in Multimedia Appendix 2). The most frequently used game core drives were ownership and possession, followed by social influence and relatedness, development and accomplishment, empowerment creativity and feedback, and unpredictability and curiosity. The most frequently used game components were points, followed by challenge, discussion forums, and mentorship or character narrative.

Table . Type of game core drives and game components used in the included studies (N=26).

Quality Assessments of Included Studies

An overview of the different risks of bias in each study is presented in Tables S4-1 and S4-2 in Multimedia Appendix 3 [13,24,25,28-30,32-36,39,42,43,45,48]. The weighted Cohen κ coefficient was 0.88, suggesting good agreement between raters [53]. Overall, 10 RCTs were assessed using the RoB2, with 6 rated as having a high risk of bias. A high risk of bias occurred in the domains outcome measurement [24,28,30,42] and missing outcome data [29,43] (Figure S4-1 in Multimedia Appendix 3). Of the 6 nonrandomized studies assessed using the ROBINS-I tool, 2 presented a serious risk of bias [34,35] and 4 a critical risk of bias [25,36,45,48] (Figure S4-2 in Multimedia Appendix 3). These nonrandomized studies were

not further included in the meta-analysis. We did not evaluate the study quality of the other 10 studies [26,27,31,37,38,40,41,44,46,47], as they were designed as study protocols or feasibility studies that did not report results for the outcomes of interest in our review.

Effects of Gamification on CAS

The 10 RCTs under each outcome of interest in this review are listed in Table S5-1 in Multimedia Appendix 4 [13,24-39,41-48]. The meta-analysis on the effect of gamification on CAS reduction contained 3 RCTs (total N=2138). One RCT reported the effect of gamification on engaging in CAS [43], while the other 2 evaluated the effect of gamification on the number of CAS acts and were included in the meta-analysis [32,33]. The gamified digital intervention conferred significant protection against self-reported numbers of CAS acts at the 3-month follow-up (Figure 2; incidence rate ratio [IRR] 0.62, 95% CI 0.44-0.88). However, this effect was not statistically significant 6 months post intervention (Figure 3; IRR 0.71, 95% CI 0.38-1.36). We did not find evidence of publication bias (Figure S6-1 in Multimedia Appendix 5).

Figure 2. Meta-analysis of randomized controlled trials assessing the effect of gamified digital interventions on the number of condomless anal sex acts among men who have sex with men 3 months post intervention [32,33]. IRR: incidence rate ratio.

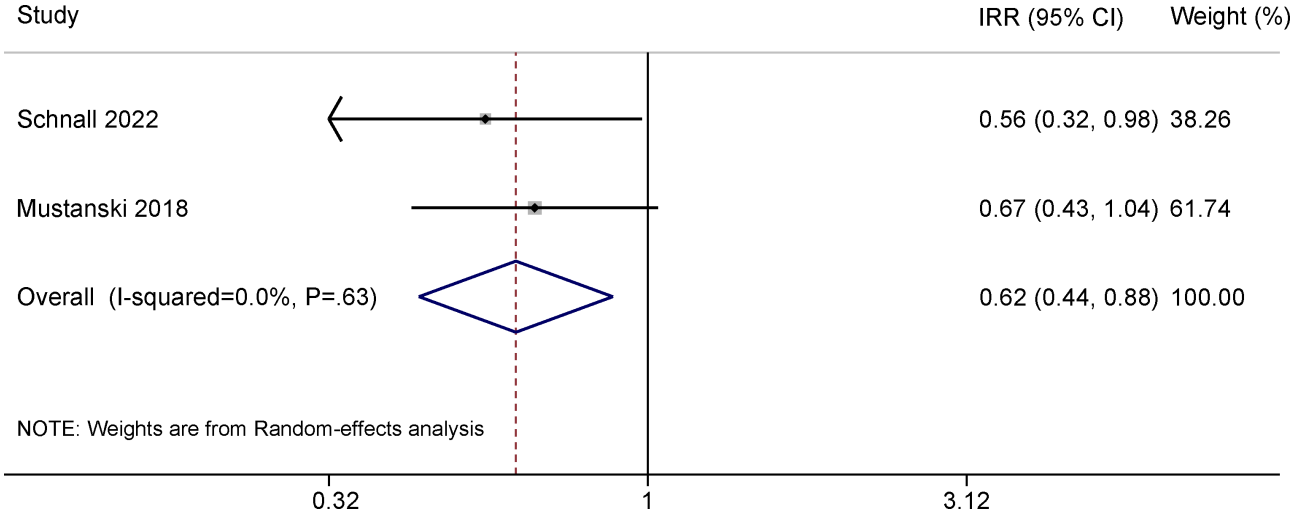

Figure 3. Meta-analysis of randomized controlled trials assessing the effect of gamified digital interventions on the number of condomless anal sex acts among men who have sex with men 6 months post intervention [32,33]. IRR: incidence rate ratio.

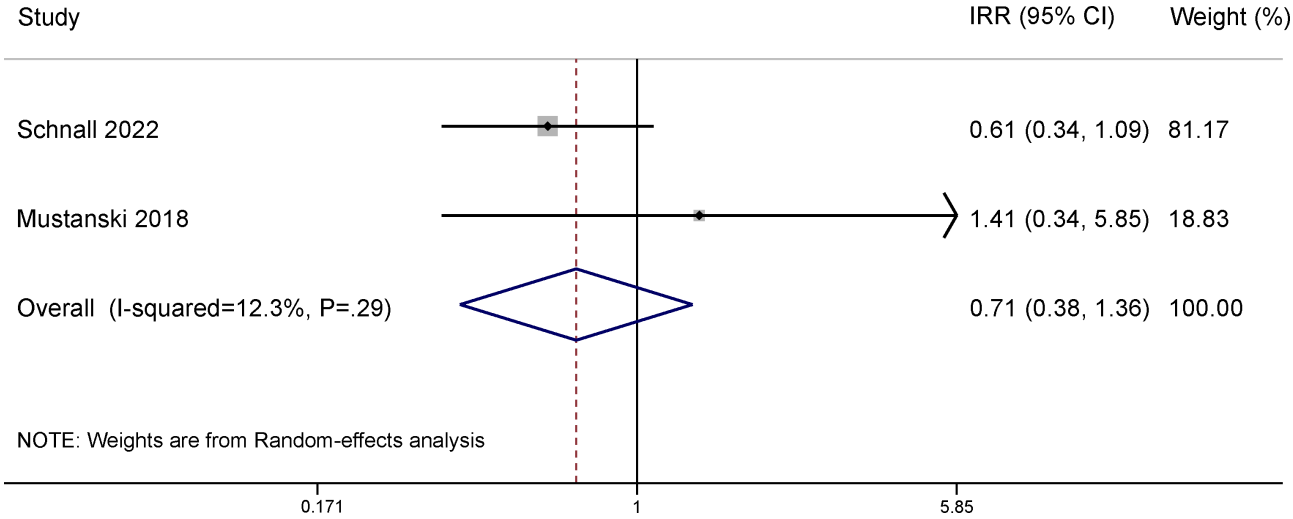

Effects of Gamification on PrEP Adherence

A total of 4 RCTs compared PrEP adherence in MSM receiving a gamified digital intervention to non–PrEP-related mobile games [29], youth-friendly services [30], the standard of care from a health educator and a study clinician [39], or educational videos on sleep hygiene and diet [24]. The meta-analysis suggested an effective but nonstatistically significant effect of PrEP adherence at the 3-month follow-up (Figure 4; RR 1.16, 95% CI 0.96-1.38) and 6-month follow-up (Figure 5; RR 1.28, 95% CI 0.89-1.84). We did not find evidence of publication bias (Figure S6-1 in Multimedia Appendix 5).

Only 1 RCT was designed to evaluate a gamified mobile app (MyChoices) to increase HIV testing and PrEP uptake, and the results showed that the MyChoices arm had a 22% higher prevalence of HIV testing over the 6-month follow-up compared to those in the standard of care arm, while there was no difference in PrEP uptake between the different intervention groups [28]. Two RCTs were implemented to evaluate the effects on ART adherence among MSM living with HIV [13,42].

They used different questions to measure ART adherence, and we did not conduct a further meta-analysis for this outcome. For example, the study conducted by Hightow-Weidman et al [13] showed that the proportion of individuals self-reporting ≥90% adherence in the past 7 days rose markedly at 13 weeks post intervention with no significant difference between study arms. Horvath et al [42] evaluated an online social support intervention (Thrive With Me [TWM]) with an RCT design, and the result did not show a significant group difference for the overall ART adherence (≥90% ART adherence in the past 30 days 1 month post intervention). We found that no RCT was conducted to evaluate the effect of the gamified digital intervention on PEP uptake, PEP adherence, and ART initiation. Further studies are still needed to evaluate the effect of the gamified digital intervention on PEP initiation, PEP adherence, and ART uptake in MSM. A meta-regression analysis was not conducted since the number of RCTs in each outcome of interest was fewer than 10.

Figure 4. Meta-analysis of randomized controlled trials assessing the effect of gamified digital interventions on pre-exposure prophylaxis adherence among men who have sex with men at the 3-month follow-up [29,30,39]. RR: risk ratio.

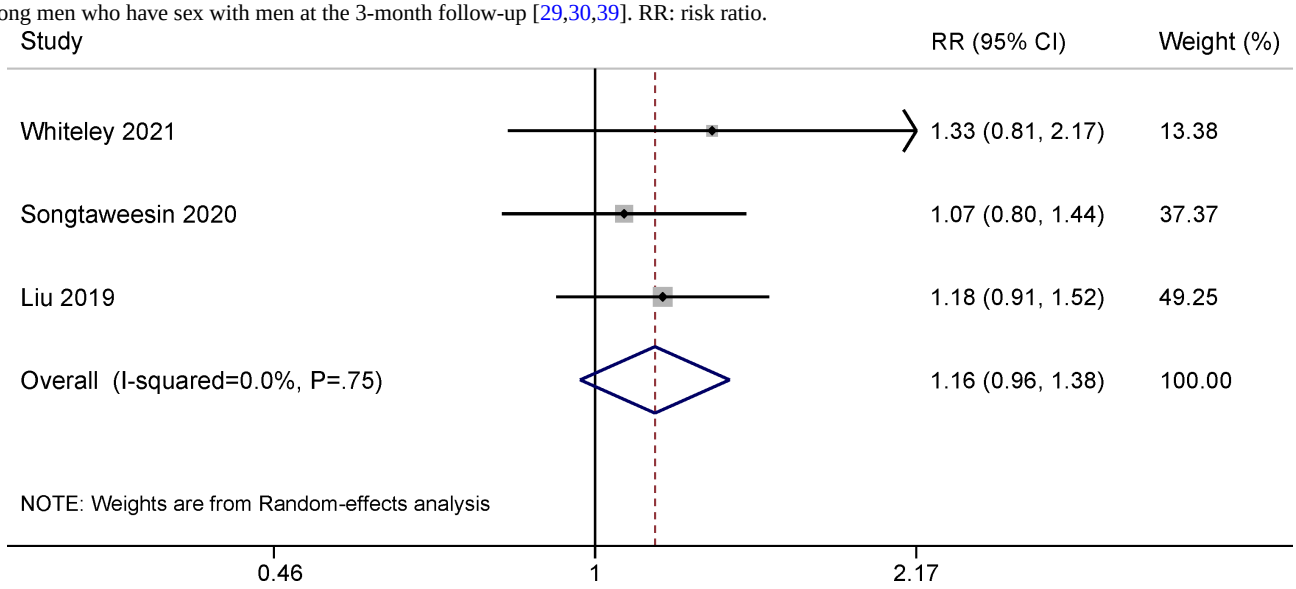

Figure 5. Meta-analysis of randomized controlled trials assessing the effect of gamified digital interventions on pre-exposure prophylaxis adherence among men who have sex with men at the 6-month follow-up [24,29,30,39]. RR: risk ratio.

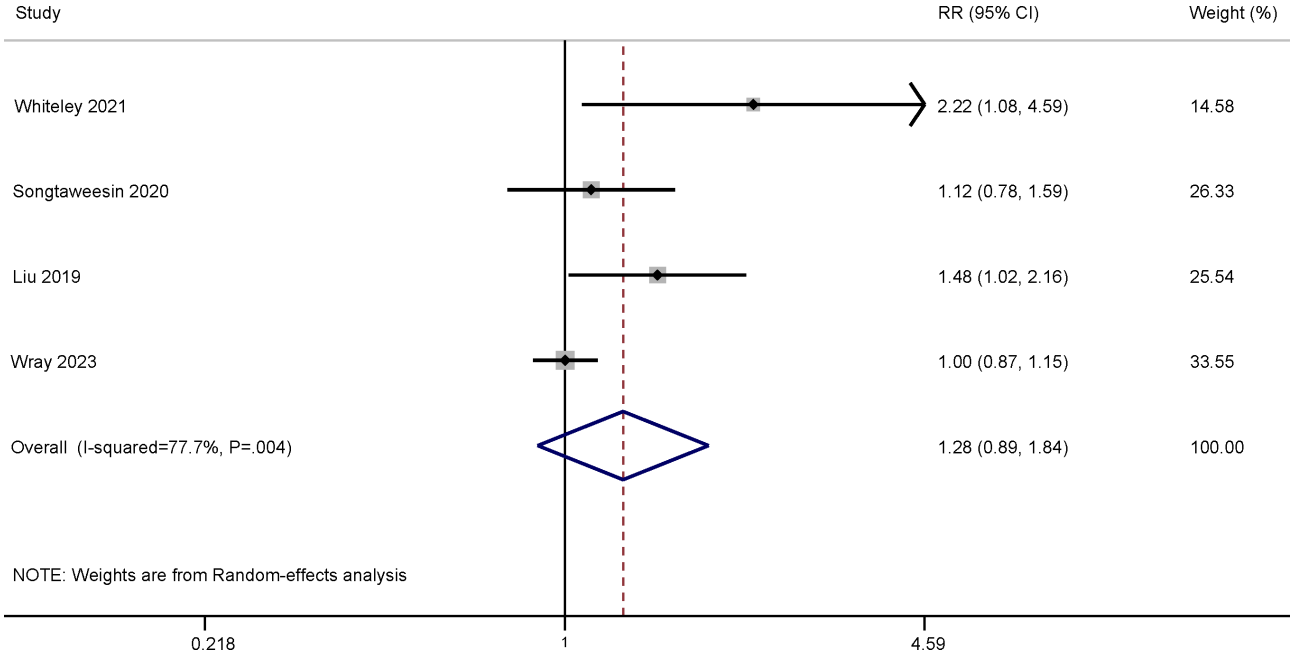

Discussion

Principal Findings

This study aimed to conduct a systematic review and meta-analysis to evaluate the effectiveness of gamification on the HIV prevention and care continuum among MSM. A total of 26 studies involving 10 RCTs were included in the systematic review. Our findings revealed that gamification of HIV prevention and control addressed HIV-specific outcomes, such as CAS, HIV testing, PrEP uptake, PrEP adherence, nPEP uptake, and ART adherence in MSM living with HIV, with most RCTs focusing on PrEP adherence (4/10, 40%), followed

by CAS (3/10, 30%). The majority of studies were published after 2018 (25/26, 96%) and conducted in the United States (19/26, 73%), and only 6 studies were conducted in low- and middle-income countries (Malaysia, Tanzania, Indonesia, Mexico, Thailand, and China), indicating that the gamification of the HIV prevention and care continuum is an area under development. Our review showed that the most frequently used game core drive was ownership and possession, and points emerged as a frequently used game component. Besides, the most used theory in gamified digital intervention development was IMB. Overall, results from the meta-analysis of RCTs showed significant positive effects of gamification on reducing the number of CAS acts and improving PrEP adherence in MSM. However, the robustness of these findings was limited by the small number of studies included in the meta-analysis.

Gamification Being Applied in the HIV Prevention and Care Continuum

Gamification is a technique that uses game components to motivate participants to engage positively in healthy behaviors. Cugelman [12] identified 7 game components that are linked to proven behavior change strategies, including goal setting, offering a challenge, feedback, reinforcement, compare progress, social connectivity, and fun and playfulness. In this review, we found the most frequently used game element was reinforcement (gaining points), followed by the capacity to overcome a challenge, which is consistent with reviews in other health areas, such as physical activity [54] and cognitive training [55]. Reinforcement represents the motivation driven by feelings of owning something and the desire to get more of it. Hence, healthy behaviors are mostly reinforced by the desire for possession. Challenge is a game component that falls under the core drive development and accomplishment, which motivates individuals through personal growth and the drive to achieve specific targeted goals [23]. Although the above game elements have been widely used in HIV prevention and care interventions, other game elements are less reported in research studies, such as unpredictability and curiosity, loss and avoidance, and scarcity and impatience. Hence, researchers must collaborate with companies focusing on gamification technology to include different game components for the future development of digital interventions.

Effects of Gamification on CAS

The meta-analysis of 2 RCTs demonstrated a 38% reduction in the number of CAS acts in the intervention group compared with the control group at the 3-month follow-up. In addition, a 29% reduction in the number of CAS acts was reported at the 6-month follow-up, with no statistical significance (IRR 0.71, 95% CI 0.38-1.36), which suggests a short-term intervention effect. These findings have important implications, as all of these RCTs enrolled young MSM (ages 13-29 years) disproportionately affected by HIV [56], and few HIV prevention interventions were targeted for young MSM [57]. Moreover, given that mobile technology provides greater access to the target population who may not be able or willing to come in person to receive HIV health service, it provides an ideal platform to reach these young gay, bisexual, and transgender individuals whose ownership of smartphones and use of mobile phone apps are increasing.

Effects of Gamification on HIV PrEP Adherence

Our pooled results indicated that gamified digital interventions effectively improved PrEP adherence in MSM. At the 3-month follow-up, those in the intervention group were 1.16 times more likely to engage in optimal PrEP dosing (≥700 fmol/punch measured by dried blood spots) than the control. The proportion of participants who engaged in optimal PrEP dosing was 28% higher in the intervention versus control groups at the 6-month follow-up. Similar results on behavior change have also been found in asthma and vaccination uptake [58,59]. Notably, in the development stage of their interventions, 3 of the 4 RCTs adopted the IMB theory, which is a behavioral change theory that may explain the effectiveness of these interventions [29,30,39]. Researchers have also suggested that interventions guided by theories are more efficient than those not driven by theories [60]. The IMB model asserts that informed and motivated participants with adequate skills for enacting adherence-related behaviors would optimally adhere to their PrEP regimen over time [61]. Interventions that integrate gamification components can educate users to interface in a more dynamic, immersive, and engaging way to make the experience more informative and motivating for individuals to promote positive health behavior change.

Some concerns should be mentioned after this review. First, more than half of studies on gamification were conducted in the United States, limiting generalizability to other countries. Second, the intervention module and duration were different in different interventions. For example, MSM had access to TWM for 5 months [62], while participants only received access to MyPEEPS over 3 months [32]. Even in an assigned intervention duration, participants' use patterns for different intervention components varied [39]. Reasons may include a lack of ongoing new features embedded in apps, and the effectiveness may be not sustained long-term if the gamification is not continuously improved.

Study Limitations

There were some limitations in this review. First, the number of RCTs available for each outcome of interest in the meta-analysis was limited, suggesting the need for further validation of our findings through additional studies. Second, as previous studies established that intervention engagement metrics (eg, frequency, duration, or amount of mobile health [mHealth] use) were positively associated with interested outcomes [13,63], we were unable to conduct an in-depth analysis of participants' electronic paradata and how these data could affect our result because of the small size of studies. Indeed, further trials are needed to better measure the effective mediators in gamification for healthy behavior. Additionally, the effects of gamification on CAS and PrEP adherence were only pooled 3 and 6 months post intervention. Accordingly, little is currently known about the longer-term impact of the gamified digital intervention.

Conclusions

This study indicated that mHealth-based gamification interventions in the HIV prevention and care continuum among MSM are in a phase of rapid evolution and continued development. Our study substantiated the short-term effect of gamification on CAS in MSM, although the long-term impact of gamified digital interventions remains to be determined.

Abstract

Background: Telemedicine technology is a rapidly developing field that shows immense potential for improving medical services. In palliative care, informal caregivers assume the primary responsibility in patient care and often face challenges such as increased physical and mental stress and declining health. In such cases, telemedicine interventions can provide support and improve their health outcomes. However, research findings regarding the use of telemedicine among informal caregivers are controversial, and the efficacy of telemedicine remains unclear.

Objective: This study aimed to evaluate the impacts of telemedicine on the burden, anxiety, depression, and quality of life of informal caregivers of patients in palliative care.

Methods: A systematic literature search was conducted using the PubMed, Embase, Web of Science, CENTRAL, PsycINFO, CINAHL Plus with Full Text, CBM, CNKI, WanFang, and VIP databases to identify relevant randomized controlled trials published from inception to March 2023. Two authors independently screened the studies and extracted the relevant information. The methodological quality of the included studies was assessed using the Cochrane risk-of-bias tool. Intervention effects were estimated and sensitivity analysis was conducted using Review Manager 5.4, whereas 95% prediction intervals (PIs) were calculated using R (version 4.3.2) and RStudio.

Results: A total of 9 randomized controlled trials were included in this study. The meta-analysis indicated that telemedicine has reduced the caregiving burden (standardized mean differences [SMD] −0.49, 95% CI −0.72 to −0.27; *P*<.001; 95% PI −0.86 to −0.13) and anxiety (SMD −0.23, 95% CI −0.40 to −0.06; *P*=.009; 95% PI −0.98 to 0.39) of informal caregivers; however, it did not affect depression (SMD −0.21, 95% CI −0.47 to 0.05; *P*=.11; 95% PI −0.94 to 0.51) or quality of life (SMD 0.35, 95% CI −0.20 to 0.89; *P*=.21; 95% PI −2.15 to 2.85).

Conclusions: Although telemedicine can alleviate the caregiving burden and anxiety of informal caregivers, it does not significantly reduce depression or improve their quality of life. Further high-quality, large-sample studies are needed to validate the effects of telemedicine. Furthermore, personalized intervention programs based on theoretical foundations are required to support caregivers.

Introduction

Background

With the continued increase in the number of individuals with multiple and severe diseases, the global demand for palliative care services is also growing [1]. Given that most patients who require palliative care prefer to spend time at home and receive the necessary care [2-4], informal caregivers play a crucial role in caring for patients. However, the cumbersome and complex care tasks may have negative impacts on their physical, psychological, and social well-being [5-7]. In recent years, telemedicine, as an emerging technology, has been increasingly used in home care [2], benefiting informal caregivers [8,9]. It may serve as a pathway to support informal caregivers of patients in palliative care, improve their health outcomes, and thus enhance the quality of palliative care [10].

The World Health Organization estimates that 56.8 million people require palliative care yearly [11]. However, there is a

prevailing shortage of professional palliative care personnel, and the majority of patients prefer to receive such care at home [2-4]. Hence, informal caregivers, usually family members or friends, assume the primary responsibility for patient care. In doing so, they adapt to changes in their role, family, and social life to provide long-term, unpaid care for patients [12,13]. Informal caregivers frequently lack professional training [4]. Thus, they face unmet supportive care needs, such as symptom management, psychological counseling, and social support [4,13], and experience anxiety, depression, physical overload, and a decline in the quality of life (QOL) [5-7]. Studies reveal that the state of informal caregivers and the condition of the patients mutually affect each other. The quality of care provided by caregivers in poor condition can be diminished, exacerbating the patient's condition. In turn, the patient's worsening condition can negatively affect informal caregivers [7,14,15]. Therefore, the demand to assist informal caregivers and address their physiological, psychological, and social health needs is urgent.

With the development of the information age, telemedicine has demonstrated tremendous potential in providing health care. Telemedicine refers to the use of information and communication technologies to facilitate communication between patients and health care workers for the assessment, diagnosis, treatment, and prevention of diseases, thereby improving patient health [16]. As a personalized medical approach, telemedicine overcomes the conventional care constraints of time and space; facilitates remote treatment, supervision, education, and care services; and promotes the rational distribution and refinement of medical resources [17]. Telemedicine has been widely applied in medical fields such as diabetes, chronic wounds, and cardiovascular diseases [18,19], benefiting patients and improving the health outcomes of informal caregivers [8,9].

In recent years, telemedicine has also provided novel ideas to guide palliative care [20]. In the field of palliative care, an increasing number of informal caregivers are opting to provide home care for patients who require palliative care [21]. Telemedicine facilitates real-time communication between professionals and family caregivers. This promotes information sharing; assists in the patient's symptom management; and helps in providing health education, psychological counseling, and social support [22]. However, the outcomes of using telemedicine with informal caregivers are controversial. For example, a randomized controlled trial (RCT) by Chen et al [23] indicated that telemedicine could alleviate caregiving burden and enhance the QOL of informal caregivers. However, Dionne-Odom et al [24] found no significant difference between the telemedicine and control groups in terms of improvements in informal caregivers' QOL, burden, or emotional state. Of the few available systematic reviews, most provide a descriptive summary of results without performing a meta-analysis to quantify the outcomes of the studies [25-27]. Thus, the intervention effects of telemedicine remain unclear.

Objectives

Given the limitations of previous reviews, we conducted a systematic review and meta-analysis. We summarized articles on the intervention effects of telemedicine among the informal caregivers of patients in palliative care, focusing on 4 health outcomes: caregiver burden, anxiety, depression, and QOL. This provides a reference for the clinical practice of telemedicine. This is the first systematic review and meta-analysis to verify the effects of telemedicine on the outcomes for informal caregivers of patients in palliative care.

Methods

Overview

This systematic review adhered to the guidelines in the 2020 PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist [28] (Checklist 1). In addition, it was registered on PROSPERO (CRD42023415688).

Ethical Considerations

As all data used were obtained from previously published articles, this research did not require ethical approval from an institutional review board or informed consent from participants.

Search Strategy

A literature search was conducted in 10 electronic databases (PubMed, Embase, Web of Science, CENTRAL, PsycINFO, CINAHL Plus with Full Text, CBM, CNKI, WanFang, and VIP) for publications dating from the establishment of each database until March 31, 2023. Following the Population, Intervention, Comparison, Outcome, and Study design principles, the searches in this systematic review were performed using Medical Subject Headings, the title or abstract, and keywords, as well as Boolean logical operations. Multimedia Appendix 1 describes the search strategy for all databases. In addition, relevant systematic reviews and references were manually screened to identify additional eligible studies.

Study Eligibility Criteria

The inclusion criteria were as follows. (1) The study population was informal adult caregivers (aged ≥18 y) caring for patients receiving palliative care for severe diseases (eg, advanced stage, incurable "stage 4" diseases). (2) Intervention measures were being provided through the internet, applications, telephone, video, or other telemedicine technologies. (3) The control group received usual care or enhanced usual care or was on a waiting list. (4) The study reported outcomes for informal caregivers focusing on 1 or more of the following aspects: caregiver burden, anxiety, depression, or QOL. (5) The study was designed as an RCT. (6) The article was published in English or Chinese.

The exclusion criteria were as follows. (1) The publications were qualitative research, conference abstracts, letters, comments, reviews, or protocols. (2) Patients were underage (aged <18 y), or palliative care indications were unrelated to life-limiting diseases (eg, chronic diseases or nonmalignant pain). (3) Interventions were not being targeted at informal caregivers. (4) The full-text article or relevant data were not accessible.

Study Selection and Data Extraction

The titles and abstracts of the retrieved literature were first downloaded and imported into Endnote X9 (Clarivate; a reference management program) to remove duplicates. Two

evaluators then independently screened the studies based on the inclusion and exclusion criteria. Any disagreements were resolved through consultation or discussion with a third researcher. Data were extracted through a predesigned table, including the name of the first author, year of publication, country, age of the caregiver, sample size, type of disease diagnosed in the patient, type and content of intervention measures, study duration, and time of the outcome assessment.

Quality Assessment

Two evaluators independently assessed the methodological quality of the included studies using the Cochrane Collaboration's tool for assessing the risk of bias [29]. Seven aspects were evaluated: (1) random sequence generation, (2) allocation concealment, (3) blinding of participants and personnel, (4) blinding of outcome assessment, (5) incomplete outcome data, (6) selective reporting, and (7) other biases. Each study was categorized as "low risk," "uncertain risk," or "high risk," with disagreements resolved through consultation or discussion with a third researcher.

Data Analysis

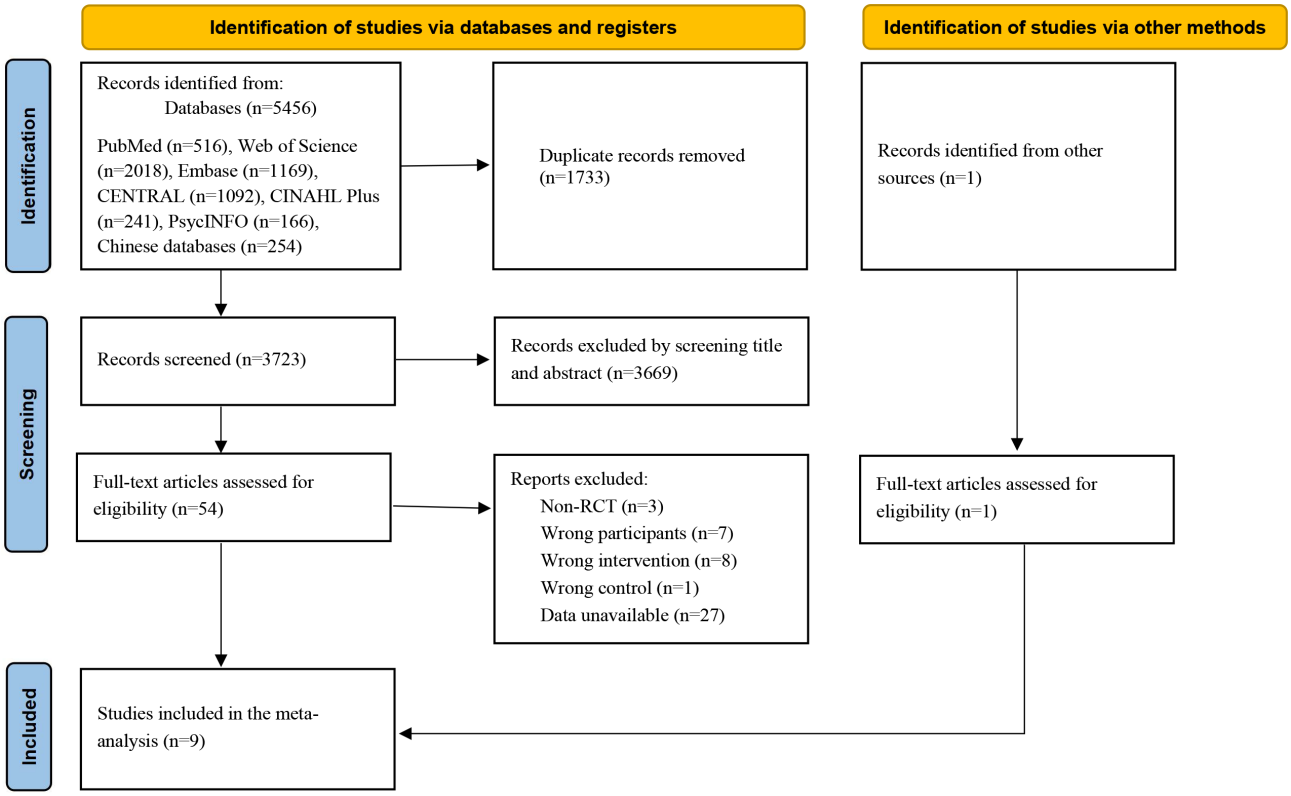
For studies with multiple measurements, only data from the last measurement were extracted for analysis. SDs were calculated according to the *Cochrane Handbook for Systematic Reviews of Interventions* if not reported [29]. If required data were not reported, we contacted the first authors of the relevant publication. Heterogeneity testing and the meta-analysis were conducted using Review Manager 5.4 (The Cochrane Collaboration). Intervention effects were estimated through standardized mean differences (SMDs) and 95% CIs, and forest plots were generated. A 2-sided P value <.05 was considered statistically significant. Heterogeneity was evaluated using the χ^2 test (with P<.10 indicating heterogeneity) and I^2 test (with I^2>50% indicating moderate heterogeneity and I^2>75% indicating high heterogeneity). If I^2≤50% and P>.10, a fixed-effect model was adopted for data merging and analysis; otherwise, a random-effects model was used. A sensitivity analysis was conducted using a one-study-out method to evaluate the robustness of the combined results. In addition, 95% prediction intervals (PIs) were calculated using R (version 4.3.2; R Foundation for Statistical Computing) and RStudio (Posit) to explain the heterogeneity across studies and estimate the true effects in similar future studies [30].

Results

Search Results and Selection

A preliminary search of the electronic databases yielded 5456 articles: 254 in Chinese and 5202 in English. After removing 1733 duplicated articles, an additional 3669 unrelated articles were excluded after evaluating their titles and abstracts, leaving 54 articles for the full-text review. From these, 8 articles were included, and with the addition of 1 more article, 9 studies were ultimately included in the meta-analysis. The screening process is detailed in Figure 1 [28].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. RCT: randomized controlled trial.



Characteristics of the Included Studies

Study Characteristics

Multimedia Appendix 2 [23,24,31-37] summarizes the main characteristics of the included studies. These studies were all RCTs published in 3 countries between 2015 and 2023: a total of 6 from the United States, 1 from the Netherlands, and 2 from China. Four studies mentioned the theoretical or conceptual framework of the intervention, including Erikson's psychosocial development theory and Bowen's family system theory [23], self-determination theory [31], shared decision-making [33], and cognitive behavioral stress management [35].

Characteristics of Informal Caregivers

The studies involved 1215 informal caregivers, with the number of participants in each study ranging from 35 to 334. The average age of the informal caregivers ranged from 45.71 (SD 11.85) to 60.1 (SD 12.5) years, and they were predominantly patients' parents, spouses or partners, and children. The types of diseases of the patient included advanced cancer, advanced heart failure, and advanced dementia.

Characteristics of Telemedicine Interventions

Telemedicine was practiced via websites, web conferences, applications, or the telephone, but primarily through websites and the telephone. A total of 4 studies provided interventions through a website. Oliver et al [33] performed a 3-arm clinical trial, where 1 group received an intervention via Facebook, which offered education and social support to informal caregivers, whereas a separate group received the ACCESS intervention. Here, in addition to the Facebook-based intervention, web conferences were incorporated to facilitate the engagement of informal caregivers in joint decision-making in palliative care. The project aimed to alleviate informal family caregivers' anxiety and depression. Pensak et al [35] implemented a 12-week intervention named Pep-Pal, which provided stress management support to informal caregivers of patients with advanced cancer via a website. The intervention program of Parker Oliver et al [34], ACTIVE, used web conferences or telephone calls to link informal caregivers to end-of-life care teams to improve caregivers' perceptions of pain management. Similarly, Fu et al [37] established real-time communication between medical staff and family caregivers of patients with advanced cancer via an internet platform to provide relevant health guidance. Furthermore, 2 studies provided intervention through an application. Schuit et al [36] developed a program called Oncokompas to provide personalized information, suggestions, and supportive care solutions tailored to the caregiver's situation. Chen et al [23] created a dyadic life review program for patients with advanced cancer and their caregivers using WeChat software to promote their QOL. In addition, 3 studies offered interventions via the telephone. Dionne-Odom et al [24] implemented a telephone intervention program named ENABLE CHF-PC, which offered psychological and problem-solving support for patients with heart failure in palliative care and their caregivers to improve their emotions, burden, and QOL. Two years later, Dionne-Odom et al [32] performed a similar intervention for patients with advanced cancer and their caregivers. Finally, Badr et al [31] provided a telephonic psychosocial intervention to enhance the QOL of patients with advanced cancer and their caregivers.

Characteristics of Controls

The control group in 1 study received enhanced usual care [33], whereas those in the remaining studies received usual care. Furthermore, in the study by Schuit et al [36], informal caregivers in the control group were allowed to use telemedicine equipment after the research ended.

Risk of Bias

A quality assessment of the included studies was conducted using the Cochrane risk-of-bias tool. Although most studies (6/9, 67%) reported using randomization, some did not detail allocation concealment, potentially leading to selection bias. Only 2 studies were determined as having a low risk of implementation bias owing to the challenge of blinding researchers and participants in telemedicine intervention trials [24,32]. Approximately half (4/9, 45%) the studies blinded the outcome assessors, and thus, their risk of measurement bias was classified as low. Three studies were determined to have a high risk of attrition bias due to elevated loss to follow-up rates or a lack of appropriate data processing methods [32,35,37]. However, no selective reporting bias was detected in the included studies. Four studies were categorized as having a high risk of other biases due to baseline differences [24,34] and small sample sizes [31,32]. The results are shown in Figure 2.

Figure 2. Risk of bias in each study [23,24,31-37]. Red, green, and yellow colors indicate high, low, and unclear risk of bias, respectively.

Meta-Analysis

Caregiver Burden

A total of 5 studies that evaluated caregiver burden were included in the meta-analysis [23,31,35-37]. Since no significant heterogeneity was observed among the included studies (I^2=0%; *P*=.64), a fixed-effect model was used for merging the data. The results revealed that telemedicine intervention could mitigate the burden on informal caregivers (SMD −0.49, 95% CI −0.72 to −0.27; *P*<.001; 95% PI −0.86 to −0.13), as shown in Figure 3A. The sensitivity analysis showed that the results were stable, as shown in Figure 4A. The results remained unchanged when studies were merged using a random-effects model.

Figure 3. Forest plot of telemedicine versus control group: (A) caregiver burden, (B) anxiety, (C) depression, and (D) quality of life [23,24,31-37]. IV: inverse variance.

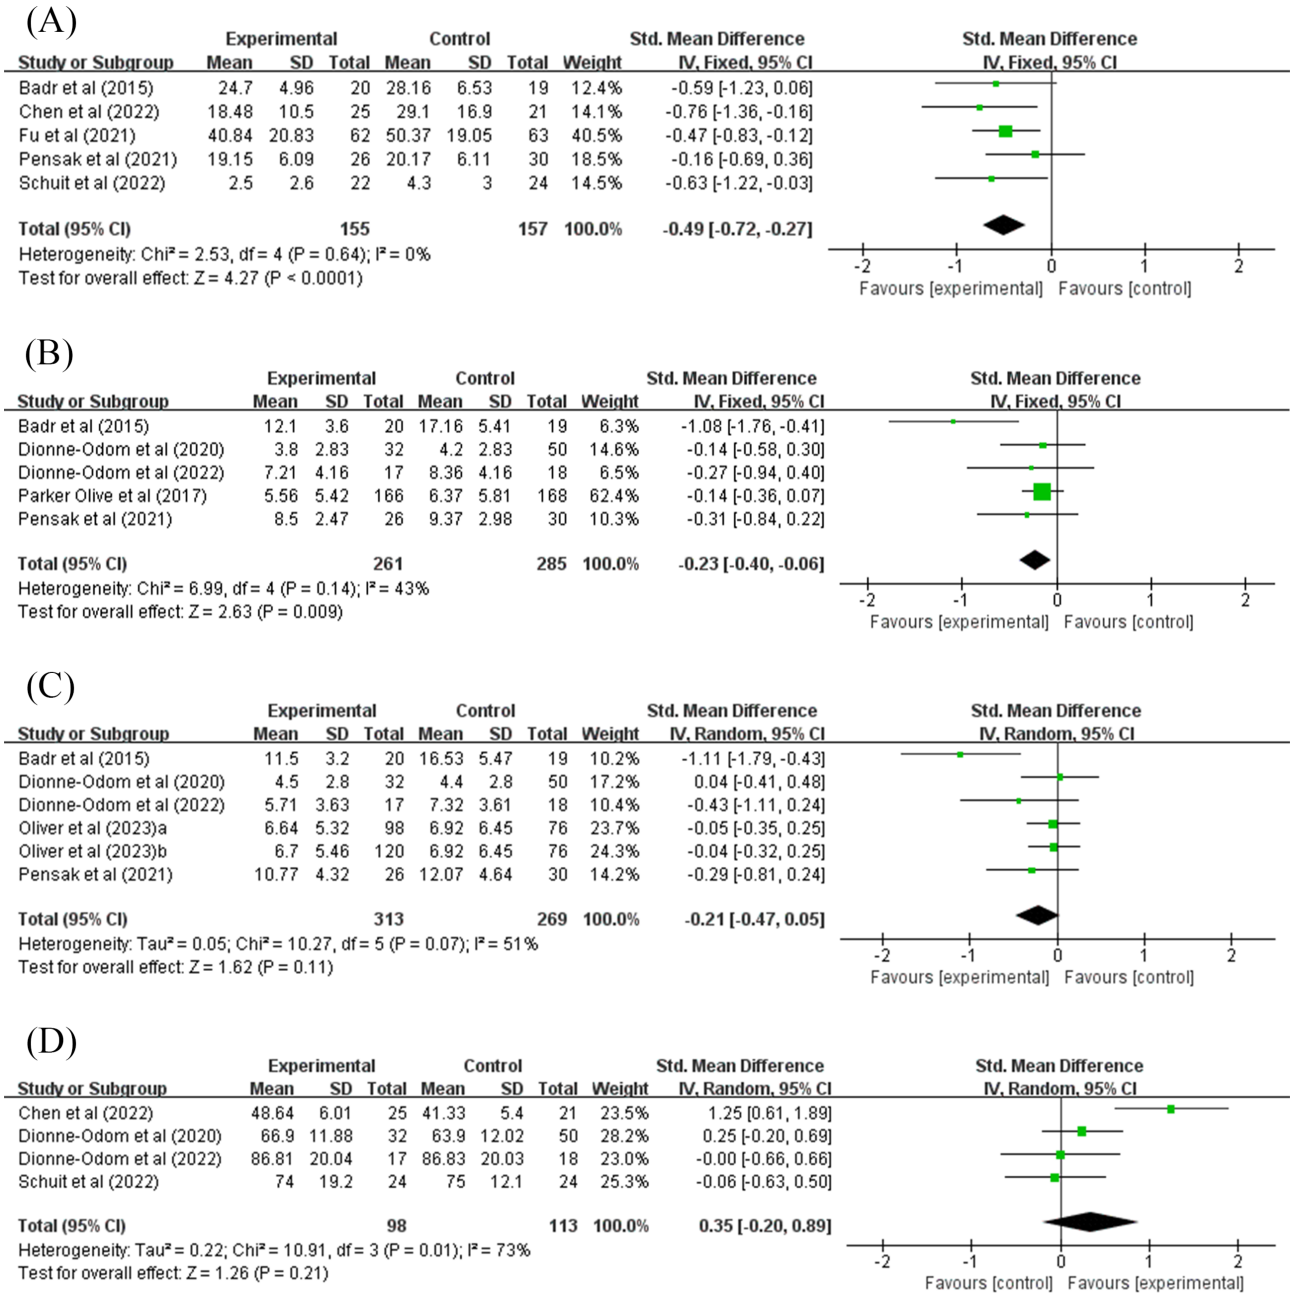


Figure 4. Sensitivity analyses: (A) caregiver burden, (B) anxiety, (C) depression, and (D) quality of life [23,24,31-37]. IV: inverse variance.

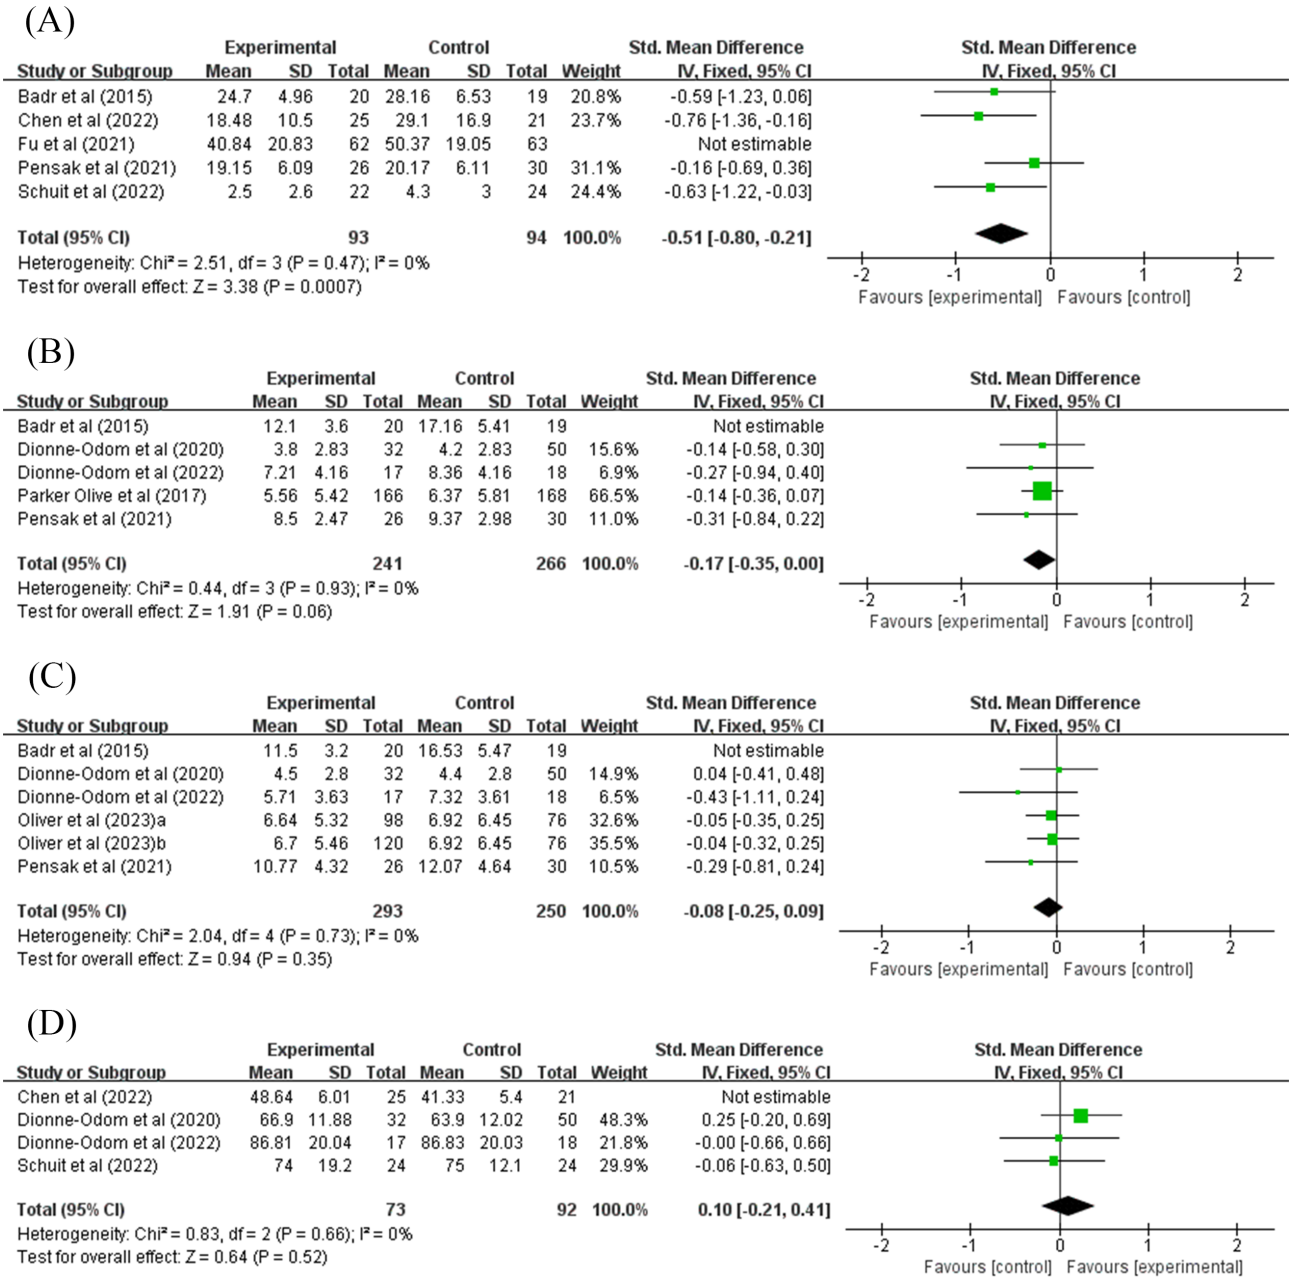

Anxiety

A total of 5 studies assessed the anxiety level of informal caregivers [24,31,32,34,35]. Due to mild heterogeneity among the included studies (I^2=43%; *P*=.14), a fixed-effect model was adopted to pool the data for analysis. The results demonstrated that telemedicine intervention could reduce informal caregivers' level of anxiety (SMD −0.23, 95% CI −0.40 to −0.06; *P*=.009; 95% PI −0.98 to 0.39), as shown in Figure 3B. The sensitivity analysis showed that after excluding Badr et al [31], the pooled results were the opposite, with I^2 decreasing to 0%, as shown in Figure 4B. This could be attributed to a higher risk of bias in this study. However, when merging studies using a random-effects model, the results still retained statistical significance (SMD −0.30, 95% CI −0.57 to −0.03; *P*=.03).

Depression

A total of 5 studies assessed the depression level of informal caregivers [24,31-33,35]. In the study by Oliver et al [33], "a" represents the ACCESS intervention and "b" represents the Facebook intervention. Due to moderate heterogeneity among the included studies (I^2=51%; *P*=.07), a random-effects model was used for merging the data. The analysis indicated that the telemedicine intervention did not result in a statistically significant difference in reducing depression among informal caregivers (SMD −0.21, 95% CI −0.47 to 0.05; *P*=.11; 95% PI −0.94 to 0.51), as shown in Figure 3C. Furthermore, the sensitivity analysis showed that no individual trial could change the results. However, after excluding Badr et al [31], the I^2 decreased to 0%, as shown in Figure 4C.

QOL of Caregivers

A total of 4 studies that assessed QOL were included in the meta-analysis [23,24,32,36]. Due to moderate heterogeneity among the studies (I^2=73%; P=.01), a random-effects model was used. The results indicated that the telemedicine intervention did not result in a statistically significant difference in improving the overall QOL of informal caregivers (SMD 0.35, 95% CI −0.20 to 0.89; P=.21; 95% PI −2.15 to 2.85), as shown in Figure 3D. Furthermore, the sensitivity analysis indicated that no individual trial could change the results. However, after excluding Chen et al [23], the I^2 decreased to 0%, as shown in Figure 4D.

Discussion

Principal Findings

The results of this review indicate that compared to conventional care, telemedicine interventions can alleviate the caregiving burden and anxiety of informal caregivers; however, they do not significantly alleviate depression or improve their QOL. The 95% PIs indicate considerable heterogeneity among the studies, and the effects of future telemedicine interventions on these outcomes remain uncertain, except for reducing caregiver burden.

Caregiver Burden

The results of the study demonstrated that telemedicine interventions could relieve the caregiving burden of informal caregivers, which is consistent with previous research [9,12,31]. The systematic review by Hu et al [9] demonstrates that internet-based interventions can effectively alleviate the stress of informal caregivers of patients with chronic diseases and improve their well-being. Chih et al [38] developed the Comprehensive Health Enhancement Support System for informal caregivers of patients with advanced cancer. The tool reduced the negative emotions of family caregivers and subsequently decreased their caregiving burden. Caregiver burden consists of both subjective and objective levels. Subjective burden includes the perceived physical, emotional, social, and economic difficulties caused by caring for individuals with serious diseases, whereas objective burden refers to the time and number of tasks devoted to patient care [39]. Telemedicine facilitates health education, assists in decision-making, helps develop problem-solving skills, and provides social support. It also improves and conserves the resources and time of informal caregivers. Thus, it is conducive to alleviating the caregiving burden at both the subjective and objective levels.

Anxiety

The results revealed that telemedicine interventions can alleviate anxiety in informal caregivers, which is consistent with the findings of previous research [8,27]. Research indicates that the likelihood of anxiety occurring in caregivers of patients with advanced cancer is 3 times that of the general population [40]. Here, factors such as overwhelming nursing pressure, inadequate self-care, and the lack of supportive care can lead to anxiety [41,42]. Currently, the proposed interventions to reduce the anxiety of informal caregivers focus on psychological education, skill training, and treatment counseling [43]. In this case, telemedicine enables monitoring, assessing, and managing patient symptoms, which can enhance informal caregivers' symptom management skills [1,37]. Moreover, it allows them to join discussions on the disease and participate in clinical decisions [20,33,44]. This can help satisfy informal caregivers' information needs and enhance their caregiving confidence and ability. In addition, telemedicine can provide psychological interventions, improve interpersonal relationships, and offer training in stress management skills [31,32], thereby alleviating symptoms of anxiety. However, the sensitivity analysis indicated that the result was unstable. To ensure greater stability, it will be necessary to gather additional data for further investigation.

Depression

The results of our research indicate that telemedicine does not have a statistically significant effect on alleviating depression among caregivers, which is consistent with the findings of previous research [45]. In addition to influencing factors such as the high nursing stress and insufficient social support observed for anxiety, an increased economic burden may also contribute to the onset of depression [42,46]. Despite its potential advantages, telemedicine requires a stable internet connection and available electronic devices. The initial investment cost of such equipment may negatively affect informal caregivers [47]. Furthermore, researchers only offered counseling on disease knowledge and mental and emotional well-being, but not economic and welfare support. Subsequently, factors including a lower baseline depression level in the study population [24], small sample size, and significant differences in intervention measures in various studies may negatively impact the combined results. These findings differ from those of Northouse et al [48], possibly due to variations in the target population. The study by Northouse et al [48] focused on informal caregivers of patients with cancer. In contrast, our research noted higher loss to follow-up rates in the population with advanced diseases, potentially impeding the discovery of beneficial outcomes. Moreover, Northouse et al [48] conducted a self-controlled study, whereas we included RCTs in which conventional palliative care can alleviate depression in informal caregivers [46]. Consequently, the extent to which telemedicine can improve depression is limited.

Quality of Life

This study found that telemedicine does not significantly improve the QOL of informal caregivers of patients in palliative care, which is consistent with the findings of earlier research [25,49]. Most informal caregivers consistently place the needs of patients above their own [50], leading to various unmet supportive care needs, such as physical, psychological, and social needs [6,51], and a subsequent decline in QOL. As QOL is a multidimensional construct, a multidisciplinary intervention is often more effective than single-faceted approaches. However, the majority of studies (3/4, 75%) in this review targeted interventions at the social-psychological level, and the results might not be ideal. Furthermore, the small sample sizes in the included studies and variations in intervention measures may have limited the possibility of revealing meaningful results.

Finally, the effectiveness of intervention measures may further be moderated by other factors such as the characteristics of informal caregivers, preexisting mental health issues, and the caregiver-patient relationship. Therefore, future efforts should aim to devise personalized interventions for specific informal caregiver populations to ensure the best possible support.

Strengths and Limitations

This study meticulously adhered to the systematic review writing process, developed a comprehensive search strategy, and selected appropriate methods for meta-analysis. To enhance the reliability of the results, only RCT studies were included. However, this review also had limitations. First, we only included available data for the analysis. Missing data may impact the combined results of the meta-analysis. Second, some included studies, especially pilot studies, have small sample sizes, which requires a cautious approach to generalizing the results. Third, the inclusion of only English- and Chinese-language articles may lead to publication bias. Last, the included studies all measured the results immediately after intervention, without evaluating the persistence of the intervention effect. Therefore, in the future, large samples and high-quality research are required to further validate the intervention effects of telemedicine and explore the most suitable intervention duration for informal caregivers.

Implications for Practice and Future Research

The findings indicated that telemedicine interventions have beneficial effects on the informal caregivers of patients in palliative care. We recommend that professional palliative care personnel consider the needs of informal caregivers, incorporating telemedicine into care plans to optimize and complement existing health care measures. When implementing such interventions, several considerations arise. First, the needs of informal caregivers are diverse and require multidisciplinary team collaboration. Second, personalized interventions should be tailored based on the demographic characteristics of informal caregivers. Finally, cost-effectiveness should be considered. In this regard, we suggest that relevant organizations establish regulations to minimize health care costs as much as possible.

Moreover, a theoretical or conceptual framework can provide the foundation of interventions, drive their development, and facilitate the prediction and explanation of their mechanism to achieve the desired effect [22]. For example, in the included studies, Badr et al [31] conducted a study based on self-determination theory. The authors hypothesized that telephone-based psychosocial interventions could improve the mental state and burden of patients and informal caregivers. Those results were statistically significant. The study by Pensak et al [35] was based on cognitive behavioral stress management theory and provided stress management training to alleviate informal caregivers' burden. In contrast, studies lacking theoretical support failed to improve patient and informal caregiver outcomes. Therefore, it is recommended that researchers have a relevant theoretical foundation when devising intervention measures to enhance the intervention effect, which will be more likely to benefit informal caregivers.

Conclusion

In summary, telemedicine can alleviate caregiving burden and anxiety in informal caregivers but does not significantly impact their depression and QOL. Despite certain outcomes lacking statistical significance, they retain clinical relevance for those engaged in family palliative care. We believe that support provided through telemedicine represents a viable means to ensure the continuity of care, address the needs of informal caregivers, and foster favorable outcomes. Future studies that involve large samples and high-quality research are still required to further validate the effects of telemedicine. Furthermore, intervention measures should be designed with a solid theoretical basis to the fullest extent.

Acknowledgments

This study was supported by the scientific research project of the Chinese Nursing Association (ZHKY202101). The funder had no role in the study design, data extraction process, data analysis, results interpretation, or manuscript preparation.

Authors' Contributions

Abstract

Background: Despite being the gold-standard method for objectively assessing sleep, polysomnography (PSG) faces several limitations as it is expensive, time-consuming, and labor-intensive; requires various equipment and technical expertise; and is impractical for long-term or in-home use. Consumer wrist-worn wearables are able to monitor sleep parameters and thus could be used as an alternative for PSG. Consequently, wearables gained immense popularity over the past few years, but their accuracy has been a major concern.

Objective: A systematic review of the literature was conducted to appraise the performance of 3 recent-generation wearable devices (Fitbit Charge 4, Garmin Vivosmart 4, and WHOOP) in determining sleep parameters and sleep stages.

Methods: Per the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement, a comprehensive search was conducted using the PubMed, Web of Science, Google Scholar, Scopus, and Embase databases. Eligible publications were those that (1) involved the validity of sleep data of any marketed model of the candidate wearables and (2) used PSG or an ambulatory electroencephalogram monitor as a reference sleep monitoring device. Exclusion criteria were as follows: (1) incorporated a sleep diary or survey method as a reference, (2) review paper, (3) children as participants, and (4) duplicate publication of the same data and findings.

Results: The search yielded 504 candidate articles. After eliminating duplicates and applying the eligibility criteria, 8 articles were included. WHOOP showed the least disagreement relative to PSG and Sleep Profiler for total sleep time (−1.4 min), light sleep (−9.6 min), and deep sleep (−9.3 min) but showed the largest disagreement for rapid eye movement (REM) sleep (21.0 min). Fitbit Charge 4 and Garmin Vivosmart 4 both showed moderate accuracy in assessing sleep stages and total sleep time compared to PSG. Fitbit Charge 4 showed the least disagreement for REM sleep (4.0 min) relative to PSG. Additionally, Fitbit Charge 4 showed higher sensitivities to deep sleep (75%) and REM sleep (86.5%) compared to Garmin Vivosmart 4 and WHOOP.

Conclusions: The findings of this systematic literature review indicate that the devices with higher relative agreement and sensitivities to multistate sleep (ie, Fitbit Charge 4 and WHOOP) seem appropriate for deriving suitable estimates of sleep parameters. However, analyses regarding the multistate categorization of sleep indicate that all devices can benefit from further improvement in the assessment of specific sleep stages. Although providers are continuously developing new versions and variants of wearables, the scientific research on these wearables remains considerably limited. This scarcity in literature not only reduces our ability to draw definitive conclusions but also highlights the need for more targeted research in this domain. Additionally, future research endeavors should strive for standardized protocols including larger sample sizes to enhance the comparability and power of the results across studies.

Introduction

Sleep problems have emerged as a widespread concern with implications on health and quality of life for many people worldwide [1]. It has been suggested that 67% of adults worldwide have sleep problems [2,3]. The amount and quality of sleep that someone enjoys have a lasting impact during wakefulness. It affects mental health; physical well-being; and even the risk of developing lifestyle diseases such as cardiovascular diseases, obesity, depression, and type 2 diabetes [4-7]. Considering that sleep is vital to our health and quality of life, it is reasonable to wonder how long someone actually sleeps each night and if someone is getting enough restful and restorative sleep to keep the body and mind in optimal condition. Hence, this is why sleep tracking has gained immense popularity over the past few years. The majority of sleep trackers provide data on sleep architecture and hypnograms through their associated apps, offering insights into sleep stages and patterns [8]. In addition, these wearables can notify you about specific factors that might be affecting your sleep patterns such as drinking water, exercise, meditation, and regular bedtimes. As such, they can be a useful tool to obtain more insights into sleeping habits and patterns and to help optimize your sleep hygiene and quality. However, to improve sleep, an accurate, objective measurement is mandatory.

Polysomnography (PSG) is the gold-standard method for objectively assessing sleep. PSG records signals of brain activity, eye movements, and muscle tone, as well as audio and video, enabling it to classify sleep stages [9]. However, PSG may not be ideal for monitoring sleep in particular settings, as it is expensive, labor-intensive, and time-consuming; requires various equipment and technical expertise; and is impractical for long-term use or in-home environment settings [10,11]. PSG involves real-time monitoring of various parameters. In addition, applying and removing the sensors, organizing the patient administration, and thoroughly analyzing the data that PSG add is quite labor-intensive for sleep technicians. In addition to applying and removing the sensors and possibly completing questionnaires and other administrative tasks, PSG requires an overnight stay at a sleep clinic or laboratory, which makes PSG time-consuming for both the sleep technicians and patients. Due to the inherent limitations of PSG, several alternatives have been proposed. First, the use of sleep diaries is inexpensive and straightforward for consumers, but the subjective self-ratings they require result in frequent inaccuracies and incompleteness [12]. Additionally, they fail to measure sleep architecture and stages. Second, electroencephalogram (EEG) wearables can provide a home evaluation of sleep architecture and stages; however, they come with a high cost and can be technologically complex [12]. Therefore, wearables using an accelerometer and photoplethysmography (PPG) are being explored as a feasible alternative, largely due to their lower cost, convenience, and ability to measure sleep in clinical and personal settings [13].

Accelerometers and PPG sensors monitor different physiological and movement patterns throughout the night. Accelerometers are small, electromechanical devices that measure acceleration along multiple axes (usually 3: x, y, and z) to detect position changes, turning over, or significant body movements during the night [14]. Due to the body movement variations specific to each sleep stage, accelerometers can provide information about wakefulness and general sleep stages. However, they may tend to overestimate sleep due to poorly distinguishing between sleep and sedentary supine wake periods (eg, lying down while reading or watching television), or they could underestimate sleep due to potential body movements during sleep being categorized as awakenings [12,15-18]. In addition, they may not be as accurate in distinguishing between different non–rapid eye movement (REM) stages and detecting subtle changes in sleep architecture [14]. By combining an accelerometer with a PPG sensor in wearables, a more comprehensive and accurate assessment of sleep could be provided. PPG sensors are a noninvasive technology that uses a light source and a photodetector at the surface of the skin to measure the volumetric variations of blood circulation and thus can be used to monitor heart rate, heart rate variability, blood flow, and blood oxygen levels [19-21]. Due to the specific cardiovascular features of each sleep stage, PPG can provide more information about the sleep stages in addition to the accelerometer [21,22]. The benefits of these sensors used in wearables are their low-cost, noninvasive nature and their ability to provide continuous monitoring and real-time data. However, the readings of PPG can be affected by motion artifacts, skin pigmentation, or tissue thickness. In addition, they could be susceptible to environmental factors such as ambient light and temperature [23-25].

Although many have doubts about their accuracy in monitoring sleep, wearable sleep-tracking devices are widely used and becoming more technologically advanced, creating strong interest from researchers and clinicians for their possible use as alternatives to PSG. This was demonstrated by Nguyen et al [26], who used wearables that provide inactivity alerts and personal feedback to increase physical activity and improve sleep for survivors of breast cancer [26].

Given the disadvantages of PSG and the corresponding growing popularity of wearable devices for sleep tracking among consumers and medical organizations, the objective of this paper was to appraise the performance of recent-generation wearable devices in determining sleep parameters and sleep stages through a review of relevant publications. To limit the overwhelming amount of wearables and their corresponding research papers, we performed a search to select a limited number of recent, frequently used wearables, using the following criteria: recent generation; good ease of use (affordable, unobtrusive, and sufficient battery life); and assessment of variables that could also be used for monitoring sleep, stress, fatigue, and sleepiness—namely, heart rate, heart rate variability, stress indicator, and activity. The candidate wearables selected up-front were Fitbit Charge 4, Garmin Vivosmart 4, and WHOOP.

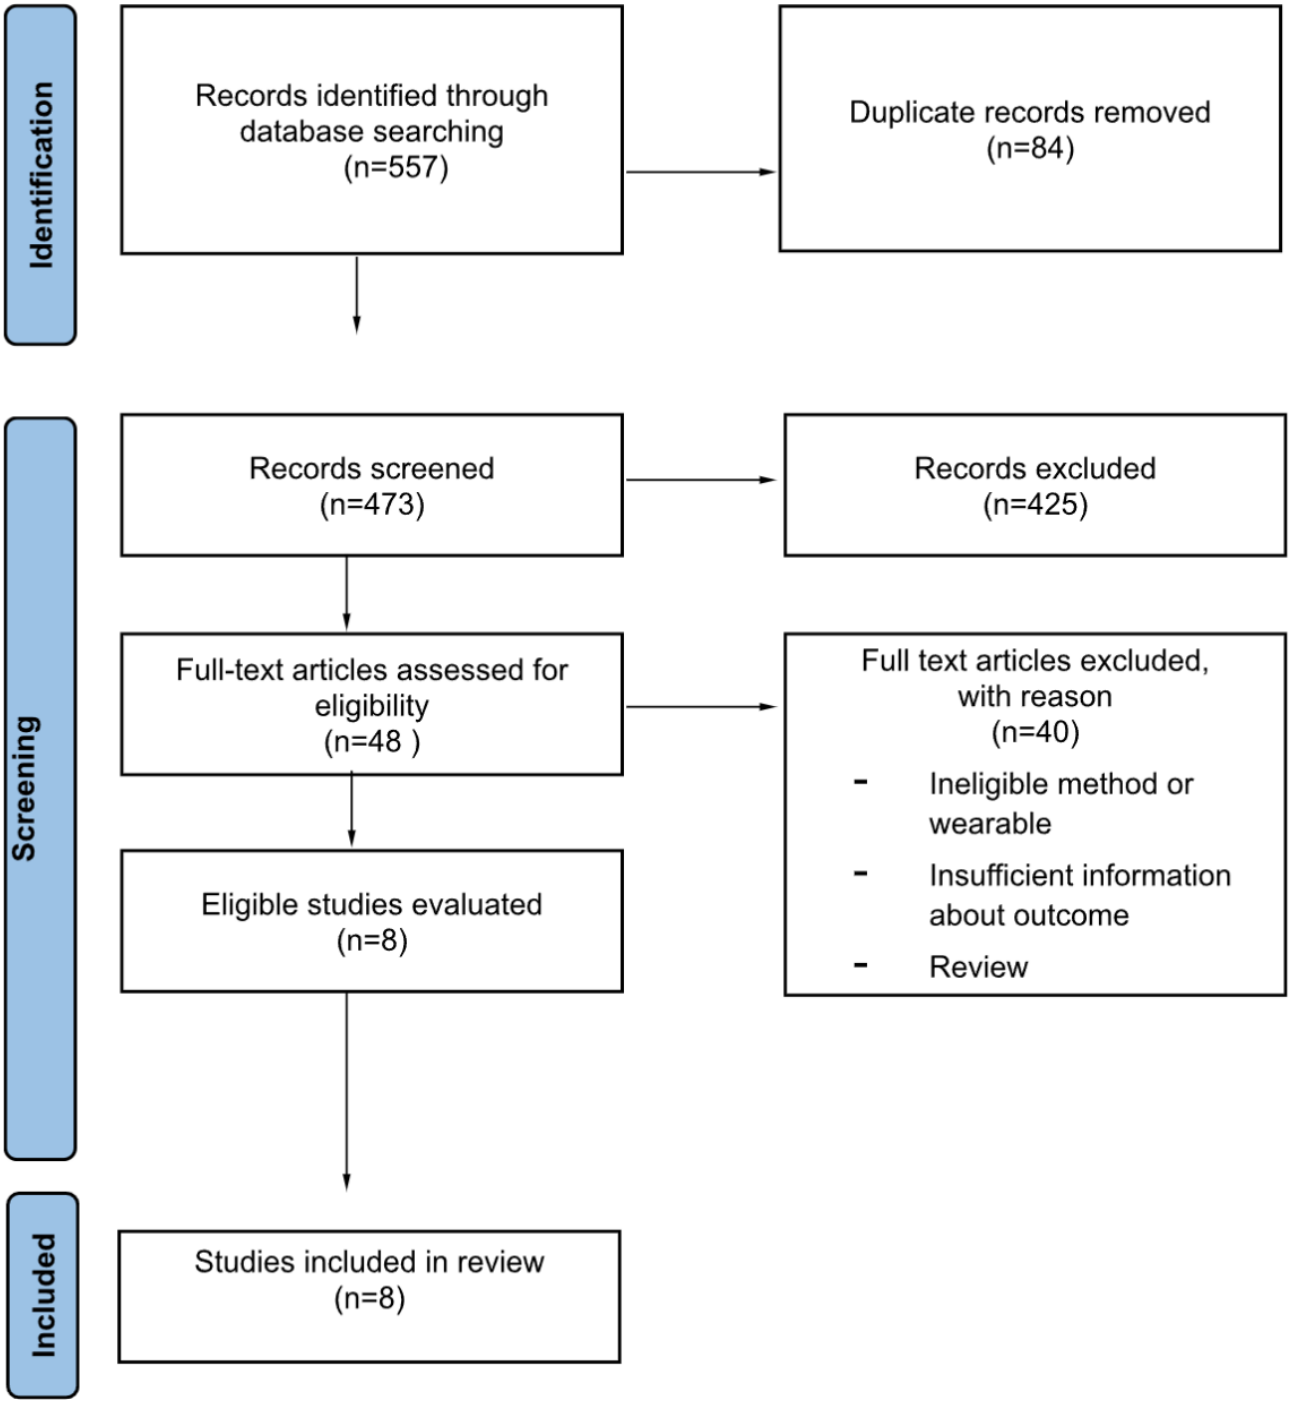
Methods

Search Strategies

In adherence with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement (Checklist 1), a comprehensive search using the PubMed, Web of Science, Google Scholar, Scopus, and Embase databases was conducted

[27]. Relevant keywords such as "validity," "accuracy," "assessment," "performance," "wearable," "sleep tracker," "sleep-tracking," "polysomnography," "wristband," "Whoop," "Fitbit Charge 4," and "Garmin Vivosmart 4" were used (see Multimedia Appendix 1). This search was initially completed by May 16, 2023, and was repeated by November 23, 2023 (see Figure 1). This systematic literature review was not registered and a protocol was not predefined.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram describing the search strategy of databases to retrieve and qualify publications of relevance for this systematic literature review.



Eligibility Criteria

Retrieved publications qualified for the review if they (1) involved the validity of sleep data of any marketed model of the candidate wearables and (2) incorporated PSG or an ambulatory EEG monitor as a reference sleep monitoring device. Exclusion criteria were as follows: (1) incorporated a sleep diary or survey method as a reference, (2) review paper, (3) children as participants, and (4) duplicate publication of the same data and findings.

Data Extraction

The following items were extracted: type of sleep tracker; number, gender, and age of participants; number of nights of sleep assessment; reference sleep monitoring device; and study outcomes relative to the denoted reference standard—the

precision of measuring the parameters of total sleep time (TST), light sleep (LS), deep sleep (DS), and REM sleep, as well as the sensitivity to sleep (the proportion of correctly classified sleep epochs by the wearable); specificity for sleep (the proportion of correctly classified wake epochs by the wearable); agreement; and if applicable, Cohen κ for multistate categorization of sleep periods. These Cohen κ values are a measure of interdevice reliability, often used in the context of validation studies where 2 or more methods of devices are used to assess a particular characteristic or condition [28]. In the case of wearable validation studies for sleep, κ values are often used to assess the agreement between the wearable device's sleep detection algorithm and a reference standard, such as PSG. In addition to the observed agreement between the devices, κ values also take into account the possibility that the agreement comes by chance. The interpretation of κ values is often categorized as follows: values ≤0 indicate no agreement, 0.01-0.20 indicate none to slight agreement, 0.21-0.40 indicate fair agreement, 0.41-0.60 indicate moderate agreement, 0.61-0.80 indicate substantial agreement, and 0.81-1.00 indicate almost perfect agreement [28].

Results

Overview of Included Studies

Figure 1 presents a visual summary of the selection and qualification of articles for this review. A total of 8 publications were retrieved through a search of databases performed by May 2023 and again by November 2023. Table 1 presents an overview of all included studies and the extracted details of each qualifying study involving the different wearable models. Few papers that met the eligibility criteria for the candidate wearables were found; we found 3 papers that satisfy the criteria for Fitbit Charge 4 [28-30], 2 for Garmin Vivosmart 4 [27,28], and 4 for WHOOP [22,30-32].

Table . Summary table of included papers in this systematic literature review.

Author (year)	Wearable	Reference	Participants, n	Sex, n	Age (y), mean (SD)	Duration
Doheny et al [33] (2021)	Fitbit Charge 4	PSG[a]	2	• N/A[b]	N/A	1 night, laboratory based; followed by 7 nights at home
Renerts et al [34] (2022)	Fitbit Charge 4	PSG	8	• N/A	N/A	1 night, laboratory based
Dong et al [18] (2022)	Fitbit Charge 4	PSG	37	• Female: 20 • Male: 17	48.8 (2.1)	1 night, laboratory based
Mouritzen et al [29] (2020)	Garmin Vivosmart 4	PSG	18	• Female: 13 • Male: 5	56.1 (12.0)	1 night, laboratory based
Stone et al [30] (2020)	Garmin Vivosmart 4 and WHOOP	Sleep Profiler (ambulatory EEG[c] monitor)	5	• Female: 3 • Male: 2	27.8 (7.6)	Home environment, 98 nights for all study devices
Miller et al [31] (2020)	WHOOP	PSG	12	• Female: 6 • Male: 6	22.9 (3.4)	10 days, laboratory based
Miller et al [32] (2021)	WHOOP	PSG	6	• Female: 3 • Male: 3	23.0 (2.2)	9 nights, laboratory based
Miller et al [22] (2022)	WHOOP	PSG	53	• Male: 27 • Female: 26	25.4 (5.9)	1 night, laboratory based

[a]PSG: polysomnography.

[b]N/A: not applicable.

[c]EEG: electroencephalogram.

Participants were diverse: healthy adults as well as participants diagnosed with Huntington disease [33,34] and chronic insomnia [18]. Sample size varied substantially between investigations, from 2 to 53 participants. The average age of the participants was 34 years old. Out of the 8 studies, 6 (75%) were fully conducted in a sleep laboratory [18,22,29,31,32,34], 1 (12%) was conducted in the home environment [30], and 1 (12%) conducted an overnight laboratory-based PSG followed by 7 nights in the home environment [33]. In all, 3 (38%) laboratory-based studies had a duration of more than 1 night [30-32].

Comparison of Sleep Parameters Assessed by Wearables Versus PSG

Fitbit Charge 4

As shown in Table 2, of the 3 Fitbit Charge 4 versus PSG comparisons, 2 (67%) reported an overestimation of TST (5 and 23 minutes), whereas 1 (33%) reported a nonsignificant underestimation of 11 minutes. For LS, 2 (67%) of the 3 comparisons reported a similar significant overestimation (37.5 and 37.7 minutes). For DS, all 3 papers reported an underestimation (4.1, 12.5, and 41.4 minutes). REM sleep was

overestimated in 2 (67%) out of 3 papers by 5.2 and 11.5 minutes and underestimated in 1 (33%) paper by 4.7 minutes. Table 3 shows the results for the sensitivity to and specificity for sleep. The sensitivity to sleep was quite high for all 3 papers (89.9%-93.6%). In contrast, the results for specificity for sleep were quite divergent (48.8%, 62.2%, and 73%). The sensitivities to DS and REM sleep could only be extracted from 2 papers: 54% and 96% for DS and 76% and 97% for REM sleep.

Garmin Vivosmart 4

Both papers comparing Garmin Vivosmart 4 to PSG or Sleep Profiler reported an overestimation of TST (27.8 and 66 minutes), as shown in Table 2. For LS, both papers again reported an overestimation (19.8 and 36.5 minutes). For DS, both papers reported an overestimation (13.4 and 33.6 minutes). On the contrary, REM sleep was underestimated by both papers by 3 and 22.1 minutes. The study from Mouritzen et al [29] reported sensitivities to LS, DS, and REM sleep of 60%, 45%, and 34%, respectively; a sensitivity to sleep of 98%; a specificity for sleep of 30%; an agreement of 48%; and a Cohen κ for multistate categorization of sleep periods of 0.20 (see Table 3).

WHOOP

As shown in Table 2, of the 4 WHOOP versus PSG comparisons, 2 (50%) reported an overestimation of TST (8.2 and 16.2 minutes), whereas the other 2 (50%) reported an underestimation (12.2 and 17.8 minutes). All 4 comparisons reported an underestimation of LS, from 3.7 to 15.6 minutes. For DS, 3 (75%) papers reported an underestimation (3.7, 15.5, and 19.6 minutes). Stone et al [30] reported a small overestimation of DS of 1.8 minutes. REM sleep was overestimated in all 4 studies, from 6 to 22.9 minutes. Table 3 shows that the studies from Miller et al [22,31,32] reported sensitivities to LS, DS, and REM sleep ranging from 58% to 62%, from 62% to 68%, and from 66% to 70%, respectively. The studies also reported a sensitivity to sleep ranging from 90% to 95%, a specificity for sleep ranging from 51% to 60%, an agreement ranging from 60% to 64%, and a Cohen κ for multistate categorization of sleep periods ranging from 0.44 to 0.47.

Comparison of the Mean Values of the Different Wearables

From Tables 2 and 3, the means of the different values extracted from the papers (ie, TST, LS, DS, REM sleep, sensitivity to sleep, specificity for sleep, sensitivity to LS, sensitivity to DS, sensitivity to REM sleep, agreement, and Cohen κ coefficient) were calculated, which are summarized in Table 4. Altogether, WHOOP deviated the least compared to the gold-standard PSG for TST, LS, and DP but showed the highest difference from PSG for REM sleep (ie, a mean overestimation of 21 min).

Table . Mean differences of the sleep parameters in minutes and means of sensitivities to sleep, specificity for sleep, and agreement assessed by the wearables compared to polysomnography.

Variable	Fitbit Charge 4	Garmin Vivosmart 4	WHOOP
TST[a] (min)	5.7	46.9	−1.4
LS[b] (min)	37.6	27.9	−9.6
DS[c] (min)	−19.2	23.5	−9.3
REM[d] sleep (min)	4.0	−12.5	21.0
Sensitivity to sleep (%)	91.2	98.0	91.7
Sensitivity to LS (%)	N/A[e]	60.0	60.0
Sensitivity to DS (%)	75.0	45.0	65.0
Sensitivity to REM sleep (%)	86.5	34.0	67.0
Specificity for sleep (%)	61.3	30.0	55.7
Agreement (%)	N/A	48	62
Cohen κ	N/A	0.20	0.46
Papers, n	3	2	4

[a]TST: total sleep time.

[b]LS: light sleep.

[c]DS: deep sleep.

[d]REM: rapid eye movement.

[e]N/A: not applicable.

Garmin Vivosmart 4 showed the largest deviations out of the 3 different wearables compared to PSG (ie, a mean overestimation of 46.9 minutes for TST, a mean overestimation of 27.9 minutes for LS, a mean overestimation of 23.5 minutes for DS, and a mean underestimation of 12.5 minutes for REM sleep). Additionally, the sensitivities to LS, DS, and REM sleep were lower compared to those of Fitbit Charge 4 and WHOOP.

The mean values of Fitbit Charge 4 deviated the least from PSG for REM sleep, with a mean overestimation of only 4 minutes. On the contrary, it showed the largest deviation to PSG for LS, with a mean overestimation of 37.6 minutes. For TST and DS, Fitbit Charge 4 showed on average better results than Garmin Vivosmart 4 but worse results than WHOOP, namely, a mean overestimation of 5.7 minutes and a mean underestimation of 19.2 minutes, respectively. The sensitivities to LS, DS, and REM sleep were higher compared to those of Garmin Vivosmart 4 and WHOOP.

Discussion

PSG is still the gold-standard method to objectively assess sleep. However, PSG is not ideal for monitoring sleep in particular settings and for long-term follow-up. To overcome these limitations, consumer sleep-tracking devices are becoming more widely used and technologically advanced, creating strong interest from researchers and clinicians for their possible application as alternatives to PSG. Since limited research has been performed to validate the different consumer sleep-tracking wearables, we aimed to review the available literature on the selected wearables to determine the most accurate, commercially available wrist-worn device that can be used in a clinical setting for long-term sleep monitoring.

Thus far, at most, only 7 relevant studies investigated the performance of Fitbit Charge 4, Garmin Vivosmart 4, and WHOOP against PSG. The study of Stone et al [30] investigated the performance of both Garmin Vivosmart 4 and WHOOP relative to Sleep Profiler. After reviewing these studies, the results suggest that WHOOP presented the least amount of disagreement relative to PSG and Sleep Profiler for TST, LS, and DS but showed the largest amount of disagreement for REM sleep. Fitbit Charge 4 and Garmin Vivosmart 4 both showed moderate accuracy in assessing sleep stages and TST compared to PSG. Fitbit Charge 4 showed the least amount of disagreement for REM sleep relative to PSG. In addition, Fitbit Charge 4 showed higher sensitivities for LS, DS, and REM sleep compared to Garmin Vivosmart 4 and WHOOP. Garmin Vivosmart 4 showed the lowest sensitivities to LS, DS, and REM sleep compared to Fitbit Charge 4 and WHOOP.

Some of the studies performed evaluations of the accuracy of wearables in detecting sleep by using an epoch-by-epoch analysis. It involves breaking down the continuous stream of sleep data of PSG into discrete time intervals called “epochs” [35]. Afterward, each epoch is compared individually to the corresponding epoch generated by the wearables. The results of the epoch-by-epoch analysis in this review showed high sensitivity to sleep, ranging from 91.2% to 98.0%, but lower specificity for sleep, ranging from 30% to 61%. The low specificity for sleep, or variability in specificity for sleep, is a commonly observed phenomenon in the validation of devices that primarily rely on actigraphy to estimate sleep [15,36,37].

The challenge of accurately separating wake episodes during sleep stems from the similarities in movement between restful wakefulness and sleep. Hence, it can be inferred that devices that have improved their ability to detect wake epochs during sleep have refined their proprietary algorithms to include metrics other than movement, such as heart rate and heart rate variability, in the detection of wakefulness [22].

Furthermore, it is crucial to contextualize the comparison of the wearables' agreement with that of PSG (see Multimedia Appendix 2), taking into consideration that the scoring of PSG is subject to variability among technicians [38]. As reported by Danker-Hopfe et al [39], the interrater reliability ranges from 86.5% to 97.5% depending on the sleep stage, with an overall accuracy of 81% and a Cohen κ coefficient of 0.7505 (see Table 5). Given this benchmark, Fitbit Charge 4 seems to provide reasonable estimations of multistate sleep. However, it is imperative to acknowledge that achieving the same level of accuracy as PSG may pose a significant challenge for wearables, particularly considering the observed low Cohen κ coefficients of the wearables. The finding of a low κ value indicates poor sleep stage differentiation despite including PPG signals. However, the beneficial role of PPG signals in accelerometer-based sleep tracking remains unilluminated, since we do not know how these signals are processed and applied [29].

Table . Sleep stage–specific degree of agreement according to American Academy of Sleep Medicine standards [38].

Stage	Agreement (%)	Cohen κ
Overall	81	0.7505
Wake	95.6	0.4608
REM[a]	97.5	0.9054
N3[b]	93.8	0.7285
N2[c]	86.5	0.7188
N1[d]	90.1	0.4608

[a]REM: rapid eye movement.

[b]N3: stage 3 non-REM sleep.

[c]N2: stage 2 non-REM sleep.

[d]N1: stage 1 non-REM sleep.

On a similar note, companies usually do not share the methodology they use to score the sleep data from the wearables, nor do they publish the kind of rigorous research sleep experts need to establish the credibility of the sleep reports they produce.

The findings of this systematic literature review about Fitbit Charge 4, Garmin Vivosmart 4, and WHOOP are based on our recent comprehensive search of databases for relevant published articles. The included research studies have certain limitations. For example, several investigations evaluating the sleep-tracking capabilities of these wearables involved a relatively limited number of participants, potentially impacting the generalizability of the results. Efforts were made to get additional information about the sample sizes and participants directly from the authors of some included studies. Unfortunately, despite our attempts to contact the authors, we did not receive a response. It is crucial to address these issues transparently, as they may impact the generalizability of our findings. Small sample sizes can introduce variability and limit the statistical power of the findings, underscoring the need for larger and more diverse cohorts to validate the devices' accuracy across different demographics and sleep conditions. Additionally, it is essential to consider that most of the studies have been conducted in controlled environments, namely sleep laboratories. Although this controlled setting allows for precise data collection and monitoring, it may not fully reflect the real-world sleep experiences of individuals in their natural environments [40]. Sleep laboratory conditions may differ substantially from home environments, where factors such as ambient light, noise, and personal sleep habits can vary widely [41]. Therefore, the generalizability of the findings from laboratory studies to everyday scenarios should be approached with caution. In addition to acknowledging the potential limitations associated with conducting studies in controlled sleep laboratory environments, it is important to recognize the presence of the "first-night effect" in both PSG and wearable sleep-tracking technologies. The first-night effect refers to the phenomenon where an individual's sleep patterns and quality may be altered due to the unfamiliarity with the sleep-monitoring setup, regardless of whether it occurs in a sleep laboratory or at home [42,43]. This phenomenon is not exclusive to sleep laboratories as it extends to home environments where individuals may experience similar disruptions during the initial adaptation to sleep-tracking devices [44,45]. Although some wearable users may initially find it uncomfortable or unfamiliar to wear a device on their wrist while sleeping, which could potentially impact their sleep quality on the first night of use, there is not a widely recognized first-night effect associated with the use of wrist-worn wearables [46]. In addition, the data of PSG and wearables were collected each time under the same circumstances and environmental factors either in a sleep laboratory or in the home environment, making the first-night effect less relevant. Another notable aspect of the studies is the variations in the duration of the validation of the wearables. The diverse durations across studies are likely due to practical constraints or differences in research protocols. Our decision to include studies with varying protocols was motivated by the aim to include as many relevant papers as possible in our

comprehensive review, considering the scarcity of literature on this topic. Future research endeavors should strive for standardized protocols including larger sample sizes to enhance the comparability and power of the results across studies.

Despite these limitations, the findings of this review indicate that the devices with higher relative agreement and sensitivities for multistate sleep (ie, Fitbit Charge 4 and WHOOP) seem appropriate for deriving suitable estimates of sleep parameters and could be used to monitor sustained, meaningful changes in sleep architecture (ie, time spent in different stages of sleep). However, analyses regarding the multistate categorization of sleep (as a specific sleep stage or wake) indicate that all devices can benefit from further improvement. Providers are continuously developing new versions and variants of wearables, which present difficulties for those undertaking independent validation studies. Nevertheless, it can be reasonably assumed that newer models from the same provider will perform at least as well, if not better, than older models when compared against the relevant gold standards [22]. However, although the wearable technology market keeps developing wearable devices, the scientific research on these wearables against PSG remains considerably limited. This scarcity in literature not only reduces our ability to draw definitive conclusions but also highlights the need for more targeted research in this domain. Therefore, the data presented here should not be considered obsolete when the models analyzed are superseded by newer models. Instead, these data should serve as the best approximation of the expected performance of any subsequent models that may be released.

Authors' Contributions

AMS and JV conceptualized and designed the structure of this systematic literature review, outlining the key themes and objectives. AMS conducted an extensive literature review, critically analyzed relevant studies, and synthesized the information to provide a comprehensive overview. AMS, NCVO, JMA, FM, BP, AN, HD, VR, GW, and JV actively participated in the review's writing and revision processes. The collaborative effort of the consortium resulted in a comprehensive and well-balanced review. Each author has approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: New interventions based on motor learning principles and neural plasticity have been tested among patients with ataxia and hemiparesis. Therapies of pedaling exercises have also shown their potential to induce improvements in muscle activity, strength, and balance. Virtual reality (VR) has been demonstrated as an effective tool for improving the adherence to physical therapy, but it is still undetermined if it promotes greater improvements than conventional therapy.

Objective: Our objective was to compare the effect on lower limb range of motion (ROM) when using VR technology for cycling exercise versus not using VR technology.

Methods: A randomized controlled trial with 20 patients with ataxia and hemiparesis was carried out. The participants were divided into 2 groups: the experimental group (n=10, 50%) performed pedaling exercises using the VR system and the control group (n=10, 50%) performed pedaling exercises without using VR. Measurements of the active and passive ROM of the hip and knee joint were taken before and after a cycling intervention, which consisted of 3 sessions of the same duration but with progressively increasing speeds (4, 5, and 6 km/h). Repeated measures ANOVAs were conducted to compare the preintervention (T_i) and postintervention (T_e) assessments within each group. Additionally, the improvement effect of using the VR system was analyzed by comparing the variation coefficient ($\Delta = 1 - [T_e / T_i]$) between the preintervention and postintervention assessments for each group. Group comparisons were made using independent 1-tailed *t* tests.

Results: Significant improvements were shown in active left hip flexion (*P*=.03) over time, but there was no group-time interaction effect (*P*=.67). Passive left hip flexion (*P*=.93) did not show significant improvements, and similar results were observed for active and passive right hip flexion (*P*=.39 and *P*=.83, respectively). Neither assessments of knee flexion (active left: *P*=.06; passive left: *P*=.76; active right: *P*=.34; passive right: *P*=.06) nor knee extension showed significant changes (active left: *P*=.66; passive left: *P*=.92; active right: *P*=.12; passive right: *P*=.38). However, passive right knee extension (*P*=.04) showed a significant improvement over time. Overall, although active and passive ROM of the knee and hip joints showed a general improvement, no statistically significant differences were found between the groups.

Conclusions: In this study, participants who underwent the cycling intervention using the VR system showed similar improvement in lower limb ROM to the participants who underwent conventional training. Ultimately, the VR system can be used to engage participants in physical activity.

Introduction

Background

Ataxia is an umbrella term for describing deficits in limb movement coordination such as dysmetria, dyspraxia, and dyssynergia [1]. The persistence of these deficits affects an individual's functional ability and poses a health challenge for both patients and clinicians.

Current scientific evidence indicates that the most effective treatment for ataxia should combine balance and coordination retraining and constraint-induced functional movement therapy [2]. However, the scientific literature still lacks a consensus on the details of these interventions and the timing of their implementation to enhance the recovery of the functionality of motor deficits in an individual [3].

On the other hand, in the field of neurophysiology, it is well known that to induce changes in neuroplasticity to achieve the functional recovery of motor deficits, the application of therapies based on the repetition of movements is required [4]. Some studies point out that the principles of motor learning are directly related to the regeneration of structures and the reorganization of neuronal function [5,6]. Moreover, the amount of practice is a key factor in motor learning, as well as the feedback provided during practice [7]. In fact, physical therapists must consider both the error feedback and activity guidance as 2 fundamental components of patient interaction during therapy to promote neuromotor learning [8]. Thus, interventions that promote normal function rather than the compensation of deficits are more recommended and should be applied to generate a physical activity plan based on the principles of motor learning and neural plasticity for patients with ataxic hemiparesis.

Prior Work

The scientific literature in the field of neurorehabilitation shows that pedaling exercises have the potential to induce improvements in muscle activity, strength, and balance [9]. This is mainly due to the fact that pedaling exercises based on the use of a cycloergometer provide a high number of flexion and extension repetitions [10] in the lower extremities for considerable periods of time. Because pedaling and walking are cyclical locomotor tasks that require the lower limb to alternate between flexion and extension [11,12], both share similar locomotor patterns of alternating muscle activation of antagonists [10,13]. Thus, cycling exercises are found to be useful for strengthening the lower limb muscles while acting as a pseudowalking task-oriented exercise. Some studies eluded that those biomechanical functions may be altered by the muscle groups involved in the pedaling tasks [14-16]. In fact, it was found that the degradation of pedaling performance in adults with hemiparesis was related to abnormalities in the execution of specific biomechanical functions [15]. Subsequently, it has been proven that human walking and cycling shared similar muscle synergies [16]. This evidence is the basis for rehabilitation treatments based on pedaling movements with potential positive outcomes for walking [16].

The ergometer is an equipment designed to perform cardiovascular work based on the alternative circular movement of the lower limb. Its use is advantageous for a muscle coordination study because balance is not an applicable factor in this kinematically constrained task [13]. In fact, applying an ergometer-based cycling routine could be useful because it requires no balance. Moreover, the exercise intensity of the ergometer-based cycling can be adapted to the user by adjusting the resistance of the pedal or the target speed. The ability to personalize the intensity of the exercise is a relevant factor for the patient's rehabilitation process. For these reasons, regular ergometer-based cycling is found to be a safer unsupervised exercise that is recommended for lower limb rehabilitation. Nevertheless, cycling exercise is also a static and repetitive form of exercise that leads to boredom and listlessness in patients. To deal with this discouragement factor, emerging technologies have been applied to elicit intrinsic motivation for rehabilitation patients [17]. Several studies pointed out the usefulness of gaming elements and virtual environments as assistive technology [18,19] and their potential effectiveness in physical therapies as opposed to conventional therapies [20].

Quite a few studies have focused on the analysis of functional metrics in virtual pedaling. A recent study evaluated the functionality of a virtual reality (VR) cycling training program that was applied to 10 patients with stroke [21]. It assessed the improvement of the bilateral asymmetry between the experimental group and the control group after the VR cycling intervention program. To evaluate this index, they equipped the ergometer pedals with force plates to determine the effect of the VR cycling training on each limb. The improvement of bilateral strength and standing balance was significantly different between VR cycling training and traditional physical training. Similarly, a previous study compared the effects of a cycling training program with extrinsic biofeedback and a nonimmersive interface versus traditional physical training on lower limb functional recovery in patients with stroke [22]. The results showed that improvements in walking endurance, walking speed, and muscle spasticity of the group using VR were significantly better than the group who underwent traditional physical training.

Objectives

The main objective of this study was to evaluate 2 different interventions: pedaling with VR and pedaling without VR. This study focused on comparing the improvements in lower limb range of motion (ROM) in pedaling activity between the group using VR and the group not using VR. To this end, a randomized controlled trial was carried out with patients with ataxia and hemiparesis. Hip and knee ROMs were measured before and after the cycling intervention. The overall aim of these analyses was to determine the effects of the 2 different interventions on short-term improvement of lower limb function and ROM.

Methods

VR System

The VR system implements extrinsic feedback strategies, gamification by levels, and personalization of the sessions with the aim of achieving greater adherence to pedaling exercise sessions. Its immersive nature means an increase in the sense of "presence," promoting the active involvement of the user.

The VR system is based on the transmission of the cycling kinematic data captured by the inertial sensors to the Oculus Quest 2 (Meta) head-mounted display (HMD) via Bluetooth. Therefore, the virtual application estimates the pedaling cycles, cadence, and distance during the exercise activity. The VR scenarios generated for this therapy consist of mapping the cycling cadence to the vehicle speed. Thus, the patient is placed inside a vehicle and visualizes the session data on the control panel while moving at the speed of the pedaling motion.

The design of the VR experience has been technically validated computationally to ensure low latency in motion analysis and visual representation of motion [23], thus preserving the embodiment effect and the sense of presence. Subsequently, the platform has also been validated from the point of view of satisfaction and ease of use of the system [24]. Additionally, considering that it is a stationary experience with an HMD that simulates a displacement, we evaluated to which extent the VR experience generates the type of motion sickness that causes fatigue, nausea, disorientation, postural instability, or visual fatigue [25]. Indeed, we verified that the platform does not generate adverse effects due to cybersickness [24].

Recruitment

The participants were patients of both sexes between 18 and 90 years of age, recruited at the Lescer Clinic applying the inclusion and exclusion criteria. Inclusion criteria were as follows: individuals were eligible if they (1) had been prescribed pedaling exercise as treatment for lower limb rehabilitation and (2) were able to perform a pedaling session with VR technology. Exclusion criteria were as follows: (1) an insufficient cognitive state, (2) an unbound bone fracture, (3) severe disorders of vision or audition (inability to perceive visual or auditory information coming from VR), and (4) any incompatibility with the use of a VR system according to the clinical record. A sample of 22 participants (n=13, 59% male and n=7, 32% female; mean age 59.90, SD 13.56 y) volunteered to participate in this pilot randomized controlled trial (Table 1). Of this 22-person cohort, 1 participant dropped out of the study and 1 participant did not complete the study (Figure 1). The cohort was randomly divided into the experimental group (EG; 9/10, 90% male and 1/10, 10% female; mean age 60.80, SD 12.26 y) with VR cycling exercises or the control group (CG; 4/10, 40% male and 6/10, 60% female; mean age 59.00, SD 14.69 y) with traditional cycling exercises.

Table . Clinical and epidemiological features of the experimental group (EG) and control group (CG) participants.

Group and participant number	Sex	Age (y)	Etiology	Condition
EG				
1	Male	57	Ischemic stroke	Hemiparesis
2	Male	71	Hemorrhagic stroke	Ataxia
3	Male	53	Hemorrhagic stroke	Ataxia
4	Male	72	MCA[a] stroke	Hemiparesis

Ethical Considerations

Ethical approval was obtained from the Research Ethics Committee of the San Pablo CEU University (550/21/51). This study has been registered at ClinicalTrials.gov (NCT05162040). All the participants were given written information in accordance with the Research Ethics Committee. The informed consent and the ability for participants to opt out was provided. Additionally, participants were informed that the data collected in this study can only be used for this study, not for secondary studies. The approval of the Research Ethics Committee of San Pablo CEU University only covers this study and does not cover a secondary analysis without additional consent. However, no additional analysis had been carried out.

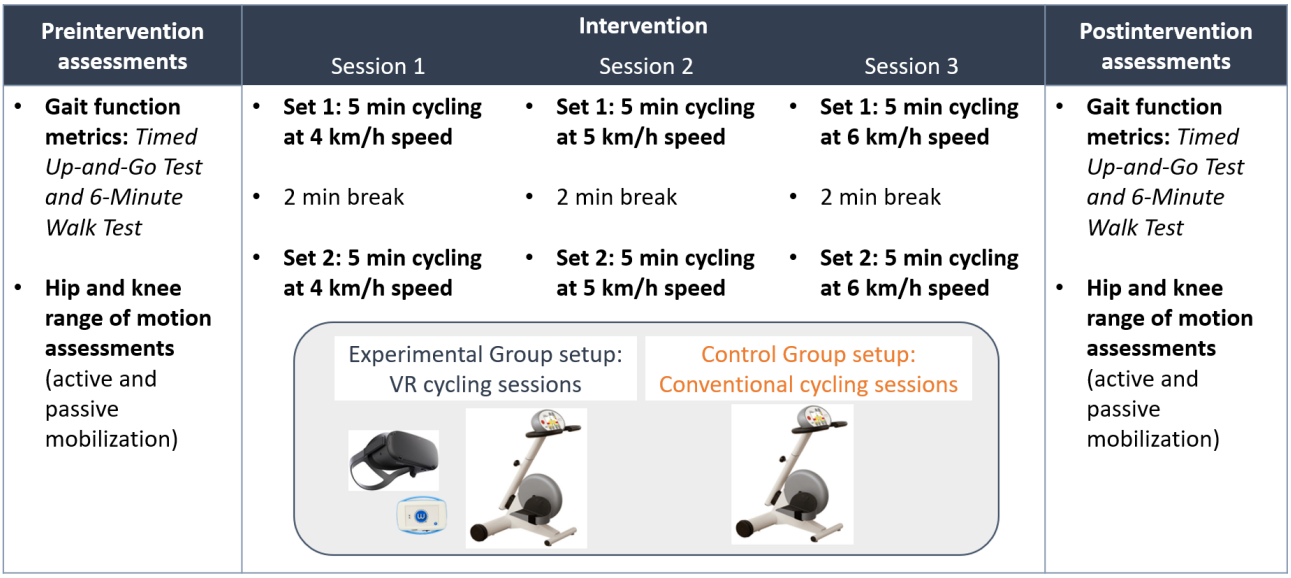
To ensure privacy and confidentiality, data are collected by employees of the agencies participating in the study. Each participant is assigned a unique code along with personal sociodemographic data and informed consent. These files remain in the custody of the principal investigator in charge of the project, while the assigned number is the one that identifies the anonymized data that was later analyzed. Finally, the participation in this study is completely voluntary; no compensation of any nature is offered to the human participants.

Intervention

This study was designed as a randomized controlled trial with 20 participants divided into 2 groups, following a block randomization method. The participants of the EG (n=10) performed pedaling exercises while using the VR system, whereas the participants of the CG (n=10) performed pedaling exercises without using the VR system. Before and after completing the exercise program, measurements of gait function metrics and joint ranges were performed to assess the effect of using VR stimulus during the cycling exercises.

The participants completed the cycling intervention simultaneously with their rehabilitation sessions. Afterward, for each participant, 3 cycling sessions were scheduled over 1 week with a maximum of 48 hours between sessions. Each session consisted of 2 sets of a 5-minute pedaling exercise spaced with a 2-minute break (to rest). Similar studies [19,26] have tested robotic unicycles in pedaling sessions at a cadence of 60 revolutions per minute. In our case, the pedaling speed of 1 cycle per second is equivalent to a target speed of 6 km/h. For this reason, it was decided to set this speed as the maximum speed and to start the first session with a slightly more comfortable speed (4 km/h) and increase it progressively (Figure 2). The participants of both groups performed the exercise following a set pedaling speed so that they received visual feedback according to the set target speed of 4-6 km/h for each session. The EG participants received visual feedback through the immersive VR application, whereas the CG participants received visual feedback on the ergometer display. All participants were instructed to maintain a constant pedaling speed throughout the session at the target cadence.

Figure 2. Summary of the intervention program for experimental and control group participants. VR: virtual reality.



Physical Assessment

For the assessment of active and passive ROM of the hip and knee joint, a specifical ROM assessment tool was used. Measurements were extracted from biomechanical analysis using an inertial motion capture system (Werium; Werium Solutions) consisting of 2 inertial sensors: 1 placed in the distal part of the extremity (moving sensor) and the other in the proximal part (fixed sensor). Both sensors send their measurements via Bluetooth to a PC that runs the data acquisition software, Pro Motion Capture (Werium Solutions). This software computes the relative angle from both angle measurements (avoiding compensations) with an accuracy of 1 degree.

Protocol

The cycling sessions for both groups consisted of the use of a leg ergometer that allows training of the lower limb. Additionally, the EG used an inertial sensor placed on the right thigh and the Oculus Quest 2 HMD (Figure 3).

Figure 3. Cycling session of a participant in the experimental group using the virtual cycling platform.

The EG underwent the following procedure each session:

- The clinician connected the inertial sensor to the Oculus Quest 2 HMD.
- The patient was seated in a nonmovable chair (with no armrests) in front of the pedaling station during the entire session. The inertial sensor was placed on the right thigh of the patient by adjusting an elastic band, and the sensor was turned on.
- The clinician fitted the Oculus Quest 2 HMD comfortably on the patient and guided him or her through the selection of the game scene. Once the game environment was entered, the clinician indicated the number of minutes of exercise and the target speed of the session so that the patient could configure these parameters on the interactive settings panel.
- Finally, the user performed 2 sets of a 5-minute cycling exercise with a 2-minute break between the sets.

Similarly, the CG underwent the following procedure each session:

- The patient was seated in a nonmovable chair (with no armrests) in front of the pedaling station during the entire session.
- The clinician turned on the ergometer's display and entered the number of minutes of exercise and the target speed of the session.
- Finally, the user performed 2 sets of a 5-minute cycling exercise with a 2-minute break between the sets.

Statistical Analysis

The data analysis model is the repeated measures model between 2 groups and the analysis of the longitudinal effect in increments of the measurements. Multifactor ANOVA analysis (with $P<.05$) were computed with SPSS Statistics (version 27.0; IBM Corp). The sample size was calculated using the software tool G*Power (version 3.1.9.7; Heinrich Heine Universität Düsseldorf). Ideally, assuming an effect size of 0.7, a minimum sample of 20 participants was required for the study to provide consistent statistical results. Since the effect size shows the strength of the relationships, it represents a minimum clinically meaningful difference. Of the many different types of effect sizes, the

G*Power software uses Cohen *d* to characterize effect size by relating the mean difference to variability. Therefore, his study standardized the effect size to 0.7 for sample size calculation and power analysis.

Results

To identify the underlying differences between the preintervention (T_i) and postintervention (T_e) assessments in each group, repeated measures ANOVAs were conducted with time ($T_i - T_e$) as the dependent variable and group as the main within-subjects factor. When the ANOVA was significant, the Bonferroni post hoc test was used. To ensure that the error variance of the dependent variables is equal across groups, the Levene test was applied beforehand for all the metrics.

In addition, to identify the improvement effect due to the use or nonuse of the VR system, the variation coefficient between the preintervention and postintervention assessments was analyzed for each group as follows: $\Delta = 1 - (T_e / T_i)$. The variation coefficient outcomes were compared between groups by the independent 1-tailed *t* test. The mean and SD of the ROM outcomes for the hip and knee of each group are shown in Table 2. The mean increase Δ for each measurement is shown in Figures 4 and 5.

Table . Hip and knee range-of-motion outcomes.

Outcome	Experimental group, mean (SD)			Control group, mean (SD)		
	Preintervention (°)	Postintervention (°)	Variation coefficient (%)	Preintervention (°)	Postintervention (°)	Variation coefficient (%)

Figure 4. Summary of increments in active and passive hip ROM parameters with SD bars. The vertical axis represents the percentage of postintervention increase or decrease of each hip ROM parameter. ALHF: active left hip flexion; ARHF: active right hip flexion; PLHF: passive left hip flexion; PRHF: passive right hip flexion; ROM: range of motion.

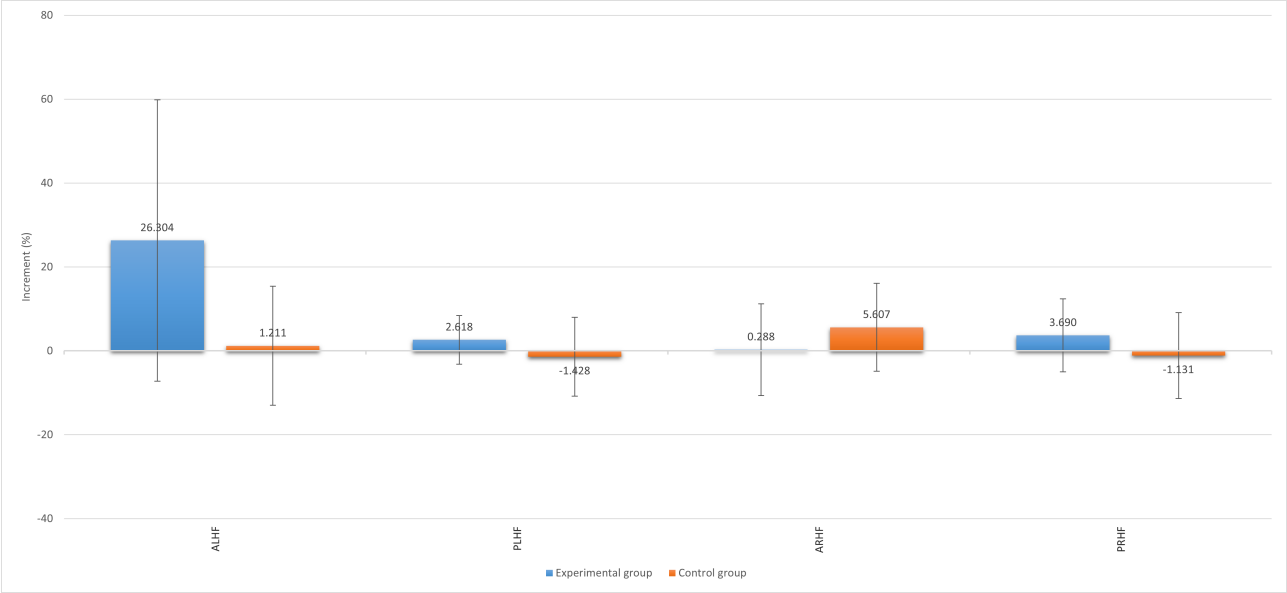

Figure 5. Summary of increments in active and passive knee ROM parameters with SD bars. The vertical axis represents the percentage of postintervention increase or decrease of each knee ROM parameter. ALKE: active left knee extension; ALKF: active left knee flexion; ARKE: active right knee extension; ARKF: active right knee flexion; PLKE: passive left knee extension; PLKF: passive left knee flexion; PRKE: passive right knee extension; PRKF: passive right knee flexion; ROM: range of motion.

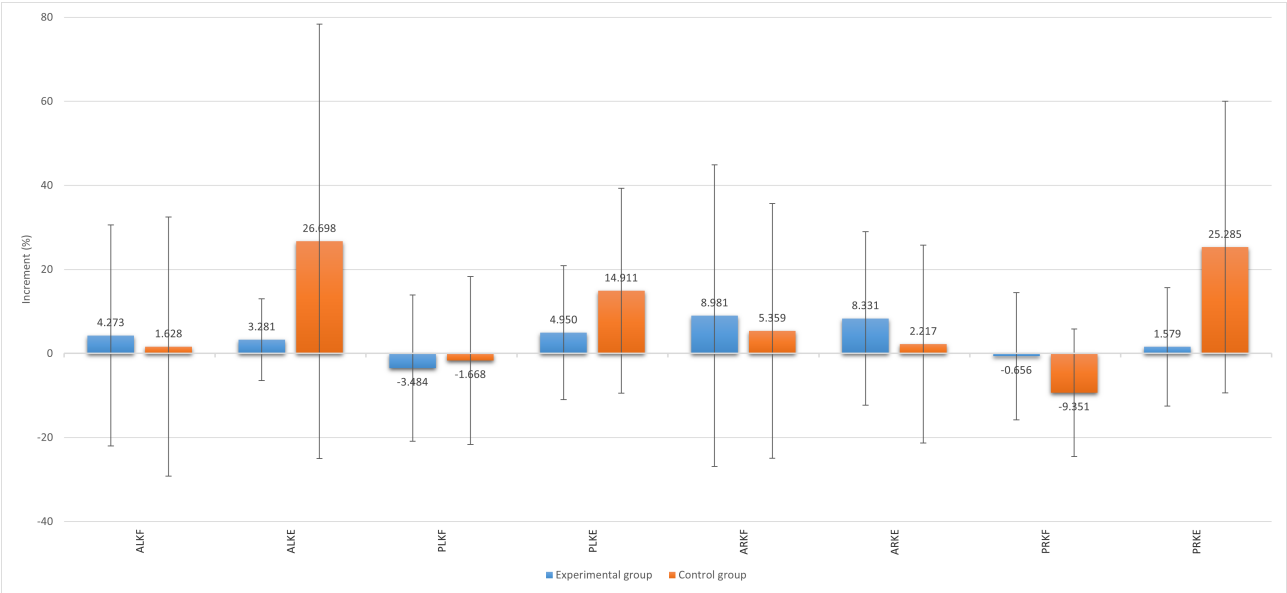

With regard to the hip flexion outcomes, the active left hip flexion results were significant by ANOVA (P=.03), with no significance observed for the between-subjects effects test (P=.67). However, the within-subjects effects test was significant for the time factor (P=.03), but no significant group-time interaction effect was found (P=.08). Despite the opposing results showing passive left hip flexion improvements for each group, there was no significance difference by ANOVA (P=.93) and no statistically significant result was obtained by the between-subjects effects test. Passive left hip flexion was statistically significant in the within-subjects effects test for the time factor (P=.008). The active and passive right hip flexion results were not significant by ANOVA (P=.39 and P=.83, respectively). In both cases, no significant results were obtained for the between- and within-subjects effects tests.

For the knee ROM measurements, when analyzing the left knee assessments, the active and passive left knee flexion outcomes were not significant by ANOVA (P=.06 and P=.76, respectively). No statistically significant results were obtained by the between- and within-subjects effects tests in both cases. Similar results were obtained for the active left knee extension outcomes. Although reasonable differences in the active and passive left knee extension increases between groups can be observed in Figure 5, neither active nor passive left knee extension were significant by ANOVA (P=.66 and P=.92,

respectively). No statistically significant results were obtained by the between- and within-subjects effects tests in both cases.

Regarding the right knee assessments outcomes, all outcomes were not significant by ANOVA (active flexion: *P*=.34; passive flexion: *P*=.06; active extension: *P*=.12; passive extension: *P*=.38). No statistically significant results were obtained by the between- and within-subjects effects tests for all cases, except for passive right knee extension, which was statistically significant for the time factor (*P*=.04) by the within-subjects effects test.

Discussion

Principal Findings

The aim of this study was to test the short-term effects of 2 different interventions on short-term improvement of lower limb function and ROM. For this purpose, a randomized controlled trial was carried out with participants with ataxia and hemiparesis.

In this study, the improvement outcomes of active and passive knee and hip joint ROMs due to the use of VR technology were inconclusive. Likewise, no statistically significant differences in the results between groups can be indicated. Even so, all the active ROMs measured—that is, performed by the patients—showed an increase with respect to the initial values. A greater disparity was observed in the passive measurements, although this may be attributed to the different passive mobilizations performed at each time by different physiotherapists. In this case, the active measurement is of special relevance in clinical terms because it indicates a ROM that the patient is able to achieve autonomously. On the other hand, large SDs in outcome variables clearly indicate that the improvements in the functional gait outcomes are not entirely consistent or represent a group effect. We observe that no significant effect can be attributed to VR intervention based on the statistical analysis of the immediate effects on gait function and joint ROM.

However, considering this similarity between groups, it can be pointed out that the use of VR has similar positive effects as the use of the conventional pedaling treatment. Thus, this immediate observation of effects leads us to conclude that the use of VR during pedaling exercise has similar effects to non-VR exercise training. Therefore, given that the use of VR technology does not worsen the improvement of lower limb ROM, and in line with the scientific literature [17-20], it may be advantageous to use it to maintain the patient's motivation.

Strengths and Limitations

A limitation of this study is the short-term nature of the intervention program. It is arguable that a longer intervention program would have shown more notable effects on functional improvement. However, assuming that it is precisely the treatment time that is one of the main causes of progress in physical improvement, the motivational impact of VR technology over time would need to be assessed. Therefore, further studies on the motivational impact of VR cycling versus conventional cycling on long-term physical activity remain to be addressed. Regarding these future studies, we suggest that cohort studies should be conducted among a population with more homogeneous neurological conditions. This recommendation is based on the limitations encountered in this study, where the difficulty of drawing conclusions about group changes or improvements with such wide SDs is presumably a reflection of the heterogeneity of the group.

Another factor to consider is that different physiotherapists were involved in taking the ROM measurements of the participants, although the measurement system was the same. This fact could be considered in future studies to evaluate interrater effects.

Future Directions

We consider it relevant to analyze, in future studies, whether these improvements in active and passive ROM are accompanied by greater muscle activation, in particular, the hamstrings, rectus femoris, gastrocnemius, and tibialis anterior muscles, as suggested by scientific literature [27].

Conclusions

The results of this trial demonstrate that pedaling exercises coordinated with VR technology works as successfully as conventional training for patients with lower limb disorders such as ataxia and hemiparesis. In this study, it was found that participants who performed the pedaling exercise program using the VR system showed similar results to the participants who performed the exercise activity without using VR technology. Overall, VR technologies can be a useful tool to help patients with ataxia and hemiparesis engage in lower limb exercise therapies.

Acknowledgments

The authors would like to thank all the participants who collaborated in this study, as well as the therapists and health care professionals from Centro Lescer for their participation in this study. The financial support for the industrial doctorate project "Desarrollo y estudio de una plataforma interactiva y un sistema electrónico de pedaleo para rehabilitación funcional de personas mayores" of the Autonomous Community of Madrid (IND2019/TIC17090) toward this research is hereby acknowledged. Grant PID2021-127096OB-I00 funded by MCIN/AEI/ 10.13039/501100011033 and by "ERDF A way of making Europe."

The funding sponsors have no role in the design of the study; the collection, analyses, or interpretation of data; the writing of the manuscript; and the decision to publish the result

Data Availability

The data sets generated or analyzed during this study are available on the GitHub repository [28].

Authors' Contributions

AR contributed to software, data curation, formal analysis, and writing–original draft. ACC contributed to data curation and methodology. CL contributed to methodology, resources, and supervision. RR contributed to funding acquisition, supervision, and writing–review and editing. JCM contributed to funding acquisition, supervision, and writing–review and editing.

Conflicts of Interest

RR is the chief executive officer of Werium Solutions, and AR is a software developer at Werium Solutions. The other authors declare no conflicts of interest.

Abstract

Background: Anticoagulation management can effectively prevent complications in patients undergoing cardiac valve replacement (CVR). The emergence of eHealth tools provides new prospects for the management of long-term anticoagulants. However, there is no comprehensive summary of the application of eHealth tools in anticoagulation management after CVR.

Objective: Our objective is to clarify the current state, trends, benefits, and challenges of using eHealth tools in the anticoagulation management of patients after CVR and provide future directions and recommendations for development in this field.

Methods: This scoping review follows the 5-step framework developed by Arksey and O'Malley. We searched 5 databases such as PubMed, MEDLINE, Web of Science, CINAHL, and Embase using keywords such as "eHealth," "anticoagulation," and "valve replacement." We included papers on the practical application of eHealth tools and excluded papers describing the underlying mechanisms for developing eHealth tools. The search time ranged from the database inception to March 1, 2023. The study findings were reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews). Additionally, VOSviewer (version 1.6.18) was used to construct visualization maps of countries, institutions, authors, and keywords to investigate the internal relations of included literature and to explore research hotspots and frontiers.

Results: This study included 25 studies that fulfilled the criteria. There were 27,050 participants in total, with the sample size of the included studies ranging from 49 to 13,219. The eHealth tools mainly include computer-based support systems, electronic health records, telemedicine platforms, and mobile apps. Compared to traditional anticoagulation management, eHealth tools can improve time in therapeutic range and life satisfaction. However, there is no significant impact observed in terms of economic benefits and anticoagulation-related complications. Bibliometric analysis suggests the potential for increased collaboration and opportunities among countries and academic institutions. Italy had the widest cooperative relationships. Machine learning and artificial intelligence are the popular research directions in anticoagulation management.

Conclusions: eHealth tools exhibit promise for clinical applications in anticoagulation management after CVR, with the potential to enhance postoperative rehabilitation. Further high-quality research is needed to explore the economic benefits of eHealth tools in long-term anticoagulant therapy and the potential to reduce the occurrence of adverse events.

Introduction

Valvular heart disease involves damage to the cardiac valves caused by various factors such as valve degeneration and rheumatic heart disease [1]. Currently, an estimated 209 million people suffer from valvular heart disease worldwide. With the aging population, it is expected that the prevalence of valvular heart disease among those aged 65 years and older will increase by 50% globally by 2030 [2,3]. Furthermore, valvular heart disease caused approximately 300,000 deaths in 2019, accounting for nearly 2% of cardiovascular disease deaths worldwide. Every year, 8.7 million life years and 10.7 million disability-adjusted life years are lost to valvular heart disease [2]. The fundamental treatment for valvular heart disease is the repair or replacement of damaged heart valves through surgery or interventional therapy. Patients need long-term oral anticoagulants after cardiac valve replacement (CVR) surgery; however, improper use of anticoagulants can lead to bleeding, embolism, eventual valve failure, repeat surgeries, and even death [4,5]. Efficient anticoagulation management (AM) plays a critical role in promoting safe medication therapy after CVR, reducing adverse events, and improving the long-term prognosis of patients.

The traditional AM model has many obstacles and challenges. On the one hand, patients need to travel between their home and hospital regularly for follow-up and laboratory examinations and long-term anticoagulant medication, which costs them a lot of time, energy, and economy after CVR and also reduces patients' confidence in rehabilitation and treatment compliance [6]. On the other hand, it is difficult for doctors to monitor and manage patients and adjust treatment plans promptly, which may affect the quality and effect of anticoagulant therapy, and increase the risk of adverse events [7]. Therefore, the exploration of personalized, intelligent, and efficient AM models is crucial in promoting cardiac recovery among patients undergoing CVR. Several guidelines highlight the potential of eHealth tools to facilitate AM and improve medical outcomes [8] and recommend the use of eHealth tools to assist physicians with anticoagulation decision-making support [9].

eHealth tools generally refer to digital devices based on information and communication technology, which can be used for disease prevention, diagnosis, treatment, monitoring, and management [10]. eHealth tools can provide patients with convenient, efficient, and accurate medical services through digital communication and remote disease management. Some studies have found that eHealth tools may become a potentially cost-effective and effective alternative to traditional "face-to-face" anticoagulation therapy. A meta-analysis of 12 randomized controlled trials (RCTs) showed that telemedicine combined with portable coagulometers significantly improved the time in the therapeutic range (TTR) and reduced the incidence of thrombotic events in patients with cardiovascular disease [11]. Inpatients undergoing anticoagulation therapy receiving the recommended dosage of anticoagulation software can effectively reduce readmissions and 30-day mortality as well as hospitalization costs [12]. A comprehensive understanding of the application status and effectiveness of eHealth tools is essential to establish a scientific, traceable, and integrated AM model.

Although several narrative reviews and meta-analyses have summarized the usage of mobile health technology in patients with cardiovascular diseases [13-15], uncertainties remain regarding the effectiveness and current status of using eHealth tools in AM of patients after CVR. A comprehensive summary of the development, application, and interrelationships among different research papers or groups is lacking. Scoping reviews entail extensive searches and a rigorous selection of research literature on a specific topic, which can include a comprehensive overview of the current research status and trends of the topic [16]. Scientometric analysis can quantitatively evaluate cooperative relationships by statistically analyzing publications and graphically presenting the social and intellectual connections of relevant literature [17]. Through the joint analysis of scoping review and scientometric analysis, the research status and trends of a certain field can be comprehensively evaluated from different perspectives, and the blind spots and unsolved problems can be determined to provide guidance and enlightenment for further research.

By conducting a scoping review and scientometric analysis, this study aimed to (1) summarize the application status of eHealth tools in AM of patients after CVR, (2) identify the hotspots and provide guidance for future research and practice, and (3) to provide a reference for promoting the wider application and sustainable development of eHealth tools in AM of patients after CVR.

Methods

Design

We used Arksey and O'Malley's [18] 5-step framework for the scoping review. This review also followed the recommended items in the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Multimedia Appendix 1). Five commonly used databases were searched, and the papers were screened based on the title, abstract, and full text. We exported the complete records of filtered papers as plain text files and imported them into VOSviewer software (version 1.6.18; Centre for Science and Technology Studies) to build visualization maps. We chose coauthorship analysis to construct network visualization maps of countries, institutions, and authors to understand the status of research collaboration in the field of eHealth tools. By cluster analysis and keyword overlay visualization, keywords are divided into different clusters and stacked over time, which can identify different themes and current research hotspots.

Scoping Review

In contrast to systematic and narrative reviews, scoping reviews focus on an initial appraisal of the current extent, scope, and

nature of the research literature and take the dissemination process further by summarizing the relevant existing research activities. It is also an appropriate way to map the key concepts and identify knowledge gaps [19]. We aimed to provide an overview of the use of eHealth tools to assist anticoagulation therapy in patients after CVR and highlight the current status, trends, and challenges in this field. Therefore, the scoping review was appropriate for this study.

Identifying the Research Question for Scoping Review

The first question that guided our scoping review was what are the range and effectiveness of eHealth tools services in AM of patients after CVR? The second one was what are the benefits and barriers of applying eHealth tools in AM?

Identifying Databases and Studies

PubMed, MEDLINE, Web of Science, CINAHL, and Embase were searched from inception to March 1, 2023. Searches were not limited to a specific geographic region, and any literature published in non-English languages was excluded. Searches included combinations of free text words and index terms using Boolean operators. Moreover, a manual retrospective search of the references was conducted as a supplement. Detailed search strategies for each database are described in Multimedia Appendix 2.

Study Selection

The Population, Concept, and Context framework is recommended by the Joanna Briggs Institute to identify the main concepts in primary review questions, guide the search strategy, and ensure application of the inclusion and exclusion criteria [20]. Therefore, we used the Population, Concept, and Context framework to regulate the scoping review process. Population was defined as patients who had undergone CVR surgery and received anticoagulant therapy postoperatively. Concept referred to the practical application and effectiveness of eHealth tools in the AM of patients after CVR. Context had no special restrictions, as eHealth tools can be applied in the patient's home, hospital, anticoagulant therapy clinic, primary care center, and so forth. The inclusion criteria were as follows: (1) publication types including cross-sectional studies, longitudinal studies, cohort studies, case-control studies, pilot studies, and RCTs; (2) published in full text; and (3) published from the inception of each database to March 1, 2023. The exclusion criteria were as follows: (1) non-English publications; (2) publication types including empirical research, reviews, editorials, reports, case reports, letters, and conference proceedings or papers or abstracts; (3) qualitative studies reporting user experiences about eHealth tools in AM of patients after CVR; and (4) studies describing only the potential mechanisms or development process of eHealth tools, rather than their practical applications. The literature records retrieved were imported into Note Express software to screen for duplicate papers. Two researchers (YW and XW) independently conducted the initial screening of the titles and abstracts based on the inclusion and exclusion criteria. Full texts were then examined for secondary screening of potentially eligible papers. Any disagreement during the screening process was resolved through discussion with the third researcher (LC), and the final selection of papers was determined based on the established criteria.

Data Extraction and Analysis

Two researchers (YW and XW) independently extracted data from the included studies using standardized tables and cross-checking their findings. Any discrepancies were resolved through discussion with the third researcher (LC). The information extracted included authors, year, country, study design, study objective, participants' characteristics, study location, content elements, outcome measures, and study conclusions. We summarized the literature on the services and effects of eHealth tools in the AM of patients after CVR and presented the main concepts and findings of the literature using data charts and tables.

Bibliometric Analysis

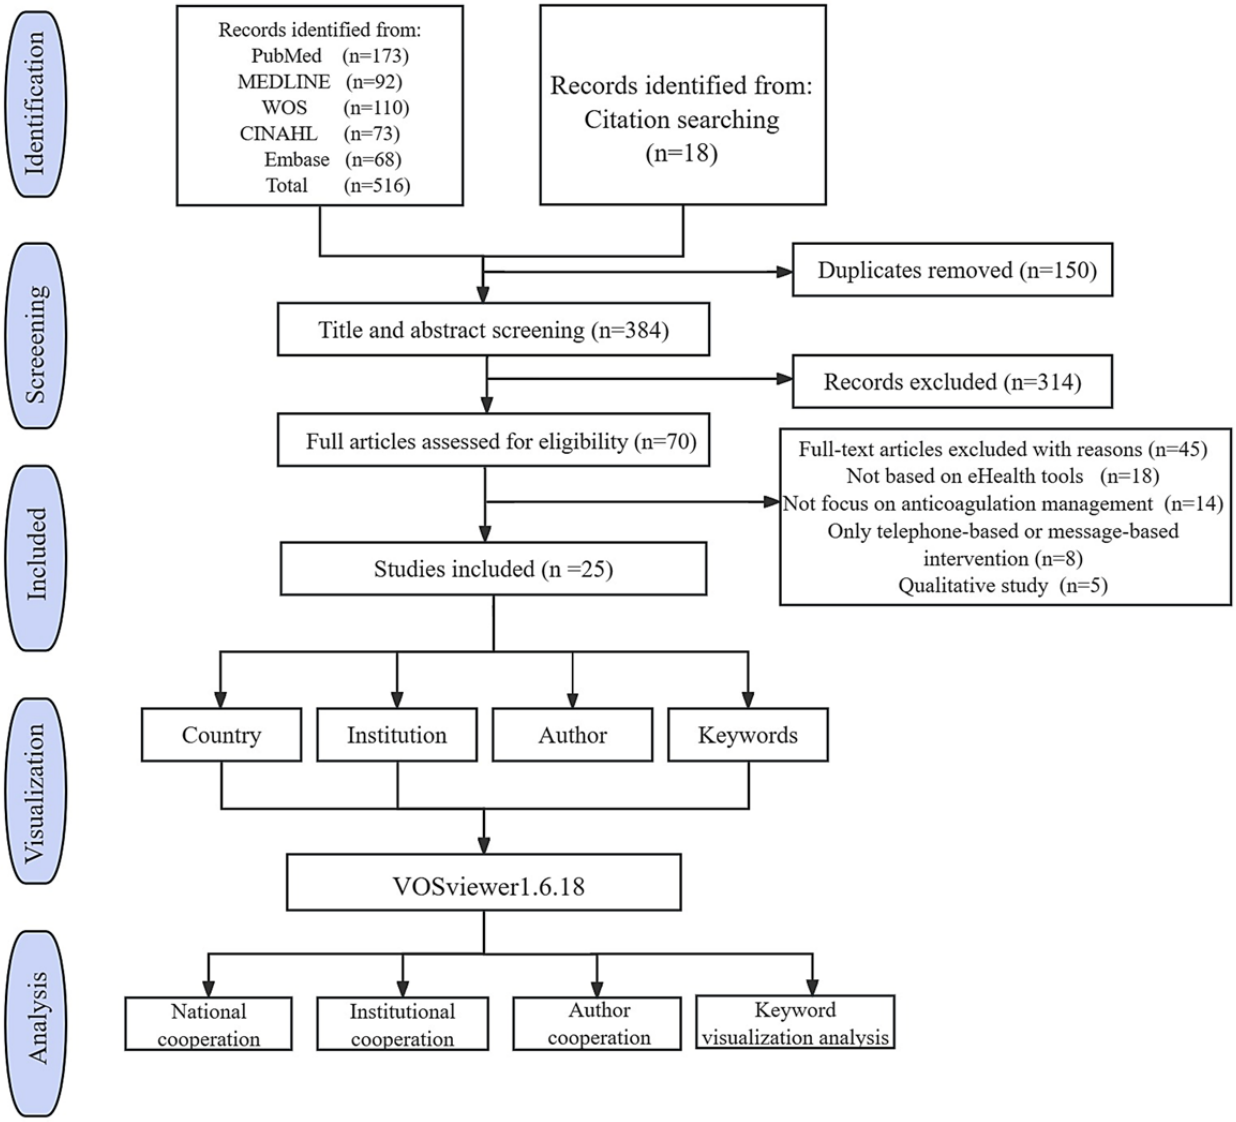
VOSviewer is a widely used tool by researchers for bibliometric analysis, providing effective visualization and revealing connections between research materials [21]. The process of scientometric analysis in this study included 2 parts. First, coauthorship analysis was performed to explore the relationship among researchers, research institutions, and countries, which contributed to understanding the trends of scientific cooperation. We chose "coauthorship" as the analysis type, selected "countries," "organizations," and "authors" as the units of analysis and "full counting" as the counting method. To achieve clearer effects, the minimum number for each project was set as 1. Second, keywords network visualization and overlay visualization were analyzed to explore the hotspots and frontiers. We chose the "author keywords" in the "co-occurrence" type for analysis, the counting method was "full counting," and the minimum cluster size to 6. We merged keywords with the same meaning and deleted redundant keywords. The minimum number was set to 1, and we obtained 40 keywords in total.

Results

Characteristics of the Included Studies

We conducted a systematic search of 5 databases, which yielded 534 studies that may be relevant to the topic. After eliminating duplicates, screening 384 titles and abstracts, and reviewing 70 full texts, we found that 25 papers met the inclusion and exclusion criteria. Figure 1 shows the selection process flowchart based on PRISMA-ScR [22]. The literature included in this study comprised 12 RCTs [23-34], 8 cohort studies [35-42], 2 pilot studies [43,44], 1 longitudinal study [45], 1 cross-sectional study [46], and 1 cross-over study [47]. The 25 papers comprised 27,050 participants in total, with the sample size for each study ranging from 49 to 13,219, the duration of intervention was 1-24 months, and the follow-up period was 1-514 months. Most of the participants were older than 40 years of age and had undergone mechanical valve replacement surgery. A table in Multimedia Appendix 3 provides a summary of the study characteristics and participant demographics.

Figure 1. Flow diagram of the article selection process based on PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines.



Types of Anticoagulation Services Offered by eHealth Tools

Through the comprehensive understanding and interpretation of the included literature, we found that eHealth tools can be broadly classified into 4: computer-based support systems, electronic health records (EHRs), telemedicine platforms, and mobile apps. The application scenarios of eHealth tools are gradually expanding from large general hospitals to primary health care centers and finally to patients' homes. Most studies have reported the beneficial effects of eHealth tools on the rehabilitation outcome and anticoagulation quality in patients undergoing CVR, reflecting the potential and application prospect of eHealth tools in this field. Table 1 shows the specific types of eHealth tools and their application scenarios. Multimedia Appendix 3 shows the specific services provided by eHealth tools and their impacts on anticoagulation outcomes.

[a]PARMA: Program for Archive, Refertation, and Monitoring of Anticoagulated patients.

Of the 25 included studies, 6 used computer-based support systems [23-27,39], 4 used EHR [33,38,43,44], 9 applied telemedicine platforms [28-32,34,35,37,40], and 6 used mobile apps [36,41,45-47]. Computer-based support systems are computer applications designed to aid clinicians in making diagnostic and therapeutic decisions in patient care [48]. Such support systems are typically installed in hospitals, large clinics for anticoagulant therapy, and primary health care centers. They can help doctors predict the appropriate dose of anticoagulants and the timing of the next international normalized ratio (INR) test based on the patient's latest INR value [23-27,39]. EHRs are generated by 1 or more interactions between medical institutions and patients [49]. Doctors use these tools to record the patients' medication information, laboratory measurement data, clinical history, or symptoms of discomfort for reference in the next visit. They use this information to make the best decision possible and summarize their clinical experience, which provides an important basis for improving the overall medical

level. EHR can be shared between primary health care clinics and hospitals through a central database to support CVR surgical follow-up [33].

A telemedicine platform is a means of receiving medical services remotely through various communication technologies [50]. It enables remote communication and data sharing between doctors and patients, thus providing digital medical services for patients after CVR, such as web-based consultation, real-time communication, and disease management [34,37,40,43]. Patients can use portable devices to measure INR at home and transmit the results to the telemedicine platforms. Doctors can then adjust the dosage of anticoagulants and the treatment plan remotely and determine the changes in anticoagulants and conditions of patients after CVR on time [28-30,35]. Moreover, telemedicine platforms can help to supervise the patient's self-management regime at home for a long time, helping patients correctly understand and implement treatment plans and improving treatment compliance and outcomes [28,29,31,37].

Mobile apps are services that run on smartphones, tablets, or other mobile devices. Some have been developed specifically for AM [36,41,42,46], while others are smartphone-based messaging apps [45,47]. In the research we included, mobile apps mainly mentioned the following four services: (1) Medication assistant: the system automatically generated an oral warfarin regimen based on the patient's latest INR value and previous warfarin dose, which were reviewed by specialists and sent to patients [42,46]. At the same time, the apps set intelligent reminders every day to urge the patient to take medicines regularly [36,41]. (2) Digital consultation: patients could communicate with doctors on the internet about their condition and anticoagulation treatment [47]. (3) Push health information: apps could send videos or pictures to help patients understand disease-related information [41,42]. (4) Patients' interactive community: the patients could communicate with other postoperative patients, share their own rehabilitation experiences, and gain support and encouragement [41].

Application Effects of eHealth Tools in AM

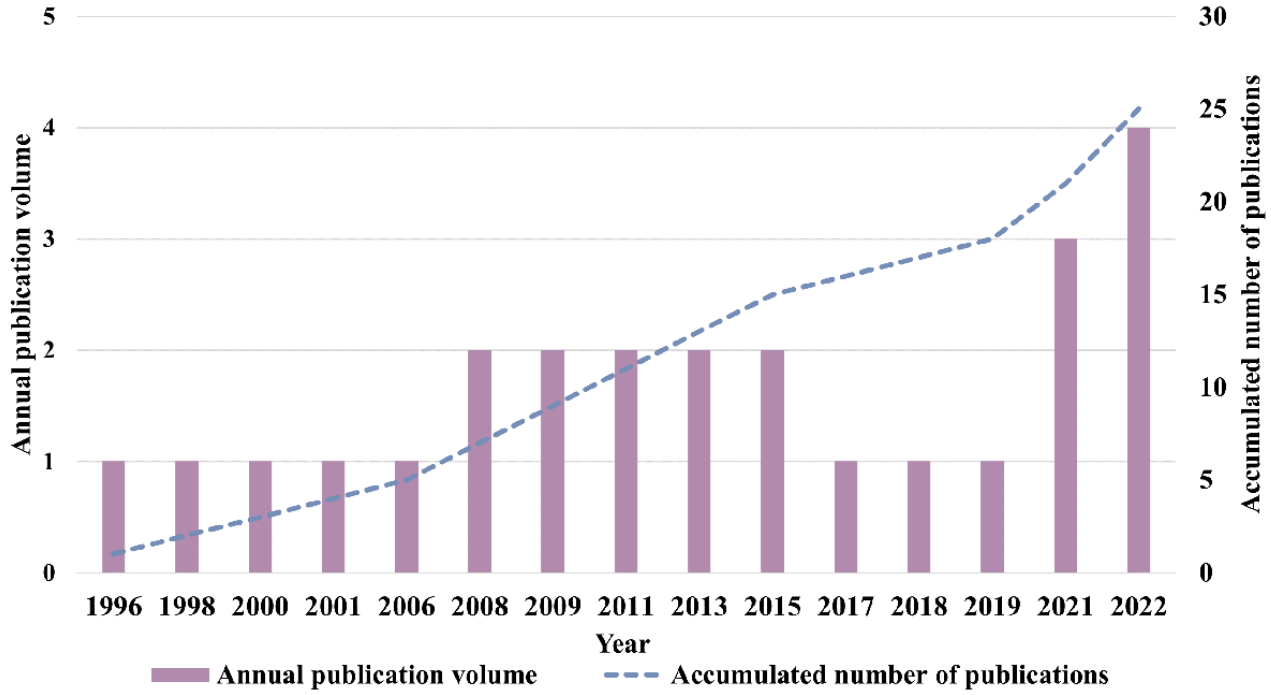
Comprehensive considering the evaluation indexes of anticoagulation effects on patients after CVR can provide better scientific guidance for clinicians and patients. In the literature included, the evaluation of eHealth tools in AM mainly involved three aspects. (1) Clinical outcome: This indicator was reported in 24 papers, including TTR (n=19) [23-28,30,32,33,35-40,42-44,47], rate of achieving target INR (n=5) [27,29,31,42,43], bleeding or thrombotic events (n=18) [23,25,27,28,30,32-42,44,45], and mortality (n=1) [34]. Seven RCTs have demonstrated that using eHealth tools for AM in patients after CVR is a secure and efficacious approach that significantly enhances TTR (P<.05) [23,25,26,28,30,32,33]. Computer-based support systems dosing was found to be more effective in improving TTR than medical staff–monitored dosage at the majority of centers (P<.001) [24,27,42]. Meanwhile, eHealth tools had a significantly higher number of INR within the target range compared to the conventional administration group (P<.05) [27,29]. However, several studies showed no statistical difference (P>.05) in the occurrence of bleeding or thrombotic events between the eHealth tools group and the conventional group [23,25,27,30,33]. (2) Economic benefits: Five papers focused on the health economic benefits of eHealth tools, including the frequency of INR tests (n=3) [24,33,43] and cost-effectiveness (n=2) [23,25]. Research showed that the cost of using computerized decision support software was offset by not going to the hospital [23]. However, when considering the costs associated with establishing a nurse-led clinic, the total cost was higher than traditional treatment [25]. In addition, patient self-testing at home could accelerate INR results, but it is not statistically significant in reducing INR test frequency and generating economic benefits [33,34]. (3) Patient satisfaction: The conclusion of 2 studies revealed that most patients were satisfied with the use of eHealth tools (P<.001) [23,44], which also improved their quality of life [29,44]. These findings demonstrate the potential of eHealth tools in enhancing AM. However, further studies are warranted to explore the economic benefits of long-term anticoagulant therapy and determine whether it can reduce the incidence of clinical adverse events in patients after CVR.

Scientometric Analysis

Publication Trends

The earliest literature on using eHealth tools for AM in patients after CVR was published in 1996. Figure 2 shows the trend of publications, with the number of published papers gradually increasing after 2019. The purple bar above the year label represents the publication volume, and the blue line shows cumulative publication trends. China (n=5) and Italy (n=4) stand out as the 2 countries with the most published papers, the United States and the United Kingdom have each published 3 papers, and other nations have published only 1 or 2 papers. Developed countries had research published around 2000, while transitional countries, such as China and India, only paid attention to this topic around 2019, which may be influenced by cultural differences and medical and economic levels. The majority of the 25 papers in this review were published in thrombus-related journals. However, the application of eHealth tools in the AM of patients after CVR involves not only cardiology and antithrombotic therapy but also the intersection and interdisciplinary cooperation of medical informatics, electronic technology, and health sciences. Some of the papers included in this review were also published in internet medicine journals. Therefore, when seeking the latest progress, readers should not focus only on traditional thrombosis-related journals.

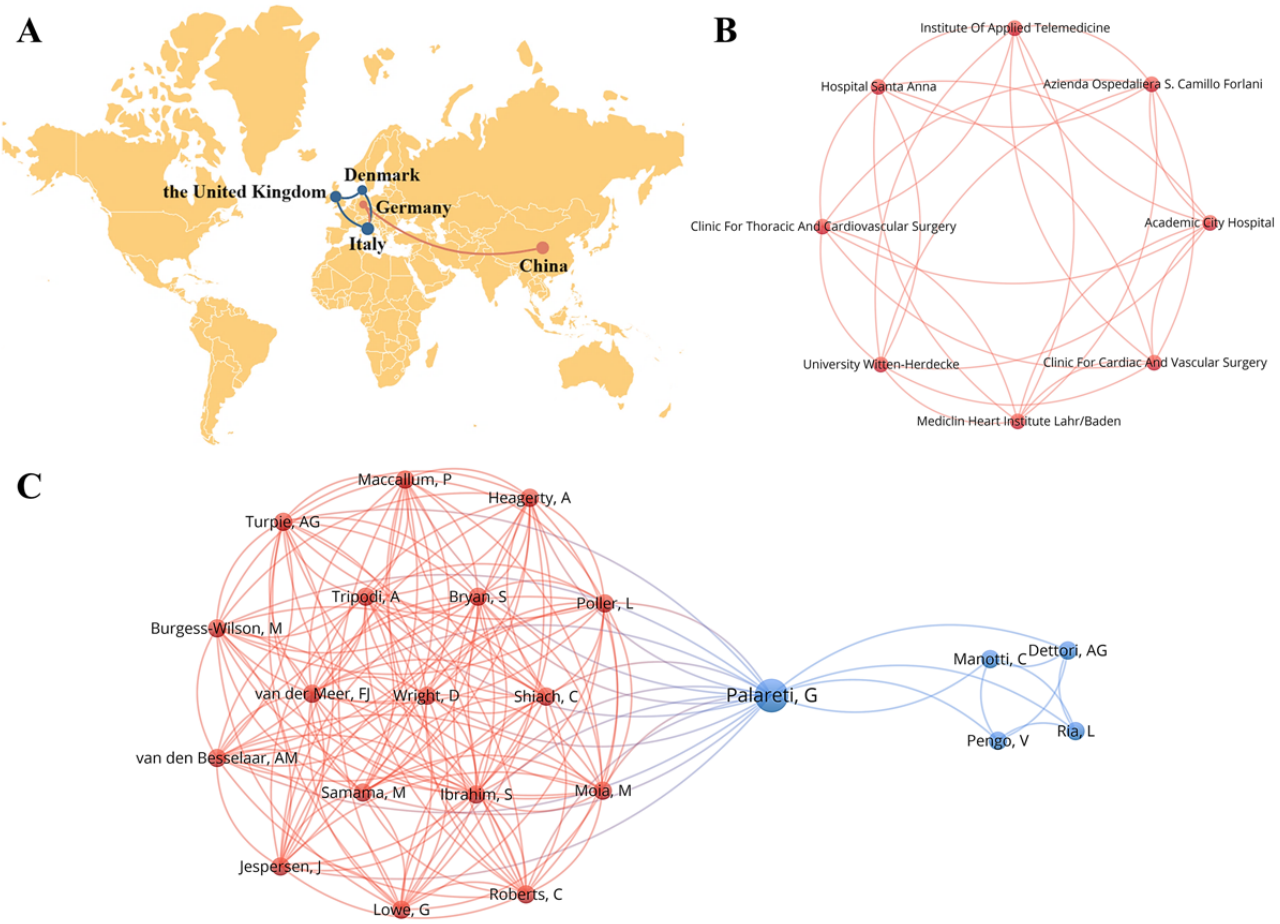
Figure 2. Publication trends of research papers of eHealth tools in anticoagulation management (AM) of patients undergoing cardiac valve replacement (CVR).



Collaborative Analysis of Countries, Research Institutions, and Authors

The 25 papers selected for this review originated from 12 countries and were associated with 46 institutions. Figure 3A depicts the academic collaboration among 5 of these countries, with China being the only transitional country represented. Each node represents a country, and the connection between nodes represents the cooperative relationship. Figure 3B shows that only 8 of 46 participating institutions show close cooperative relationships, and most of them are from Italy. Each node represents an institution, and the connection between nodes represents the cooperative relationship. It should be noted that there are deficiencies in the exchanges and cooperation between transitional and high-income countries, which poses challenges in enhancing the sharing and complementarity among international academic resources. Furthermore, 89 authors participated in the publication of 25 papers. Each node represents an author, the node size depends on the number of authorial publications, and the different colors of the line represent different cooperation networks (Figure 3C). Two collaborative networks have been formed centered on Palareti G, who is affiliated with the Orsola-Malpighi Hospital in Italy and plays a crucial role in the development of eHealth tools in the AM of patients after CVR.

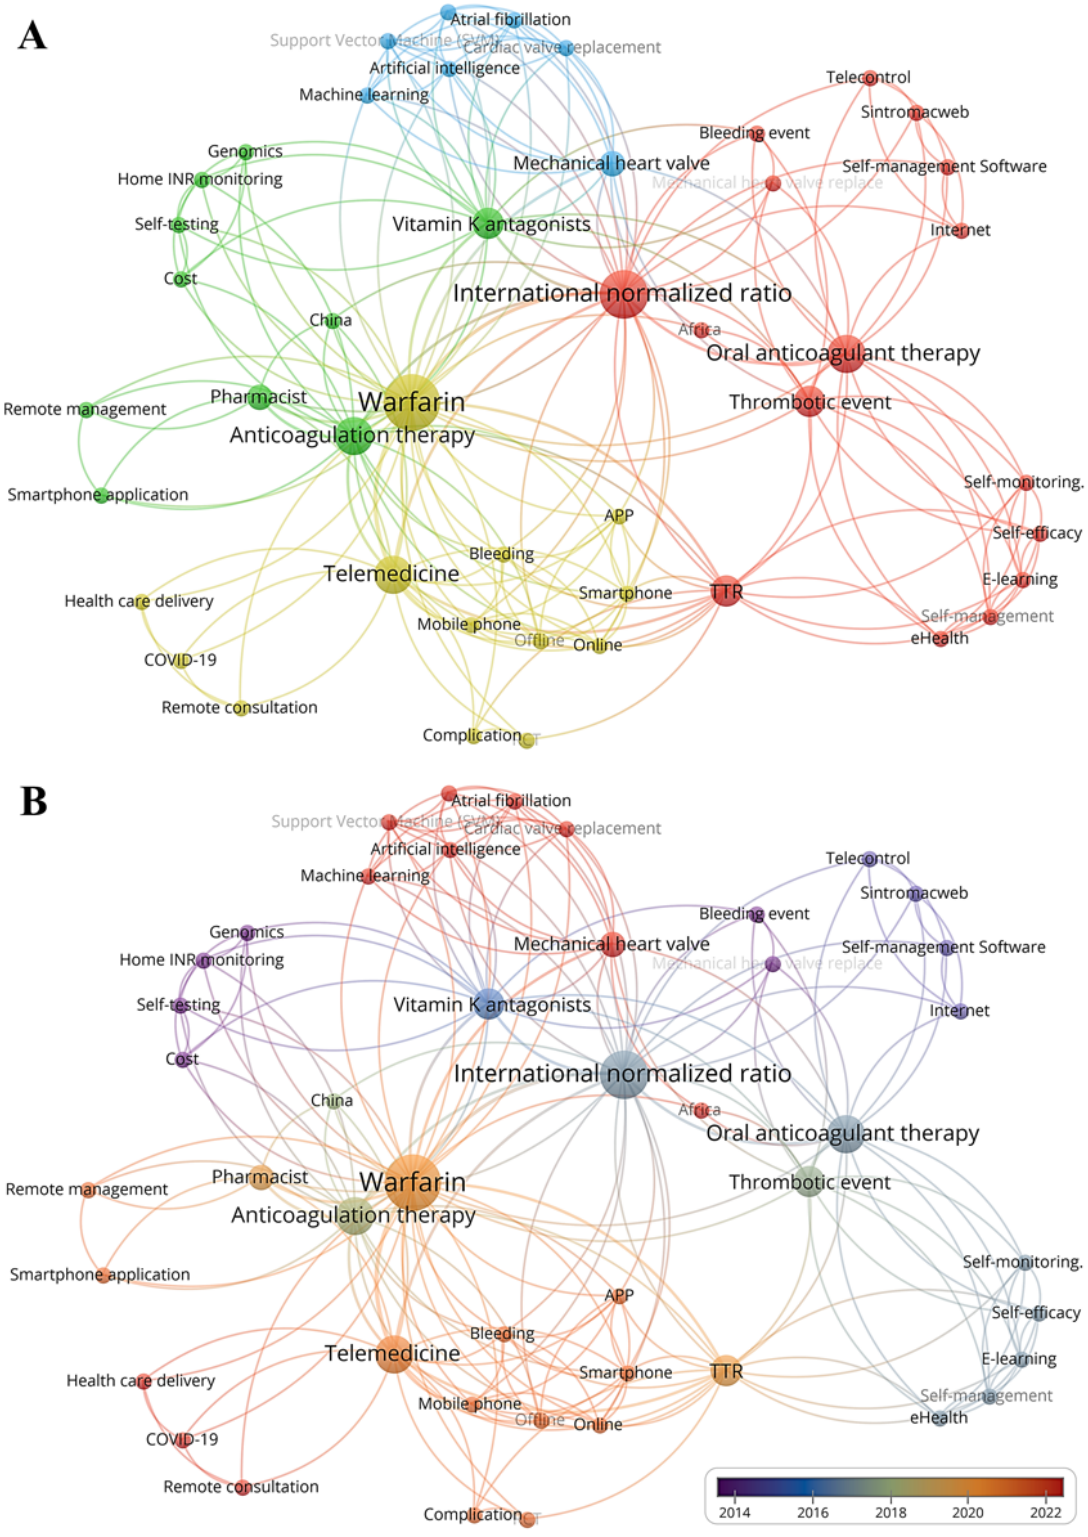
Figure 3. Collaborative network among countries, research institutions, and authors in publications related to the use of eHealth tools for anticoagulation management (AM) in patients after cardiac valve replacement (CVR). (A) Cooperation map among countries. (B) Collaboration network among research institutions. (C) Cooperation network of authors.



Keyword Co-Occurrence Analysis and Cluster Analysis

To present the keyword map more clearly, a cluster analysis was conducted for keywords. Figure 4A indicates that current research on the application of eHealth tools in AM after CVR is mainly focused on 4 distinct areas. The node size indicates the frequency of keyword occurrence, and different colors represent different clusters. We found that 16 keywords in the red cluster were closely related to thrombus formation and bleeding, 10 keywords in the green cluster related to the innovation of INR test techniques (home testing, self-testing, etc), keywords in the blue cluster referred to artificial intelligence (AI) and machine learning, and yellow cluster included telemedicine, health care delivery, and remote consultation.

Figure 4. Visualization of keywords of eHealth tools in anticoagulation management (AM) of patients undergoing cardiac valce replacement (CVR). (A) Keywords clustering visualization. (B) Keywords overlay time visualization.



To further explore the hotspots and future directions, we superimposed time on keyword clustering to create keyword overlay visualization (Figure 4B). The larger the node size, the higher the frequency of keywords and the color of nodes corresponded to the average appearance time of keywords. According to high-frequency keyword analysis, anticoagulant drugs for patients undergoing CVR mainly included vitamin K antagonists led by warfarin. Additionally, the research hotspots of eHealth tools in AM have focused on AI, machine learning, and smartphone apps in recent years. Amruthlal et al [46] constructed warfarin dosage prediction models by linear regression, support vector regression, logistic regression, and multilayer perceptron and found that the prediction model based on support vector regression showed the best predictive performance. Support vector regression was installed in a simple user-friendly Android mobile app. The introduction of advanced

machine learning algorithms provides more choice and support for AM, which may help to improve the efficiency and accuracy of anticoagulant treatment.

Discussion

Summary

This review provides a full evaluation and scientometric analysis of the use of eHealth tools in the AM of patients undergoing CVR surgery. We identified and included 25 studies investigating eHealth tools, such as computer-based support systems, EHRs, telemedicine platforms, and mobile apps. The development of eHealth tools is becoming increasingly important in promoting AM, and the emergence of machine learning and AI has introduced new opportunities for innovation and promotion. Over the past decade, there has been a lack of large-sample and long-term follow-up RCT studies on AM based on eHealth tools, highlighting the need for further research to verify their roles and effects. There remain many areas for improvement to promote the application of eHealth tools in the AM of patients after CVR.

Key Developments and Benefits Provided by eHealth Tools for AM

The AM of patients after CVR involves a large workload, complex patient information, high technical content, and a long follow-up period. The establishment and application of eHealth tools can improve the efficiency of clinical and management work [36,41,48,49]. The computer-based support system facilitates the standardization of anticoagulant recommendations and avoids differences in the dosage prescribed by medical staff, especially in primary health care institutions lacking anticoagulation therapy experience [51]. However, previously, due to technological limitations, these systems could not closely approximate doctors' judgment and decision-making skills, and manual verification and intervention were needed to ensure accuracy [24]. With the development of machine learning, the use of deep learning, reinforcement learning, and ensemble learning are increasing gradually in warfarin management after CVR, which can further improve the accuracy of prediction [52,53]. Additionally, doctors can adjust anticoagulant doses of patients more accurately according to their EHR, thus avoiding excessive or insufficient therapy and reducing the occurrence of complications. Although these 2 eHealth tools are highly targeted, easy to operate, and improve work efficiency, their functions are relatively simple and not enough for more comprehensive management of patients undergoing anticoagulant therapy after CVR.

Telemedicine platforms and mobile apps offer a promising solution for expanding access to high-quality medical resources by providing a digital communication channel between clinicians and patients who have undergone CVR [32-36,38,39,41,44]. Through these 2 ways, doctors can provide electronic prescriptions, digital consultations, health education, and self-management support to not only help patients better understand postoperative rehabilitation but also develop their knowledge and skills and improve the compliance, safety, and effectiveness of AM. However, telemedicine platforms depend on high-quality communication devices to be compatible with other medical devices and systems to perform remote processing of medical data and real-time monitoring of patients. In contrast, mobile apps are more portable and can be used anytime and anywhere, with a more intuitive interface and personalized services for anticoagulant therapy [39,44-47]. However, the older population, who comprise the majority of patients undergoing CVR surgery, may have difficulty learning and adapting to mobile apps and data on the internet. This may affect the accuracy of communication and information transfer between doctors and patients and limit postoperative follow-up. Additionally, practical limitations, such as network instability, data security, low degree of automation, and the need for medical institution support, could affect the effectiveness of telemedicine platforms and mobile apps.

Research on Hotspots of eHealth Tools Based on Scientometric Analysis

Research on the use of eHealth tools for AM after CVR surgery is lacking on a global scale. Developed nations have conducted more studies in this area, which may be attributed to their advanced economic status, superior medical quality, technical proficiency, and greater patient acceptance [54,55]. To promote the development of eHealth tools, it is suggested that countries provide a platform for exchanging and sharing the latest research results and invite scholars from different fields to participate in medical exchange programs, visiting scholar programs, medical conferences, and seminars. Moreover, universities can encourage students to effectively establish a cooperative culture, organize interdisciplinary research groups, conduct interdisciplinary training and education, and cultivate medical talents with an interdisciplinary background and international vision.

Based on the results of keyword clustering and overlay visualization, AI and machine learning have been adopted as research methods for developing eHealth tools and become a hotspot in recent years. These methods have provided valuable insights for future research. Genetic algorithms, backpropagation neural networks, and adapted neural-fuzzy inference system models have the potential to establish more accurate and stable prediction models of warfarin individual maintenance dose for patients after CVR [52,56]. Medical professionals can use biometric technology to visually identify the patient, the medication, and the confirmed ingestion, thereby reducing the risk of noncompliance in patients' anticoagulant therapy [57]. To promote the wide application and sustainable development of eHealth tools, it is necessary to research intelligent auxiliary tools, combining sophisticated machine learning techniques and AI models to enhance the precision and dependability of prediction and innovate anticoagulant therapy tools.

Future Directions for eHealth Tools in AM of Patients After CVR

In 25 studies included, although the main outcome indicators of eHealth tools in AM covered most of the clinical indicators, they could not fully reflect the overall situation of patients from the perspectives of economy, society, psychology, and user experience. Therefore, it is suggested that improvements can be made in the following aspects: (1) Patient interaction indicators: Researchers can monitor the frequency of patients

logging in or using eHealth tools in the background, learn about their experience and needs, and then adjust the tool design and functions accordingly. For example, a user interface with voice support, large font, and novice guidance can help patients overcome the potential obstacles in using eHealth tools [58]. (2) Indicators of acceptability: Researchers should evaluate the acceptance of patients and health care providers using patient-physician satisfaction, use rate, and patient-medication compliance. (3) Anticoagulant dosage index: This can be used to evaluate the accuracy and consistency of manual administration and eHealth tool–assisted administration to ensure the correctness of AM decisions. (4) Sustainability indicators: Patients can evaluate the user experience of eHealth tools from engagement, function, esthetics, and information quality to ensure long-term use and promotion [59].

In addition to the aforementioned optimization metrics, several other important factors should be considered to facilitate eHealth tools. First, it is critical to ensure that the design of eHealth tools is compatible with other medical devices and systems that the patients may use (eg, blood clotting machines and electrocardiographs). To minimize errors and improve data accuracy, these tools should connect seamlessly, allowing data to be shared and integrated across different platforms. Lubitz et al [60] used compatible, wearable devices and Android or iOS smartphones–assisted electrocardiogram patch monitoring, which effectively identified undiagnosed atrial fibrillation at an early stage. Second, providing effective training and support to older or less educated patients is critical for increasing the acceptance and use of eHealth tools. Previous studies have shown that tailored coaching and education programs can help patients operate these tools effectively [61]. Third, the use of advanced machine learning algorithms and AI models helps further improve the accuracy and reliability of eHealth tools. Zeng et al [62] used various machine learning to construct a dynamic anticoagulant treatment scheme for hospitalized patients after CVR surgery. The results showed that the performance of reinforcement learning was significantly better than the other algorithms, and the quality of anticoagulation was significantly optimized [62]. Finally, implementing effective evaluation mechanisms for patients lost to follow-up is critical to ensure they receive appropriate anticoagulant treatment over the long term. Porter et al [63] conducted a 2-year follow-up of patients receiving oral anticoagulants and found that 12-week INR test intervals were feasible, which saved patient's time and improved their compliance [63]. By addressing these factors and optimizing the application of eHealth tools in the AM of patients after CVR, it is possible to significantly improve the overall therapeutic effect and reduce the risk of complications.

Limitations

This review has some limitations. First, we did not assess the quality of the included studies because the study was to provide a comprehensive overview of the existing research landscape related to the application of eHealth tools in AM for patients after CVR. However, we believe that evaluating the quality of the literature will increase the significance of the study. Second, we did not include studies published in the form of other sources, such as qualitative studies, because we were unable to identify eligible studies. Third, concluding trends based on 25 papers are limited, and the conclusions of scientometric analysis should be interpreted with caution. The scientometric analysis in our research is influenced by several limitations, such as the omission of qualitative data, language barriers, and the potential for sample bias. To address the constraints associated with scientometric analysis, researchers can broaden their data sources, integrate qualitative data, and encompass papers published in various languages.

Conclusions

The application of AM based on eHealth tools is expected to truly reflect the social and economic benefits of digital intelligence, thus benefiting patients undergoing CVR. This study provides an overview of the scope, benefits, and future development of eHealth tools in AM for researchers, health care professionals, and post-CVR patients. However, the economic benefits and long-term impact of adverse events need further explored. It is suggested that future eHealth tools in AM should concentrate on enhancing patient contact, acceptance, cost-effectiveness, and sustainability while combining sophisticated algorithms to enhance the precision and dependability of eHealth tools.

Abstract

Background: Among the millions of mobile apps in existence, thousands fall under the category of mobile health (mHealth). Although the utility of mHealth apps has been demonstrated for disease diagnosis, treatment data management, and health promotion strategies, to be effective they must reach and be used by their target audience. An appropriate marketing strategy can ensure that apps reach potential users and potentially convert them to actual users. Such a strategy requires definitions of target end users, communication channels, and advertising content, as well as a timeline for effectively reaching and motivating end users to adopt and maintain engagement with the mHealth app.

Objective: The aim of this study was to identify strategies and elements that ensure that end users adopt and remain engaged with mHealth apps.

Methods: A systematic search of the PubMed, PsycINFO, Scopus, and CINAHL databases was conducted for suitable studies published between January 1, 2018, and September 30, 2022. Two researchers independently screened studies for inclusion, extracted data, and assessed the risk of bias. The main outcome was dissemination strategies for mHealth apps.

Results: Of the 648 papers retrieved from the selected databases, only 10 (1.5%) met the inclusion criteria. The marketing strategies used in these studies to inform potential users of the existence of mHealth apps and motivate download included both paid and unpaid strategies and used various channels, including social media, emails, printed posters, and face-to-face communication. Most of the studies reported a combination of marketing concepts used to advertise their mHealth apps. Advertising messages included instructions on where and how to download and install the apps. In most of the studies (6/10, 60%), instructions were oriented toward how to use the apps and maintain engagement with a health intervention. The most frequently used paid marketing platform was Facebook Ads Manager (2/10, 20%). Advertising performance was influenced by many factors, including but not limited to advertising content. In 1 (10%) of the 10 studies, animated graphics generated the greatest number of clicks compared with other image types. The metrics used to assess marketing strategy effectiveness were number of downloads; nonuse rate; dropout rate; adherence rate; duration of app use; and app usability over days, weeks, or months. Additional indicators such as cost per click, cost per install, and clickthrough rate were mainly used to assess the cost-effectiveness of paid marketing campaigns.

Conclusions: mHealth apps can be disseminated via paid and unpaid marketing strategies using various communication channels. The effects of these strategies are reflected in download numbers and user engagement with mHealth apps. Further research could provide guidance on a framework for disseminating mHealth apps and encouraging their routine use.

Introduction

Mobile Health Apps

Among the vast array of mobile apps currently available, health care apps serve various purposes, including disease diagnosis [1], health promotion, and disease prevention [2,3]. Such uses of mobile technology to provide patients with health care support or health service providers with technical support in a direct, low-cost, and engaging manner fall under the category of mobile health (mHealth) [4].

With approximately 200 new mHealth apps released every day, the number available now exceeds 300,000 [5]. One factor in this proliferation is the increasing use of mHealth technology by health service providers who not only seek advice from apps but also prescribe them to their patients [6]. In October 2020, Germany became the first country to cover the prescription costs of certain mHealth apps through statutory health insurance [7]. Moreover, because mHealth apps have the potential to replace a number of health provider tasks, it has been suggested that expertise in the use of mHealth-related technologies should be recognized as an essential competency for providers [1].

Dissemination of mHealth Apps to Users

The amount of academic research on mHealth apps has also increased, particularly in the areas of usability, effectiveness, adoption, and assessment. However, the highly important aspects of dissemination and marketing are as yet underexamined. App marketing refers to measures aimed at making a mobile app better known and acquiring users (ie, generating app downloads) and, moreover, contacting users and encouraging them to reach a specified goal [8].

An mHealth app is not a stand-alone product that can work effectively without human interaction, which cannot take place if users are unaware that a certain app exists and is accessible. Such “human touches,” although extraneous to the app itself, can be crucial for promoting use [9].

As users are key actors in mHealth adoption, it is critical to understand how they navigate the various stages from app discovery to frequent use. Google has created such a model [10]. It consists of four key stages: (1) discover (users come across an app and download it to their device), (2) onboard (the process of first use and registration), (3) engage (users start using the app regularly), and (4) embed (the desired outcome as users view the app as “vital” to their lives). Only a small proportion of users currently reach the embedment stage with any app [10]; for instance, the literature is sparse regarding the long-term integration and penetration of mobile interventions within mental health and other support service settings [11].

Increasing the chances of an app achieving embedment requires understanding users and placing them at the core of mHealth services. This process would start with persona definitions: fictional archetypes of actual product users. A persona enables program designers to create high-quality programs that effectively meet user needs [2]. In the marketing world, this also means segmenting users and locating them on the marketing funnel, which is a visual representation of the different phases in a customer’s journey toward conversion and their relationship with a product. By segmenting customers based on where they are located in the funnel, marketers target these groups much more effectively [12].

Positive customer experiences and journeys rely on ensuring that the consumer sees value in an app as a channel for accessing products and services and as a 2-way platform for seamless interactions. Although marketing strategies play a crucial role during the early stages of the customer journey, they have been subjected to very little analysis [13].

Marketing of Health Apps

A successful marketing strategy can ensure that an mHealth app reaches potential users and ease the adoption process. Such a strategy would clearly define target end users; determine the appropriate communication channels, content, and timelines to effectively reach users; and market the app as an attractive product, encouraging people to download it and become regular users. The strategy would include a mix of activities, depending upon the type of app and upon the stage of the launch period (from before the launch to after the launch), including email marketing, targeted advertising, and social media promotion [14].

Marketing services have evolved alongside information and communication technologies. In turn, digital marketing has provided a series of customized platforms for communicating with specific stakeholders using computers, smartphones, and tablet computers [15]. These channels enable information to be gathered and include websites as well as various social media platforms such as Facebook, YouTube, X (the platform formerly known as Twitter), Pinterest, TikTok, and LinkedIn. Traditional marketing also remains an option, with products being promoted on radio and television channels, as well as via printed posters in public spaces, flyers, and face-to-face conversations [16].

The cost of promoting an app will depend upon where money is spent, and those promotional activities that do not cost money will demand time. Although potential customers may be offered incentives such as money or supplemental products, the marketer or marketing firm involved in digital marketing can be offered a fee per click, download, or install. A small pilot trial of activities that cost money is recommended to assess results [14].

Specialized services are available for driving digital campaigns; for example, Facebook Ads Manager is a paid service that oversees paid digital marketing campaigns across the Facebook platform. Google Universal App Campaigns (UAC) is another paid service that promotes mobile apps by distributing marketing messages across Google formats and networks, such as the first page of applicable Google search results and small banner advertisements on relevant YouTube channels [17]. As Google

shares information among platforms, including Google Display Network, YouTube, and Google Play Store, Google UAC can capture the number of Google-driven impressions, clicks, and installs on Android devices.

The effectiveness of a marketing strategy can be observed not only through the number of app downloads but also by the effects of users interacting with the app. Referred to as mobile app engagement, this is defined by a variety of operational metrics, such as the number of log-ins, the number of days of use, the number of pages visited, and the number of tasks or modules completed [18]. Another gauge of marketing effectiveness is user onboarding. In the context of mobile apps, user onboarding is the process of providing instructions and highlighting key benefits and features via a set of example screens when the user first launches the app [19].

Objectives

The aim of this study was to review existing evidence on strategies and elements relevant to how the dissemination of mHealth apps is currently carried out and how these elements contribute to encourage user onboarding and engagement with mHealth apps.

Methods

Overview

This study was carried out following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [20] (Multimedia Appendix 1). The protocol of this review was registered with PROSPERO (CRD42022352369) [21].

Eligibility Criteria

Eligible sources were academic papers. All cohort studies, cross-sectional studies, and randomized controlled trials reporting on the dissemination and marketing of an mHealth app were included. The outcome expected from included studies was strategies and elements relevant to how the dissemination of mHealth apps is currently carried out and how these elements contribute to encourage user onboarding and engagement with mHealth apps.

Editorials, letters to the editor, scoping reviews, systematic reviews, meta-analyses, conference abstracts, commentaries, essays, book chapters, and study protocols were excluded, as were studies with any other study design (eg, bibliometric analysis, modeling study, systematic or web search or review of apps, landscape analysis, and scorecard analysis). We also excluded studies with participants aged <18 years and those not reporting the expected outcome. Search languages were limited to French and English.

Information Sources and Search Strategy

Searches were conducted on PubMed, PsycINFO, Scopus, and CINAHL databases over the 5-year period from January 1, 2018, to September 30, 2022 (refer to Multimedia Appendix 2 for the search strategy). The following search terms were used individually or combined according to Medical Subject Headings terms: “apps,” “mHealth,” “marketing,” “promotion,” and “dissemination.” Moreover, we conducted searches on JMIR and mHealth journals and cross-checked the reference lists of the selected studies to locate additional studies that met the inclusion criteria. The main outcome was dissemination strategies for mHealth apps.

Study Selection and Data Collection Process

All retrieved studies were imported into Rayyan (Rayyan Systems Inc) [22] and duplicate records eliminated. Screening consisted of blind peer review by 2 independent investigators. Any conflict was resolved through discussion or the adjudication of a third investigator.

Results

Selection of Studies

We identified 638 records through database searches (PubMed: n=215, 33.7%; PsycINFO: n=60, 9.4%; Scopus: n=283, 44.4%; and CINAHL: n=80, 12.5%) and 10 records through JMIR and mHealth journal searches. Of the total 648 records, 127 (19.6%) duplicates were removed. Next, of the remaining 521 articles, 502 (96.4%) were removed after title and abstract screening. The reasons for exclusion were unrelated outcome or outcome other than the subject of our review (309/502, 61.6%), study protocol (136/502, 27.1%), published review (48/502, 9.6%), study participants aged <18 years (6/502, 1.2%), and other study design (3/502, 0.6%). We then assessed the remaining 19 full texts for eligibility and excluded 9 (47%) for unrelated outcomes; thus, 10 (53%) papers were included in this review. A PRISMA-compliant flow diagram [20] of the paper selection process is shown in Figure 1. The characteristics of the studies selected are summarized in Table 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the paper selection procedure.

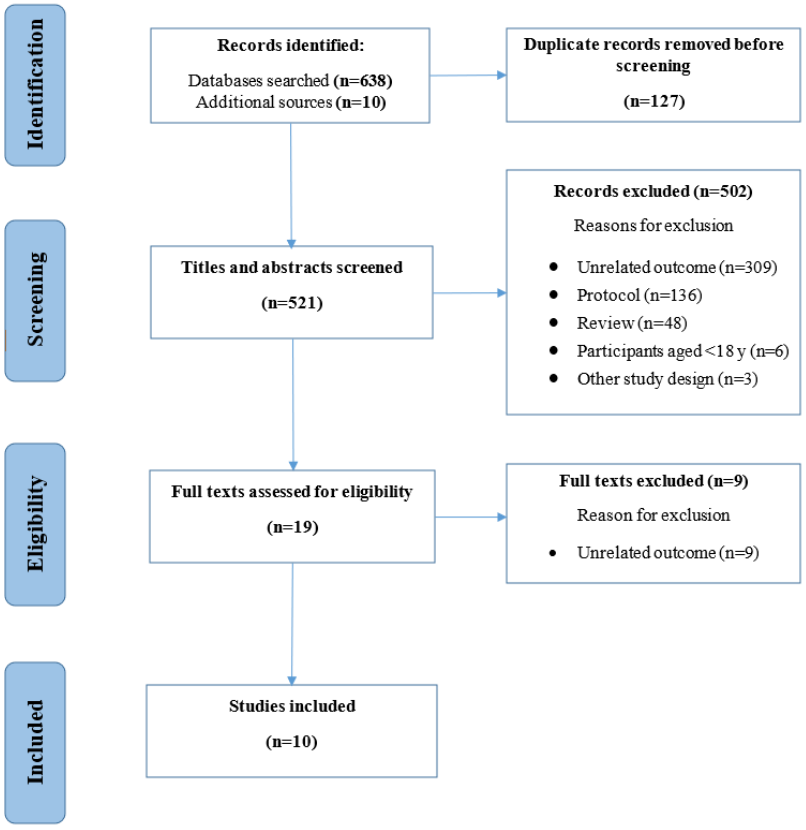

Table 1. Characteristics of the selected studies.

Authors, year; country	Population	Intervention	Outcomes	Design	Quality	Limitations
Kvedarienė et al [23], 2019; Lithuania	• N=149 • Sex: 55% female • Age: 18-60 (mean 37.2, SD 10.4) years • Other details: Lithuanians with allergic rhinitis and asthma	Monitoring of allergic rhinitis and asthma in real life in Lithuanian MASK - air app users	• High app engagement • User retention rate was 107 days of use/user • Patients are satisfied with the app overall	Longitudinal study	Low	• Selection bias: patients recruited from an allergy clinic
Buss et al [24], 2022; Australia	• N=46 • Sex: 50% female • Age: ≥45 (median 62, IQR 56-67) years • Other details: residing in Australia	Test the feasibility of an app-based intervention for cardiovascular and diabetes risk awareness and prevention	• The app scored the highest for the information section and the lowest for the engagement section of the scale • Nonuse and dropouts were too high, and adherence was too low to consider the intervention in its current form feasible • Asking people aged ≥45 years to download the app and expect them to use it over 3 months without additional interaction was not feasible	Nonrandomized controlled trial (cohort study)	Low	• Small sample size • Nonuse and dropouts too high, adherence too low
Arshanapally et al [17], 2022; United States	• N=NI[a] • Sex: NI • Age: 18-45 years • Other details: parents with children aged <5 years, speaking English or Spanish	Investigate the outcomes of a paid digital marketing campaign to promote an mHealth[b] app about parent-engaged developmental monitoring	• Paid digital marketing can be an effective strategy to promote mHealth apps targeting parents of young children • Google-driven marketing messages in English had a higher clickthrough rate than those in Spanish	Implementation study	Low	• No relevant limitations
Resnick et al [25], 2021; United States	• N=41 • Sex: 76% female • Age: ≥18 (mean 51, SD 12) years • Other details: non-Hispanic Black patients, speaking English	Assess the usability, acceptability, and user engagement of the Healthier Together mobile app	• The app strongly engaged participants, with promising results on participants' knowledge of cancer prevention behaviors and success in achieving their cancer prevention behavioral goals	Mixed methods intervention	Low	• Small sample size • Nonprobabilistic purposive sample of non-Hispanic Black patients at 2 internal medicine primary care clinics • Participants were incentivized US $40 to complete the baseline, in-person, 40-month enrollment process and interview and US $60 for completing the 45-month exit telephone interview

Authors, year; country	Population	Intervention	Outcomes	Design	Quality	Limitations
Zlotorzynska et al [26], 2021; United States	• N=NI • Sex: 0% female • Age: 18-24 years • Other details: YMSM[c]	Paid web-based recruitment campaign to recruit HIV-negative or unknown status YMSM for 4 randomized controlled trials of mHealth HIV prevention interventions	• Instagram advertisements yielded the highest proportions of eligible contacts who were racial or ethnic minority individuals and aged <18 years	Randomized controlled trials	Moderate	• Participants offered incentive to enroll in study
Rajani et al [27], 2021; United Kingdom	• N=154 • Sex: 38.8% female • Age: 18-65 years • Other details: smokers	Examine the association among perceived usefulness, perceived ease of use, and frequency of use of gamification features embedded in smoking cessation apps on self-efficacy and motivation to quit smoking	• The use of the apps was associated with increased self-efficacy and motivation-to-quit levels 4 weeks after app use compared with baseline • Perceived frequency of use of gamification features was associated with an increase in self-efficacy and motivation to quit • Higher baseline self-efficacy and motivation to quit were both associated with smaller increases in self-efficacy and motivation-to-quit levels 4 weeks after using the mobile apps compared with preapp use	Observational study	Low	• Participants incentivized
Roberts et al [28], 2019; United Kingdom	• N=32 • Sex: 68.8% female • Age: ≥18 (mean 60, SD 11; range 37-78) years • Other details: diagnosed with breast, prostate, or colorectal cancer	To seek opinions of survivors of breast, prostate, and colorectal cancer regarding using apps to promote PA[d]	• Multiple factors affect engagement with PA apps, and this is highly personalized • Apps that promote walking are the most appealing for survivors of cancer • PA apps should be integrated into cancer care	Cross-sectional study	Low	• Small sample • Participants were offered a £10 (US $12.7) voucher as an incentive for completion of study, and costs were reimbursed if asked to install an app that was not free to download
Bidargaddi et al [29], 2018; United States and Australia	• N=1255 • Sex: NI • Age: NI • Other details: NI	To study the effect of time-varying push notifications on engagement in self-monitoring activity	• Pushing a notification with a tailored health message affects near-time proximal engagement with the self-monitoring activity in the app	Microrandomized trial design	High	• No relevant limitations
Hui et al [30], 2018; United States	• N=101 • Sex: 87.1% female • Age: ≥16 years • Other details: patients with active asthma	The impact of different recruitment strategies and app features on adoption and continued use	• Adherence was dependent upon motivation derived from a sense that the health care professional and researcher were interested in the results and that using an app to support their self-management could improve their asthma control	Cohort study	Low	• Selection bias: participants recruited at clinics
		Market tests of the CycleBeads app in 7 countries		In-app microsurveys	Low	• No relevant limitations

Authors, year; country	Population	Intervention	Outcomes	Design	Quality	Limitations
Haile et al [31], 2018; Egypt, Ghana, India, and Jordan	• N=NI • Sex: 100% female • Age: ≥18 years • Other details: NI		• Social media campaigns proved to be an easy low-cost approach to advertising the CycleBeads app			

[a]NI: no information.

[b]mHealth: mobile health.

[c]YMSM: young men who have sex with men.

[d]PA: physical activity.

Of the 10 selected studies, 6 (60%) were observational studies (longitudinal, cohort, implementation study, mixed methods, and cross-sectional), 1 (10%) reported on 4 randomized controlled trials [26], 1 (10%) reported on in-app microsurveys [31], and 1 (10%) reported on a microrandomized trial [29].

According to the Scottish Intercollegiate Guidelines Network (SIGN) [32] criteria, 8 (80%) of the 10 studies were of low quality, 1 (10%) of moderate quality, and 1 (10%) of high quality. A low-quality rating resulted from a small sample size, the study design (mostly observational), or possible selection bias. A summary of the design, quality, and limitations of the included studies can be found in Table 1.

The selected 10 studies covered 8 countries—Lithuania, the United Kingdom, Australia, the United States, Egypt, Ghana, India, and Jordan—with 50% (5/10) of the studies conducted in the United States and 20% (2/10) in the United Kingdom.

The number of participants in the selected studies ranged from 32 to 1255. Of the 10 studies, 3 (30%) that recruited participants through social media and used impressions and clicks as a proxy measure of their number did not state the number of participants. In 6 (60%) of the 10 studies, 50% to 100% of the participants were female; sex information was not given in 2 (20%) of the 10 papers, 1 (10%) study targeted adolescent and young male individuals, and 1 (10%) targeted female individuals only.

Objectives of the Marketing Strategy

In each of the studies reviewed, we looked for the objective of the marketing strategy implemented through the lens of the Google model of mobile app user journey (discover, onboard, engage, and embed) [10] (Table 2). We found that 60% (6/10) of the studies aimed to drive people to discover their mHealth apps (come across the apps and download them), get onboard (start using the apps), and stay engaged by using the apps for a couple of weeks or months. Marketing strategy in 30% (3/10) of the studies targeted the discover and onboard stages, whereas 1 (10%) of the 10 studies aimed at the engage stage only.

Table 2. Summarized results of reviewed studies.

Authors, year	Channels	Procedures of each dissemination strategy: How was it done?	Effects and results of each dissemination strategy	Objective with regard to the Google model for users' journey with apps
Kvedarienė et al [23], 2019	Face-to-face	• Health personnel trained patients how to use the app at a clinic	• The duration of app use in patients ranged from 1 to 680 (median 54, IQR 23-151) days • There was an increased frequency when the reported days were >200 (18%) • Adherence to mobile apps was higher when the app was promoted by physicians and when the users were taught how to use it	Discover, onboard, and engage
Buss et al [24], 2022	Email	• Participants received an email and a user guide that included instructions to download an app from the app store on their mobile phones and then use it for 3 months • Researchers encouraged regular use • If they had questions or technical issues, participants could get in touch with researchers via email	• Of the 46 participants, 20 (43%) never used the app, and 15 (33%) dropped out • Adherence to app use (using the app at least once/week over 3 months) was 17% (8/46) • The median time between the first and last app use was 54 days • The research team did not actively engage with participants early in the study to verify that all participants could install the app • The intervention did not involve direct contact with health care professionals • The app did not contain enough interactive features	Discover, onboard, and engage
Arshanapally et al [17], 2022	Social media	• Google- or Facebook-driven marketing message: when a user clicked on a marketing message, they were directed to either the Google Play Store or the Apple App Store, depending upon device type • Google Universal App Campaigns distributed marketing messages across several Google formats and networks • Facebook Ads Manager distributed marketing messages across the Facebook platform	• The Google-driven marketing messages garnered a total of 4,879,722 impressions and 73,956 clicks (clickthrough rate: 1.52%); from these clicks, there were 13,707 installs of the app on Google Play Store (18.53% install rate); the overall cost/install was US $0.93 • The Facebook-driven marketing messages garnered a total of 2,434,320 impressions and 44,698 clicks (clickthrough rate: 1.84%); the average cost/install for Facebook could not be calculated because of the limitation of collecting Facebook-driven installs data • Animated graphics generated the greatest number of clicks among both English and Spanish audiences on Facebook when compared with other types of images	Discover, onboard, and engage
Resnick et al [25], 2021	Face-to-face	• In-person information about the app, followed by installation of the mobile app on the participant's mobile phone and instructions on how to select a goal, choose share settings, and invite other social ties • Weekly SMS text messages reminding participants to check in, share goal progress, and invite relatives	• Of the 171 participants, 41 (24%) downloaded the app • Engagement with the app (mean number of check-ins/participant out of 8 possible weekly check-ins during the study period) was 5.7 • Of the 41 participants, 31 (76%) checked in during at least 4 of the 8 weeks • The mean System Usability Scale score was 87 (SD 12; median 90, IQR 78-95)	Discover, onboard, and engage

Authors, year	Channels	Procedures of each dissemination strategy: How was it done?	Effects and results of each dissemination strategy	Objective with regard to the Google model for users' journey with apps
Zlotorzynska et al [26], 2021	Advertisements on Grindr, Snapchat, Instagram, and Facebook	• Advertising was purchased on Facebook, Instagram, Snapchat, Twitter, and Grindr; users who clicked on banner advertisements were taken directly to a study-specific eligibility screener and, if eligible, were asked to provide contact information for follow-up by respective study site staff • The Facebook Ads Manager proprietary algorithm allocated the distribution of advertisement placements (news feed, right-hand column, and Instagram feed and stories) that would provide the best performance • Advertising copy was written to give a very brief description of the study, identify the organization conducting study recruitment, mention the study incentive, and provide a call to action for potential participants seeking to learn more • Snapchat advertisements were created using Snap Publisher and were in the form of short videos up to 10 seconds long; these videos rotated through various stock photo images and superimposed text • Instagram placements were used to test advertisement performance • Images used in advertisements included stock photos, which were either purchased from web-based stock photo vendors (eg, Shutterstock) or accessed through Facebook's free stock photo catalog integrated within the Facebook Ads Manager • Recruitment through various in-person and community outreach efforts included posting flyers, tabling at community events, reaching out to past study participants, and recruiting through clinics serving youth	• Grindr and Snapchat advertisements produced the highest clickthrough rate compared with Facebook advertisements; these advertisements had the lowest proportions of users who initiated eligibility screeners • Facebook advertisements yielded the lowest cost/eligible contact, whereas advertisements on Twitter had the highest • Facebook or Instagram advertisements had much higher rates of screening and ultimately yielded much lower costs/eligible participant • The cost/eligible participant was markedly higher for the Instagram advertisements campaigns	Discover and onboard
Rajani et al [27], 2021	Social media and paper posters	• Participants were recruited via social media, and posters were displayed in public places in London, United Kingdom • Participants were provided instructions on the internet on how to download and start using the app	• Of the 138 participants who installed the app, 116 (84.1%) completed all 4 weeks of the study • A 1-point increase in the average perceived frequency of gamification features was statistically significantly associated with a 3.35-point increase in self-efficacy from baseline to study end (β=3.35, 95% CI 0.31-6.40)	Discover and onboard
Roberts et al [28], 2019	Face-to-face, paper posters, email, and social media			Discover, onboard, and engage

Authors, year	Channels	Procedures of each dissemination strategy: How was it done?	Effects and results of each dissemination strategy	Objective with regard to the Google model for users' journey with apps
		• Participants recruited via advertisements within community-based cancer support groups (either by verbal descriptions from group leaders at meetings or via posters, flyers, and email mailing lists), Facebook cancer support groups, and charitable organizations • Participant randomly assigned to download 2 of 4 apps (Human, The Walk, The Johnson & Johnson Official 7 Minute Workout, and Gorilla Workout) • Guidance in downloading and installing each app was provided, if required; participants were asked to spend approximately 2 consecutive weeks using the apps	• Of the 40 participants, 32 (80%) completed the study (dropout rate: 20%) • Reasons for dropping out were lack of time, family circumstances (eg, bereavement), and not wanting to update their smartphone's operating system or register credit card details with Google Play • Factors affecting engagement included participants' perceptions of the advantages and disadvantages of using apps to support physical activity, the relevance of the app to the user, the quality of the app, and the behavior change techniques used to promote physical activity	
Bidargaddi et al [29], 2018	Push notifications	• Push notifications were sent at 1 of 6 chosen time points throughout the day, and a user could either receive or not receive a push notification at a chosen time point • At each considered time point, users were randomized to either receive or not receive a push notification containing a tailored health message with a 50% probability; once a time point was considered, the user was then considered unavailable for the remainder of the day • To mitigate the risk of users either turning off notifications or deleting the app owing to receiving too many push notifications, users were classified as either "available" or "unavailable" at each time point, and only those time points when users were "available" were considered for the push notification decision; several rules were applied to determine availability	• Sending a push notification containing a tailored health message was associated with greater engagement in a mobile health app • The effect of the pushed notifications is sustained over time; push notifications containing tailored health messages can attenuate the rate at which users disengage • Users who used the app less frequently were "unavailable" to receive push notifications on a greater number of days than those who used the app more often	Engage
Hui et al [30], 2018	Social media and face-to-face	• Researchers sent letters inviting people to use the app for up to 3 months • Practice nurses approached adults with active asthma to try out a prototype app • The app was also advertised via social media (Facebook and Twitter [now known as X]) • Nurses were not expected to teach patients to download and use the app • Technological support was provided by the research team and the app developer • The messages on social media included brief information and a link to information for patients on how to download the app	• A total of 300 patients received information on the app and study from Facebook, Twitter, or organic searches • Only 135 patients downloaded the app, with 111 (82.2%) registering an account on the app • Social media attracted 87 users, but only 15 (17%) used the app for 30 days • A total of 24 patients were recruited, and 13 (54%) continued for 30 days • Successful adoption was dependent upon the ease of downloading and sufficient motivation • Some patients needed technological assistance with downloading the app and starting to use the features	Discover, onboard, and engage
Haile et al [31], 2018	Social media and face-to-face	Series of culturally appropriate Facebook campaigns for each country of interest		Discover and onboard

Authors, year	Channels	Procedures of each dissemination strategy: How was it done?	Effects and results of each dissemination strategy	Objective with regard to the Google model for users' journey with apps
			• Within 10 months after advertising, there were 356,520 app downloads; the cost/download (paid by the advertiser) was lowest in Nigeria at US $0.17, followed by Egypt (US $0.26), Ghana (US $0.27), India (US $0.30), Jordan (US $0.36), Kenya (US $0.41), and Rwanda (US $0.69) • Most of the app users were aged 20-29 years and married or in exclusive relationships	

Channels and Procedures of Each mHealth App Dissemination Strategy

As shown in Table 2, mHealth app promotion was conducted through various channels, including paper posters, face-to-face communications, email, and social media. The most reported channels were face-to-face [23,25,28,30,31] and social media [17,27,28,30,31], both of which appeared in 50% (5/10) of the studies. Messages were intended to inform people about the existence of the app, what it does and the benefits of using it, where to find the downloading link, downloading instructions, and information on how to use the app. Messages through these channels used text, voice-overs, and short videos. Messages on social media and email included a shortened URL to download the app. Face-to-face interactions [23,25,28,30,31] provided the opportunity for training support, including demonstrating app features, installing and using the app, and solving technical issues.

Google Play Store and Apple App Store were the main web repositories to which potential users were redirected for download. In addition, the social media pages of various organizations, such as the Facebook pages of cancer support groups [28], were also used to promote apps and provide download links.

Effects of Dissemination Strategies

Advertising performance was influenced by many factors, including but not limited to advertising content and creativity, competing advertisements within platforms, and emerging platforms that attracted users to new digital spaces [26]. The reviewed papers revealed that social media advertisements attracted substantial downloads over a short period with a large number of impressions [13] and prompted patients to respond to invitations to use the app. However, without the motivation provided by a trusted professional, users quickly ceased their use of the app; a dual promotion strategy was then used to increase app adoption: using social media for its reach and ease of response as well as promoting personal invitations from trusted health care professionals [25].

In 1 (10%) of the 10 studies, embedded push notifications were sent to users to keep them engaged with the app [24]. This effect was sustained over time, and push notifications containing tailored health messages reduced the rate at which users disengaged. The timing of notifications was a key factor, with the results suggesting that users were more likely to engage with an app within 24 hours when push notifications were sent at midday on a weekend. Animated graphics generated a greater number of clicks than other image types [17].

The success of mHealth app dissemination strategies in these studies was measured in terms of adherence, app use, the duration of app use, impressions, clicks, app downloads, and installs. Marketing messages with simple direct calls to action, such as "Track your child's development," generated high clickthrough rates (CTRs) [17].

Marketing Messages and Content of Communications

In some cases, promotional messages included questions prompting people to download and test the app, such as "Would you like to test an app that helps you manage your asthma better? [shortened URL] Need a helping hand to manage your asthma? Try our new app [shortened URL]" [30]. One study included the inquiring headline "Ever think of testing at home?" and explanatory body text: "Fenway Health is looking for young men to help test out a mobile app to support sexual health" [26].

In a study promoting an mHealth app about parent-engaged developmental monitoring [17], marketing messages with animated graphic interchange format (GIF) images as well as images of younger children performed higher than messages without GIF images and images of older children.

Paid or Nonpaid Marketing Campaigns

The paid marketing campaign platforms that were used included Facebook Ads Manager and Google UAC; in addition, advertisements were placed on Grindr, Snapchat, and Instagram [17,26,31]. In 50% (5/10) of the studies, participants were offered incentives to participate [24-28]. Of these 5 studies, 4 (80%) were conducted in the United States and 1 (20%) in Australia. No study reported that paid marketing resulted in higher app adoption than unpaid campaigns.

Key Indicators of mHealth App Marketing Strategies

Various metrics were used in the reviewed studies to assess mHealth app marketing strategies. Key indicators included nonuse rate, dropout rate, and adherence rate, as well as median time between first and last app use, which was generally measured in days or weeks. Nonuse rate was defined as the proportion of participants who never used the app [24], and the duration of use was assessed by determining the reported number

of days of use [23]. The longest duration of app use was 680 days [23].

Dropout rate was defined as the proportion of participants who completely stopped using the app at least 14 days before they received an invitation to complete the end-of-study survey. Adherence rate was defined as the proportion of participants who used the app at least once every week over 3 months of the study [24].

Specific indicators for paid marketing strategies were cost per click (CPC), defined as the amount of money spent per click secured in each advertisement campaign or advertisement set; CTR, the number of clicks divided by impressions; and cost per impression [26]. Impression is the number of times an advertisement is viewed by a user on an advertising platform. For advertisements seen multiple times by the same user, each view is counted as an impression. Additional indicators were the number and percentage of clicks that took people through to the eligibility screener and of those who were eligible for the study [26].

People Implementing the Marketing Processes

In the studies reviewed, we found that promotional messages were mainly disseminated by researchers, trained nurses, and other health practitioners. Technological support was only provided by the research team and app developers. In some cases, recently enrolled patients contributed to promoting the app by sending download invitations to their family and friends [25].

Marketing Concepts Reported in the Reviewed Studies

Inspired by a book on how to successfully distribute apps [12], we screened the included studies to identify the marketing concepts that were used to promote mHealth apps in these studies (Table 3).

Table 3. Marketing concepts [12] reported in the reviewed studies.

Authors, year	Incentivization[a]	Personalization[b]	Mobile app attribution[c]	Loyalty marketing[d]	Remarketing or retargeting[e]	A/B testing[f]	Programmatic marketing[g]	Predictive marketing[h]	Thought-leadership marketing[i]	Content marketing[j]	Behavioral marketing[k]

Haile et al [31], 2018[m]			✓							✓	

[a]The incentivized model is the strategy of making a product, program, or other offering more attractive to customers by offering an incentive in exchange for buying or participating. In the app business, incentivization is normally used to quickly amass app installs. Of the 10 studies, half of the studies (n=5, 50%) used incentivization.

[b]Personalization involves customizing the timing and content of marketing messages to the target user based on their preferences, habits, and behavior patterns. Personalized messages refer to every user by name and entice the user to become more engaged with an app with the right kind of incentive based on their characteristics, such as age, gender, location, profession, and financial segment. Half of the studies (5/10, 50%) used personalization.

[c]Mobile app attribution is the process of recording and measuring the actions of app users, such as installs, level completions, in-app purchases, and other milestones. Mobile app attribution is essential to app marketing because it helps produce the data that are gathered and analyzed to measure how well marketing campaigns are working. The majority of the studies (7/10, 70%) used mobile app attribution.

[d]Loyalty marketing is a marketing strategy that focuses on nurturing existing customers rather than acquiring new ones. Only 1 (10%) of the 10 studies used loyalty marketing.

[e]Remarketing or retargeting targets every individual who has come into contact with the product but has not converted or who converted but later abandoned the app. It allows marketers to reconnect with these categories of users and "bring them back" or increase the time they spend engaging with the app. None of the studies used remarketing or retargeting.

[f]A/B testing involves the use of several versions of the same advertisement distributed to different groups with different designs, color coding, calls to action, and message content to determine which version produces the highest conversion rate. Of the 10 studies, only 2 (20%) used A/B testing.

[g]Programmatic marketing is the automated algorithm-based real-time buying and selling of advertising space through a bidding system, with the aim of reaching the right customers at the right time. None of the studies used programmatic marketing.

[h]Predictive marketing involves using data science based on customer behavior and habits to make smarter marketing decisions. By gathering and analyzing data about user behavior and identifying patterns, marketers can make forecasts about user behavior and make informed decisions about the likelihood of the success of their marketing content and offerings. Of the 10 studies, only 1 (10%) used predictive marketing.

[i]Thought-leadership marketing is the process of positioning a company as a leader in a specific domain by supplying customers with top-quality information. Only 1 (10%) of the 10 studies used thought-leadership marketing.

[j]Content marketing is a marketing strategy that involves producing content that potential customers find useful, valuable, and relevant. Content marketing is highly effective at building a loyal user base and converting leads into customers. More than one-third of the studies (4/10, 40%) used content marketing.

[k]Behavioral marketing involves segmenting the app's user base based on user behavior with the aim of refining the marketing strategy and more effectively targeting users. More than one-third of the studies (4/10, 40%) used behavioral marketing.

[l]These studies (n=6, 60%) used single-channel marketing, which involves reaching users through a single channel, eg, Facebook advertisements.

[m]These studies (n=4, 40%) used multichannel marketing, which involves >1 channel, as opposed to an omni-channel marketing campaign, which attempts to reach users through all available channels.

In summary, most of the studies (7/10, 70%) reported using a combination of marketing concepts to advertise their mHealth apps. The most used concept was mobile app attribution (7/10, 70%). Mobile app attribution is essential to app marketing because it helps produce the data that are gathered and analyzed to measure how well marketing campaigns are working [12]. Furthermore, 40% (4/10) of the studies reported using at least 2 channels to market their mHealth apps.

Discussion

Principal Findings

We found that the marketing strategies used in almost all included studies (9/10, 90%) were aiming to drive at least app discovery and onboarding, with more than half (6/10, 60%) also targeting user engagement to mHealth apps. Social media, emails, television or radio, posters or flyers, and face-to-face communications were all used in the reviewed studies to inform people about the existence of mHealth apps, invite them to download, encourage them to use the apps, and maintain engagement. This is consistent with an integrative review of methods used to promote mobile apps, which also cited app store optimization via keywords and the inclusion of screenshots and videos for greater conversion rate, the use of push notifications, the promotion of apps via influencers, and the leveraging of user review and ratings [13].

Social media attracted many downloads over a short period, whereas emails were most often used for sharing instructions on how to download apps and interact with research teams for technical support.

The strategies used to promote mHealth apps included paid and unpaid marketing, and metrics such as CPC and CTR were used to measure effectiveness. Offering incentives to people to download and use the app did increase app downloads and use. However, it has been shown that people are less likely to keep using an app after incentivization, although the monetary value of the incentive could have a significant effect on the adherence [3]. Furthermore, a focused strategy is required to maintain a low app churn rate [12].

Factors Influencing Engagement, Onboarding, or Adherence to mHealth Apps

Reasons for User Engagement, Onboarding, or Adherence to the App

Onboarding was often reliant on the ease of downloading and sufficient motivation. In the study by Hui et al [30], adherence stemmed from awareness that a health care professional and a researcher were interested in the results and that using an app to support self-management could improve a participant's control of their health condition. Additional factors in engagement included the perceptions of the advantages and disadvantages of using apps to support self-management specific to an individual's health needs, the relevance of the app to the user, the quality of the app, and the behavior change techniques used to promote health [28]. All these factors are among those reported by a literature review that identified retention factors related to apps, such as feedback, appropriate reminders, and in-app support from peers or coaches [33]. Our findings also align with those of another systematic review that listed individualized reminders, user friendliness and technical stability of the apps, and personal support from health care professionals as intervention-related factors influencing adherence [3].

Push notifications and weekly SMS text messages inviting check-in were also used to influence user engagement [26], herein defined by number of check-ins. This is also consistent with the findings from a systematic review [34] that assessed 15 commercial apps for diabetes prevention and found that the app that included the notification features for activity tips, goal progress tips, goals adjustment, and completed goals had the highest engagement mean score (4.5 points out of 5). However, we argue that push notifications should not be a one-size-fits-all solution because marketing research suggests that among app users, just 50% accept push notifications from their favorite app, and 30% disable all push notifications [35].

In our review, user engagement was also influenced by the health goals that participants selected. This finding also aligns with that of a previous systematic review that further suggested that users could disengage at any time and re-engage at a later stage when needed. Thus, this feature might be particularly useful for addiction research targeting relapse prevention strategies [36].

Barriers to User Engagement, Onboarding, or Adherence to the App

From the studies included in this review, reasons for nonadoption included problems in app installation [24,30]; the use of other health apps that better suited participants' needs and preferences; and other concerns, such as prioritizing COVID-19 over the condition addressed by the app [28]. Indeed, marketing can be influenced by competing health information targeting the same users. When people were concerned about contracting COVID-19 and seeking a pandemic-related app, they were less motivated to use an app being promoted to tackle other health issues [17,24]. This could lead to competition among mHealth apps for potential users or health care providers.

Other potential barriers to adoption included a lack of early active engagement with participants to verify that they could install the app, no direct contact with health care professionals,

and not enough interactive features. Indeed, as reported in another systematic review, being less informative and less interactive can lead to a very low engagement mean score [34].

The study by Roberts et al [28] reported that technical issues and concerns about data security reduced engagement. Similar concerns about data security with mHealth apps had been previously pointed out in the literature [37,38].

Return on Investment in Marketing

Although dependent upon the budget available, a decision threshold for the cost of marketing campaigns for mHealth apps to reach a certain level of engagement would be beneficial. According to a study on industry-specific Google benchmarks, for the health care sector overall, these costs amount to a CTR of 3.27% and a CPC of US $2.62 for Google Search and a CTR of 0.59% and a CPC of US $0.63 for the Google Display Network [39]. A similar study on industry-specific Facebook benchmarks produced a CTR of 0.83% and a CPC of US $1.32 for health care [40]. However, it is important to note that comparing CTR and CPC with industry-specific benchmarks for the entire health and medical field should not be the sole method of evaluating effectiveness because these benchmarks may be too broad [17].

People Involved in Marketing mHealth Apps

The most productive marketing team is a multitude of satisfied users championing the app on social media, encouraging their friends and colleagues to download it, and giving it 5-star reviews. Creating a strong user support system and feedback loop, regularly updating the app based on user feedback, and doing whatever it takes to keep users happy are the most important marketing tactics that can be deployed [12].

We found that in studies that investigated age and sex differences in engagement with apps, the age of research participants did not predict app engagement [24,25]. However, there were statistically significant differences in sex and app use, with more male participants using the apps in question than female participants, but not in the duration of app use [24,30]. This result is contradictory with that of another study that found that female sex positively influenced adherence [3]. Therefore, we could not draw conclusions on the effect of sex and age on app adherence and thus leave it to further research.

Marketers of mHealth apps should always consider the motivations of the app audience; for example, the study by Roberts et al [28] stated that apps promoting walking can be appealing to survivors of cancer. Similar findings were highlighted elsewhere [3]. In addition, consideration must be given to the timing of interventions intended to maintain engagement. Data should be collected to predict the moments that users will be available and receptive to in-app notifications.

Limitations

We have noted confusion surrounding the term *user engagement*. Engagement with digital health interventions and engagement with mHealth apps are not clearly separated. This study focuses on the latter, defined as a set of actions by a user within an mHealth app [18]. This differs from user engagement with digital health interventions, which is conceptualized in terms of both experience and behavior [41]. This confusion may explain why many of the studies identified during the database searches had to be excluded: they addressed outcomes related to changes in health behavior; for example, most of the excluded papers reported levels of user engagement with a health intervention, such as increased physical activity, but not engagement with an mHealth app. However, we recognize that these definitions are interlinked: research has shown that app engagement can motivate behavior change [25]. We have noted the same confusion with the term *user embedment*. In the 10 reviewed studies, only 1 (10%) referred to embedment as integrating a functionality within the app.

Most of the studies we reviewed (9/10, 90%) were conducted in high-income countries, with half being carried out in the United States (5/10, 50%). This may limit generalizability in low- and middle-income countries. Moreover, we only searched for papers written in French and English. We also note that the filters we applied with our search terms combination to avoid noise could have excluded some potentially useful papers. This could explain why the reviewed studies mostly reported research conducted in the United States and Europe (8/10, 80%).

Our findings may also be subject to observer bias [42] because in every reviewed study the research team members were involved in the diffusion processes. In some of the studies (2/10, 20%), participants received in-person physical assistance with app installation. This would be impossible for users in many settings. The generalizability of these findings is also limited by the fact that none of the included studies covered the dissemination of mHealth apps among health care personnel.

Implications and Future Research

Integration of mHealth Apps Into Routine Clinical Practice

None of the studies we reviewed aimed to address the embedment of mHealth apps in routine practice as part of their marketing strategy. To tackle the issue of the embedment of mHealth apps, researchers have proposed a framework for prescribing apps and outlined the key issues that need to be addressed to enable app dissemination in clinical care. This includes education and awareness, the creation of digital formularies, workflow and electronic health record integration, payment models, and patient or provider support [43]. As suggested by this framework, a starting point for the integration of mHealth apps into routine clinical practice would be education and awareness, meaning the promotion of mHealth apps, the aim of which would be to create a base of users downloading the apps because the number of app downloads and interactions over time also provides an indication of sustained uptake over time [11].

At this critical point of creating a user base, inspired by the synthesis of our findings, we offer a set of recommended uses of different channels (Table 4). This would first be applicable during the launching phase of the app and to lead users through their app onboarding stage. The use of these channels could change depending upon the objective of the marketing strategy.

Table 4. Recommended uses of channels to promote mobile health apps.

Channel and recommended use	Targeted people	Supportive marketing concepts
Email		
Inform about the existence of the app, link for download, functionalities, app release notes and app updates, and general information regarding the app (developer, brand owner, and sponsor)	High-level users (influencers and decision-makers) and target base users (health care providers and day-to-day users of the app)	A/B testing
Give instructions on how to download and install and use the app	High-level users (influencers and decision-makers) and target base users (health care providers and day-to-day users of the app)	A/B testing
Provide technical support and answers to users' questions; share user guide and tips	Effective users	A/B testing
Social media		
Inform about the existence of the app, and share the link for download	Potential target base users (health care providers and day-to-day users of the app)	A/B testing, incentivization, loyalty marketing, thought-leadership marketing, and content marketing
Engage in direct interactions to provide technical support and answers to users' questions	Potential target base users (health care providers and day-to-day users of the app)	A/B testing, incentivization, loyalty marketing, thought-leadership marketing, and content marketing
Television		
Short promotional video report on the app and its functionalities, as well as 1- to 3-minute video spots with speech by high-level users (influencers and decision makers) recommending the apps	Potential target base users (health care users and day-to-day users of the app)	Incentivization and thought-leadership marketing
Posters or flyers		
Infographics and key text message to inform about the existence of the app and its main value; include a QR code and text to indicate link to download	Potential target base users (health care providers and day-to-day users of the app)	Predictive marketing and incentivization
Face-to-face interaction: in-person training or meeting		
Inform about the existence of the app, link for download, functionalities, app release notes and app updates, and general information regarding the app (developer, brand owner, and sponsor)	High-level users (influencers and decision makers) and potential target base users (health care providers and day-to-day users of the app)	A/B testing
Give instructions on how to download, install, or use the app; share and explain user guide and discuss tips	High-level users (influencers and decision makers) and potential target base users (health care providers and day-to-day users of the app)	A/B testing
Face-to-face interaction: in-person ad hoc (unplanned) encounter		
Engage in direct interactions to provide technical support and answers to users' questions	Health care providers and day-to-day users of the app	Remarketing or retargeting and personalization
Sell the app (highlight its main value) and manage to install it on users' devices; explain how to use it and discuss tips	Health care providers and day-to-day users of the app	Remarketing or retargeting and personalization

Social media could be a beneficial entry point for motivating people to download an app, and human interaction is key during the engagement phase. Therefore, mHealth app promoters should provide users with training and support to start and continue using the apps. This can be done by maintaining communication through social media, including app-dedicated pages. At this point, content marketing—producing content that potential customers find useful—is valuable. It has been demonstrated that content marketing is highly effective in building a loyal user base and converting leads into customers [12].

It is important to note that although social media marketing also tends to attract people who are not the intended audience, communication through email requires a list of targeted email addresses. This entails contacting people directly and requesting their addresses or interacting with someone who will reveal potential users' email addresses or share an app link with potential users; for instance, a hospital director may share information about an app with hospital staff or share an attendance list containing the email addresses of hospital staff.

Future public health campaigns targeting the parents of young children should consider crafting marketing messages for social media campaigns with animated GIF images as well as images of young children.

As time-varying push notifications have been shown to contribute to mHealth app user engagement, developers should

interact with health care providers to implement this strategy. One approach to this is to apply mobile app attribution: the process of recording and measuring the actions of app users, such as installs, level completions, and in-app purchases [12].

Future Research

Finally, future research could be dedicated to developing a framework on how to disseminate mHealth apps. Such a framework, in addition to various marketing concepts presented in this review, should take into account additional considerations that are specific to mHealth apps, such as data confidentiality and privacy, and segment users on the marketing funnel [12] based on the best available evidence on engaging users with mHealth apps. One issue impeding the dissemination of apps that emerged in our study was the existence of competing apps. Some researchers have suggested that digital formularies or app libraries could help to address this. Digital formularies provide a short list of available apps, and providers could search these formularies and know what is available for a specific diagnosis or purpose [43]. Further research could explore and expand on the effectiveness of digital formularies as a dissemination channel for mHealth apps and the enablers of embedment of mHealth apps into routine practice. Finally, further research could aim to address the gap in identifying specific marketing strategies that would effectively drive the embedment of mHealth apps into routine practice.

Conclusions

The dissemination of mHealth apps takes place via face-to-face interactions, email, and printed posters and social media channels with diverse results. The effects of these strategies are reflected in download numbers and user engagement with mHealth apps. The results of this study will serve to guide future research and guide the marketing of mHealth apps for their routine use within the health sector.

The development of a framework for health care designers to promote their apps within health systems would be immensely beneficial. Such a framework would help systematize the dissemination of mHealth apps and guide the impact assessment of the dissemination strategies.

Abstract

Background: The increasing incidence of gestational diabetes mellitus (GDM) is a global health problem that is more likely to occur in pregnant women with overweight or obesity. Adhering to a healthy lifestyle is associated with a reduced risk of GDM. With the development of IT, mobile health (mHealth) interventions have become widely available in health care. However, there are no definitive conclusions on the effectiveness of mHealth-based lifestyle interventions in preventing GDM.

Objective: This study aims to evaluate the impact of mHealth-based lifestyle interventions on GDM and other pregnancy outcomes in pregnant women with overweight or obesity.

Methods: A systematic literature search was conducted in 5 English databases (MEDLINE, Embase, Web of Science, CENTRAL, and CINAHL) and 4 Chinese databases (CBM, CNKI, Vip, and Wanfang) to identify randomized controlled trials (RCTs) on the effectiveness of mHealth-based interventions for GDM from inception to January 10, 2023. In total, 2 authors independently screened the studies and extracted the data. The quality of the included studies was examined using the Cochrane risk-of-bias tool. Data synthesis was conducted using Review Manager (version 5.4; The Cochrane Collaboration).

Results: A total of 16 RCTs with 7351 participants were included in this study. The included studies were published between 2014 and 2021 and were conducted in China, the United States, Australia, New Zealand, the United Kingdom, Ireland, and Norway. The sample sizes of the studies ranged from 75 to 2202, and the duration of the mHealth-based lifestyle interventions ranged from 4 to 28 weeks. Compared with usual care, mHealth-based lifestyle interventions significantly reduced the incidence of GDM (odds ratio [OR] 0.74, 95% CI 0.56-0.96; P=.03; I^2=65%), preterm birth (OR 0.65, 95% CI 0.48-0.87; P=.004; I^2=25%), macrosomia (OR 0.59, 95% CI 0.40-0.87; P=.008; I^2=59%), and gestational weight gain (mean difference=−1.12 kg, 95% CI −1.44 to −0.80; P<.001; I^2=43%). The subgroup analysis showed that interventions delivered via apps (OR 0.55, 95% CI 0.37-0.83; P=.004; I^2=44%), provided by obstetricians (OR 0.69, 95% CI 0.51-0.93; P=.02; I^2=60%), and targeted at Asian populations (OR 0.44, 95% CI 0.34-0.58; P<.001; I^2=0%) and that used the International Association of Diabetes and Pregnancy Study Groups diagnostic criteria (OR 0.58, 95% CI 0.39-0.86; P=.007; I^2=69%) showed a statistically significant reduction in the risk of GDM.

Conclusions: mHealth-based lifestyle interventions had a favorable impact on the prevention of GDM in pregnant women with overweight and obesity. Future studies need to further explore the potential of mHealth-based interventions for GDM through better design and more rigorous large-scale RCTs.

Introduction

Background

Gestational diabetes mellitus (GDM) is defined as a carbohydrate intolerance of varying severity with onset or first recognition during pregnancy [1]. GDM is one of the most common obstetric complications, with the prevalence varying from 7.5% to 27% in different areas [2]. GDM is associated with substantial adverse pregnancy outcomes such as neonatal hypoglycemia and macrosomia as well as long-term metabolic risk in pregnant women and their offspring [3]. Risk factors for GDM include age, ethnicity, overweight or obesity, and family history of diabetes [4]. As obesity becomes a global epidemic, perinatal overweight and obesity are also a growing concern [5]. In recent decades, the rates of overweight and obesity among women of reproductive age have increased dramatically [6]. In the United States, 60% of women are overweight or obese during pregnancy compared with 30% in Europe and 10% in Asia [7]. In pregnant women with overweight and obesity, it is estimated that the risk of GDM is more than twice that of other pregnant women [8]. Unhealthy lifestyle behaviors are a critical factor that affects overweight and obesity during the perinatal period [9]. Numerous randomized controlled trials (RCTs) have attempted to reduce the incidence of GDM through diet [10], physical activity [11], or combination interventions [12]. However, when lifestyle interventions are provided in a personalized way, they are commonly expensive and may lack scalability from the perspective of public health [13]. Therefore, there is an urgent need for effective real-world solutions that address the demand of pregnant women seeking personalized support, information, and guidance to help reduce the risk of GDM.

As IT advances and more people use electronic devices, mobile health (mHealth) has developed rapidly [14]. mHealth is commonly defined as health care services provided by health care professionals using telecommunications technology [15]. mHealth has been applied in many areas of perinatal health care, with medical staff providing health care services to pregnant women through multimedia methods such as mobile apps, software, SMS text messages, email, web-based diaries, and integrated systems combining various components of digital communications technologies [16]. Studies have shown that mHealth care can reduce gestational weight gain (GWG); improve pregnant women's health behaviors; and reduce the number of medical visits, thereby decreasing financial burden [13]. However, the impact of mHealth interventions on pregnancy outcomes in women with overweight or obesity is uncertain. More and more systematic reviews have found an effect of lifestyle interventions based on mHealth technology on diabetes prevention among adults with overweight and obesity [17,18]; however, little is known about their effectiveness in the perinatal population. Several previous reviews have attempted to synthesize the results of mHealth-based lifestyle programs for pregnant women, but none have evaluated the quantitative effects of these programs [19,20]. There is still no consensus on the impact of mHealth lifestyle interventions on preventing GDM and other pregnancy outcomes in women with overweight or obesity.

Objectives

Therefore, we conducted a systematic review and meta-analysis of RCTs to summarize mHealth interventions delivered in different ways and assess the effectiveness of mHealth-based lifestyle interventions in reducing the risk of GDM.

Methods

This systematic review and meta-analysis follows the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [21] and is presented in Multimedia Appendix 1. It was registered in PROSPERO on November 18, 2021, with registration number CRD42021286995.

Search Strategy

A systematic literature search was conducted in 5 English databases (MEDLINE, Embase, Web of Science, CENTRAL, and CINAHL) and 4 Chinese databases (CBM, CNKI, Vip, and Wanfang) for studies published in English and Chinese. A systematic search was conducted combining Medical Subject Headings (MeSH) and free-text terms, including *overweight* (MeSH) OR *obesity* (MeSH); *pregnan** OR *prenatal* OR *antenatal* OR *maternal* OR *gestational*; *gestational diabetes mellitus* OR *gestational diabetes* OR *GDM* OR *T2DM* OR *impaired fasting glucose* OR *impaired glucose tolerance*; *telemedicine* (MeSH) OR *telerehabilitation* (MeSH) OR *telecommunications* (MeSH) OR *electronic health* OR *eHealth* OR *ehealth* OR *mHealth* OR *mobile health* OR *telecare* OR *eHealthcare* OR *mcare* OR *telemonitor** OR *telerehab** OR *telemanagement* OR *mobile communication* OR *remote consult* OR *mobile technolog** OR *mobile devic** OR *mobile app** OR *internet* (MeSH) OR *web** OR *online* OR *smartphone* (MeSH) OR *telephone* (MeSH) OR *cell phone* (MeSH) OR *cellular phone* (MeSH) OR *mobile phone* OR *messag** OR *SMS*. The searches were unlimited by time up to January 10, 2023, and were limited to RCTs. The full details of the search strategy for each database are provided in Multimedia Appendix 2. We complemented this strategy by manually searching the reference lists of included studies and related reviews.

Inclusion and Exclusion Criteria

In total, 2 researchers (YH and CH) independently screened the titles and abstracts and selected the studies in accordance with

the eligibility criteria. Any disagreement was resolved through discussion with a third researcher (QH). Studies were included if they met the following inclusion criteria: (1) pregnant women with overweight (BMI ≥25 kg/m^2) or obesity (BMI ≥30 kg/m^2; population); (2) mHealth interventions including pregnancy nutrition, physical activity, weight management, and health behavior education delivered via the internet, websites, telephone, app, SMS text message, email, or other types of information and communications technologies (intervention); (3) usual care, routine care, conventional care, or standard care without mHealth (comparison); (4) incidence of GDM, postpartum hemorrhage, preterm birth, cesarean delivery, pregnancy-induced hypertension, macrosomia, neonatal gestational age, and GWG (outcome); (5) RCTs (study design); and (6) English or Chinese (language). There were no restrictions regarding the year of publication. We excluded studies that (1) included women with either type 1 or type 2 diabetes mellitus before pregnancy or with existing GDM; (2) contained incomplete data; (3) lacked data related to GDM; or (4) were study protocols, comments, editorials, and conference abstracts.

Study Selection and Data Extraction

The reference management program EndNote X9 (Clarivate Analytics) was used for data management. The studies were imported into EndNote after an extensive database search. After removing duplicates, 2 authors independently reviewed the titles and abstracts according to the eligibility criteria. Disagreements were resolved through discussion or consultation with a third researcher. Data were extracted by an independent researcher (YH) using the predesigned data collection forms, and the extracted data were verified by a second researcher (CH). Disagreements were resolved through consensus. The extracted data included the authors, year, country, study design, sample size, participant characteristics, intervention, control, GDM criteria, and outcomes.

Quality Assessment

In total, 2 researchers (YH and CH) independently assessed the studies' risk of bias in accordance with the *Cochrane Handbook for Systematic Reviews of Interventions*. This tool consists of 6 items: selection bias, performance bias, detection bias, attrition bias, reporting bias, and other biases. Each item was judged as "low risk," "high risk," or "unclear risk." A third researcher (QH) was available if there was a difference in opinion in assessing the risk of bias.

Data Synthesis and Analysis

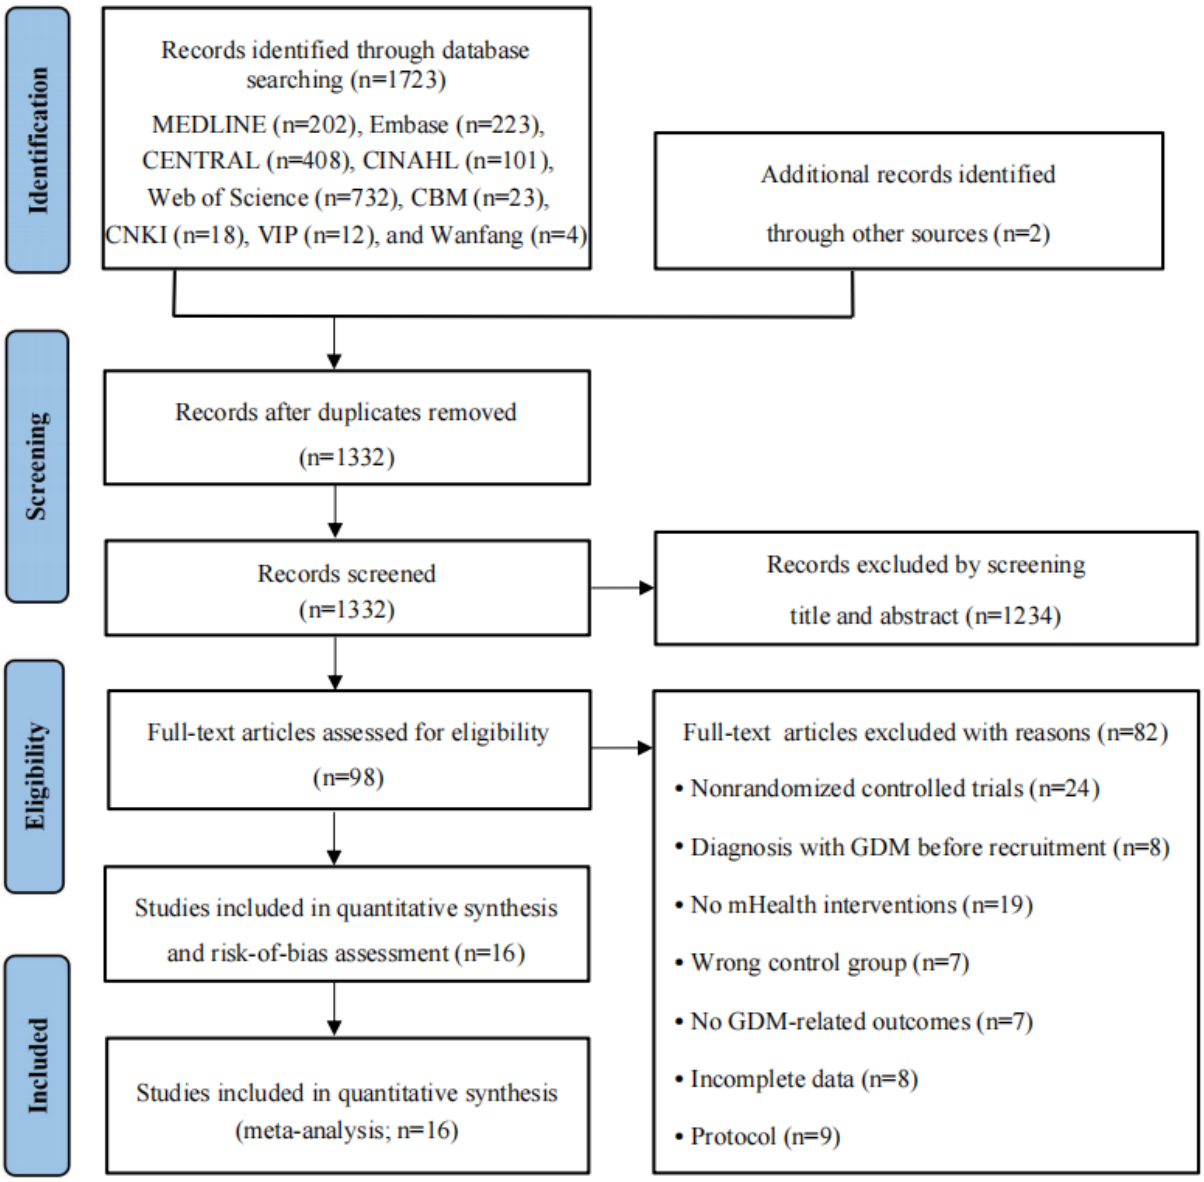
Statistical analyses were conducted using Review Manager (version 5.4; The Cochrane Collaboration). The overall effect difference was considered statistically significant if the 2-tailed *P* value was <.05. Continuous variables were presented using the mean difference, and dichotomous variables were described using the odds ratio (OR) with a 95% CI. Heterogeneity was assessed using the Cochran *Q* test and the I^2 statistic. We considered <25%, 25% to 50%, 50% to 75%, and >75% as low, moderate, high, and severe heterogeneity between the studies, respectively. If I^2≤50% and the *P* value was >.10, a fixed-effects model was considered; otherwise, a random-effects model was used. The sources of heterogeneity were explored using subgroup analysis. A funnel plot was constructed to check for potential publication bias.

Results

Study Selection

Figure 1 shows a PRISMA flowchart of the study selection process. A total of 1725 records were retrieved from 9 electronic databases. After removing duplicates (393/1725, 22.78% of the studies), 1332 studies were included for screening. Of these 1332 studies, we then excluded 1234 (92.64%) based on the relevance of the abstract and title, and the remaining 98 (7.36%) studies were assessed for eligibility. After full-text review, 84% (82/98) of the studies were excluded for the reasons outlined in Figure 1. Finally, 16 studies were included in the review and meta-analysis.

Figure 1. Flowchart of study selection. GDM: gestational diabetes mellitus; mHealth: mobile health.



Characteristics of the Included Studies

Study Characteristics

The characteristics of the included studies are shown in Table 1. The 16 studies included in this review and meta-analysis were RCTs, 4 (25%) of which were multicenter RCTs. The included studies were published between 2014 and 2021 and were conducted in China (8/16, 50%) [22-29], the United States (2/16, 12%) [30,31], Australia (2/16, 12%) [32,33], New Zealand (1/16, 6%) [34], the United Kingdom (1/16, 6%) [35], Ireland (1/16, 6%) [36], and Norway (1/16, 6%) [37]. A total of 7351 participants were included in the studies, and the sample sizes varied from 74 [34] to 2153 [32]. In total, 38% (6/16) of the studies included pregnant women with obesity [23,24,26,28,33,35], and 62% (10/16) included both pregnant women with overweight and pregnant women with obesity [22,25,27,29,30,31,32,34,36, 37]. A total of 81% (13/16) of the articles reported diagnostic criteria for GDM. The incidence of GDM was determined by screening pregnant women using an oral glucose tolerance test. The diagnostic criteria for GDM were inconsistent among the included studies. In total, 56% (9/16) of the RCTs used the International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria (2010) [22,23,25,27-29,34-36], 12% (2/16) used the World Health Organization 2013 criteria [33,37], 6% (1/16) used the Australasian Diabetes in Pregnancy Society criteria [32], and 6% (1/16) of the RCTs used the Carpenter-Coustan criteria [30]. All the RCTs (16/16, 100%) reported more than 1 outcome.

Table 1. Characteristics of the included studies.

Author, year, and country	Study design	Sample size	Participant characteristics	Intervention	Control	GDM[a] criteria	Outcomes
Dodd et al [32], 2014, Australia	Multicenter RCT[b]	2153; IG[c]: 1080; CG[d]: 1073 (1:1)	Women with a singleton pregnancy between 10 and 20 wk of gestation and a BMI of ≥25 kg/m^2	Phone, in person	Standard care	ADPSC[e]	LGA[f], macrosomia, PIH[g], pre-eclampsia, GDM, PTB[h], CS[i], and PPH[j]
Sagedal et al [37], 2015, Norway	RCT	591; IG: 296; CG: 295 (1:1)	Women with a singleton pregnancy at ≤20 wk of gestation who had a prepregnancy BMI of ≥25 kg/m^2	Phone, website, in person	Standard care	WHO[k]	GWG[l], GDM, LGA, SGA[m], pre-eclampsia, PTB, PPH, and NW[n]
Seneviratne et al [34], 2015, New Zealand	RCT	74; IG: 37; CG: 37 (1:1)	Women aged 18-40 y with a BMI of ≥25 kg/m^2 and a singleton pregnancy of <20 wk of gestation	Software, device, home-based, in person	Usual care	IADPSG[o]	NW, hypoglycemia, GWG, GDM, PIH, PTB, CS, PPH, MVPA[p], and pre-eclampsia
Poston et al [35], 2015, United Kingdom	Multicenter RCT	1280; IG: 629; CG: 651 (1:1)	Women aged ≥16 y with a BMI of ≥30 kg/m² and a singleton pregnancy between 15 and 18 wk plus 6 d of gestation	Phone, email, DVD, pedometer, logbook, in person	Standard care	IADPSG	GDM, FBG[q], pre-eclampsia, CS, PPH, GWG, HOMA-IR[r], GL[s], GI[t], fat, MVPA, LGA, and NW
Simmons et al [33], 2017, Australia	Multicenter RCT	192; IG: 92; CG: 100 (1:1)	Women with a BMI of >29 kg/m^2, ≤19 (–6 to , 6) d of gestation, and a singleton pregnancy	Email, phone, pedometer, device, in person	Usual care	WHO	GDM, FBG, HOMA-IR, insulin, NW, LGA, SGA, MVPA, and sugar intake
Chen [22], 2017, China	RCT	160; IG: 80; CG: 80 (1:1)	Women with a prepregnancy BMI of ≥24 kg/m^2 and a singleton pregnancy between 8 and 12 wk of gestation	Mobile apps, SMS text messages, in person	Usual care	IADPSG	BMI, GDM, CS, and NW
Kennelly et al [36], 2018, Ireland	RCT	498; IG: 241; CG: 257 (1:1)	Singleton pregnant women between 10 and 15 wk of gestation with a BMI between 25.0 and 39.9 kg/m^2	Mobile app, email, in person	Usual care	IADPSG	GDM, GWG, GL, GI, PIH, CS, HOMA-IR, NW, LGA, and SGA
Li [23], 2018, China	RCT	1000; IG: 500; CG: 500 (1:1)	Women with a BMI of ≥28 kg/m^2, aged >18 y, and with a singleton pregnancy between 8 and 12 wk of gestation	Phone, in person	Usual care	IADPSG	GDM, GWG, NW, and macrosomia
Tang et al [24], 2019, China	RCT	136; IG: 68; CG: 68 (1:1)	Pregnant women with a BMI of ≥28 kg/m^2 aged >18 y	Mobile app, software	Standard care	N/A[u]	Macrosomia, CS, hypoglycemia, and GDM
Ferrara et al [30], 2020, United States	Multicenter RCT	389; IG: 195; CG: 194 (1:1)	Women at 8-15 wk of gestation with singletons, with a prepregnancy BMI of 25-40 kg/m², and aged ≥18 y	Phone, device, in person	Usual care	Carpenter and Coustan criteria	GWG, caloric intake, MVPA, FBG, HOMA-IR, GDM, PIH, pre-eclampsia, CS, NW, and macrosomia

Author, year, and country	Study design	Sample size	Participant characteristics	Intervention	Control	GDM[a] criteria	Outcomes
Cao [25], 2020, China	RCT	96; IG: 48; CG: 48 (1:1)	Women aged 22-38 y with a BMI of ≥24 kg/m^2 and a singleton pregnancy between 8 and 12 wk of gestation	Mobile apps, SMS text messages, in person	Usual care	IADPSG	FBG, GDM, BMI, CS, NW, and LGA
Wu and Guang [26], 2020, China	RCT	140; IG: 70; CG: 70 (1:1)	Pregnant women with a BMI of ≥28 kg/m^2 aged >18 y	Mobile app, in person	Usual care	N/A	BMI, NW, GDM, PIH, CS, PTB, macrosomia, and PPH
Liu et al [31], 2021, United States	RCT	217; IG: 112; CG: 105 (1:1)	Pregnant women aged 18-44 y with a gestational age of ≤16 wk and a prepregnancy BMI of ≥25 kg/m^2	Phone, software, SMS text messages, in person	Standard care	N/A	GWG, PTB, LBW[v], macrosomia, SGA, GDM, PIH, CS, and NW
Zhou et al [27], 2021, China	RCT	104; IG: 52; CG: 52 (1:1)	Singleton pregnant women with a BMI of ≥24 kg/m^2 and aged >18 y	Mobile app, in person	Usual care	IADPSG	FBG, 2-hour BG[w], GDM, CS, PTB, and macrosomia
Kang and Sung [28], 2021, China	RCT	106; IG: 53; CG: 53 (1:1)	Women with a BMI of ≥28 kg/m^2, aged >18 y, and with a singleton pregnancy between 12 and 20 wk of gestation	Mobile app, in person	Usual care	IADPSG	GDM, FBG, 2-hour BG, HbA_{1c}[x], CS, PTB, and macrosomia
Ding et al [29], 2021, China	RCT	215; IG: 104; CG: 111 (1:1)	Pregnant women with a BMI of ≥24 kg/m^2 at the onset of pregnancy, aged <35 y, and at <12 wk of gestation	Mobile app, in person	Usual care	IADPSG	Energy intake, GDM, FBG, GWG, CS, PTB, PIH, preeclampsia, PPH, NW, and macrosomia

[a]GDM: gestational diabetes mellitus.

[b]RCT: randomized controlled trial.

[c]IG: intervention group.

[d]CG: control group.

[e]ADPSC: Australasian Diabetes in Pregnancy Society criteria.

[f]LGA: large-for-gestational-age infant.

[g]PIH: pregnancy-induced hypertension.

[h]PTB: preterm birth.

[i]CS: cesarean section.

[j]PPH: postpartum hemorrhage.

[k]WHO: World Health Organization.

[l]GWG: gestational weight gain.

[m]SGA: small-for-gestational-age infant.

[n]NW: neonatal weight.

[s]GL: glycemic load.

[t]GI: glycemic index.

[u]N/A: not applicable.

[v]LBW: low birth weight.

[w]BG: blood glucose.

[x]HbA_{1c}: glycated hemoglobin.

Characteristics of the mHealth Interventions

The details of the mHealth interventions are presented in Multimedia Appendix 3 [22-37]. The interventions were divided into 3 groups: exercise only, diet only, and mixed interventions. Regarding the delivery mode, 12% (2/16) of the studies [23,32] provided mHealth interventions through phone counseling, 25% (4/16) of the studies [26-29] only provided the interventions through mobile apps, and 62% (10/16) of the studies [22,24,25,30,31,33-37] adopted a combination of methods. The duration of the mHealth interventions ranged from 4 to 28 weeks. The mHealth interventions were delivered by various types of personnel, including a single provider in 12% (2/16) of the studies [29,32] and multidisciplinary prenatal care providers in 88% (14/16) of the studies [22-28,30,31,33-37].

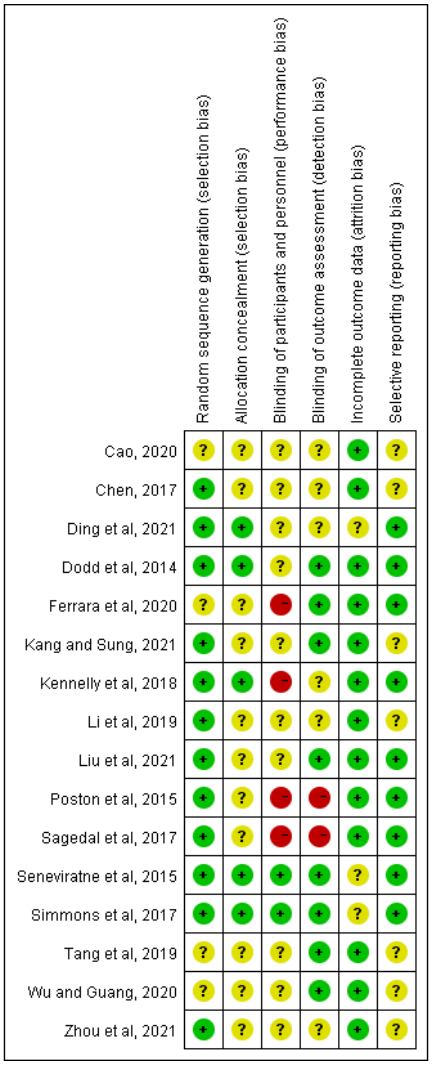
Characteristics of the Comparators

Most studies (14/16, 88%) briefly described the control group, which generally included regular maternity visits and education on diet and exercise during pregnancy. In the control groups, all studies provided standard or usual care for participants, which was based on the different countries' perinatal practices and local hospital guidelines.

Risk of Bias

The Cochrane risk-of-bias tool was used to assess the risk of bias in each study, and the results are shown in Figure 2 [22-37]. A total of 75% (12/16) of the studies described the details of the randomization scheme, and the risk of random sequence generation was low. Only 31% (5/16) of the studies reported allocation concealment, with a low risk of selection bias. Blinding of participants or staff was difficult because of the nature of the mHealth interventions; thus, 25% (4/16) of the studies, which did not blind the participants or staff, were rated as having a high risk of bias, and 62% (10/16) of the studies were rated as unclear regarding the risk of bias. A total of 12% (2/16) of the studies did not report the outcome assessment and were rated as having a high risk of detection bias. In total, 81% (13/16) of the included studies described details of participant dropout and had a low risk of bias. A total of 56% (9/16) of the studies followed preregistered protocols for analysis and outcome reporting, and the remaining 44% (7/16) did not provide information on published protocols or registrations and had an unclear risk of reporting bias. The funnel plot showed no publication bias in any of the included studies (Multimedia Appendix 4).

Figure 2. Results of the risk-of-bias assessment of the included studies [22-37].



Meta-Analysis Results

Primary Outcome: the Incidence of GDM

The pooled analysis of the 16 RCTs with 7351 participants showed that the mHealth interventions significantly decreased the incidence of GDM in women with overweight and obesity (OR 0.74, 95% CI 0.56-0.96; *P*=.03; I^2=65%; Figure 3 [22-37]).

Table 2 provides the results of the subgroup analyses, and the forest plots are presented in Multimedia Appendix 5 [22-37]. The subgroup analysis conducted based on the different interventions showed that diet (OR 0.61, 95% CI 0.29-1.28; *P*=.19; I^2=61%), exercise (OR 1.11, 95% CI 0.57-2.17; *P*=.76; I^2=0%), or a combination of the 2 (OR 0.71, 95% CI 0.51-0.99; *P*=.05; I^2=74%) were not statistically significantly associated with reduced risk of GDM. When compared with the control groups, app-based mHealth interventions were significantly effective in reducing GDM (OR 0.55, 95% CI 0.37-0.83; *P*=.004; I^2=44%). Another subgroup analysis conducted based on different providers indicated that interventions provided by obstetricians and nurses were effective in reducing GDM (OR 0.69, 95% CI 0.51-0.93; *P*=.02; I^2=60%). Interventions targeted at Asian populations (OR 0.44, 95% CI 0.34-0.58; *P*<.001; I^2=0%) and using the IADPSG as a diagnostic criterion for GDM showed a reduction in GDM compared with the control groups (OR 0.58, 95% CI 0.39-0.86; *P*=.007; I^2=69%).

Secondary Outcomes: Maternal and Neonatal Outcomes

Effect on GWG

A total of 50% (8/16) of the studies examined the effects of mHealth-based interventions on GWG [23,29-31,34-37]. There were statistically significant differences in decreases in GWG between the mHealth intervention groups and the control groups (mean difference=−1.12 kg, 95% CI −1.44 to −0.80; P<.001; I^2=43%; Figure 4 [23, 29-31,34-37]). The effects of the mHealth-based lifestyle interventions on maternal and neonatal outcomes are shown in Table 3.

Figure 4. Forest plot of the effect of mobile health interventions on gestational weight gain [23, 29-31,34-37]. IV: inverse variance.

Effect on Cesarean Delivery

A total of 56% (9/16) of the studies explored the effects of mHealth-based interventions on cesarean delivery [22,24-26,30,32,34-36]. The pooled results showed no significant difference between the mHealth intervention and control groups (OR 0.89, 95% CI 0.79-1.00; P=.05; I^2=39%). Forest plots of maternal and neonatal outcomes are shown in Multimedia Appendix 6 [22-37].

Effect on Pregnancy-Induced Hypertension

A total of 56% (9/16) of the studies assessed the effects of mHealth-based interventions on the risk of pregnancy-induced hypertension [26,29-32,34-37]. Compared with the control groups, the groups with mHealth-based interventions did not show statistically significant decreases in pregnancy-induced hypertension (OR 0.96, 95% CI 0.80-1.15; P=.63; I^2=31%).

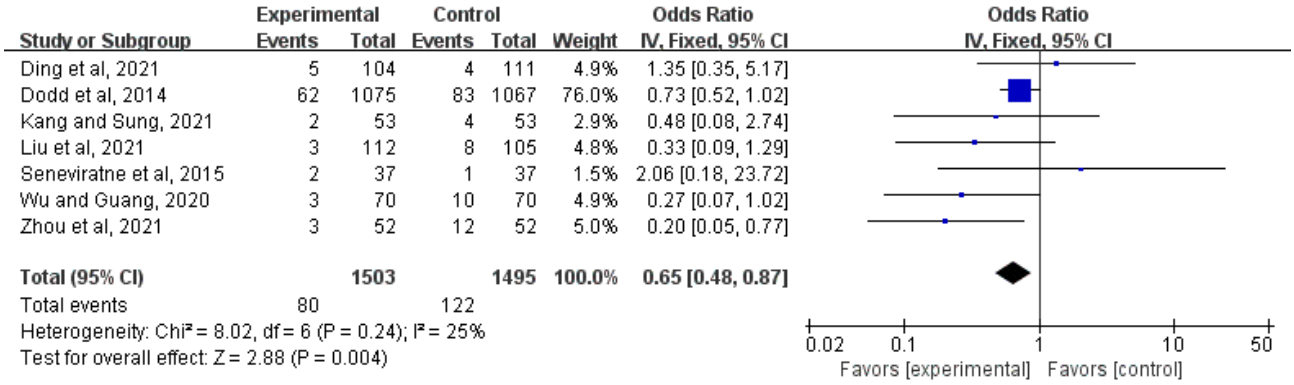
Effect on Postpartum Hemorrhage

A total of 38% (6/16) of the studies assessed the effects of mHealth-based lifestyle interventions on the risk of postpartum hemorrhage [26,29,32,34,35,37]. There were no statistically significant decreases in postpartum hemorrhage between the groups with mHealth-based interventions and the control groups (OR 1.06, 95% CI 0.90-1.24; P=.49; I^2=17%).

Effect on Preterm Birth

A total of 44% (7/16) of the studies explored the effects of mHealth-based interventions on the risk of preterm birth [26-29,31,32,34]. Statistically significant differences in decreases in preterm birth were found between the mHealth intervention groups and the control groups (OR 0.65, 95% CI 0.48-0.87; P=.004; I^2=25%; Figure 5 [26-29,31,32,34]).

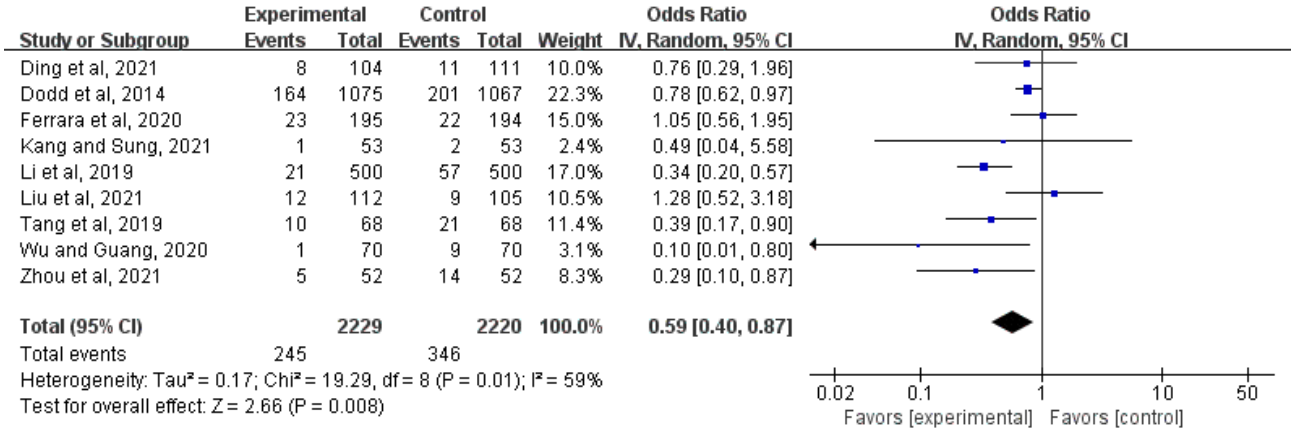
Figure 5. Forest plot of the effect of mobile health interventions on preterm birth [26-29,31,32,34]. IV: inverse variance.



Effect on Macrosomia

A total of 56% (9/16) of the studies evaluated the effects of mHealth-based interventions on the risk of macrosomia [23,24,26-32]. Statistically significant differences in decreases in macrosomia were found between the mHealth intervention groups and the control groups (OR 0.59, 95% CI 0.40-0.87; P=.008; I^2=59%; Figure 6 [23,24,26-32]).

Figure 6. Forest plot of the effect of mobile health interventions on macrosomia [23, 24,26-32]. IV: inverse variance.



Effect on Large-for-Gestational-Age Infants

A total of 31% (5/16) of the studies explored the effects of mHealth-based lifestyle interventions on large-for-gestational-age infants [32,33,35-37]. Compared with the control groups, the mHealth intervention groups did not show statistically significant decreases in large-for-gestational-age infants (OR 0.80, 95% CI 0.60-1.06; P=.12; I^2=51%).

Effect on Small-for-Gestational-Age Infants

In total, 25% (4/16) of the studies assessed the effects of mHealth-based lifestyle interventions on small-for-gestational-age infants [31,33,36,37]. Compared with the control groups, the mHealth intervention groups did not show statistically significant decreases in small-for-gestational-age infants (OR 1.10, 95% CI 0.78-1.55; P=.60; I^2=0%).

Discussion

Methodological Quality of the Included Studies

The methodological quality of the included studies was assessed using the Cochrane risk-of-bias tool. A total of 25% (4/16) of the studies did not report details of randomization methods, and 75% (12/16) of the studies did not report allocation concealment and were at risk of selection bias. In total, 25% (4/16) of the studies did not blind participants and researchers. Therefore, there was a high risk of performance bias in these studies. A total of 12% (2/16) of the studies did not blind the outcome assessors and were rated as having a high risk of detection bias. The included studies reported complete data with low attrition bias. Finally, the funnel plot showed no substantial publication bias among the included studies. Therefore, the overall methodological quality was moderate, and larger samples and well-designed randomized trials are needed in the future.

Summary of Principal Findings

Effectiveness of mHealth Interventions

A total of 16 RCTs were included in this systematic review and meta-analysis. All of these studies offered mHealth lifestyle interventions for perinatal women with overweight or obesity. Pooled results showed that the mHealth interventions reduced the incidence of GDM, which was consistent with the results of a previous study [38]. Various strategies have been proposed to prevent GDM effectively, and the primary intervention strategy is to change the lifestyle. Lifestyle interventions, including dietary guidance, physical exercise, weight management, health education, and blood glucose self-monitoring, are first-line strategies for GDM prevention [39]. The benefits of lifestyle interventions are mediated by mechanisms that improve glycemic variables and outcomes in type 4 and type 2 diabetes by increasing insulin sensitivity and reducing oxidative stress, which has been demonstrated in studies in other populations [40]. Compared with conventional lifestyle interventions, mHealth-based lifestyle interventions can make health education more attractive by providing more intuitive and vivid education and consultation with the help of electronic devices. In addition, pregnant women need to maintain close and continuous contact with the medical team during pregnancy and communicate effectively in the event of pregnancy complications and conscious fetal abnormalities. The advantage of mHealth technology is its ability to provide time-sensitive connectivity and high-quality health care for pregnant women in all regions [41]. mHealth lifestyle interventions enable pregnant women to maintain a healthy diet and engage in appropriate physical activity on a daily basis to encourage a healthier lifestyle during pregnancy, thus reducing the incidence of GDM.

Subgroup Analysis

In this review, we classified mHealth lifestyle interventions into 3 groups based on delivery approach: app-based interventions, phone-based interventions, and mHealth interventions delivered via a computer. Subgroup analysis demonstrated that app-delivered mHealth interventions were highly effective in reducing the risk of GDM in women with overweight or obesity. mHealth telephone-based interventions and interventions delivered via a computer had no significant effect on the prevention of GDM. Perinatal women usually have different problems and specific needs during pregnancy. Personalized applications can focus on individual characteristics and tailor goals and actions to diverse populations [42]. In this way, medical staff can leverage app-based mHealth interventions to provide health care tailored to the specific needs of pregnant women with overweight or obesity. In contrast, the applications help medical staff remotely monitor real-time parameters related

to the health of pregnant women who are overweight or obese during pregnancy, observe whether they are adhering to a healthy and appropriate lifestyle, facilitate communication with them, and help them control their blood sugar and reduce the incidence of GDM [43].

Regarding the different providers of the interventions, the results of the subgroup analysis reported that mHealth interventions delivered by medical staff, including obstetricians and nurses, were effective in preventing GDM. It has been suggested that different models of care provided by various intervention providers may influence outcomes. mHealth interventions delivered by dietitians may focus on the food needs of women during pregnancy [44], whereas exercise physiologists are more concerned with physical activity during pregnancy [45]. Medical staff usually focus on the overall health of pregnant women, providing nutrition, exercise, weight management, and other comprehensive knowledge of pregnancy health care [46].

Subgroup analysis showed that mHealth interventions combining diet and exercise were effective in preventing gestational diabetes in women with overweight or obesity. Combined interventions with diet and exercise appeared to have a greater impact on GDM than interventions with diet or exercise alone, and the effects of diet and exercise on GDM were indistinguishable [47]. Type 2 diabetes has been proven to be preventable through combined diet, exercise, and weight loss interventions [48]. Another subgroup analysis found that mHealth-based lifestyle interventions were effective in preventing GDM in Asian populations. However, the pooled effects of interventions on the risk of GDM in predominantly White populations did not reach statistical significance. The disease burden of GDM varies by race because of multiple factors, including socioeconomic status, lifestyle, and culture, and the prevalence of GDM is significantly higher among Asian and Hispanic populations than among White populations [49]. The results of the subgroup analysis showed that, in studies using the IADPSG diagnostic criteria for GDM, mHealth-based lifestyle interventions had a significantly greater effect on GDM. The prevalence of GDM varies widely worldwide, at least in part because of a lack of consistency in screening and diagnostic criteria. Using lower glucose level thresholds as recommended by the IADPSG, significantly higher numbers of women with GDM were identified compared with using other diagnostic criteria [50].

Maternal and Neonatal Outcomes

Our meta-analyses revealed that the combined effect of mHealth interventions reduced the incidence of preterm birth, macrosomia, and excessive GWG. A review summarized the evidence regarding the influence of maternal diet before and during pregnancy on preterm birth. The results indicated that better maternal diet quality during pregnancy, characterized by a high intake of vegetables, fruits, whole grains, dairy products, and protein, played a significant role in reducing the risk of premature birth [51]. In addition, this study was in line with the findings of Fair and Soltani [52], who conducted a systematic review of the effectiveness of lifestyle interventions on weight gain in women with overweight or obesity during pregnancy and found that lifestyle interventions slightly reduced weight gain during pregnancy by 0.3 to 2.4 kg compared with standard care. There is no robust evidence that mHealth-based interventions are associated with a lower prevalence of postpartum hemorrhage, pregnancy-induced hypertension, cesarean sections, or any alteration in gestational age, consistent with a previous systematic review [53]. One reason for this nonsignificant effect may be the insufficient power of the combined sample size. Another possibility is the short duration of the interventions (median 18 wk), which might have been inadequate to affect some obstetric complications and neonatal outcomes. Further studies are needed to actively explore the associations between mHealth interventions and maternal and neonatal outcomes.

Strengths and Limitations

This systematic review and meta-analysis has several strengths. We combined MeSH terms and keywords covering pregnancy and mHealth to conduct a comprehensive search in 5 primary English electronic databases and 4 main Chinese electronic databases to minimize the possibility of publication bias. We used a robust 3-step search strategy to include databases containing published and unpublished RCTs. To minimize bias, the review methods were preregistered in accordance with the PRISMA statement. In addition, some of the studies included in this meta-analysis were conducted in Western, high-income countries, and some were conducted in Eastern, lower-income countries. Our meta-analyses provided an excellent synthesis of the responses of participants from different cultural backgrounds to mHealth interventions.

However, there were also some limitations to this review. First, we only retrieved studies published in English or Chinese owing to language limitations. Studies published in other languages were not included in the review, which may have led to some publication bias. Second, the methodological quality of the included studies was not optimal, and some studies had a risk of performance bias and detection bias. Third, the included studies varied in sample size, participant characteristics, components of the mHealth interventions, and intervention implementation methods, which may have led to high heterogeneity. Moreover, key variables such as the exact start of the intervention and intensity of physical activity were missing and incomplete in some studies and may have biased the pooled effects. Finally, not all the included studies reported the safety and cost-effectiveness of the mHealth interventions.

Conclusions

This systematic review and meta-analysis demonstrated that mHealth-based lifestyle interventions have a favorable impact on the prevention of GDM in pregnant women with overweight and obesity. mHealth interventions are a convenient and effective way to support pregnant women with overweight and obesity in out-of-hospital self-management in the context of rapid advances in IT and faster transmission speed. However, the potential of mHealth-based interventions for GDM needs to be further explored with better design and more rigorous large-scale RCTs.

Authors' Contributions

All authors made substantial contributions to the study. YH initiated the study. CH and QH conducted the data extraction and analyses. YH wrote the first draft of the manuscript. BL critically reviewed and revised the manuscript. All authors have read and approved the final manuscript.

Abstract

Background: Depression is the most common psychiatric disorder among older adults. Despite the effectiveness of pharmacological and psychological therapies, many patients with late-life depression (LLD) are unable to access timely treatment. Telecare has been shown to be effective in addressing patients' psychosocial issues, while its effectiveness in serving patients with LLD remains unclear.

Objective: This study aimed to evaluate the effectiveness of telecare in reducing depression and anxiety symptoms and improving quality of life (QoL) in patients with LLD.

Methods: Databases including the Cochrane Library, Web of Science, PubMed, Embase, and EBSCO were searched for randomized controlled trials (RCTs) evaluating the effectiveness of telecare for LLD from database establishment to December 28, 2022.

Results: A total of 12 RCTs involving 1663 participants were identified in this study. The meta-analysis showed that (1) telecare significantly reduced depressive symptoms in patients with LLD compared to those in usual care (UC; standardized mean difference [SMD]=–0.46, 95% CI –0.53 to –0.38; *P*<.001), with the best improvement observed within 3 months of intervention (SMD=–0.72, 95% CI –1.16 to –0.28; *P*<.001); (2) other scales appeared more effective than the Patient Health Questionnaire-9 for LLD in telecare interventions (SMD=–0.65, 95% CI –0.96 to –0.35; *P*<.001); (3) telecare was more effective than telephone-based interventions for remote monitoring of LLD (SMD=–1.13, 95% CI –1.51 to –0.76; *P*<.001); (4) the reduction of depressive symptoms was more pronounced in patients with LLD with chronic conditions (SMD=–0.67, 95% CI –0.89 to –0.44; *P*<.001); (5) telecare was more effective for LLD in Europe and the Americas than in other regions (SMD=–0.73, 95% CI –0.99 to –0.47; *P*<.001); (6) telecare significantly reduced anxiety symptoms in patients with LLD (SMD=–0.53, 95% CI –0.73 to –0.33; *P*=.02); and (7) there was no significant improvement in the psychological components of QoL in patients with LLD compared to those receiving UC (SMD=0.30, 95% CI 0.18-0.43; *P*=.80).

Conclusions: Telecare is a promising modality of care for treatment, which can alleviate depression and anxiety symptoms in patients with LLD. Continued in-depth research into the effectiveness of telecare in treating depression could better identify where older patients would benefit from this intervention.

telecare; depression; anxiety; quality of life; older adults; meta-analysis

Introduction

Statistics show that the world's population older than 60 years will double between 2015 and 2050, increasing from 12.0% to 22.0% [1]. With the rapid growth of the older population, late-life depression (LLD) has gradually emerged as a hot topic in the field of geriatric medical research. LLD refers to depressive disorders occurring in adults older than 60 years [2,3]. Research findings indicate a global prevalence of LLD of 28.4% [4], which could potentially be higher among individuals with concurrent physical ailments. As a geriatric syndrome with multifactorial etiology, LLD is highly associated with medical problems that pervade later life, including diabetes, hypertension, and dementia [2,5]. LLD is often chronic or recurrent and is associated with functional impairment, diminished health-related quality of life (QoL), and impaired social-psychological functioning [3,6]. A study confirmed that health care costs for patients with LLD were 43.0% to 52.0% higher for outpatient services and 47.0% to 51.0% higher when outpatient and inpatient services were combined, compared to those for individuals without LLD [7].

Despite its high prevalence and severe adverse outcomes, LLD is often overlooked and inadequately treated due to other complications resulting from aging-related issues. Psychopharmacotherapy and psychotherapy have been demonstrated to be effective for people with depression [6]; however, these treatments still have limitations, such as medical side effects and poor treatment adherence [8,9]. Due to mobility issues, geographic isolation, stigma associated with mental illness, and negative beliefs about treatment, older adults have limited access to health care or may be unwilling to seek help from health care institutions [10-12]. Additionally, underuse of professional mental health services, including low detection rates by health care providers and the lack of awareness among older patients regarding the severity of their condition [13,14], is also one of the factors that impede the treatment of LLD. Limited by these factors, only a minority of older adults receive appropriate treatment for depression. Therefore, there is an urgent need to study the clinical effectiveness of alternative therapies for depression, which are more socially acceptable and easily available.

In recent years, there has been increasing attention toward using telecare to support the management and well-being of mental health [15]. Telecare refers to the delivery of health care directly to users, typically in their own homes, supported by information and communication technologies such as telephone, videoconferencing, and applications [16,17]. Health care professionals can remotely provide consultation, assessment, and intervention services to patients [18]. These services include, but are not limited to, lifestyle monitoring, remote monitoring of vital signs for diagnosis, as well as long-distance assessment and education. The benefits of telecare are evident. Evidence suggests that as a promising strategy, telecare services can serve as a medium to overcome certain barriers, thereby enhancing mental health care and increasing opportunities to access evidence-based care under different conditions [19]. Particularly, telecare benefits older adults who are socially isolated or physically frail due to illness, disability, or other familial roles [17,20]. Currently, telecare has been widely used in the management of various chronic conditions among older adults, such as diabetes, hypertension, Parkinson disease, etc, yielding positive outcomes [21-23]. Depression is a commonly observed chronic condition among older adults, closely associated with an approximate 50% increase in chronic disease-related health care costs [24]. Given the significant impact of LLD on patients' QoL and its potential consequences on decreased productivity or suicide, ensuring continuity of care is imperative. Telecare has been proposed as an effective alternative to help bridge this treatment problem. Considering the complexity and severity of LLD, it is necessary to further explore whether telecare is effective in improving health outcomes for patients with LLD.

Previous reviews have assessed the evidence related to the use of telecare for managing mental health issues [11,25]. In the field of psychiatry, telecare has been found to significantly impact mental health outcomes in older adults, including reducing emergency visits and hospitalizations, as well as improving cognitive function [11]. However, the efficacy of telecare for depression is inconsistent. Some studies suggest the effectiveness of telecare in reducing symptoms of depression [11,26], while others indicate that the impact of telecare on improving depressive symptoms is limited, even yielding contradictory results [27,28]. Previous meta-analyses examining the effectiveness of telecare on depression have mostly focused on adult populations [25-27]. However, compared to other age groups, LLD is considered to be different [14]. Differences in study design, intervention methods, and treatment intensity may contribute to varying clinical outcomes in telecare treatments for LLD. Despite recent meta-analyses demonstrating significant efficacy of telemedicine in alleviating depressive symptoms among older adults, the evaluation of its evidence remains limited [29]. Due to inherent heterogeneity in inclusion criteria, interpretation of these results should be approached cautiously. The severe clinical outcomes and interfering factors often pose significant challenges in the treatment of LLD. Determining whether telecare management is effective for LLD is critical. It is unclear how effective telecare is in improving depression, anxiety symptoms, and QoL in patients with LLD. Therefore, this systematic review and meta-analysis explored the efficacy of telecare for LLD.

Methods

This systematic review was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (Multimedia Appendix 1) [30].

Search Strategy

We conducted searches in Cochrane Library, Web of Science, PubMed, Embase, and EBSCO for randomized controlled trials (RCTs) published from the inception of the databases up to December 28, 2022, without any language restriction. MeSH (Medical Subject Headings) and free search terms were both used in the literature search. The search terms included "cell Phones," "telemedicine," "smartphone," "mobile applications," "mobile phone*," "telephone*," "telehealth," "tele-healthcare," "electronic health*," "application*," "m-health," "messaging," "depression," "depressive disorder," "depress*,"

"Major depression," "sadness," "late-life depression," "LLD," "aged," "elder*," "geriatric," "senior people," "RCTs," etc. All titles, keywords, and abstracts have been reviewed in accordance with our search criteria. In this study, these research articles were exclusively published in English, focusing on telecare interventions for LLD. The specific search strategy is shown in Multimedia Appendix 2.

Study Selection and Data Exclusion

The inclusion criteria were the following: (1) studies were RCTs reported in full text with their title and abstract; (2) the average age of the study population was at least 60 years; (3) participants were diagnosed with depression in accordance with any established diagnostic criteria or with a score above a cutoff of any established depression rating scale at baseline; (4) the studies compare telecare (mobile phone, telephone, app, video, etc) participants with the control group receiving usual care (UC; routine, offline, or standard care); and (5) any health care professional providing care (ie, psychiatrists, family physicians, nurses, psychologists, etc).

Exclusion criteria were the following: (1) patients with manic or psychotic episodes or symptoms; (2) studies not related to the objective of this review and insufficient data, such as failure to report depression scale scores; and (3) books and studies without full text and studies in the format of abstracts of conference papers.

Data Extraction

Two authors independently reviewed all the databases, with specific search strategies for the relevant articles (MW and CYL). The software EndNote X9 (Clarivate) was used to import all the references and remove duplicates. After removing duplicates, the relevance of the title and abstract of the articles was evaluated. Any disagreements were discussed until a consensus was reached. After screening the title and abstract, the articles were selected for the next step of a full-text review. The 2 authors screened the full-text articles independently (MW and CYL). Finally, eligible articles included in the study were processed based on inclusion and exclusion criteria. Any discrepancies that arose during the assessment were resolved by a third reviewer (FY). Two authors independently extracted data from the included studies and entered them into a predesigned data extraction form. Data extracted for this study included the following: first author, year of publication, country, sample size, mean age, intervention approach, duration, presence or absence of comorbid chronic conditions, depression degree, and outcome measurement tools (Table 1).

Table 1. Basic characteristics of the included studies (N=12; all are randomized controlled trials).

First author (year); country	Sample size, N (TC[a]/UC[b])	Age (years), mean (SD)	Duration	Comorbid chronic diseases	Depression degree	Outcomes
Rollman (2009) [31]; United States	302 (150/152)	TC: 64 (10.8); UC: 64 (11.2)	Baseline, 8 months	Yes	Moderate	HAM-D[c] and SF-36[d]
Aburizik (2013) [32]; United States	52 (29/23)	TC: 66.4 (7.9); UC: 64.1 (10.5)	Baseline, 10 weeks	Yes	Mild	PHQ-9[e] and BDI[f]
Lee (2014) [23]; Korea	25 (12/13)	TC: 66.7 (7.9); UC: 65.4 (8.6)	Baseline, 6 months	Yes	Mild, moderate	CES-D[g]
Villani (2014) [33]; Italy	80 (40/40)	TC: 71 (4); UC: 73 (5)	Baseline, 12 months	Yes	Moderate, severe	PHQ-9 and STAI-6[h]
Pickett (2014) [34]; United States	124 (60/64)	TC: 69.1 (10.9); UC: 68.6 (10.7)	Baseline, 12 weeks	No	Mild	PHQ-9
O'Neil (2014) [35]; Australia	121 (61/60)	TC: 61.0 (10.2); UC: 58.9 (10.7)	Baseline, 6 months	Yes	Mild, moderate	PHQ-9, CDS[i], and SF-12[j]
Gellis (2014) [36]; United States	94 (46/48)	TC: 80.1 (7.8); UC: 78.3 (6.9)	Baseline, 3 months, and 6 months	Yes	Mild, moderate	PHQ-9, HAM-D, and SF-12
Yang (2019) [37]; China	212 (107/105)	TC: 61.25 (8.60); UC: 60.85 (10.80)	Baseline, 12 months	Yes	Mild, moderate	HADS-D[k] and SDS[l]
Naik (2019) [21]; United States	225 (136/89)	61.9 (8.3)	Baseline, 6 months, and 12 months	Yes	Moderate	PHQ-9
Dobkin (2020) [22]; United States	72 (37/35)	TC: 65.62 (9.76); UC: 64.80 (9.62)	Baseline, 3 months, and 6 months	Yes	Moderate	HAM-D, BDI, HAM-A[m], and SF-36
Almeida (2021) [38]; Australia	200 (79/121)	≥65	Baseline, and 52 weeks	No	Mild, moderate	PHQ-9, GAD-7[n], and SF-12
Koehler (2021) [39]; Germany	156 (79/77)	TC: 68.30 (9.13); UC: 64.34 (11.35)	Baseline, 12 months	Yes	Moderate	PHQ-9 and SF-36

[l]SDS: Zung Self-Rating Depression Scale.

[m]HAM-A: Hamilton Anxiety Rating Scale.

[n]GAD-7: 7-item Generalized Anxiety Disorder Scale.

Quality Assessment

Two authors (MW and CYL) independently assessed the quality of the studies using the Cochrane Risk of Bias tool [40]. The assessment tool included 7 items (random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective reporting, and other bias), and authors judged each item individually as "low risk," "high risk," and "unclear risk." The study was considered to be of high quality with a low risk score for at least 4 domains, of which 3 key areas had to be included (random sequence generation, allocation concealment, and incomplete outcome data). Consensus was reached by 2 authors (MW and CYL) through discussion with a third evaluator (FY).

Statistical Analysis

Data were analyzed using Stata (version 16.0; StataCorp) and Review Manager (version 5.3; The Cochrane Collaboration). Intervention effects were estimated by calculating Cohen *d* standardized mean differences (SMDs) and 95% CIs [41]. All studies reported outcomes as continuous data. The Cochran Q

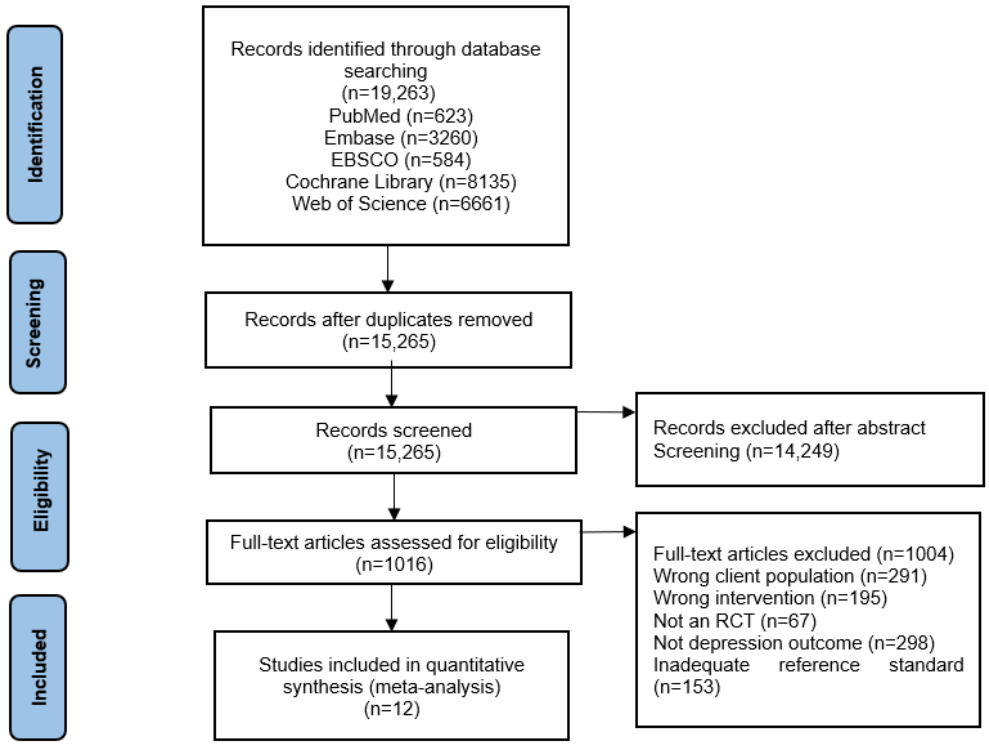
statistic and I^2 statistic were used to assess the statistical heterogeneity between selected studies. Random-effects models were used when study heterogeneity was high (P<.10; I^2>50%); otherwise, a fixed-effects model would be used. When heterogeneity identified across studies was high, we further performed subgroup analyses to explore possible explanations for heterogeneity. Publication bias was measured using a funnel plot and Egger linear regression analysis, and P<.05 on the Egger test indicated statistically significant publication bias [42].

Results

Literature Search

The database search yielded 15,265 articles, of which 14,249 publications were excluded. A total of 1016 full-text articles were assessed for eligibility. Finally, only 12 studies were eligible for inclusion in this meta-analysis [21-23,31-39], all of which were RCTs published between 2009 and 2021. The PRISMA flow diagram is shown in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. RCT: randomized controlled trial.



Risks of Bias and Quality Assessment

Overall, the quality of the included studies was moderate, of which 5 (41.7%) were of high quality. These studies show that the main bias in the blinding of participants and personnel may be caused by the nature of the intervention measures. All 12 articles reported adequate random sequence generation and, therefore, had a low risk of bias in this regard. In addition, 5 studies reported allocation concealment, which is a low risk of bias. As for detection bias, the assessors were blinded in 7 studies, the presence of blinding was unclear in 3 studies, and 2 studies were not blinded. The risks of study attrition bias and reporting bias were both low. Other risks of bias were also low but were unclear in 1 study. The specific risk of bias and quality assessment results are shown in Figures 2 and 3 [21-23,31-39].

Figure 2. Overall risk of each type of bias.

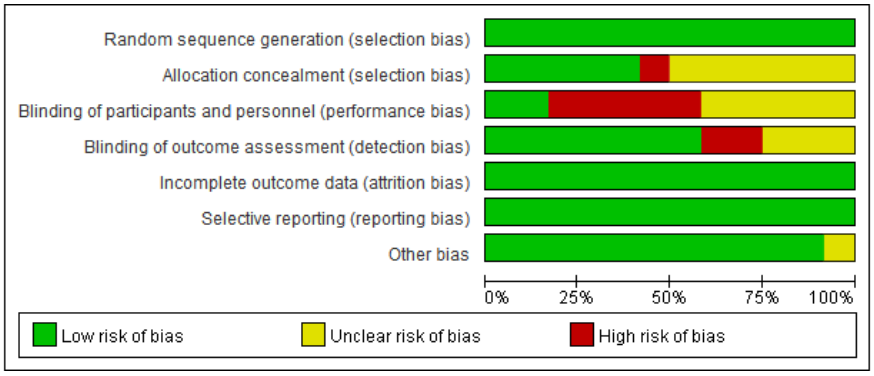


Figure 3. Risk of bias in each study.

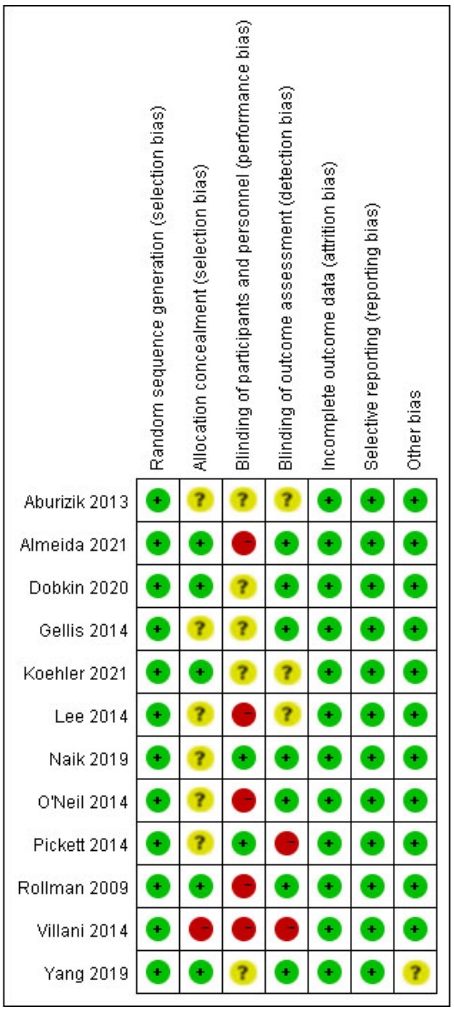


Study and Patient Characteristics

The characteristics of the studies included are summarized in Table 1. A total of 1663 patients with LLD were involved, with an average age of over 60 years in each group. The sample size ranged from 25 [23] to 302 [31] participants. Studies were carried out across 6 countries, including the United States (n=6) [21,22,31,32,34,36], Korea (n=1) [23], Italy (n=1) [33], Australia (n=2) [35,38], China (n=1) [37], and Germany (n=1) [39]. Nine of these used telephone-based interventions, while the remaining studies used remote monitoring systems. Durations ranged from 10 weeks to 52 weeks. Depression, anxiety symptoms, and QoL were substantial influencing factors of treatment for older adults. Therefore, our primary outcome of interest was depression, and secondary outcomes were anxiety symptoms and QoL. Depression was evaluated using the Hamilton Depression Rating Scale, Patient Health Questionnaire-9 (PHQ-9), Beck Depression Inventory, Center for Epidemiological Survey, Depression Scale, Cardiac Depression Scale, Hospital Anxiety and Depression Scale, and Zung Self-Rating Depression Scale. Anxiety symptoms were assessed using Spielberger's State Trait Anxiety Inventory, Hamilton Anxiety Rating Scale, and the 7-item Generalized Anxiety Disorder Scale. QoL was assessed using the 12-Item Short Form Survey and the 36-Item Short Form Survey. A higher score on the scales indicated better QoL and

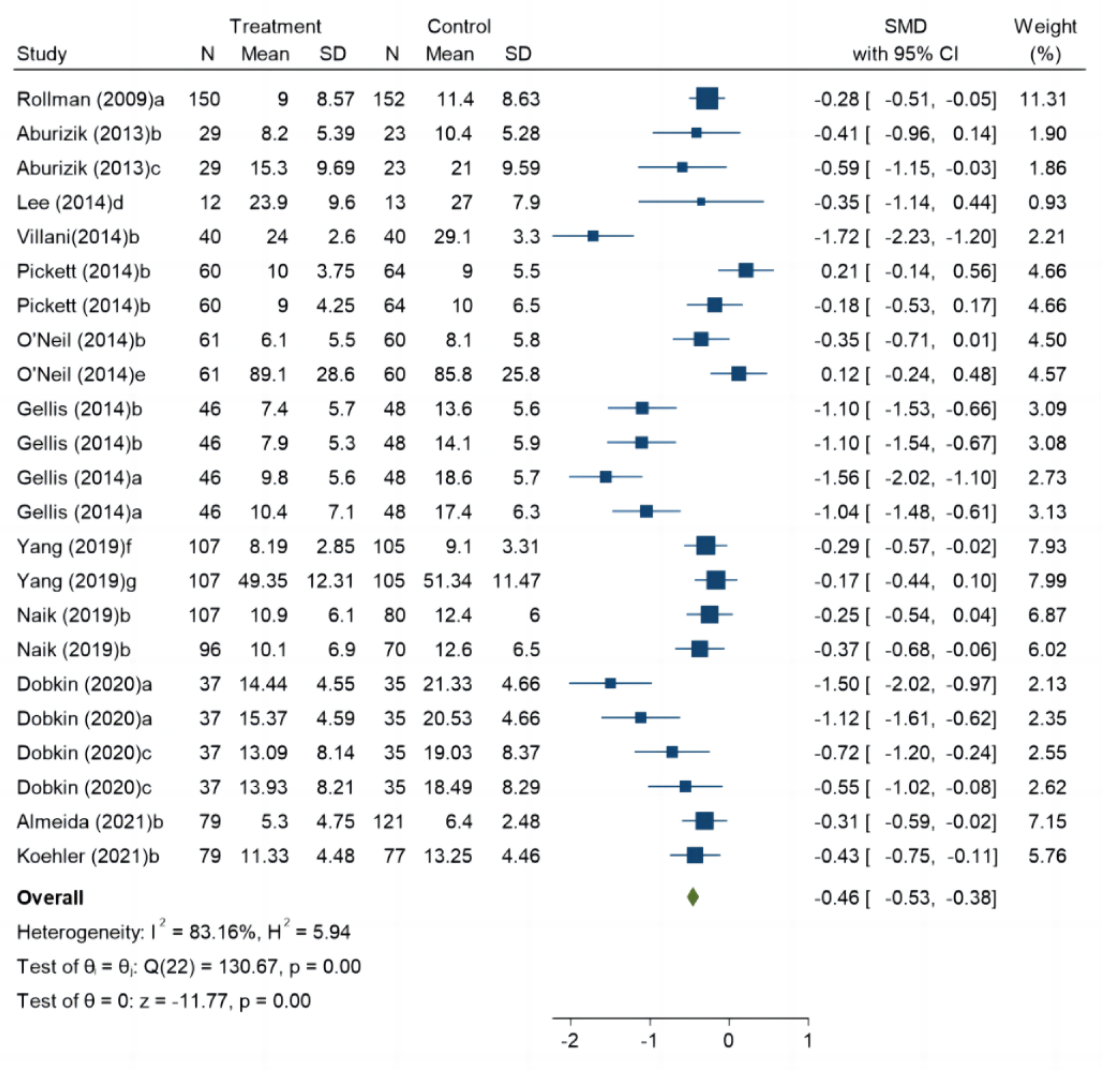
greater severity of depression and anxiety symptoms. The specific interventions are available in Multimedia Appendix 3.

Depression Symptoms

A total of 12 RCTs involving 1663 participants were identified in this meta-analysis to calculate the effectiveness of telecare on depression, anxiety symptoms, and QoL in patients with LLD.

To compare the effects of telecare and UC in improving LLD, we included data from 12 of these studies. Our results show that telecare significantly reduced depressive symptoms in patients with LLD compared to those in UC (SMD=–0.46, 95% CI –0.53 to –0.38; *P*<.001). Fixed-effects model analysis revealed significant heterogeneity among the 12 included studies (I^2=83.16%; *P*<.001; Figure 4) [21-23,31-39].

Figure 4. Forest plot for primary outcomes: depression. a: Hamilton Depression Rating Scale; b: Patient Health Questionnaire-9; c: Beck Depression Inventory; d: Center for Epidemiological Survey, Depression Scale; e: Cardiac Depression Scale; f: Hospital Anxiety and Depression Scale; g: Zung Self-Rating Depression Scale.



To address high heterogeneity, we performed subgroup analyses grouped by the type of scale (PHQ-9 or others), duration time (≤3 months or >3 months), device type (telephone-based or remote monitoring system), comorbid chronic diseases (presence or absence), and region (Europe and the Americas or others).

Random-effects models indicated that telecare significantly reduced depressive symptoms in patients with LLD compared to the UC participants (SMD=–0.59, 95% CI –0.80 to –0.38; *P*<.001). Results of subgroup analysis by duration showed that short-term (≤3 months) interventions (SMD=–0.72, 95% CI –1.16 to –0.28; *P*<.001) were more effective than long-term (>3 months) interventions (SMD=–0.52, 95% CI –0.75 to –0.29; *P*<.001); other scales (SMD=–0.65, 95% CI –0.96 to –0.35; *P*<.001) were more effective than the PHQ-9 (SMD=–0.53, 95% CI –0.83 to –0.22; *P*<.001); the remote monitoring system (SMD=–1.13, 95% CI –1.51 to –0.76; *P*<.001) was more effective than telephone-based interventions (SMD=–0.38, 95% CI –0.56 to –0.20; *P*<.001); the effect on patients with LLD with chronic diseases (SMD=–0.67, 95% CI –0.89 to –0.44; *P*<.001) was better than that on patients with LLD without comorbid chronic diseases (SMD=–0.10, 95% CI –0.41 to 0.20; *P*=.07); and telecare was more effective in Europe and the Americas (SMD=–0.73, 95% CI –0.99 to –0.47; *P*<.001) than in other regions (SMD=–0.22, 95% CI –0.35 to –0.09; *P*=.42; Table 2).

Table 2. Subgroup meta-analysis for patients with late-life depression.

Subgroups	Cohen *d* SMD[a]	95% CI	*P* value	Heterogeneity (I^2; %)
Overall	–0.59	–0.80 to –0.38	<.001	86.42
Duration				
≤3 months	–0.72	–1.16 to –0.28	<.001	86.91
>3 months	–0.52	–0.75 to –0.29	<.001	84.72
Type of scale				
PHQ-9[b]	–0.53	–0.83 to –0.22	<.001	87.13
Others	–0.65	–0.96 to –0.35	<.001	86.21

[a]SMD: standardized mean difference.

[b]PHQ-9: Patient Health Questionnaire-9.

Meta-regression analysis showed that heterogeneity may not be related to the year of publication (*P*=.42), total sample size (*P*=.21), study area (*P*=.35), comorbid chronic disease (*P*=.47), duration (*P*=.75), and outcome measurement tools (*P*=.29). However, only the intervention device (*P*=.004) may have contributed to the heterogeneity.

Sensitivity Analysis and Publication Bias

The stability and reliability of the results of this meta-analysis and potential factors contributing to heterogeneity were explored by sensitivity analysis to assess the effect of the data of each study on the combined effect value (ie, SMD). The results of the sensitivity analysis showed that excluding each study individually had no significant effect on the combined effect value, and the study results were stable and reliable (Figure 5) [21-23,31-39]. Publication bias was assessed using funnel plots and Egger test indicators. The funnel plot was symmetrically distributed on both sides (Figure 6), and the Egger test showed no significant publication bias (*P*=.05).

Figure 5. Sensitivity analysis of effect value (standardized mean difference).

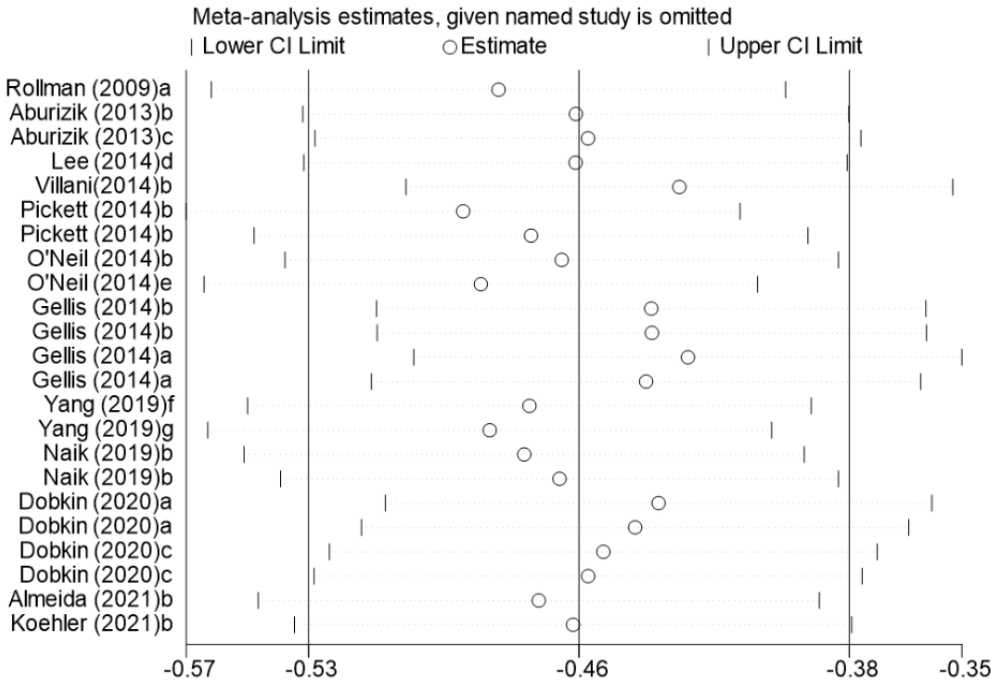

Figure 6. Funnel plot showing publication bias. SMD: standardized mean difference.

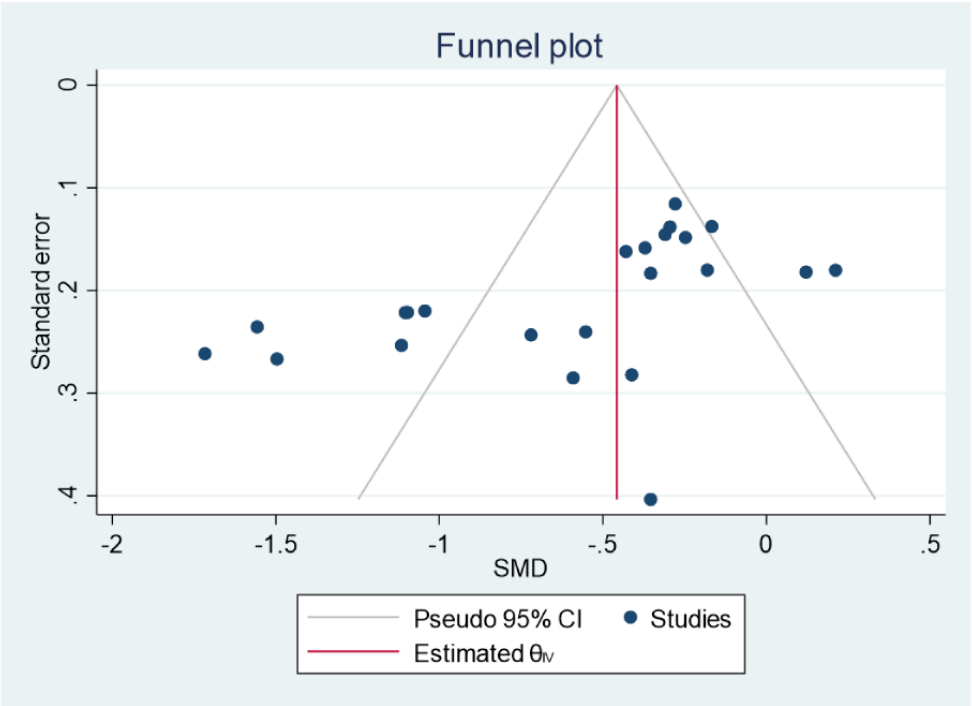
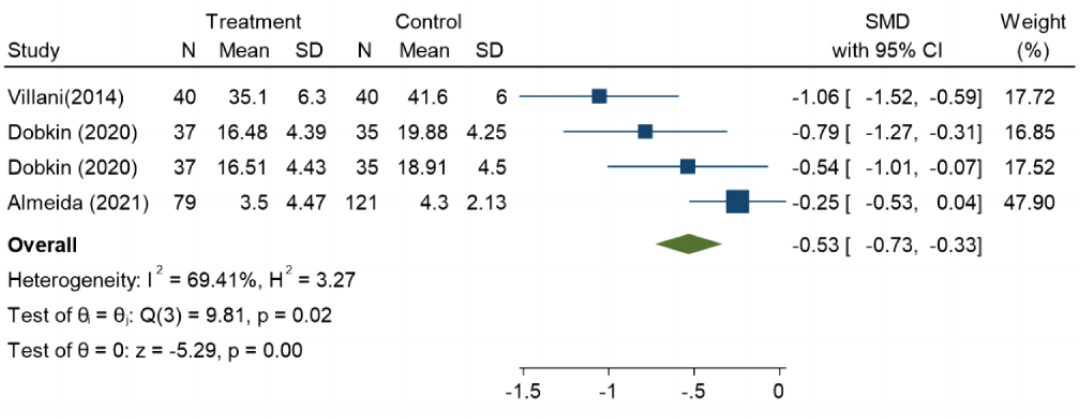


Anxiety Symptoms

To examine the efficacy of telecare in reducing anxiety compared with that of UC, we included 3 articles on patients with LLD. The results showed that telecare significantly reduced anxiety symptoms in patients with LLD (SMD=–0.53, 95% CI –0.73 to –0.33; *P*=.02; Figure 7) [22,33,38].

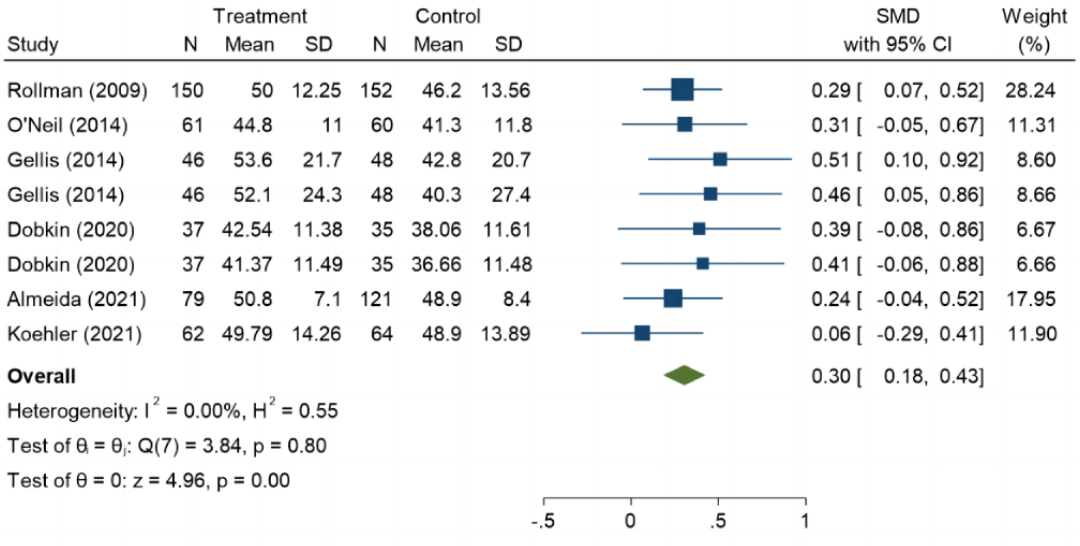
Figure 7. Forest plot of secondary outcome: anxiety.



QoL

Six studies assessed the mental components of QoL by using the Medical Outcomes Study Short Form survey. Our meta-analysis shows that the QoL of patients with LLD improved, but, overall, it was not significant (SMD=0.30, 95% CI 0.18-0.43; *P*=.80; Figure 8) [22,31,35,36,38,39].

Figure 8. Forest plot of secondary outcome: quality of life.



Discussion

Principal Findings

This meta-analysis shows that compared with UC, telecare significantly reduces symptoms of depression and anxiety but has no significant effect on improving QoL in patients with LLD.

Primary Outcome Measures

The pooled results show that telecare has a significant effect on reducing depressive symptoms in patients with LLD, which is consistent with the findings of previous studies [25,26,29]. Apart from dealing with depression itself, the increased severity of LLD is also related to factors such as aging, chronic disease, and socioeconomic stress [5]. Telecare offers unique and innovative opportunities for treating depression symptoms in older adults. Patients with LLD can leverage the advantages of telecare to connect with health care professionals, overcoming geographical distance and physical limitations, thereby reducing the psychological burden of coping with the disease [43]. Furthermore, professional psychological support is crucial for patients with LLD, and it can encourage patients to express their feelings and release stress [44]. However, it is worth noting that despite telecare offering more possibilities for treating LLD, the complexity of the medical population makes it challenging. Telecare can provide greater coverage for health care, yet considerations such as individual needs of older patients or environmental backgrounds need to be factored in [45]. Currently, offering targeted telecare services to a large population of older adults in rural, remote, or underserved areas remains a challenge [10]. In particular, older adults face significant barriers in using telephone and internet connections during the COVID-19 pandemic [46]. As a result, telecare management may not be as effective for this population as for others. The size of the research effect will depend on the nature of the intervention and the quality of the study [47]. High-quality telemedicine will help older adults benefit both physically and mentally. Further investigation and more research are necessary.

Subgroup analysis indicates that the effectiveness of telecare in treating LLD can be influenced by measurement tools,

durations, intervention devices, comorbid chronic conditions, and regions involved. In terms of depression measurement tools, other scales appear to be more effective than PHQ-9 (0.65% vs 0.53%), which may be related to measurement errors caused by differences in specific items and the generalizability of different measurement tools [48]. Results from durations of ≤3 and >3 months showed a reduction in depressive symptoms in patients with LLD, with short-term interventions proving to be more effective (0.72% vs 0.52%). Short-term interventions focus more on addressing specific issues or symptoms, producing immediate effects. For older adults, short-term interventions might be more readily accepted as long-term treatments could induce fatigue or a lack of patience. Our findings differ slightly from those of another study [49], which implemented more targeted interventions based on different treatment responses, confirming the more significant effectiveness of long-term interventions. Therefore, there is insufficient evidence to conclusively establish that telecare is necessarily superior in short-term intervention efficacy for LLD compared to long-term interventions. In fact, for depression management, a combination of short-term and long-term interventions is often required to deliver comprehensive and enduring support and management [50].

Subgroup analysis also found that remote monitoring systems appear to be more effective than telephone-based management (1.13% vs 0.38%). The remote monitoring system ensures timely and accurate transmission of patients' symptom information and data to health care professionals, enabling patients to receive effective treatments [51]. Telecare was more effective in patients with LLD with comorbid chronic conditions compared to those without such comorbidities (0.67% vs 0.10%). Co-occurrence of chronic medical conditions and depression is common. Evidence suggests that older adults with chronic illness are more likely to be affected by depressive symptoms than those without chronic illness [2,5,7]. Older adults with chronic conditions are more likely to seek medical care and adherent to treatment [52]. Therefore, while actively treating chronic conditions, there might be a degree of alleviation in depressive symptoms among older adults. Telecare was more effective in Europe and the Americas in improving depressive symptoms in patients with LLD compared than in other regions (0.73% vs 0.22%). The health care systems in Europe and the Americas are generally more developed, which may lead to more comprehensive support for telecare [53]. In low- and middle-income countries, the resources available for geriatric mental health care are considered severely inadequate [54]. Nevertheless, telecare is beginning to have an important impact on many aspects of health care in transitional countries [55].

Secondary Outcome Measures

Telecare has a positive effect on improving anxiety symptoms of patients with LLD. This result is consistent with findings from other studies [56]. Telecare offers a more convenient access method, allowing patients to receive treatment at home, thereby circumventing the inconvenience and anxiety associated with hospital visits [16,17]. Health care professionals can engage with patients more frequently through telecare, gaining insights into their symptoms and emotional fluctuations. This allows for adjustments in the treatment plan to effectively meet the unique needs of this population [18,57]. Additionally, the symptoms of anxiety and depression are often co-occurring [58], particularly among older adults. Due to the similarity between depression and anxiety symptoms, many treatment approaches are shared between the two. A recent meta-analysis suggests that psychotherapy delivered remotely is as effective as face-to-face therapy for anxiety disorder [59]. This evidence is based on outcomes obtained from different age groups. It may be more challenging to create a trusting relationship remotely than in person [60]. Older adults have negative views about health IT performing accurately and dependably, which will have a significant impact on the acceptance of telecare [61]. In brief, when using telecare for addressing emotional disorders in older adults, closer supervision and guidance might be necessary. Health care professionals need to distinguish the appropriateness of using telecare for communication and, in turn, individually tailor patient care.

We found that the mental component of QoL in patients with LLD improved after using telecare; however, this difference was not significant compared to that with the use of UC. This finding aligns with results from other studies [62,63]. Improving QoL is a comprehensive issue that includes not only improvements in health care but also social, psychological, and emotional factors [64]. Influenced by these factors, it is difficult to compare the results of QoL considering different contexts. Several results from RCTs with older adults using telemonitoring systems showed an improvement in the participants' QoL [65,66]; other telemonitoring RCTs could not achieve congruent results [67]. Improvements in QoL often require deeper interactions and personalized care. In particular, participants with mental disorders may benefit from individual and tailored solutions provided by general practitioners [68]. When using telecare, it is crucial to acknowledge that each subpopulation of marginalized older adults has differing strengths and needs. The studies we included focused more on managing the disease itself, which may weaken overall effectiveness. It is not easy to present telemedicine to the older population. The limitations inherent in older adults may lead to difficulties in receiving telecare, including the lack of technical literacy, equipment access barriers, cognitive function, etc [11]. These reasons could explain why telecare is not significant in improving the QoL of patients with LLD. The potential value of telecare in maintaining the QoL for individuals with LLD warrants further exploration. While this study did not reveal a positive impact of telecare on the QoL for patients with LLD, it has been established that telecare can assist patients with LLD in gaining more information about health services.

Limitations

This study still had some limitations. First, most of the studies included in the review lacked sufficient measure detail, leading to irreversible bias. Our study mainly included 2 interventions based on telephone and remote monitoring to reduce this bias. Second, the measurement tools used in this study lacked standardization and heavily relied on self-reports from participants, introducing a degree of subjectivity and concealment that is not as rigorous as structured interviews. However, we attempted to validate the effectiveness of the results by using authoritative scales. Third, differences in the

specific intervention methods, frequency, and content among the included studies may lead to clinical heterogeneity across different studies.

Conclusions

Our meta-analysis shows that telecare has a positive impact on depressive and anxiety symptoms, despite high heterogeneity in depression symptoms. Therefore, studies with larger sample sizes and homogeneity were required to determine the effects of telecare in patients with LLD. Future research can continue to refine telecare systems and assess the specific needs of older vulnerable populations for more accurate evidence.

Abstract

Background: Musculoskeletal diseases affect 1.71 billion people worldwide, impose a high biopsychosocial burden on patients, and are associated with high economic costs. The use of digital health interventions is a promising cost-saving approach for the treatment of musculoskeletal diseases. As physical exercise is the best clinical practice in the treatment of musculoskeletal diseases, digital health interventions that provide physical exercises could have a highly positive impact on musculoskeletal diseases, but evidence is lacking.

Objective: This systematic review aims to evaluate the impact of digital physical health exercises on patients with musculoskeletal diseases concerning the localization of the musculoskeletal disease, patient-reported outcomes, and medical treatment types.

Methods: We performed systematic literature research using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. The search was conducted using the PubMed, BISp, Cochrane Library, and Web of Science databases. The Scottish Intercollegiate Guidelines Network checklist was used to assess the quality of the included original studies. To determine the evidence and direction of the impact of digital physical health exercises, a best-evidence synthesis was conducted, whereby only studies with at least acceptable methodological quality were included for validity purposes.

Results: A total of 8988 studies were screened, of which 30 (0.33%) randomized controlled trials met the inclusion criteria. Of these, 16 studies (53%) were of acceptable or high quality; they included 1840 patients (1008/1643, 61.35% female; 3 studies including 197 patients did not report gender distribution) with various musculoskeletal diseases. A total of 3 different intervention types (app-based interventions, internet-based exercises, and telerehabilitation) were used to deliver digital physical health exercises. Strong evidence was found for the positive impact of digital physical health exercises on musculoskeletal diseases located in the back. Moderate evidence was found for diseases located in the shoulder and hip, whereas evidence for the entire body was limited. Conflicting evidence was found for diseases located in the knee and hand. For patient-reported outcomes, strong evidence was found for impairment and quality of life. Conflicting evidence was found for pain and function. Regarding the medical treatment type, conflicting evidence was found for operative and conservative therapies.

Conclusions: Strong to moderate evidence was found for a positive impact on musculoskeletal diseases located in the back, shoulder, and hip and on the patient-reported outcomes of impairment and quality of life. Thus, digital physical health exercises could have a positive effect on a variety of symptoms of musculoskeletal diseases.

Introduction

Background

A total of 1.71 billion people are affected by musculoskeletal diseases worldwide [1]. They are characterized by chronic pain, functional disability, impairment, and reduced quality of life [1,2]. The most commonly affected body regions are the lower back and neck, with a period prevalence over the last 12 months of up to 61.3% and 45.7% [3], respectively, and a common disease is osteoarthritis, with a prevalence of up to 17.9% [4]. In addition to the high biopsychosocial burden [5], the evident increase in the incidence of musculoskeletal diseases over the last decades [6] results in high economic costs because of lost workdays and conservative or operative medical treatments [5]. To overcome such undesirable consequences, evidence-based, effective, and cost-saving health interventions are required. Therefore, the use of digital health interventions is a promising approach.

Digital health interventions aim to manage a wide range of diseases and health issues using digital devices such as smartphones, tablets, computers, or wearables, including mobile apps, telerehabilitation and web-based physician visits, web-based interactive programs, or tracking tools [7]. The use of mobile apps is increasing, with common intervention types categorized as physical exercise and fitness, lifestyle and stress, diet and nutrition, or medication reminders and educational materials [7]. In some countries, such as Germany, so-called digital health applications are also supported by health insurers after being evaluated as medical devices [8]. However, owing to their cost-saving potential and the increasing number of commercially available digital health interventions [7], further research is needed to evaluate the impact of different types of digital health interventions on specific diseases.

Previous systematic reviews have extensively evaluated the impact of digital health interventions on internal diseases. Positive effects have been demonstrated in treating chronic obstructive pulmonary disease [9], cardiovascular disease [10], and diabetes [11]. These effects encompass improvements in clinically relevant outcomes such as quality of life, health-related impairments, amelioration of risk factors and their consequences, as well as the control and management of HbA1c levels. For musculoskeletal diseases, only 2 previous systematic reviews have evaluated the impact of digital health interventions as a primary outcome. One review [12] showed that there are substantial clinical benefits in the management of musculoskeletal diseases for the patient-reported outcomes of pain (9 out of 19 studies) and functional disability (10 out of 16 studies). The results show that digital health interventions as adjuncts and as stand-alone treatments are not inferior but partly superior compared with interventions based on standard therapy, nondigital self-management, noninteractive digital measures, or no intervention. However, in this previous review, no evidence synthesis was performed. In addition, a further review [13] conducted a meta-analysis and showed moderate-quality evidence that digital health interventions are effective in reducing pain and improving function and self-management in patients with musculoskeletal disease. The included studies considered digital health interventions as interventions that are to be used only at home and as adjuncts to standard clinical care, compared with standard care, noninteractive digital interventions, or no intervention. Taken together, the use of digital health interventions as an adjunct to regular therapy could have positive health-related effects for both internal and musculoskeletal diseases, although less evidence is available for the latter.

However, little is known about the relationship between clinically relevant factors, such as the localization of the musculoskeletal diseases, patient-reported outcomes, or the type of applied conservative or operative medical treatments, and the effects of different types of digital health interventions in the treatment of musculoskeletal diseases. In terms of evidence-based medicine, such relationships must first be clarified when using digital health interventions as a regular treatment option for specific musculoskeletal diseases. Because of the increasing number of original studies, more systematic research is needed to review and assess the existing evidence. Previous systematic reviews [12,13] have included all types of digital health interventions, providing a comprehensive overall result across all biopsychosocial domains. As physical exercise is the best clinical practice for the treatment of musculoskeletal diseases [14], digital physical health exercises could have a highly positive impact on musculoskeletal diseases. However, little is known about how the effects of digital physical health exercises are related to the aforementioned clinically relevant factors.

Objective

Therefore, this systematic review aimed to evaluate the impact of digital physical health exercises on patients with musculoskeletal diseases concerning the localization of the musculoskeletal disease, patient-reported outcomes, and medical treatment types. In addition, a best-evidence synthesis was conducted to estimate the direction and strength of the existing evidence.

Methods

Research Design and Eligibility Criteria

The systematic review was conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [15]. Eligibility criteria according to the population, intervention, comparison, outcome, study design (PICOS) scheme [16] were applied. Table 1 presents the inclusion criteria according to the PICOS scheme. Textbox 1 presents the search line.

The corresponding keywords are also presented. Studies were not reviewed if they did not report on a specific musculoskeletal disease, if the digital health intervention included no physical exercises, if no control group was considered, or if none of the included patient-reported outcomes were assessed as a primary outcome. All methodological steps were performed by 1 author and validated by a second author. Uncertainties were discussed until consensus was reached. Because of the literary nature of this study, ethics approval was not required.

Table 1. PICOS[a] scheme for the definition of the inclusion criteria and the presentation of the corresponding keywords.

	Population	Intervention	Comparison	Outcome	Study design
Inclusion criteria[b]	Patients with any musculoskeletal disease according to the definition of the WHO[c]	Any digital health intervention using home-based physical exercises	Any conventional or no therapy	Patient-reported outcomes pain, function, disability, and quality of life assessed by established and validated clinical questionnaires or scales	Randomized controlled trials

Literature Search, Study Selection, and Risk of Bias

The literature search was performed on July 21, 2022, using the PubMed (MEDLINE), BISp (Federal Institute of Sport Science), Cochrane Library, and Web of Science databases. The search line included terms presented in Table 1. The "outcomes" category was not included in the search strategy but was considered in the subsequent study inclusion and selection process. No filters or other restrictions were used. The retrieved records were exported to a reference manager (EndNote 20, Clarivate). All duplicates were identified using the software and were removed after a manual review. On the basis of the defined eligibility criteria, studies were included or excluded by reviewing the titles, abstracts, and full texts. Full texts were accessed via public or open access and university accounts. If the full texts were not accessible, the authors were contacted. The study quality and the associated risk of bias were assessed using the Scottish Intercollegiate Guidelines Network checklist for randomized controlled trials [17]. The checklist consisted of 10 items related to the internal validity and 2 items related to the overall assessment of the studies. For each included study, all items were answered with "yes," "no," "can't say," or "not applicable." The study quality was then finally rated throughout the "Scottish Intercollegiate Guidelines Network checklist for randomized controlled trials: Notes for completion of checklist" as "not acceptable," "borderline," "acceptable," and "high," as previously done [18]. The definitions of these quality classifications are presented in Textbox 2.

Textbox 2. Definitions for ratings of the overall methodological study quality.

High quality

- Most criteria met. Little or no risk of bias. Results unlikely to be changed by further research.

Acceptable quality

- Most criteria met. Some flaws in the study with an associated risk of bias. Conclusions may change in the light of further studies.

Borderline quality

- Crude effect estimates have been presented or have been calculated (thus no confounders have been considered), but the study is otherwise acceptably sound with respect to other possible biases.

Not acceptable quality

- Either most criteria not met, or significant flaws relating to key aspects of study design. Conclusions likely to change in the light of further studies.

Note: Definitions according to Asker et al [18].

Data Extraction and Synthesis of Results

Data extraction was performed according to the PICOS scheme. A best-evidence synthesis was conducted to clarify the evidence for digital physical health exercises on clinically relevant factors clustered as (1) localization of the musculoskeletal diseases, (2) patient-reported outcomes (according to the eligibility criteria), and (3) medical treatment types (conservative vs operative). Within these clusters, the study results were individually classified as positive, negative, or equal for each clinically relevant factor. In accordance with a previous study [14], the study results were classified as positive or negative if the intervention or control group showed statistically better significant study results than the other group for >50% of the outcome parameters that were used to examine the respective clinically relevant factors. If no statistically significant differences were reported between the intervention and control groups, the study results were classified as equal. With regard to the best-evidence synthesis, the established criteria [18] are summarized in Table 2, and to increase the validity, only studies with at least acceptable study quality were included [19].

Table 2. Criteria of best-evidence synthesis according to Asker et al [18].

Rating	Study quality	Criteria
Strong evidence	≥2 high-quality studies	≥75% consistent findings in these studies
Moderate evidence	1 high-quality study and/or ≥2 acceptable-quality studies	≥75% consistent findings in these studies
Limited evidence	1 acceptable-quality study and/or ≥1 borderline-quality study	N/A[a]
Conflicting evidence	Conflicting results in several studies of any quality	<75% of studies reported concordant results
No evidence	No admissible studies were found	N/A

[a]N/A: Not applicable.

Results

Literature Search, Study Selection, and Risk of Bias

Figure 1 shows the flowchart of the literature search including the study selection process according to the PRISMA guidelines. On the basis of the eligibility criteria, of 10,441 records, 30 (0.29%) studies were finally included in the risk of bias assessment. Although 1453 studies were identified as duplicates, 8958 studies that did not meet the inclusion criteria addressed no musculoskeletal diseases, were not randomized controlled trials, or addressed other outcomes. Table 3 summarizes the results of the risk of bias assessment.

There were 10 studies with high quality [20-29], 6 studies with acceptable quality [30-35], 10 studies with borderline quality [36-45], and 4 studies with not acceptable quality [46-49]. Thus, because of the not acceptable and borderline qualities of 14 studies, 16 studies were further analyzed and finally included in the best-evidence synthesis.

Figure 1. Flowchart of the literature search including the study selection process according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. RCT: randomized controlled trial.

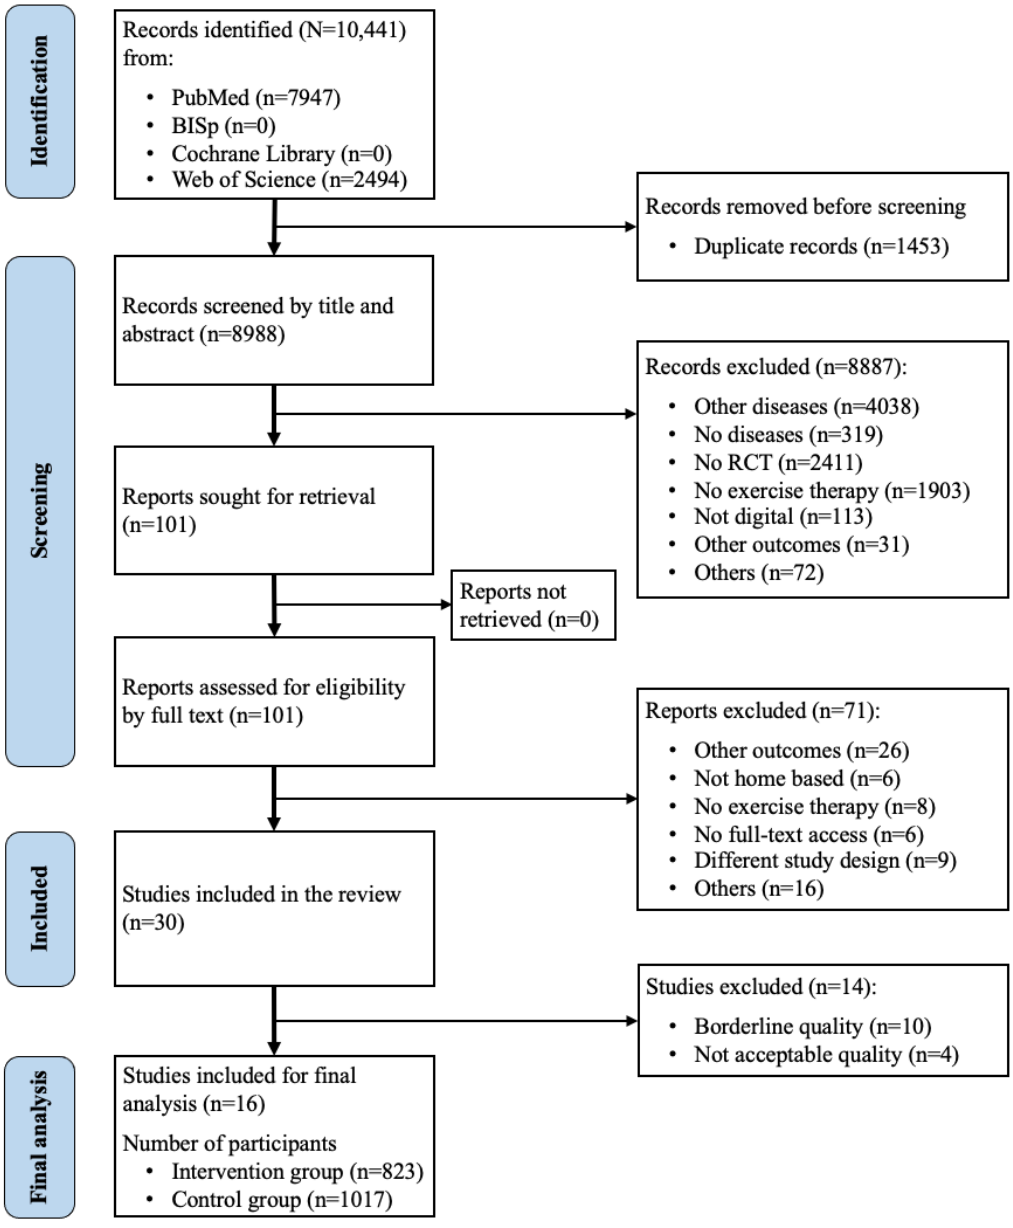

Table 3. Results of the 30 studies checked for the risk of bias assessment using the Scottish Intercollegiate Guidelines Network checklist.

Study Characteristics

Table 4 presents the study characteristics of the 16 included studies according to the PICOS scheme.

The publication period ranged from 2011 [35] to 2022 [29,34], whereby 3 studies were published each in 2018 [21,31,32], 2019 [22,23,25], and 2021 [20,27,33]. The most common publication country was Australia, with 3 studies [27,28,30], followed by 2 studies each published by Spain [22,34], Canada [26,35], and the United States [21,25]. Across the 16 studies, 1840 patients were investigated, and the sample sizes ranged from 34 [33] to 350 patients [21]. The reported dropout rate was up to 18% (6/34) [33]. The average age of the patients varied from 38.5 [20] to 66 years [26,35], and the average female proportion across all studies reported was 61.35% (1008/1643) and varied from 51% (148/290) [25] to 100% (34/34) [33]. Regarding the localization of the musculoskeletal diseases, 7 studies were on knee-specific diseases such as total knee arthroplasty [25,26,32,35], knee osteoarthritis [21,27], and chronic knee pain [30]. This was followed by 4 studies on back-specific diseases such as low back pain [24,29,31] and chronic neck pain [20]. A total of 2 studies were on hand-specific diseases [22,34], whereas only 1 study was found for each full body [33], shoulder-specific diseases [23], and hip-specific diseases [28]. Regarding the patient-reported outcomes, 14, 12, 6, and 5 studies investigated pain [20-23,25-27,29-35], function [21,23,25-30,32-35], disability [20,22,24,29,31,34], and quality of life [20,27-30], respectively. In the 16 included studies, 26 different patient-reported outcomes were investigated. With regard to the digital health interventions, 7, 5, and 4 studies used app-based [20,22,23,28,31,32,34], web-based [21,25,27,29,30], and telerehabilitation-based physical exercises [24,26,33,35], respectively, whereby the duration of the digital health interventions ranged from 7 days [32] to 12 months [21]. As control groups, 9 studies used physiotherapy [20,21,23,25,26,28,31,32,35]; 4 studies used paper-based exercises [22,25,29,34]; 2 studies used internet-based information material [27,30]; and 1 study each used global postural re-education [20], waiting list [21], clinic-based McKenzie therapy [24], and no therapy [33].

Table 4. Summary table of all study characteristics according to the population, intervention, comparison, outcome, study design (PICOS) scheme.

Study	Population and setting	Intervention and assessment	Outcomes

Abadiyan et al [20]	• Sample size: n=60
	• Average age: 38.5 y
	• Female: 55%
	• Disease: chronic neck pain
	• Country: Iran
		• I[a] ("Seeb" app+ GPR[b]): n=20
		• C1[c] (GPR alone): n=20
		• C2[d] (conventional PT[e]) n=20
		• Duration: 8 wk
		• Survey dates: baseline, 8 wk
			• Drop out: 3%
			• I: 5%, C1: 5%, and C2: 0%
			• Pain:
			  • app+GPR>GPR
			  • app+GPR>PT
			• Neck disability index:
			  • app+GPR>GPR
			  • app+GPR>PT
			  • GPR>PT
			• Quality of life:
			  • app+GPR>PT
			  • GPR>PT

Allen et al [21]	• Sample size: n=350 • Average age: 65.3 y • Female: 71.7% • Disease: knee osteoarthritis • Country: United States	• I (IBET[f]): n=142 • C1 (conventional PT): n=140 • C2 (WL[g]): n=68 • Duration: 12 mo • Survey dates: baseline, 4, and 12 mo	• Drop out: 13.1% • I: 21.1%, C1: 7.9%, and C2: 7% • Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC[h]) and other functional tests • IBET=PT=WL
Bennell et al [30]	• Sample size: n=148 • Average age: 61.2 y • Female: 56.1% • Disease: chronic knee pain • Country: Australia	• I: internet-based education material supported by videoconferences with physiotherapist for home exercises (n=74) • Control group: internet-based education material only (n=74) • Duration: 9 mo • Survey dates: baseline, 3, and 9 mo	• Drop out: 10.1% • I: 11% and C: 10% • Pain and function: education+PT>education • Quality of life: education+PT>education
Blanquero et al [22]	• Sample size: n=50 • Average age: 50.0 y • Female: 82% • Disease: carpal tunnel release • Country: Spain	• I: ReHand app for physical home training (n=25) • Control group: paper and home-based physical exercise program (n=25) • Duration: 4 wk • Survey dates: baseline, 4 wk	• Drop out: 0% • Hand disability and pain: app based>paper based
Chhabra et al [31]	• Sample size: n=93 • Average age: 41.2 y • Female: not reported • Disease: chronic low back pain • Country: India	• I: Snapcare app for physical home training (n=45) • Control group: conventional therapy (n=48) • Duration: 12 wk • Survey dates: baseline, 12 wk	• Drop out: 0% • Pain: app based=conventional • Disability: app based>conventional • Current Symptom Score: app based>conventional
Choi et al [23]	• Sample size: n=84 • Average age: 54.5 y • Female: 68% • Disease: frozen shoulder • Country: Korea	• I: app (no name given) for physical home training (n=42) • Control group: conventional home-based self-exercises (n=42) • Duration: 3 mo • Survey dates: baseline, 4, 8, and 12 wk	• Drop out: 0% • Pain and range of motion: app based=conventional
Fatoye et al [24]	• Sample size: n=56 • Average age: 48.7 y • Female: not reported • Disease: chronic low back pain • Country: Nigeria	• I: telerehabilitation home-based McKenzie therapy (TBMT[i]; n=24) • Control group: clinic-based McKenzie therapy (CBMT[j]; n=32) • Duration: 8 wk • Survey dates: baseline, 4, and 8 wk	• Drop out: 16% • I: 13% and C: 19% • Disability: TBMT=CBMT

Study	Population and setting	Intervention and assessment	Outcomes
Fleischman et al [25]	• Sample size: n=290 • Average age: 65.0 y • Female: 51% • Disease: total knee arthroplasty • Country: United States	• I: web-based PT at home (n=96) • C1: paper-based PT at home (n=97) • C2: formal outpatient PT (n=97) • Duration: 6 mo • Survey dates: baseline, 4-6 wk, 6 mo	• Drop out: 15.9% • I: 17%, C1: 27%, and C2: 6% • Knee flexion and Knee Injury and Osteoarthritis Outcome Score (KOOS[k]): • Web PT=paper PT=PT
Hardt et al [32]	• Sample size: n=60 • Average age: 65.9 y • Female: 57% • Disease: total knee arthroplasty • Country: Germany	• I: PT+"GenuSport" app (PT+app; n=33) • Control group: PT (n=27) • Duration: 7 d • Survey dates: daily for 7 d	• Drop out: 10% • I: 15% and C: 7% • Active range of motion, pain, function, KOOS, and Knee Society Score: PT+app>PT
Hernando-Garijo et al [33]	• Sample size: n=34 • Average age: 53.4 y • Female: 100% • Disease: fibromyalgia • Country: Mexico	• I: telerehabilitation with home-based aerobic exercises (n=17) • Control group: no additional intervention (n=17) • Duration: 15 wk • Survey dates: baseline, 15 wk	• Drop out: 18% • I: 18% and C: 18% • Pain: telerehabilitation>nothing • Physical function: telerehabilitation=nothing
Moffet et al [26]	• Sample size: n=205 • Average age: 66.0 y • Female: 51.2% • Disease: total knee arthroplasty • Country: Canada	• I: home-based telerehabilitation (n=104) • Control group: home-visiting PT (n=101) • Duration: 2 mo • Survey dates: baseline, 2, and 4 mo	• Drop out: 6.3% • I: 9.6% and C: 2.9% • WOMAC, KOOS, function, and range of motion: telerehabilitation=PT
Nelligan et al [27]	• Sample size: n=206 • Average age: 60.0 y • Female: 61.2% • Disease: knee osteoarthritis • Country: Australia	• I: website (information+active exercises) and text messages (n=103) • Control group: website with information only (n=103) • Duration: 24 wk • Survey dates: baseline, 24 wk	• Drop out: 12.6% • I: 12.6% and C: 12.6% • Pain, WOMAC, KOOS, quality of life: website information+exercise>website information only
Nelson et al [28]	• Sample size: n=70 • Average age: 64.5 y • Female: 63% • Disease: total hip replacement • Country: Australia	• I: telerehabilitation and technology-based home exercise (n=35) • Control group: PT and paper-based home exercise (n=35) • Duration: 6 wk • Survey dates: baseline, 6 wk, 6 mo	• Drop out: 1% • I: 3% and C: 0% • Quality of life and function: telerehabilation+exercise=PT+exercise
Özden et al [29]	• Sample size: n=50 • Average age: 41.3 y • Female: 60% • Disease: low back pain • Country: turkey	• I: telerehabilitation with Fizyoweb software (n=25) • Control group: same exercises with paper-based instructions (n=25) • Duration: 8 wk • Survey dates: baseline, 8 wk	• Drop out: 7% • I: 7% and C: 7% • Pain, function, disability, and quality of life: telerehabilation>paper based
Rodríguez Sánchez-Laulhé et al [34]	• Sample size: n=36 • Average age: 59.8 y • Female: 61% • Disease: rheumatoid arthritis • Country: Spain	• I: CareHand app for exercises and self-management and monitoring tools (n=14) • Control group: paper-based home exercises (n=22) • Duration: 3 mo • Survey dates: baseline, 1, 3, and 6 mo	• Drop out: 16% • I: 7% and C: 22% • Function: app based>paper based • Pain and disability for upper extremity: app based=paper based
Tousignant et al [35]	• Sample size: n=48 • Average age: 66.0 y • Female: not reported • Disease: total knee arthroplasty • Country: Canada	• I: telerehabilitation by videoconference with a physiotherapist (n=24) • Control group: conventional PT (n=24) • Duration: 2 mo • Survey dates: baseline, 2, and 6 mo	• Drop out: 15% • I: 12% and C: 17% • Disability: telerehabilation=conventional PT • Function: telerehabilation>conventional PT • Functional activity, physical functioning, and physical pain: conventional PT>telerehabilation

Synthesis of Results by Best‐Evidence Synthesis

Tables 5, 6, and 7 show the results of the best-evidence synthesis with regard to the cluster of the localization of the musculoskeletal diseases, patient-reported outcomes, and medical treatment types, respectively.

Regarding the localization of the musculoskeletal diseases, there was strong evidence that digital physical health exercises had a positive impact on the musculoskeletal diseases located in the back. Although moderate evidence was obtained for diseases located in the shoulder and hip, evidence for fibromyalgia (the entire body) is limited. Conflicting evidence was found for diseases located in the knee and hand. For the patient-reported outcomes, there was strong evidence that digital physical health exercises had a positive impact on disability and quality of life. Conflicting evidence was found for pain and function. Regarding the medical treatment types, operative and conservative therapies both achieved conflicting evidence. Figure 2 shows the evidence found across the 3 defined clusters for studies included in the best-evidence synthesis.

Table 5. Best-evidence synthesis for the localization of the musculoskeletal diseases.

Localization	Study	Musculoskeletal disease	Results	Study quality	Evidence
Back	Abadiyan et al [20]	Chronic neck pain	+[a]	High	Strong[b]
Back	Chhabra et al [31]	Chronic low back pain	+	Acceptable	Strong[b]
Back	Fatoye et al [24]	Chronic low back pain	=[c]	High	Strong[b]
Back	Özden et al [29]	Chronic low back pain	+	High	Strong[b]
Shoulder	Choi et al [23]	Frozen shoulder	=	High	Moderate
Hip	Nelson et al [28]	Total hip arthroplasty	=	High	Moderate

Discussion

Principal Findings

This systematic review aimed to evaluate the impact of digital physical health exercises on patients with musculoskeletal diseases concerning the localization of the musculoskeletal disease, patient-reported outcomes, and medical treatment types. In addition, a best-evidence synthesis was conducted to estimate the direction and strength of the existing evidence. The main findings were that (1) strong evidence was found for a positive impact on musculoskeletal diseases located in the back and on the patient-reported outcomes of disability and quality of life and (2) moderate evidence was found for a positive impact on musculoskeletal diseases located in the shoulder and hip.

The first main finding was that strong evidence was found for a positive impact on musculoskeletal diseases located in the back and on the patient-reported outcomes of disability and quality of life (Figure 2). Our findings are partly supported by a previous systematic review with a meta-analysis [13] showing moderate-quality evidence for the positive impact on the patient-reported outcome of disability. In contrast to the previous review [13] and to another systematic review [12], conflicting evidence for the patient-reported outcomes of pain and function was found. It should be noted that 1 study [12] found some clinical benefits for pain and function but did not conduct an evidence synthesis or a meta-analysis. In addition, the outcomes of pain and function represent health-related outcomes, and the outcomes of disability and quality of life are the resulting consequences. Therefore, pain acts as a protective mechanism and can lead to disability [50]. With appropriate exercises,

patients learn to compensate for their disabilities [20,30], whereas exercise alone can provoke pain [51]. As disabilities are part of the concept of health-related quality of life [52], these outcomes are mutually dependent, and identical strong evidence is plausible.

In addition, it should be mentioned that both previous systematic reviews included all types of digital health interventions, and we explicitly focused our systematic review on the impact of digital physical health exercises. Regarding this, our findings add that this type of intervention shows strong evidence to have an overall positive impact on the musculoskeletal diseases located in the back, independent of the investigated outcomes [20,24,29,31]. Back-related musculoskeletal diseases usually arise because of muscular causes and are often caused by a lack of physical activity [53]. Participants recruited in back pain–related studies are often middle-aged and have an office occupation [20]. The use of digital physical health exercises in such patients can be considered highly effective because of the increased physical activity targeting muscle strengthening and the teaching of exercise techniques [20,24,29,31]. Overall, the application of digital physical health exercise in patients with musculoskeletal diseases shows versatile positive effects, especially for musculoskeletal diseases located in the back and for the improvement of disabilities and quality of life. However, the type of digital health interventions seems to influence the effects on the specific patient-reported outcome, and more studies to investigate this relationship are needed.

The second main finding was that moderate evidence was found for a beneficial effect on musculoskeletal diseases of the shoulder and hip (Figure 2). As this systematic review is the first to evaluate the association between digital physical health exercises and different localizations of musculoskeletal diseases, no evidence levels from previous research is available for clarification. There is only 1 other systematic review on the effectiveness of digital health interventions for total hip arthroplasty [54]. The review found no significant improvements in the studied patient-reported outcomes. For the shoulder, another systematic review examined the effectiveness of telerehabilitation for musculoskeletal diseases compared with normal in-person physiotherapy [55] and found very low to low evidence. In this context, our findings suggest that digital physical health exercises may also be effective in treating musculoskeletal diseases of the shoulder and hip. However, it should be noted that only 1 study each was found for shoulder- and hip-specific musculoskeletal diseases, whereas several studies were found for back- or knee-specific musculoskeletal diseases (Table 5). Therefore, our results must be interpreted with caution, as a small number of high-quality studies may result in stronger evidence, according to the definitions of the best-evidence synthesis [18], than the presence of many lower-quality studies. Overall, the results demonstrated that digital physical health exercises could have a positive effect on a variety of health-related outcomes, regardless of the localization of the musculoskeletal diseases. However, the number of studies investigating the relationship between the effectiveness of digital health interventions and the localization of musculoskeletal diseases is small, and more studies are needed, especially for localizations other than the knee and back.

An additional interesting finding is the conflicting evidence in the medical treatment types concerning operative and conservative approaches (Figure 2). Although the underlying reasons remain unknown, it can be stated that the operative treatment (ie, carpal tunnel release and total knee arthroplasty) has no impact on the overall stimulus-response mechanism of the digital intervention, requiring further studies for clarification.

Limitations

Although this systematic review increases knowledge of the positive impacts of digital physical health exercises on musculoskeletal diseases, there are a few limitations. Because of the heterogeneity of the included studies (eg, different numbers of patients, interventions, body regions, and control groups), a meta-analysis could not be performed. Instead, and as an established alternative approach, a best-evidence synthesis [18] was used. A strength of this approach is that it is possible to estimate an evidence level for various categories despite the large study heterogeneity. However, a limitation is that no quantitative analysis (eg, in terms of statistical significance) can be conducted [56]. An additional limitation of our review is that we did not register the study plan in PROSPERO a priori. The reason is that according to the PRISMA guidelines, registration is currently recommended but not mandatory [15]. Furthermore, all studies that included digital health interventions beyond active exercises were not included. Therefore, some studies could be lost, but the aspect of physical exercise as an established clinical treatment for musculoskeletal diseases could be focused on for the first time.

Conclusions

There is strong to moderate evidence for the beneficial impact of digital physical health exercises for musculoskeletal diseases located in the back, shoulder, and hip. There is limited or conflicting evidence for other localizations. In addition, strong evidence was found for the patient-reported outcomes of disability and quality of life, whereas conflicting evidence exists for other commonly investigated patient-reported outcomes such as pain and function. Thus, digital physical health exercises could have a positive effect on a variety of health-related outcomes of musculoskeletal diseases. To implement digital physical health exercises in evidence-based medicine for musculoskeletal diseases, more high-quality randomized controlled trials are needed to clarify the relationship between the impact of digital physical health exercises and clinically relevant factors such as localization, patient-reported outcomes, and medical treatment types.

Acknowledgments

The study was funded by the Open Access Publishing Fund of Leipzig University supported by the German Research Foundation within the Open Access Publication Funding program. The authors acknowledge the support from Leipzig University for Open Access Publishing.

Authors' Contributions

JN, FW, and MWH conceived the study and were involved in the conceptual process. JN performed the literature search and data analysis, and MWH validated these steps. JN wrote a raw version of the manuscript, and FW and MWH revised the raw version and wrote the final manuscript together with JN. CG critically revised the final manuscript and made additional changes. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Successful post-knee replacement rehabilitation requires adequate access to health information, social support, and periodic monitoring by a health professional. Mobile health (mHealth) and computer-based technologies are used for rehabilitation and remote monitoring. The extent of technology use and its function in post-knee replacement rehabilitation care in low and middle-income settings are unknown.

Objective: To inform future mHealth intervention development, we conducted a scoping review to map the features and functionality of existing technologies and determine users' perspectives on telerehabilitation and technology for self-management.

Methods: We followed the Joanna Briggs Institute methodology for scoping reviews. We searched the Embase, Medline, PsycINFO via OVID, and Cochrane Central Register of Controlled Trials databases for manuscripts published from 2001 onward. We included original research articles reporting the use of mobile or computer-based technologies by patients, health care providers, researchers, or family members. Studies were divided into the following 3 categories based on the purpose: validation studies, clinical evaluation, and end user feedback. We extracted general information on study design, technology features, proposed function, and perspectives of health care providers and patients. The protocol for this review is accessible in the Open Science Framework.

Results: Of the 5960 articles, 158 that reported from high-income settings contributed to the qualitative summary (64 studies on mHealth or telerehabilitation programs, 28 validation studies, 38 studies describing users' perceptions). The highest numbers of studies were from Europe or the United Kingdom and North America regarding the use of a mobile app with or without wearables and reported mainly in the last decade. No studies were from low and middle-income settings. The primary functions of technology for remote rehabilitation were education to aid recovery and enable regular, appropriate exercises; monitoring progress of pain (n=19), activity (n=20), and exercise adherence (n=30); 1 or 2-way communication with health care professionals to facilitate the continuum of care (n=51); and goal setting (n=23). Assessment of range of motion (n=16) and gait analysis (n=10) were the commonly validated technologies developed to incorporate into a future rehabilitation program. Few studies (n=14) reported end user involvement during the development stage. We summarized the reasons for satisfaction and dissatisfaction among users across various technologies.

Conclusions: Several existing mobile and computer-based technologies facilitate post-knee replacement rehabilitation care for patients and health care providers. However, they are limited to high-income settings and may not be extrapolated to low-income settings. A systematic needs assessment of patients undergoing knee replacement and health care providers involved in rehabilitation,

involving end users at all stages of development and evaluation, with clear reporting of the development and clinical evaluation can make post-knee replacement rehabilitation care in resource-poor settings accessible and cost-effective.

Introduction

Knee arthroplasty is the gold standard treatment for end-stage osteoarthritis when conservative treatments fail to relieve symptoms [1]. Wound care and postarthroplasty physiotherapy are essential components of this treatment. Poor adherence to physiotherapy could delay the recovery and lead to suboptimal functional outcomes [2]. Beyond in-hospital clinical care and initiation of physical therapy before discharge, continued and reliable access to information, support from health care providers, awareness of the recovery pathway, easy access to rehabilitation centers, and periodic monitoring are influential factors for optimal recovery [3-6]. In addition to an uneventful surgery, postarthroplasty outcomes are associated with several patient-related factors such as their preoperative physical and mental state, comorbidities, social support, and socioeconomic status, emphasizing the need for personalized approaches [7]. Hence, monitoring of the rehabilitation phase is essential, whether at clinics, in rehabilitation units, or at home [8-10].

Technology-assisted remote monitoring methods are increasingly being advocated in high-income countries. There is low to moderate-quality evidence on the superiority of telerehabilitation compared with unsupported home-based rehabilitation and noninferiority compared with clinic-based monitoring with respect to range of motion (ROM), pain, function, quality of life, and cost-effectiveness at 3 months between clinic-based and home-based rehabilitation strategies using technology [11-17]. Hence, current evidence supports the adaptation of technology-based rehabilitation as feasible, as safe, and as good as clinic-based monitoring with an additional benefit of saving out-of-pocket expenditure. Technology-based approaches are diverse, varying from telehealth [17] to virtual reality techniques [13] aimed at improving adherence to physical therapy and facilitating remote monitoring [12] of patient progress during the post-acute rehabilitation phase [18].

Therefore, the aim of this scoping review was to summarize the extent, range, and nature of technology used for provision of rehabilitation or to monitor progress following knee arthroplasty. This scoping review aimed to address the following objectives:

1. To map the characteristic features and functionality of the technologies, guiding or theoretical framework for designing the technology, and evaluation methodologies of mobile technology–based apps for rehabilitation monitoring and self-management following knee arthroplasty
2. To understand the patient and physical therapist perspectives regarding the use of mobile technology–based apps for rehabilitation monitoring and self-management following knee arthroplasty

To our knowledge, there are no existing scoping reviews that address our aims [19]. The information from this review will help us and other researchers make an informed decision on future mobile health (mHealth) interventions for monitoring post-knee arthroplasty rehabilitation care by physiotherapists and orthopedic surgeons and to promote self-management by individuals. This review will also help highlight existing gaps in the context of low and middle-income countries (LMICs).

Methods

We conducted this scoping review following the Joanna Briggs Institute (JBI) methodology for JBI Scoping Reviews [20] and consulted the PRISMA-ScR (Preferred Reporting Items for Systematic Review and Meta-Analyses Extension for Scoping Reviews) checklist for reporting [21]. The protocol was registered at the Open Science Framework [22].

Data Sources and Searches

To identify relevant studies, an electronic database literature search was conducted in the Embase, Medline, PsycINFO via OVID, and Cochrane Central Register of Controlled Trials (CENTRAL) databases using the following key terms: “Knee arthroplasty OR Knee replacement,” “mobile,” “web,” “remote sensor,” “computer,” “telerehabilitation,” and “m-health” (Tables S1 and S2 in Multimedia Appendix 1). The search was executed in October 2021 and updated in August 2023. The search was restricted to 2001 onward. There were no language restrictions during the search. We searched the reference list of included articles to identify potentially eligible studies.

Study Selection

Predefined inclusion criteria were articles reporting the use of mobile or computer apps or any other technologies such as sensor-based devices for delivering or monitoring rehabilitation either scheduled or following knee joint replacement. We also included proof- of-concept papers that described the development process of a mobile or technology-based solution for rehabilitation. The purpose of technology could be for a health care provider to monitor rehabilitation adherence, to aid patient-health care provider communication, to promote self-management, to act as reminders, or to act as a source of education or any other function that is aimed at rehabilitation care following knee replacement. The app or technology could be used by patients, health care providers, researchers, or a family member. Included studies could have been conducted in the community or home for any clinical setting in any geographic region. The studies were required to be original research articles, and we included experimental and observational studies using quantitative or qualitative research methods. Reviews (narrative or systematic reviews), non-English

articles, and articles without abstracts or full texts were excluded.

Data Extraction

Screening of manuscript titles and abstracts was conducted by 2 independent reviewers using the web app Rayyan [23]. Prior to screening, reviewers discussed inclusion and exclusion criteria to ensure consistency between individuals. Two reviewers assessed the eligibility of the full text, and disagreements were resolved by discussion. Systematic reviews were not included in the review but were used to obtain potentially relevant references. Multiple publications originating from a single technology were grouped and presented as 1 study.

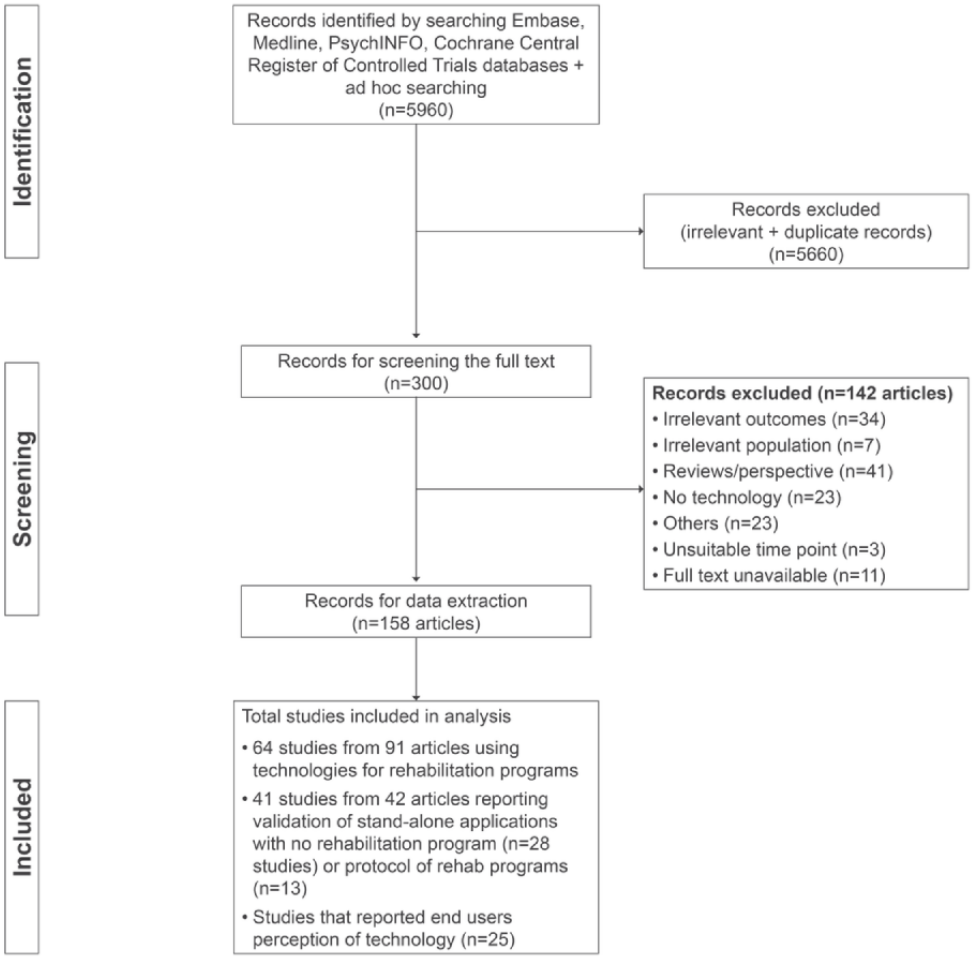
For data charting purposes, the studies were divided into the following 3 categories: (1) studies that had no rehabilitation program but included an app or a technology to assess ROM or gait and were validation studies, (2) studies reporting the use of a mobile or computer app or a telehealth delivery platform for a rehabilitation program with or without sensor-based devices and wearable sensors, (3) studies that reported end users' perceptions of the technology used for rehabilitation monitoring. Data on the general information for the studies, features of the technology, the proposed function, and perspectives of health care providers and patients were extracted and entered in Microsoft Excel. If only the protocol of a planned study was available, there was no information on clinical evaluation, or the study included <6 individuals, we did not extract data beyond the general information.

Results

Search Results

The database search, including the ad hoc search, yielded 5960 articles. Of these articles, 300 articles were considered potentially relevant. Of these, 158 articles were included for data extraction, 131 articles were excluded, and 11 articles were not available (Table S3 in Multimedia Appendix 1). Of the 158 articles, 91 articles (64 studies) reported the clinical evaluation of a technology-based rehabilitation program, 29 articles (28 studies) reported the validation or a proof of concept of technology intended to be used for rehabilitation, and 13 articles were protocols of evaluation studies. In addition, 25 articles reported end users' perceptions on technology (Figure 1) as stand-alone articles or part of clinical evaluation studies (n=13), totaling 38 studies. The 13 studies that reported the perceptions of technology that were also included in rehabilitation program studies were removed from the final list of included full-text articles to avoid double counting.

Figure 1. Process of identifying and including studies according to PRISMA-ScR (Preferred Reporting Items for Systematic Review and Meta-Analyses Extension for Scoping Reviews).

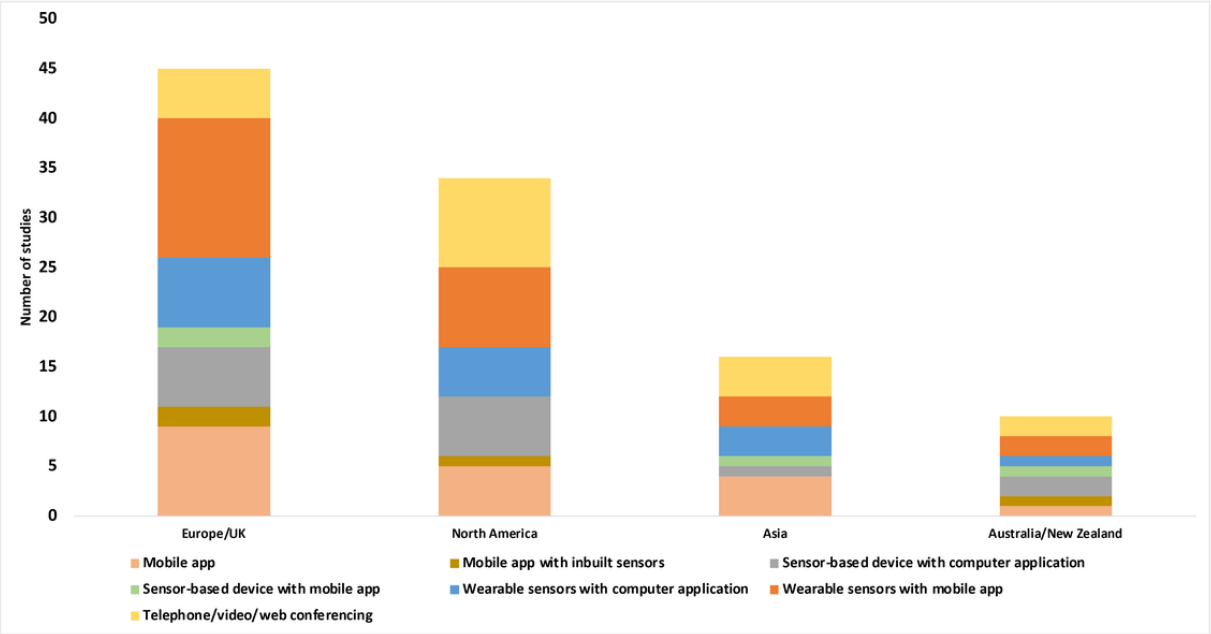


Technology for Rehabilitation

Characteristics of the 105 Studies

Studies were reported from Europe and the United Kingdom (n=45) [11, 24-60, 62-66, 169, 170], North America (n=34) [6, 67-99], Australia and New Zealand (n=10) [100-109], and Asia (n=16) [110-125]. None of the studies were from LMICs. Reports of mobile-based technologies represented the highest number (54/105, 51.4%) [6, 25-27, 31, 32, 36, 37, 41-50, 52, 55, 56, 58-60, 62, 64, 67-69, 74, 75, 78, 80, 82, 83, 90-92, 95, 101, 103, 106-108, 112, 113, 117, 121-126, 169], followed by computer applications (31/105, 29.5%) [24, 29, 30, 33-35, 39, 53, 54, 57, 65, 66, 70, 73, 76, 79, 84-86, 89, 93, 97, 98, 100, 102, 104, 111, 114, 116, 120, 127], and tele/video/web conferencing (20/105, 19%) for rehabilitation monitoring [28, 38, 51, 63, 71, 72, 77, 81, 87, 88, 94, 96, 99, 105, 109, 110, 115, 118, 119, 170]. The highest use of mobile apps associated with or without a wearable was in Europe and the United Kingdom, followed by North America. Tele/video/web conferencing was used across regions, with the highest number in North America (Figure 2).

Figure 2. Number of studies published by region based on different technologies (n=105).



Validation Studies

There were 28 validation studies. Studies that validated stand-alone technologies included those to assess ROM (n=16) [24, 29, 43, 45, 48, 49, 52, 68, 73, 84, 100, 101, 111, 112, 116, 125] or gait or posture (n=10) [29, 30, 33, 53, 57, 74, 89, 97, 102, 124], and 2 studies involved technologies to monitor exercises [98, 114]. The technologies involved were either wearables (n=20) [24, 29, 30, 33, 45, 48, 49, 57, 68, 73, 84, 89, 97, 98, 100, 111, 112, 114, 116, 125], sensor-based devices (nonwearables; n=4) [53, 66, 102, 124], or inbuilt sensors available within a smartphone (n=4) [43, 52, 74, 101] (Table S4 in Multimedia Appendix 1).

In terms of study design, 9 were cross-sectional studies [33, 48, 52, 57, 84, 89, 97, 101, 116], 7 were cohort or longitudinal studies [45, 53, 68, 74, 100, 111, 125], 5 were pre-post studies [29, 30, 43, 73, 102], 1 was an uncontrolled trial [112], 1 was a randomized controlled trial (RCT) [66], and 5 were articles that described the proof of concept or development plan for the technologies [24, 49, 98, 114, 124]. The participant sample size ranged from 1 to 60. Most studies reported reliability between a standard or universal goniometer and smartphone app goniometry and the clinical evaluation of sensors to measure gait parameters (Table S4 in Multimedia Appendix 1). In 7 studies, gait was measured using sensors provided by a health care provider in a hospital setting [29, 33, 57, 74, 89, 97, 102], and 3 studies did not describe the measurement setting [30, 53, 124].

Clinical Evaluation Studies

There were 64 clinical evaluation studies. The technology consisted of a mobile or computer app with a wearable device (n=18) [6, 26, 31, 32, 39, 44, 46, 50, 54, 64, 67, 69, 90, 92, 95, 106, 108, 169], a mobile or computer app with a sensor-based device (n=13) [25, 34, 35, 40, 42, 65, 70, 76, 79, 85, 86, 93, 120], only a mobile app (n=14) [36, 37, 55, 56, 62, 75, 78, 80, 83, 107, 113, 117, 123, 128], or only telephone or videoconferencing (n=19) for remote monitoring [28, 38, 51, 63, 71, 72, 77, 81, 88, 94, 96, 99, 105, 109, 110, 115, 118, 119, 170]. Of the studies that used a mobile app, 9 studies were developed only for iOS [55, 67, 69, 71, 77, 92, 106, 107, 109], 1 was an Android app [42], 7 were for both Android and iOS devices [28, 36, 56, 88, 108, 115, 117], and 21 studies did not specify the platform (Multimedia Appendix 2). A web-based clinician portal for synchronous or asynchronous remote monitoring of patients was reported by 36 studies (Table 1). The number of published studies and the intervention arm sample size (ranging from 7 to 2292), especially for those that included wearable sensors and mobile apps, steadily increased over the last 2 decades (Figure 3).

Table 1. Summary of application functionality (N=64).

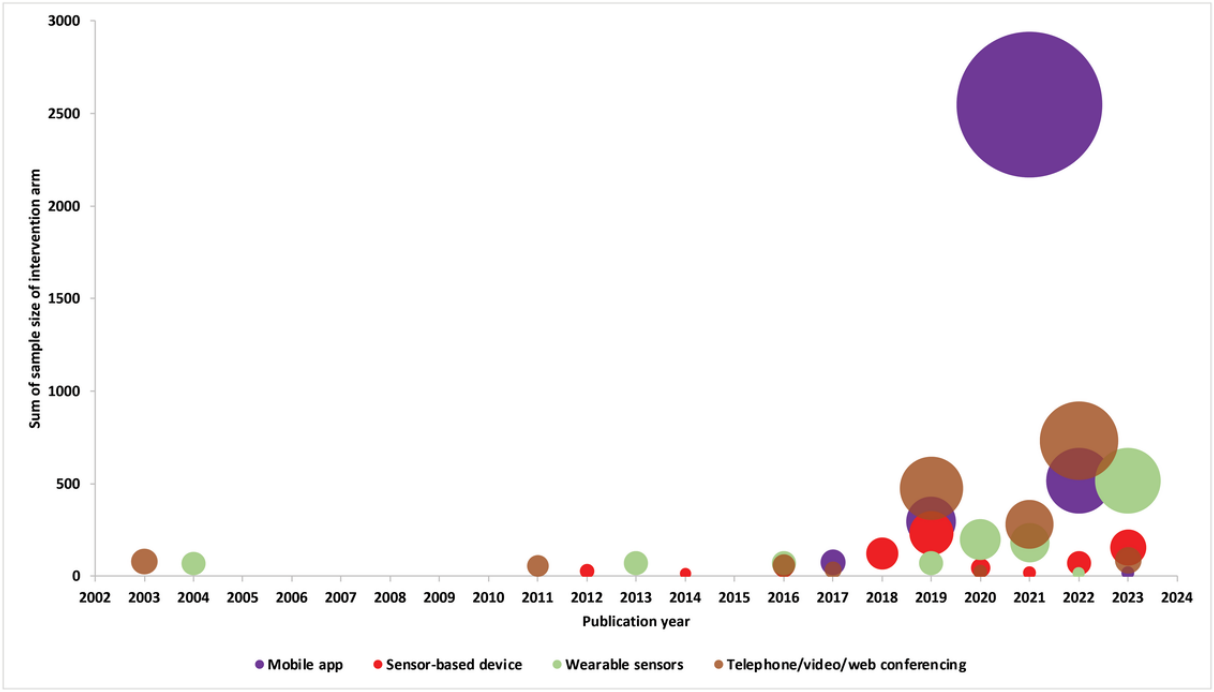
Figure 3. Technologies developed over the years by sample size (n=64), with the size of the bubble indicating the sample size of the intervention arm of all the studies published that particular year per technology category. Mobile app = mobile app + mobile app with inbuilt sensors; sensor-based device = sensor-based device with a mobile app + sensor-based device with a computer application; wearable sensors = wearable sensors with a mobile app + wearable sensors with a computer application + wearable sensors.



Although most studies described the features and functionality of the technology to deliver the intervention, they lacked details about the technological aspects that could benefit future researchers. For example, 2 studies [31, 86] explicitly reported information on the software, programming language and tools used, or calibration procedures either along with the main study or cited the article that described the development phase. Information on conceptualization of the technology-based intervention was described in only 3 studies [37, 38, 120]. End users' involvement was typically late during the development phase (ie, prototype stage) and involved refining the functionalities and features of technology [32, 51, 64, 65, 75-77, 80, 86, 88, 115, 118, 169] prior to deployment. Patient feedback on their needs at an early development phase was reported only by Blasco et al [28].

Clinical effectiveness was tested using an RCT design in 57.8% (37/64) of the studies [6, 25, 28, 34-36, 39, 42, 44, 50, 51, 54, 55, 62, 63, 65, 67, 70-72, 77, 79, 90, 94-96, 99, 105, 106, 108-110, 117-119, 128, 170], and the rest of the studies were either retrospective comparative cohort studies (n=3) [26, 37, 78], uncontrolled cohort studies (n=9) [46, 56, 69, 76, 81, 83, 85, 92, 169], cross-sectional studies (n=1) [86], or non-RCTs (n=14) [31, 32, 38, 40, 64, 75, 80, 88, 93, 107, 113, 115, 120, 123].

We found 13 study protocols, of which 12 were RCTs published between 2013 and 2023 [11, 41, 47, 58-60, 82, 87, 91, 103, 104, 122], for which we could not find a published report and hence were not included in this summary. User experience was measured in trials using quantitative (n=9) [32, 34, 38, 50, 55, 94, 96, 105, 123], qualitative (n=2) [61, 128], and mixed methods (n=3) [39, 90, 109] approaches.

Application Functionality for Rehabilitation Programs

The key functionalities of the telerehabilitation technologies extracted from 64 studies are summarized under 4 themes, namely education and enablement, monitoring progress, communication, and goal setting (Table 2).

Table 2. Themes of the key functionalities of the telerehabilitation technologies.

[f]SA: synchronous from app.

[g]AP: asynchronous from physiotherapist.

[h]SC: scheduled call.

[i]AA: asynchronous from app.

[j]DS: danger signs.

[k]NU: non-use.

Education and Enablement

An exercise repository in the form of videos, text, or infographics was one of the main features in the studies (n=53), of which only 20 studies described the list of exercises (Table S5 in Multimedia Appendix 1). Education for patients was part of the rehabilitation program in 17 studies. Table S6 in Multimedia Appendix 1 lists the topic areas covered in the education materials. Regarding exercise, 6 studies reported using an e-diary for maintaining an exercise log, 11 studies reported using reminders to perform exercises, and 13 studies reported using a tracker for exercise adherence (Multimedia Appendix 2). Feedback on the appropriateness of exercise performance was synchronous (biofeedback or virtual reality) from the app (n=19), directly from the health care provider via a video call with the patients (patient performing exercise live, measurement of ROM during video call, transmission of virtual avatar data to health care provider; n=14), or provided via both (n=6; Table 2). Feedback to the patient, which was either in the form of push notifications or a progress summary, was asynchronous from the app using automated programs in 2 studies. Asynchronous feedback from a health care provider in the form of instructions, messages, or an exercise regimen was reported in 13 studies. Feedback via both the app and a health care provider was provided in 3 studies (Table 2). Only 7 studies [6, 51, 75, 115, 117, 123, 128] had an option for peer support for patients.

Measuring Progress

Measurement of patient-reported outcomes such as pain (n=19) was an inbuilt feature in the app. Changes in knee function and activity were monitored directly via wearables or captured using patient-reported outcome measures. These included ROM in 15 studies, knee function in 8 studies, physical activity in 20 studies, sedentary behavior in 5 studies, and sleep in 4 studies. Automatic alerts were provided to the health care provider for any danger signs such as knee pain, wound health, opioid consumption, function, ROM, number of steps, exercise adherence, and any negative response to questions after entering the postoperative follow-up in 9 studies; for non-use of the technology by patients in 4 studies; and for scheduled consultations in 18 studies (Table 2).

Communication

Mobile app–enabled 1-way communication included push messages, notifications, reminders, patients' replies to inbuilt questions in the app, information sent to the patient by the health care team, and an SMS text messaging bot (n=10). Two-way communication, either via an app or in face-to-face visits, was reported in 41 studies. In addition, 11 studies reported a combination of both 1 and 2-way communication, and 1 study did not provide sufficient information about communication. Electronic communication was delivered in the form of text, audio or video messages, and direct communication (Table 2).

Goal Setting

Goal setting for exercises, activity, pain management, knee function, ROM, muscle strength, rehabilitation, and discharge as part of the rehabilitation program was reported in 23 studies. The goals were set by either the health care provider or the patient (Table 2).

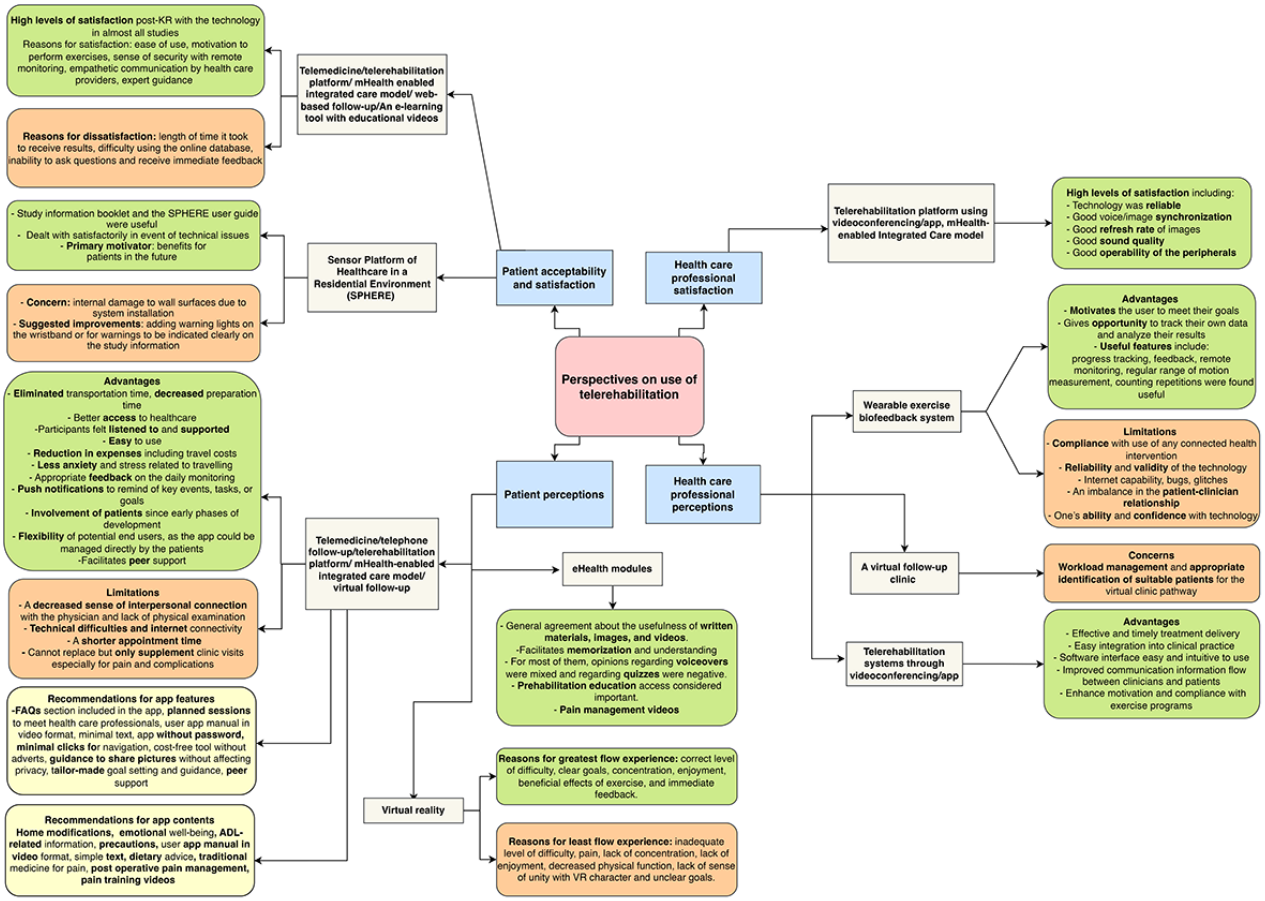
End Users' Perceptions

Of the 38 studies that reported user perspectives, 2 focused on the perspectives of health care providers, 27 focused on the perspectives of patients and caregivers, and 9 focused on the perspectives of both groups (health care providers and patients and caregivers). The approach for data collection was quantitative (n=23), qualitative (n=9), or mixed methods (n=6). The sample size ranged from 2 to 200 health care providers and from 5 to 2292 patients (Tables S7 and S8 in Multimedia Appendix 1).

Commonly used quantitative questionnaires to assess satisfaction were the System Usability Scale [129] and the net promoter score [130]. To ratify the experience with telerehabilitation, the Telemedicine Perception Questionnaire was used [131]. Acceptability and usability were assessed using the acceptance of information technology questionnaire [132] and the Telemedicine Usability Questionnaire [133]. Some studies used bespoke questionnaires to report user experience and satisfaction [32, 39, 61, 90, 94, 105, 109, 134-146].

Overall, health care providers perceived telerehabilitation and the use of technology such as biosensors as a way of improving efficiency in providing care [146], patient adherence to exercises [39, 136, 146], patient-physician communication [136], and case management [137, 146]. The main factors associated with user satisfaction with e-consultations were reliable technology, good voice or image synchronization, the refresh rate of images, sound quality, and operability of the peripherals [94, 96, 138, 139]. The key factors they perceived would influence use and uptake of technology were decreased workload (rather than increased) [140], reliability of measurements aided by technology [146], ability to measure functional outcomes objectively [141], clearer criteria when choosing appropriate patients to be enrolled in the program [140], self-efficacy in the use of technology [94, 138, 146], and ease of reporting and tracking of patient data [90]. Patients and health care providers felt e-learning modules, push notifications, and appropriate feedback from sensors and virtual reality improved self-management [138, 142-144] (Figure 4).

Figure 4. Perceptions of patients and health care providers about the technology used. ADL: activities of daily living; FAQs: frequently asked questions; KR: knee replacement; mHealth: mobile health; VR: virtual reality.



Patient satisfaction levels were reported when teleconsultation was provided via a computer, smartphone, or tablet [34, 39, 55, 56, 80, 92, 105, 121, 123, 134, 135, 145, 147-149]; telephone [61], videoconferencing [38, 77, 94, 105, 139, 141, 150-152], a web-based system [32, 50, 90, 96, 140, 153], and an mHealth-enabled integrated care model [46, 88, 138]. Patients were satisfied with telemonitoring due to improved access to services, continued support after discharge from hospital, ability for self-management, reduced need for clinic visits, reduction in cost and travel time, ability of health care providers to provide personalized care [32, 61, 94, 121, 136, 138, 140, 141, 145, 153-155], ease of use [34, 50, 55, 56, 92, 105, 135, 138, 147, 148], motivation to perform exercises [134, 135], sense of security with remote monitoring [134, 155], and empathetic communication by a health care provider [121, 135, 136, 145, 152, 155]. The reasons for dissatisfaction were lack of an in-person examination, shorter appointment times, delay in receiving reports (eg, x-ray), and an inability to transfer pictures from one technology to another [140, 145, 149, 153]. Patients provided suggestions for the app functionalities to improve the ease of use such as minimal clicks, an instructional video for app navigation, and restriction of commercial advertisements [149]. Home modifications [149], emotional well-being, information related to activities of daily living in simple text,

dietary advice, frequently asked questions, and use of traditional medicine for postoperative pain management were a few of the suggestions for app content [121].

Patients were generally satisfied with the telerehabilitation program and were ready to recommend it to others [39, 80, 85, 96, 121, 135, 151]. The use of technology for rehabilitation was influenced by computer literacy [141, 150]. However, interruption of virtual physiotherapy sessions due to poor internet issues [139] was not commonly reported (Figure 4).

Discussion

Principal Findings

This scoping review summarized the extent, user perceptions, range, and nature of technologies used to support rehabilitation following knee arthroplasty. All studies reported in this review were from upper and middle-to-upper–income countries, with a steep increase in studies in the last decade. The technologies focused on enabling patients to remember prescribed exercises as well as be able to perform them appropriately by providing synchronous and asynchronous feedback via biosensors or virtual reality. Motivation and support during recovery via technology-enabled 1-way or 2-way communication gave patients access to health care providers. Self-management and monitoring of progress were dependent on active input using e-diaries by patients or passive input through wearables. In the context where these technologies were evaluated, end users were satisfied and found remote monitoring to be acceptable for routine use.

The last decade has seen an exponential increase in the number of arthroplasties worldwide [156]; however, a corresponding increase in technological solutions to facilitate remote monitoring is nonexistent in resource-limited settings such as LMICs where the need for monitoring and a continuum of care may be higher due to lower literacy levels and lack of access to rehabilitation clinics. Research on this topic that can inform clinical practice is nonexistent in the LMIC context. Despite a high penetration of the smartphone market [157] in LMICs, a higher initial investment to develop the technology, especially in the health care sector [158], or a lack of publication of such efforts could be reasons. In LMICs, there is an increasing trend of lower limb joint replacement procedures [156]. High out-of-pocket expenditures incurred due to home visits by physiotherapists or clinic visits by patients [159] dictate the need for a cost-effective and feasible technology-based strategy to fit the context while using lessons learned from available research.

There is unequivocal evidence that there is a need for physical and psychological support from professionals during the recovery period for pain management, adherence to exercises, and modifications to therapy planning based on one's progress [3, 160, 161]. The apps were either focused on a single function (such as communication or knowledge transfer) or were multifunctional. They were generally received well by end users; however, the usability and acceptability of these applications or remote monitoring modalities cannot be extrapolated to low health literacy and tech literacy settings. The challenges we expect with using remote monitoring in the LMIC context could be inequitable smartphone access or tech literacy, internet speed, affordability of wearables, the burden to the health system if these needs are provided free of cost, and the need for educational content in multiple languages in countries with a non-native English-speaking, multilingual population such as in India [162].

Implications for Future Research

mHealth interventions have the potential to expand the reach and effectiveness of health support by facilitating behavior change. However, to ensure these "digital behavior health interventions" effectively engage users and are effective, both microengagement (the mHealth interface) and macroengagement (evidence-based behavior change techniques) are essential [163, 164]. However, we found only a handful of studies that reported user involvement during the development stage [28, 32, 51, 58, 64, 65, 75-77, 80, 86, 88, 115, 118, 169]. Studies rarely provided an adequate explanation of the theoretical behavioral framework behind the technology-based interventions [165].

Since the context and technologies are so varied, any new applications that are developed, especially in the LMIC context, should undertake formative research with end users to understand their needs, understand their preferences, and study the local digital regulatory requirements before investing time and effort. Feasibility and pilot testing by a multidisciplinary team should be crucial steps before a full-scale evaluation [69, 166], and embedding end users' involvement and documenting their experiences at every stage are vital to refining future interventions [164]. Further, the rehabilitation protocols should map the application features with the desired function [167, 168], and this should be confirmed by means of a process evaluation embedded within the clinical evaluation to inform the mechanism of the impact in a real-life setting [147].

Limitations

This review needs to be interpreted in light of the following limitations. This scoping review focused only on technology interventions for post-knee replacement rehabilitation and hence cannot be extrapolated to other orthopedic procedures. We did not include articles for which the full text was not available. Further, incomplete reporting on the features and functions of the technology is possible and may have affected our qualitative summary and conclusion.

We did not perform a consultation phase as per the guidelines [20], and the research question was formulated upon discussion between the researchers of the scoping review team, physiotherapists, and clinicians. We limited our search from 2001 onward; however, since knee arthroplasty and mHealth came into practice in the last 2 decades, this restriction in the search may not have an implication for our review findings.

Conclusion

Several technologies have been identified to promote adherence, increase self-efficacy, enhance self-management, and support remote monitoring. However, all the available technologies have been developed and used in developed countries. The need for remote monitoring is compelling in resource-limited

countries where knee arthroplasty is on the rise. However, irrespective of the context, it is important to involve a multidisciplinary team and include users' perspectives during the development stage.

What Was Already Known About the Topic

Computer and mobile technologies to support rehabilitation following knee arthroplasty are in wide use. Telerehabilitation and remote monitoring are as effective and safe as clinic-based rehabilitation programs. They reduce out-of-pocket expenditure or health cost expenditure by reducing the time to discharge following surgery and the number of clinic visits after discharge.

What This Study Adds

This study provides a map of the types of technology and the functionality of mobile and computer-based multifunction applications. We summarized end users' perceptions and reasons for satisfaction or dissatisfaction with available technology. The findings reflect the lack of research and readily available technologies for LMICs.

Acknowledgments

The authors would like to thank distinguished Professor Gordon Guyatt, in the Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, Ontario, Canada, for providing expert comments. We also thank Dr. Shyamashree Biswas, Research Intern at the George institute, for assisting with the quality check of the extracted data.

This scoping review is a part of a fellowship funded by DBT/Wellcome Trust India Alliance (grant number: IA/CPHI/20/1/505224).

Authors' Contributions

ND conceptualized the protocol and conducted the search. ND, SP, PS, and ShP screened and extracted the data. The first draft was written by SP. RM and AK interpreted the study findings and gave significant feedback to the early drafts. RMad provided expert comments and suggestions and edited the later version of manuscript. ND takes responsibility for the data. All authors read and agreed to the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Smart home technology (SHT) can be useful for aging in place or health-related purposes. However, surveillance studies have highlighted ethical issues with SHTs, including user privacy, security, and autonomy.

Objective: As digital technology is most often designed for younger adults, this review summarizes perceptions of SHTs among users aged 50 years and older to explore their understanding of privacy, the purpose of data collection, risks and benefits, and safety.

Methods: Through an integrative review, we explored community-dwelling adults' (aged 50 years and older) perceptions of SHTs based on research questions under 4 nonmutually exclusive themes: privacy, the purpose of data collection, risk and benefits, and safety. We searched 1860 titles and abstracts from Ovid MEDLINE, Ovid Embase, Cochrane Database of Systematic Reviews, and Cochrane Central Register of Controlled Trials, Scopus, Web of Science Core Collection, and IEEE Xplore or IET Electronic Library, resulting in 15 included studies.

Results: The 15 studies explored user perception of smart speakers, motion sensors, or home monitoring systems. A total of 13 (87%) studies discussed user privacy concerns regarding data collection and access. A total of 4 (27%) studies explored user knowledge of data collection purposes, 7 (47%) studies featured risk-related concerns such as data breaches and third-party misuse alongside benefits such as convenience, and 9 (60%) studies reported user enthusiasm about the potential for home safety.

Conclusions: Due to the growing size of aging populations and advances in technological capabilities, regulators and designers should focus on user concerns by supporting higher levels of agency regarding data collection, use, and disclosure and by bolstering organizational accountability. This way, relevant privacy regulation and SHT design can better support user safety while diminishing potential risks to privacy, security, autonomy, or discriminatory outcomes.

Introduction

Smart home technologies (SHTs) typically consist of one or more devices connected through the Internet of Things, which can transmit user data to various stakeholders [1]. Commonly used SHTs include Wi-Fi–enabled cameras, smart speakers with embedded voice assistants, or ambient assisted-living networks of sensors. SHTs are often controllable through smartphones, web platforms, or voice interaction [2]. These networked devices can be useful to the general population for a variety of reasons, but specifically for the aging population, they allow monitoring health status and enable information sharing with health care practitioners, family, or caregivers, potentially alleviating pressure on such networks [3-6]. Until recently, researchers have noted a gap in user perception studies focusing on older adults' (aged 65 years and older) unique needs, preferences, and ethical factors in SHT adoption or decision-making [4]. Others have noted the need for further research that involves users from older age groups outside of the laboratory [2]. Overall, researchers have an active interest in better understanding user perceptions to remove the barriers to SHT adoption for aging populations.

Related studies have also focused on the pressing ethical implications of SHTs in terms of privacy, autonomy, and security [3,5-7]. Insights from surveillance studies and gerontology literature warn that such systems can limit user autonomy by flagging spontaneous behavior as "abnormal or deviant" in ways that could discourage users from deviating from daily routines where movements are continually monitored [3,5]. Others have noted the potential for exploiting vulnerable SHT users through surveillance capitalism, in which user behavioral data are commodified by commercial actors, resulting in exacerbated power imbalances [7,8]. For instance, some commercial-grade smart devices have the potential to make behavioral data available to advertisers, third parties, and insurance companies in ways that can disproportionately and negatively affect vulnerable individuals and groups [1,7,8]. Moreover, security issues with any internet-enabled technology can lead to unauthorized data access by malicious actors, exacerbating the potential for harm [9,10].

With these insights in mind, the aim of this paper is to explore the potential benefits and drawbacks of SHTs from the perspective of users aged 50 years and older. Despite the abovementioned privacy and security risks, it has been well established that SHT users are often limited in their knowledge of the purpose of SHT data collection [11,12]. On the other hand, SHTs are often seen as safety-enhancing [13]. Moreover, as mentioned in our related larger review paper on SHT users of all ages (Percy Campbell et al, unpublished data, January 2024), user perception studies frequently pertain to younger populations and such technology is more often designed for younger groups [14]. Because of the usual emphasis on younger age groups and technology, our goal is to incorporate the views of older demographics regarding the paradoxical benefits and drawbacks of SHTs. To do so, we collected user perception studies related to 4 nonmutually exclusive themes: privacy, the purpose of data collection, risk and benefits, and safety. To our knowledge, we are the first to compile research findings spanning these 4 categories, leading to unique insights that can inform private sector data protection regulation and SHT design, especially for older adults. We constructed four research questions prior to our literature search. (1) Privacy: What are SHT users' privacy attitudes? (2) Purpose: What are SHT users' understandings of the purpose of why and how their data are collected? (3) Risk or benefits: What do users think about the possible benefits and potential risks of harms of SHTs? (4) Safety: What are SHT users' safety perceptions?

Methods

Overview

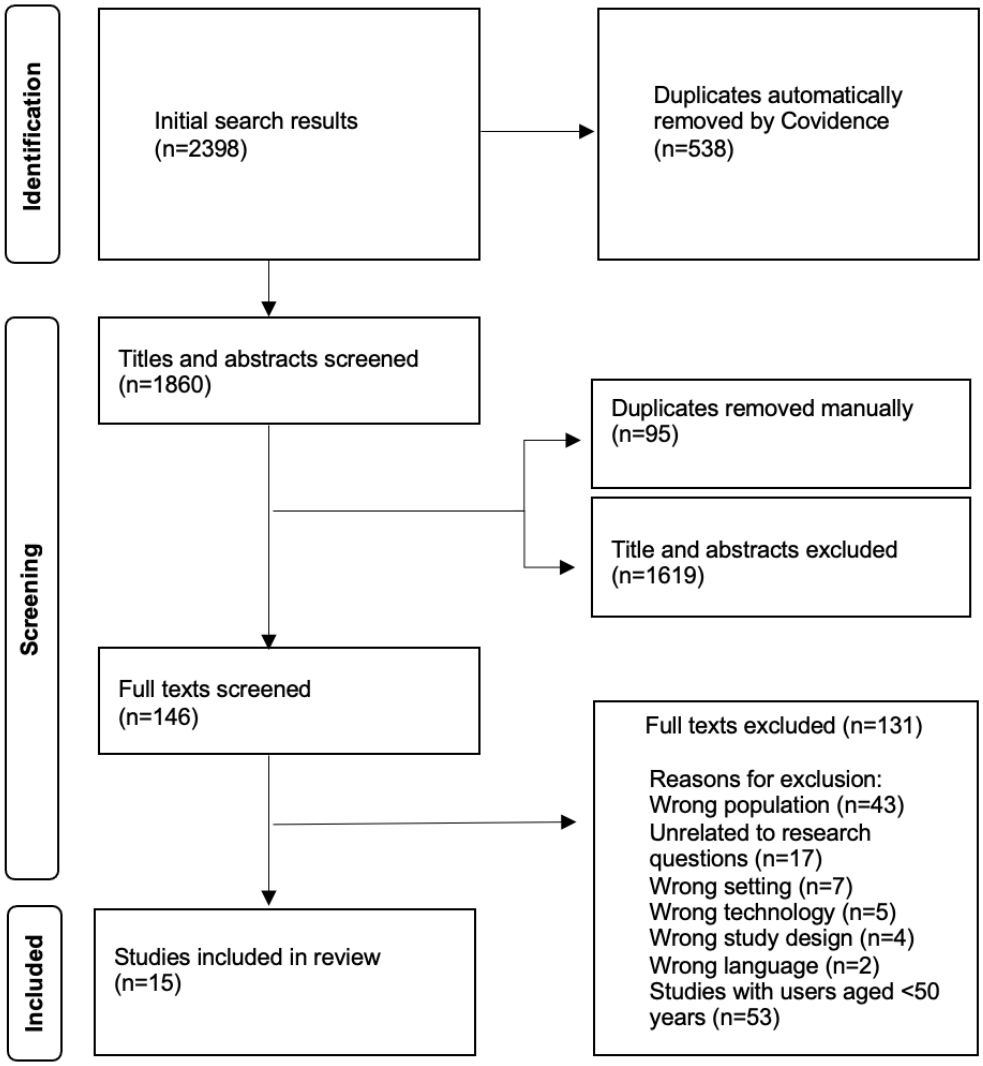
This section outlines our search strategy and the inclusion and exclusion criteria for paper selection. Research questions were crafted to examine the interdisciplinary literature on user perceptions of smart home surveillance. We used an integrative review framework to provide an established, rigorous, and comprehensive review method. An integrative approach is well suited to consolidating an expansive range of articles from varied theoretical backgrounds and empirical methods, allowing for a deeper understanding of a given phenomenon [15].

Search Strategy

The search for peer-reviewed English studies was conducted in October 2021. The research team selected relevant keywords based on 4 research questions listed in the previous section. A health information specialist helped to further identify and refine the search keywords (Multimedia Appendix 1) and selected the following databases to find relevant journal articles using the following databases: Ovid MEDLINE, Ovid Embase, Cochrane Database of Systematic Reviews (Ovid), Cochrane Central Register of Controlled Trials (Ovid), Scopus; Web of Science Core Collection, and IEEE Xplore or IET Electronic Library (IEL). No time frame for the publication date was specified. The results were imported into Covidence reference management software to manage the screening process. The duplicate studies were removed automatically by Covidence and manually by team members.

Following duplicate removal, 4 team members were involved in the review process, which included a title or abstract screening round and a full-text review screening round. Articles were eligible for full-text review if they initially appeared to meet inclusion criteria in the title and abstract phase. Next, in the full-text review phase, each article was read in full and subsequently accepted or rejected based on inclusion and exclusion criteria. To ensure reliability and to mitigate subjective biases, article selection in each research phase required acceptance from 2 team members working independently. The rare instance of disagreement between researchers over whether to accept or reject an article was resolved through the involvement of other team members in weekly team meetings. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1) outlines the screening processes.

Figure 1. PRISMA flow diagram of extracted studies. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Inclusion and Exclusion Criteria

Eligible studies were those focused predominantly on smart home users' perceptions of privacy, data collection purposes, perceived risks or benefits, and physical safety impacts of SHTs. Selected studies included SHT users aged 50 years and older, aside from 1 study where the participant age range spanned from 48 to 84 years with a mean age of 67.8 years and the aging population was the key focus [16]. The studies were included if participants were community dwelling rather than residing in care home facilities (eg, nursing homes), assisted living facilities, or hospitals. These clinical settings produce additional complexities associated with SHTs (eg, legal requirements, staff, and patient or resident consent), which were beyond the scope of this review. Qualitative, quantitative, and mixed methods empirical peer-reviewed studies that measured user perception of smart home surveillance were included. Common methods from accepted studies included questionnaires, surveys, interviews, and focus groups.

The following enumerates our exclusion criteria: (1) studies focused exclusively on wearables or smartphones due to their use outside of the home and further surveillance potential such as location tracking; (2) smart energy grid studies focused solely on cost or energy sustainability; (3) technical articles (eg, algorithm or system development) or theoretical articles; (4) system feasibility studies that were unrelated to user perception; (5) other review papers; (6) usability or acceptability studies that were unrelated to privacy, data collection purpose, risk, or safety.

Thematic Analysis

Once the full-text screening phase had been completed, key details from each accepted study were entered into a shared Microsoft Excel sheet. The sheet was used to record the article title, author, publication year, country, method, demographic breakdown of participants (age or gender), and a short summary of key findings under the corresponding themes of privacy, the purpose of data collection, risk or benefits, and safety. The articles were classified under 1 or more themes when insights could be linked to our related research questions. These findings were then reported throughout the results section, which has been organized by theme. Summarizing articles by theme allows for patterns and contradictions to emerge from the data, ultimately facilitating analysis in the discussion section.

Results

Study Characteristics

Throughout the first phase, 2398 titles and abstracts were screened by our research team. The team selected 146 articles for full-text review, of which 78 were excluded based on the screening criteria mentioned in the previous section. The 68 remaining articles were selected for a larger user perception review paper on users of all age groups. Of those 68 studies, the 15 studies that focused primarily on adults aged 50 years and older were included here. Publication dates ranged from 2011 to October 2021. The results included 6 qualitative, 5 quantitative, and 4 mixed methods studies. Sample sizes ranged from 8 to 447 participants. Studies were conducted in the United States (n=4), the United Kingdom (n=3), Philippines (n=1), South Korea (n=1), Germany (n=1), Finland (n=1), the Netherlands (n=1), and 3 studies sampled participants from India, Thailand, Indonesia, and Malaysia. Participants' mean ages ranged from 66.4 years to 86.67 years. Further demographic details are available in Table 1.

Table 1. Study characteristics: location, SHT[a] type, user demographics, method, and theme.

Reference	Location	SHT type	Demographic of participants	Method	Key themes
Albina and Hernandez [17]	Philippines	Sensors, cameras	• N=118 • Age range: 60 to ≥81 years • 34.3% female • 65.7% male	Survey	Enhanced safety and privacy concerns
Arthanat et al [18]	United States	Thermostats, voice assistants, home security systems, cameras, and remote controlled lights and appliances	• N=447 • Age range: 65-95 years • 68.8% female • 31.2% male	Survey	Enhanced safety
Choi et al [2]	United States	Smart speakers, cameras, door or window sensor, and multisensor	• N=37 • Age range: N/A[b] • 75% female • 22% male	Semistructured interview	Privacy concerns
Chung et al [19]	United States	Smart speakers (voice assistant)	• N=47 • Age range: N/A • 49% female • 51% male	Survey	Privacy concerns and risk or benefits (lack of affordability)

Ghorayeb et al [13]	United Kingdom	Nonmedical sensors: (SPHERE[c] system: environmental and wearable and video sensors	• N=13
			• Group 1 (users): N=6
			  • Age range: 66-88 years
			  • 67% female
			  • 33% male
			• Group 2 (nonuser): N=7
			  • Age range: 67-89 years
			  • 57% female
			  • 43% male
				Focus groups	Privacy concerns, safety concerns, and purpose of data collection (unaware or forgetful)

Jo et al [20]	South Korea	Environmental sensors, Bluetooth smart bands, and receivers	• N=9 • Age range: 68-87 years • 100% female	Focus groups	Fewer privacy concerns, purpose of data collection (aware), and enhanced safety
Kirchbuchner et al [16]	Germany	Sensors	• N=60 • Age range: 48-84 years • 70% female • 30% male	Survey	Privacy concerns, risk or benefits, and enhanced safety
Leikas and Kulju [21]	Finland	Sensors	• N=8 • Age range: 70-85 years • 88% female • 12% male	Focus groups	Enhanced safety, risk or benefits (improved independent living), privacy concerns, and purpose of data collection (unaware)
O'Brien et al [22]	United States	Smart speakers (voice assistant)	• N=125 • Age range: N/A • Sex: N/A	Thematic analysis of Amazon smart speaker reviews	Enhanced safety
Pal et al [4]	India, Thailand, Indonesia, and Malaysia	Smart homes	• N=239 • Age range: 55 to 75+ years • 34.3% female • 65.7% male	Survey	Privacy concerns and risk or benefits (security concerns)

Reference	Location	SHT type	Demographic of participants	Method	Key themes
Pal et al [23]	India, Thailand, Indonesia, and Malaysia	Smart homes	• N=239 • Age range: 55 to 75+ years • 34.3% female • 65.7% male	Survey	Privacy concerns and risk or benefits (lack of affordability)
Pal et al [24]	India, Thailand, Indonesia, and Malaysia	Smart homes	• N=239 • Age range: 55 to 75+ years • 34.3% female • 65.7% male	Survey	Privacy concerns and risk or benefits (poor design)
Psychoula et al [25]	United Kingdom	Sensors	• N=41 • Age range: N/A • 76% female • 24% male	Survey or semistructured interview	Privacy concerns (limited) and purpose of data collection (aware)
Rogerson et al [26]	United Kingdom	Sensors (light, temperature, and movement)	• N=19 • Age range: N/A • 47% female • 53% male	Semistructured interview	Privacy concerns (limited) and enhanced safety
Van Hoof et al [27]	Netherlands	Mobility monitoring, voice response, fire detection, and wandering prevention	• N=12 • Age range: 63-87 years • 83% female • 17% male	Semistructured qualitative interview	Privacy concerns (limited), enhanced safety, and risk (dependence on internet)

[a]SHT: smart home technology.

[c]SPHERE: Sensor Platform for Healthcare in a Residential Environment

Thematic Results

Overview

Table 1 shows the same papers classified under our research questions related to privacy, the purpose of data collection, risks and benefits, and safety. A total of 13 studies related to user privacy perception, 4 studies explored users' understandings of the purpose of their data collection, 7 studies related to the benefits and risks of SHTs, while 9 studies pertained to user safety perception.

In summary, our results show that users display a diverse range of perspectives on privacy, the purpose of data collection, risks and benefits, and safety. Although privacy is often seen as an important value in need of protection, nuanced perspectives showed that users were more comfortable with certain types of devices over others, and more comfortable with certain groups of data recipients than others. Participants were sometimes unaware of SHT data collection purposes, although others expressed higher levels of understanding when their SHT functions were adequately explained to them. However, in some cases, the details of SHTs' purpose and function were forgotten over time. Often, users lacked confidence in explaining what data their devices collected or why. Security risks, including hacking and data breaches, were often cited user concerns, while SHT convenience was frequently seen as a major benefit. Overall, despite varying levels of concern in the aforementioned areas, users were generally enthused about safety-enhancing benefits of SHTs. These safety benefits may be especially important to older adults with health concerns in particular, as SHTs can act as emergency contact tools or direct lines of support with health care providers, caregivers, and family. In what follows, the key findings are explained in further detail and separated by theme.

Privacy: What Are SHT Users' Privacy Attitudes?

A total of 13 studies discussed privacy perspectives in general, with some flagging privacy as an important consideration in SHT adoption [2,17]. This section explores a range of user privacy attitudes, where environmental or motion sensors were the most accepted type of SHT [20,26] compared to smart speakers or cameras which were considered invasive [2,16], participants indicated the need to control access to their SHT data [13,21]. Many participants were skeptical about the handling of their personal information by service providers and third parties [4,23,24]. However, over time, some users forgot about the presence of sensors that collected electricity, light, temperature, and movement data [26]. In another study, most participants forgot about the presence of nonmedical sensors that collected environmental and activity data in the home [13].

Certain SHTs were generally viewed as nonthreatening, such as door and window sensors, multisensors [2], fall detection and health monitoring sensors [20], or light, temperature, and movement sensors [26]. Some participants considered sensor systems to be preferable in comparison to alternative arrangements such as institutionalization, which was generally seen as undesirable due to a lack of privacy and restricted visitation rights [27]. In early smart home models, networks of motion sensors, fall detectors, emergency voice response, and fire detection sensors were seen preferably by users, except for 1 participant who removed the technology from her home due

to privacy and autonomy concerns [27]. This participant enjoyed standing in the hallway which would set off alarms, and in turn, alerted staff. However, although most participants did not feel they were being "watched or monitored" the authors also noted that "some are even not fully aware of the presence of the UAS (Unattended Autonomous Surveillance) system at home" [25].

In terms of data sharing, participants expressed mixed attitudes. In a UK study, interviews (n=41) showed older adults were open to having behavioral data collected and shared with family members or health care providers. Here, researchers noted that older adults were more open to sharing data for health care purposes than younger people [25]. One study from South Korea reported that participants (n=9) used environmental sensors for energy management and health-related sensors for fall detection and activity monitoring and reported willingness to share their health-related data with friends, family, and health care practitioners [20]. By contrast, others expressed the need to limit their data sharing to select parties. Those equipped with environmental, wearable, and video sensors in the United Kingdom preferred to share data with health care practitioners instead of family or friends (n=7) [13]. In a survey of 118 older adults (aged 60 years and older) in the Philippines, participants were concerned about assistive technology data access and sharing from environmental sensors and cameras [17].

In Germany, older adults (n=60) perceived cameras to be privacy-invasive compared to other SHTs. Here, privacy was prioritized above other potentially relevant adoption considerations, such as ease of use. Again, study participants preferred to limit data sharing, rejecting commercial service providers as legitimate data recipients [16]. Additionally, in a US study (n=37), the IP web cameras were considered more invasive than other SHTs such as smart speakers, door and window sensors, or multisensors [2]. Some participants expressed concern over smart speaker developers listening in to private conversations, while others were unperturbed [2]. Users were comfortable using smart speakers for certain purposes such as alarms, reminders, and searching for online information. However, many were hesitant to use medical SHTs that shared their health data; 1 user specifically noted their discomfort with the potential for pharmaceutical companies to profile them with targeted advertisements based on health-related data [2]. In another US survey with 47 Amazon smart speaker (Alexa) users, some participants expressed concern over their conversations being monitored, while others were indifferent [19]. The following section discusses the extent to which users understood the purpose of their SHT data collection.

Purpose: What Are SHT Users' Understandings of the Purpose of Why and How Their Data Are Collected?

A total of 4 studies revealed insight into what participants understood about the purposes of their SHT data collection. In using SHTs for health care purposes, participants in Jo et al [20] were generally aware of the purposes of their sensor data collection. In this study, researchers had explained to participants what data were collected, how they were stored, and who had access to their data. However, study participants most often relied on support networks such as friends, family, or neighbors to help with their privacy decisions regarding SHTs. One issue arose, however, when participants in another study were taught about the functions of their SHTs. They eventually forgot the purposes of why those sensors were installed and, by extension, what information was being transmitted [13]. Focus group participants expressed a lack of confidence in their knowledge of whether sensors were measuring water consumption levels, humidity levels, body movement, the number of people in the room, and how alarms are triggered by artificial intelligence (AI) [13]. Similarly, focus group participants in Finland lacked confidence in their knowledge of who had access to their movement sensor data, for what purposes, and whether they had access to it themselves [21]. As noted elsewhere, SHT users often have a sense that privacy issues are present, but are unsure of "what data is collected, or how or why" [19]. Overall, apart from 1 study under this category [20], participants expressed limited understanding of the purposes of the collection of their SHT data [13,21,25]. As will be further discussed, a lack of privacy literacy around the types of surveillance SHTs contribute to is an issue with users of all age groups, younger demographics included. A lack of literacy in this area may result in difficulties in obtaining ongoing consent and informed decision-making regarding SHT use.

Risk and Benefits: What Do Users Think About the Possible Benefits and Potential Risks of Harm of SHTs?

A total of 7 studies explored user perceptions of SHT risks and benefits. Overall, participants identified data security threats as significant risks [16,19,21,23,24]. These perceived risks were mostly divided between disquiet over malicious data breaches, such as through hacking and misuse of personal data by smart home providers. Malicious data breaches were generally characterized by users as the unauthorized access of data by criminal parties; 1 survey (n=60) found that participants, the majority of whom had no prior experience with SHTs, were mainly concerned with criminal access to their data [16]. Similarly, the larger survey sample (n=237) in the study by Pal et al [23] showed that older adults did not trust smart home companies to securely handle their data or prevent data breaches. Specifically, the authors found that SHT users wanted their personal data to be anonymized and did not trust SHT providers to provide adequate or desired protections [23].

Alongside malicious data breaches, the misuse of personal data by SHT providers was consistently described as a risk by study participants. These concerns were mirrored in commercial contexts: focus group discussions (n=14) showed that SHT users were knowledgeable about the collection of their consumer data and were uncomfortable with their lack of agency in the use of the data [21]. Another study by Pal et al [24] (n=239) further affirmed that SHT users are uncomfortable with corporate access to their personal information. From specific medical and commercial contexts to overarching sentiments, users appear dissatisfied with the current levels of data protection offered by SHTs.

Users described additional risks beyond data collection. These included concerns over SHT dependence: semistructured interviews (n=12) demonstrated that power outages or system

failures were flagged as risks by SHT users [27]. Participants also expressed concern over steep learning curves with new SHTs, as well as a potential lack of agency in selecting their own devices and controlling use of the devices [24]. Additionally, affordability was consistently identified as a risk, with concerns that SHTs would not offer benefits worth their price [4]. This finding was reiterated by Chung et al [19] where 24 of 47 (51%) surveyed users reported that affordability surpassed other risks. Overall, malfunction, affordability, and user trust represent additional risks identified by older adults using SHT.

Alongside risks, participants aged 50 years and older noted distinct positive benefits conferred by SHTs. Users were commonly enthusiastic about assistive smart home devices, including mobility monitoring, voice response, fire detection, and wandering prevention technology. Participants believed these SHTs gave them greater independence and reduced the burden on supportive family members and caregivers [21,27]. Similarly, the survey responses (n=239) in the study by Pal et al [23] indicated that users enjoyed home automation, which increased their daily convenience, especially those users who experienced or expected to experience physical or cognitive ailments. Survey participants simultaneously identified the abovementioned risks while reportedly appreciating SHTs' value, thus creating the need to trade their reservations for SHT convenience [24]. Finally, users gained self-confidence with digital technology by mastering newly installed SHTs; however, learning to use the devices was sometimes perceived as a barrier and a deterrent to use [19]. These varied findings comprise the social benefits identified by users; however, enhanced physical safety was among the most noted. The following section explores safety perceptions in greater detail.

Safety: What Are SHT Users' Safety Perceptions?

A total of 9 studies discussed the role of SHTs in safety enhancement, where participants were generally enthused about their devices' safety features and support for aging in place [16,17,20-22,26,27]. Safety has been viewed as an important component of smart home adoption, especially for older adults with health issues [18]. Sensor users have even expressed the need to trade their privacy for increased safety through SHTs, especially for older adults living alone who experience memory problems [23].

All types of SHTs were considered useful for safety purposes, especially in an accident or emergency. In one example, stroke survivors in the United Kingdom felt safer using motion sensors in the home, as these gave them the feeling that they were being looked after [26]. In South Korea, participants found environmental and wearable sensors to be beneficial for aging in place and reported enhanced feelings of safety [20]. The ability to share their behavioral data was seen as a form of safety assurance among users [20]. Participants using ambient intelligent systems also reported enhanced feelings of safety in the home in the Netherlands, especially in the event of a fall or when feeling unwell and unable to access the phone [27]. Fall detection and other health-related safety features and burglary detection were generally well accepted [16]. Likewise, in the Philippines, assistive technology users reported enthusiasm about increased feelings of safety in the home through emergency response features [17]. Sensor Platform for Healthcare in Residential Environment users were subject to environmental, wearable, and video sensors. They were mainly concerned about the limited ability of human operators to react quickly enough in the event of an emergency [13].

Smart speakers embedded with voice assistants were also perceived to improve safety [22]. In a study examining 125 Amazon smart speaker reviews, safety features were commonly mentioned by older adults and caregivers. For example, emergency contact features such as "Ask My Buddy" were popular among reviewers [22]. In the words of one reviewer [22],

> *If I call out "Alexa, tell My Buddy to alert contacts," she sends an alert via cell phone voice and text to my contact list telling them to check on me. This is great in the event of anything from a slip in the shower to any medical or emergency issue or if I feel in danger.*

Throughout our collected studies, this sentiment appears to reflect the preference for the safety-enhancing features that SHTs may provide among many adults aged 50 years and older.

Discussion

Paradoxical Nature of SHTs

Throughout the analysis of 15 studies, study participants identified numerous benefits and drawbacks of SHTs. Overall, our findings indicated that SHT users aged 50 years and older found value in SHTs for several reasons beyond the superficial purposes of convenience or entertainment. Perceived benefits included enhanced independence levels for older adults and increased confidence levels with technology [19,21,27]. They were also widely perceived to support health and well-being through fall prevention or emergency contact features and were seen to enhance physical safety levels at home [16,17,20-22,26,27].

Conversely, participants voiced several concerns pertaining to device affordability [4,19], device reliability, criminal data breaches [16], or a lack of trust in SHT companies in securing user data [23]. If user consent over SHT data collection is to be considered meaningful, it should be ongoing, which poses an issue in cases where users expressed limited understanding of data flows and access [21]. As mentioned by homecare field professionals and related employees, this challenge can be particularly difficult for those who develop memory issues in later years [21]. This is complicated by the fact that privacy concerns sometimes fade over time and participants sometimes forget about the existence of their SHTs altogether [13,26]. Low levels of understanding around SHT data collection purposes, use, and disclosure span all age groups [28] but may be especially detrimental to older people who have SHTs installed by others for health and safety purposes.

It follows that the need for higher levels of user autonomy regarding data access is a consistent finding that requires further attention [4,16,21,23-25]. This is especially important because SHTs are often marketed in ways that promote increased autonomy for older adults. However, if SHT settings are not

carefully configured and managed, they may increase independence in some ways while simultaneously diminishing it in others [28]. Data sharing and intrusive monitoring may create issues related to privacy, autonomy, or attempts at behavioral control [29]. Higher levels of user autonomy would require a strong understanding and access to controls over data monitoring and use. Otherwise, these issues can be mitigated by designers embedding tightly controlled "privacy by default" settings. The SHTs should occasionally prompt users to review and manage privacy settings and restrict data flows where unnecessary for device functionality. Finally, some older adult users may consider creating a set of guidelines and privacy preferences for caregivers to follow should memory or cognitive capacities diminish.

Despite a general unease with data sharing among third parties or service providers, one major limitation of our selected studies is the lack of detailed participant discussion on the potential for SHTs to influence insurance rates, targeted ads, or the increased difficulty in differentiating consumer data from health data. Recall that participants rejected commercial providers as data recipients [2,16]. Commercial SHTs such as smart speakers commodify user data [1,30,31], potentially inferring user health data in the process [32] and sharing such information with third parties with unknown goals or incentives. In cases where commercial-grade SHTs are used as care or safety devices for older people with health issues (eg, [19,22]), should such data still be commodified by commercial actors? SHTs can reveal mental and physical health status, mood, personality traits, and sensitive activity recognition, among other personal details [32-34]. In some cases, SHT or wearable data can also be used to influence personalized insurance rates in ways that may be disadvantage older adults with health issues [7].

Moreover, SHT developers in health care spaces have noted the difficulty in differentiating what is or should be considered medical and health data versus what is not [5]. If users are unaware of what types of data they are sharing (eg, [13,21]), to what extent is autonomous decision-making enabled or respected? When commercial-grade SHTs are used to infer health data, they may be treated as consumer data, facilitating access by public and private sector actors outside of user knowledge or meaningful consent. Many people would likely object to commercial actors gaining access to health care data from hospital settings for the purposes of third-party advertising, yet inferring user behavioral and health patterns through SHTs and wearables is possible. The discriminatory issues with targeted advertising, data brokers, and marketer classifications of different groups of people are well known [35]. Currently, studies linking the ways that SHT data contribute to targeted ads through behavioral patterns or biometric markers such as voice are in their infancy [30,33]. Additional research is needed on how SHT data from older adults are treated by SHT companies; what the subsequent targeted advertising or personalized insurance outcomes may be, either now or in the future; and whether such outcomes are discriminatory in nature.

For these reasons, the ethical implications of inferring health-related data from commercial SHT products should be considered alongside the abovementioned user privacy concerns. In short, the challenges in protecting SHT user privacy and autonomy are ongoing [3] and can be further complicated by the involvement of inferred or self-reported health-related data. As has been recommended elsewhere [2,6,14,29,36] SHT developers should prioritize design choices that better support members of all age groups through user-centric design, considering multiple stakeholders, such as older adults, nurses, and caregivers. Others have advocated for an ethical by-design (EbD) approach to implementing digital technology not only through co-design and product development but also through transdisciplinary research [29,37]. Alongside EbD choices, private sector privacy regulation could further protect users through a data justice approach that privileges human rights over commercial interests.

At a global level, the technological ability to collect and aggregate data for surveillance has outpaced regulatory mechanisms [38]. Using a data justice framework is a logical path forward to the ethical use of technology in ways that benefit both individuals and groups without further disempowering them through surveillance imperatives that do not suit their needs. Taylor's [38] data justice framework includes three pillars: (1) visibility, (2) engagement, and (3) antidiscrimination. The first pillar, visibility, refers to the understanding that representation in certain databases can be beneficial to individuals and groups, such as in health care or welfare services. However, it also recognizes the right to privacy and the need to opt out of databases, such as those aggregated by commercial bodies [38]. As shown throughout our findings, many users indicated preferences in sharing their data with health care providers instead of family or friends [13] and preferred not to share with manufacturers, marketers, or other third parties [16]. The second pillar, digital engagement and disengagement, supports individual autonomy by encouraging personalized decisions regarding a user's preferred level of technological engagement and control over circumstances [38]. For our purposes, the right to digital disengagement would help support older adult SHT users in situations where personalized human care is their preferred option for certain purposes or where only select SHT functions were preferred. The third pillar, the right to challenge data-driven discrimination, allows for the ability to challenge bias in algorithmic decision-making and outcomes [38]. This last pillar may be particularly important as AI capabilities continue to develop alongside rising SHT popularity. Although issues with gender and racial bias with AI platforms are well documented within the literature, digital ageism is currently understudied and is thus in need of further critical analysis [28,36]. The ability to evaluate and challenge ageist bias is an important task as consumer-grade devices become more popular among aging populations. Taken together, regulatory frameworks following Taylor's [38] 3 pillars of data justice can be used to construct meaningful guidelines around how SHT data should be managed by private sector actors. This way, those who choose to engage with such technology in their homes can enjoy the potential health and safety benefits of SHTs while preventing or mitigating challenges to privacy, autonomy, and discrimination that can be detrimental to older age groups.

Strengths and Limitations

To the best of our knowledge, we are the first to research SHT user perception under the 4 themes of privacy, the purpose of

data collection, risk and benefits, and safety. Previous reviews have largely focused on rehabilitation or health care settings exclusively, whereas we have also incorporated user perception of commercial SHT surveillance. Our review engaged with interdisciplinary fields across the social sciences, computer sciences, engineering, legal studies, and nursing. We have also applied insights from the surveillance studies literature to findings from gerontology research. In terms of limitations, as we excluded studies that focused solely on nonusers, we may have missed potential insight into why individuals do not adopt SHTs. We also excluded studies on smartphones or wearable devices, due to their ability to be used outside the home, which may have further limited our findings. We did not include other search methods such as hand searching for references and did not reconduct the search after October 2021 both of which may have resulted in additional relevant studies. We did not conduct a quality appraisal of our included studies, resulting in another potential limitation. As many of these studies were written about users in global North countries, the extent to which these findings are representative of other regions requires further inquiry. Finally, only English language studies were reviewed, so relevant non-English papers may have been omitted.

Conclusions

In conclusion, through our review of 15 studies, we have demonstrated a variety of perceived benefits and drawbacks from research participants over the age of 50 years. Although SHTs are seen as beneficial for safety enhancement such as emergency contact and convenience purposes, many users are also concerned about the privacy and or security risks, such as a lack of knowledge over where their data were going or a lack of control over who had access. These findings add to the growing body of literature highlighting the need for more age-inclusive technology design. This becomes especially important as commercial-grade SHTs are increasingly positioned to be used for care or health-related purposes for aging populations. In tandem with age-inclusive efforts such as EbD approaches [29], we further encourage the use and development of technology that enhances home safety while respecting the need for user privacy and autonomy. To do so, we have recommended data justice [38] as an equitable approach to these issues through regulatory guidelines.

Future directions for research in this area include studies on how privacy regulators can better support adults aged 50 years and older who use SHT or wearable devices for health or safety purposes. Further work is also needed on how privacy settings can be made more easily accessible and flexible to support everyday users in various contexts. As mentioned, robust analysis is needed where there is a current gap in the literature pertaining to the link between older adults, targeted advertisements or personalized insurance pricing, and SHTs or wearables [28], both in the practical application of such commercial relationships and through user perception studies. For further insight on this topic, subsequent user perception research on SHTs in general should actively include participants over the age of 50 years, especially in the oldest age categories, as opposed to targeting younger populations exclusively. Finally, beyond privacy and security, user perception studies on related ethical issues such as AI discrimination and the potential impacts on user autonomy should be further explored.

Abstract

Background: In the modern world, mobile apps are essential for human advancement, and pandemic control is no exception. The use of mobile apps and technology for the detection and diagnosis of COVID-19 has been the subject of numerous investigations, although no thorough analysis of COVID-19 pandemic prevention has been conducted using mobile apps, creating a gap.

Objective: With the intention of helping software companies and clinical researchers, this study provides comprehensive information regarding the different fields in which mobile apps were used to diagnose COVID-19 during the pandemic.

Methods: In this systematic review, 535 studies were found after searching 5 major research databases (ScienceDirect, Scopus, PubMed, Web of Science, and IEEE). Of these, only 42 (7.9%) studies concerned with diagnosing and detecting COVID-19 were chosen after applying inclusion and exclusion criteria using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol.

Results: Mobile apps were categorized into 6 areas based on the content of these 42 studies: contact tracing, data gathering, data visualization, artificial intelligence (AI)–based diagnosis, rule- and guideline-based diagnosis, and data transformation. Patients with COVID-19 were identified via mobile apps using a variety of clinical, geographic, demographic, radiological, serological, and laboratory data. Most studies concentrated on using AI methods to identify people who might have COVID-19. Additionally, symptoms, cough sounds, and radiological images were used more frequently compared to other data types. Deep learning techniques, such as convolutional neural networks, performed comparatively better in the processing of health care data than other types of AI techniques, which improved the diagnosis of COVID-19.

Conclusions: Mobile apps could soon play a significant role as a powerful tool for data collection, epidemic health data analysis, and the early identification of suspected cases. These technologies can work with the internet of things, cloud storage, 5th-generation

technology, and cloud computing. Processing pipelines can be moved to mobile device processing cores using new deep learning methods, such as lightweight neural networks. In the event of future pandemics, mobile apps will play a critical role in rapid diagnosis using various image data and clinical symptoms. Consequently, the rapid diagnosis of these diseases can improve the management of their effects and obtain excellent results in treating patients.

Introduction

Following the widespread and rapid outbreak of COVID-19, the disease crossed geographical borders and had a devastating impact on the health, economy, and well-being of the worldwide population. According to the World Health Organization (WHO), high-severity COVID-19 was reported in 16%-21% of patients and almost 3% died. In the case of other variants, however, local statistics in many countries indicated a high mortality rate, with some studies estimating a mortality rate of 4% or higher. Due to the novelty of the disease, ways to deal with it were not known early on; still, researchers considered the screening and rapid diagnosis of patients and their separation from healthy people to be significant steps in fighting the disease [1,2].

Early and low-cost diagnosis of infections in any pandemic is essential for pandemic control. Therefore, if it is possible to diagnose and quarantine infected cases in the earliest phases of an outbreak, the outbreak can be managed in the epidemic phase and will not become a pandemic. In the COVID-19 pandemic, various diagnostic methods have been used, with the polymerase chain reaction (PCR) test being the primary diagnostic tool. Nevertheless, PCR is a time-consuming and costly method; until being diagnosed with this diagnostic test, patients might freely transmit COVID-19 and accelerate its conversion into a pandemic by increasing the transmission rate [3,4].

In the COVID-19 pandemic, a wide range of technologies came to aid in the faster diagnosis and screening of people with infection, many of which proved successful. Meanwhile, mobile phones, as highly abundant tools and an information gateway, helped people update their information and make more accurate decisions. In addition to being a platform for installing essential and valuable apps to detect people with infection, smartphones help track people and examine the keywords used by them for making a diagnosis [5-7].

Numerous technical and review studies have addressed smartphone apps for COVID-19 management. Many of these studies have dealt with various mobile apps used to estimate the prevalence, lessons, opportunities, and challenges of these devices and disease management. Still, none of them has adequately focused on detection and diagnosis. This study is the first to systematically review all the studies that have used smartphone technology to detect and diagnose COVID-19. Previous reviews have examined a limited number of studies. Herein, by covering the maximum number of databases, an effort was made to explore all published papers that used smartphones to diagnose COVID-19. In the area of mobile apps for the diagnosis of COVID-19, a thorough and complete study has not been conducted. Alnazi [8] examined apps related to COVID-19 released on Google Play. The 12 studies reviewed included mobile-based software for contact tracing, awareness building, appointment booking, and online consultation. The author only reviewed free apps, however, and although this study was conducted in 2021, it did not include many scientific or commercial apps [8].

Asadzadeh et al [9] determined the scope of mobile solutions in the COVID-19 pandemic and reviewed 16 mobile app studies on COVID-19–related data processing. The reviewed studies were classified into 4 categories: prevention, diagnosis, treatment, and protection. Despite noting a different range of mobile apps, this study did not mention the details and algorithms of these studies [9].

Aslani et al [10] studied mobile health apps in pandemics and epidemics. They examined 17 studies and explored common respiratory diseases and lung infections. Although this study was published during the COVID-19 pandemic, it did not mention mobile apps related to COVID-19 [10].

Kondylakis et al [11] examined 12 studies on mobile apps for COVID-19 data analysis in a more comprehensive investigation. These 12 studies covered the following domains: training, information sharing, risk assessment, self-management of symptoms, contact tracing, home monitoring, and decision-making. Still, this study did not include studies using machine learning (ML) methods to predict and diagnose COVID-19. It also did not deal with mobile apps for COVID-19 diagnosis and primarily focused on studies on COVID-19 education, care, and management using mobile apps [11].

Almalki et al [12] analyzed and discussed all the apps available on Google Play and the Apple Store and provided a brief explanation. Among its flaws, this study did not review scientific or academic studies and only examined mobile apps available in the market, many of which were developed without scientific or clinical supervision. Therefore, it is difficult to rely on these apps, as they lack scientific support and cannot be introduced to or proposed by the communities [12].

Table 1 lists some studies that have addressed mobile apps for COVID-19 data management, including the first author's name, the country, the main topic, and the number of studies covered.

Table 1. Related studies on mobile apps for detecting and diagnosing COVID-19.

Author and country	Main topic	Studies covered, n
Alanzi [8], Saudi Arabia	Mobile app used during COVID-19	12
Asadzadeh et al [9], Iran	Mobile health solutions	16
Aslani et al [10], Iran	Mobile health apps for epidemic and pandemic outbreaks	17
Kondylakis et al [11], Greece	Mobile app for COVID-19	12
Almalki et al [12], Saudi Arabia	Implemented an app to combat COVID-19	115

This study aimed to fill the gap left by previous reviews by conducting a comprehensive review of studies on smartphone apps for the diagnosis of COVID-19, providing solutions based on technological models, and answering research questions so that researchers and health systems can envision devices and their apps in preventing future pandemics.

Methods

Search Criteria

This systematic review, which was conducted for the first time using this method, aimed to identify relevant studies related to detecting and diagnosing COVID-19 using a variety of smartphone apps. The systematic search strategy was developed based on previous studies and the authors' knowledge. The main objective was to address the following analytical questions (AQs):

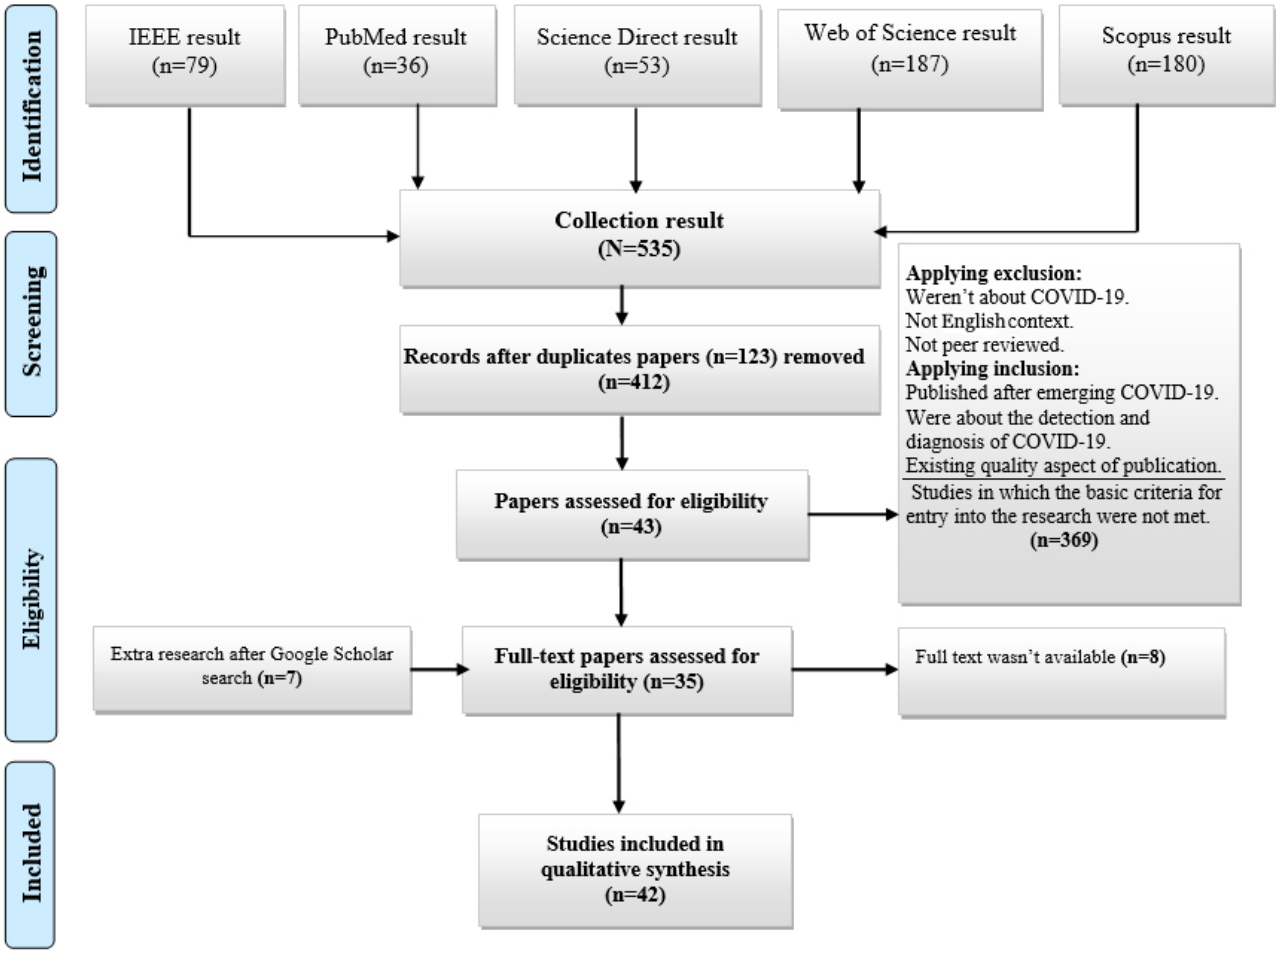
- AQ1: What are the uses of smartphones for COVID-19 detection and diagnosis?
- AQ2: What data do smartphones use to detect and diagnose COVID-19?
- AQ3: Which artificial intelligence (AI) methods and algorithms are used to process smartphone data?
- AQ4: How successful have smartphone apps been in COVID-19 detection and classification?
- AQ5: What suggestions can be made to improve the quality of mobile apps in disease diagnosis and pandemic control?

We reviewed electronic databases publishing papers on medicine and computer science. We concluded that PubMed, Web of Science (WoS), Scopus, IEEE, and ScienceDirect contain the most relevant papers. The search used the following keywords and logical expressions: ((“COVID-19”) AND (Detection OR Diagnosis) AND (Smartphone OR Mobile Application OR Mobile App)). The investigation was conducted from November 1, 2019, to late April 2022, and relevant published papers were extracted. The Embase database was eliminated from the examination due to the proximity of the publications.

Data Extraction

Relevant studies and the main elements of their methodology and results were recorded in data extraction forms in order to identify AI algorithms and techniques. Two researchers (authors AMR and MG) performed data extraction, and discrepancies between the researchers were resolved by discussion with an independent researcher (author AH). The extracted data elements included the first author's name, country of origin, research population, data used, purpose, method, the role of the mobile app, and the evaluation method. The search in reputable databases was performed based on the search strategy, and 535 papers were extracted. After reviewing the papers' abstracts and full texts, applying the inclusion and exclusion criteria, and selecting papers relevant to the title of this study, 42 (7.9%) full-text papers were finally selected. This process was performed based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart, as shown in Figure 1.

Figure 1. The review process and how to exclude papers according to the PRISMA flow diagram. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

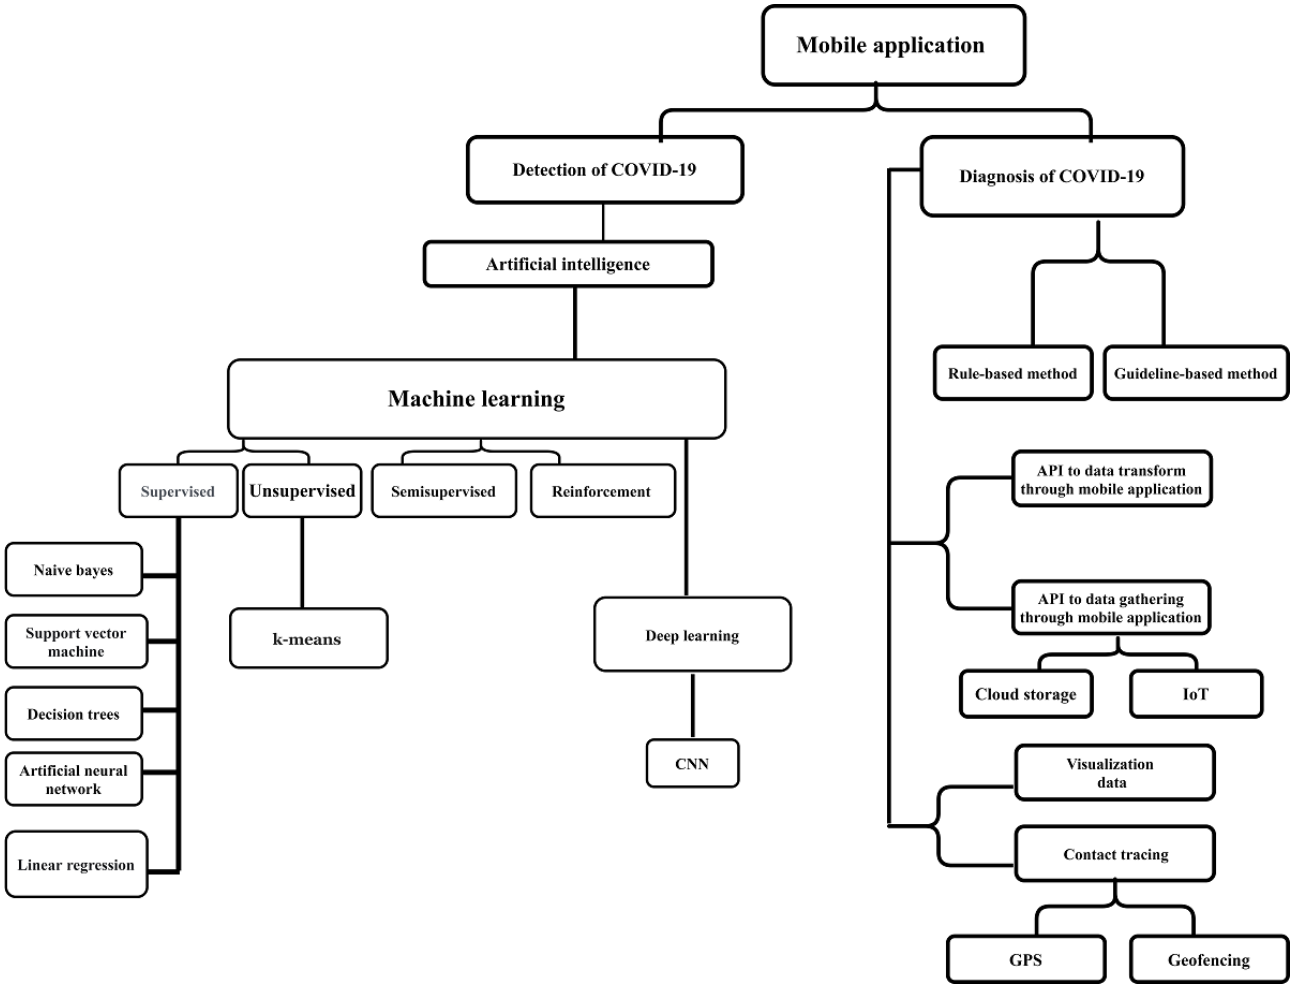


Results

Study Details

Due to the newly emergent status of COVID-19, the titles, abstracts, and keywords of all the papers published between 2020 and 2022 were reviewed, and 42 (7.9%) of 535 papers were ultimately selected as eligible. By comprehensively examining the mobile apps, we found that the role of smartphones was described in 6 areas with different types of COVID-19 data sets, including "Smartphones play the role of a platform for data collection," "visualizing the input data," "installing AI-based processing software," "determining contact tracing," and "COVID-19 data processing based on role-based and guideline-based methods," to detect and diagnose COVID-19. A taxonomy was developed to better organize the content and concepts related to mobile apps for COVID-19 diagnosis and detection, as shown in Figure 2.

Figure 2. Taxonomy of mobile applications for the COVID-19 pandemic. API: application programming interface; CNN: convolutional neural network; IoT: internet of things.



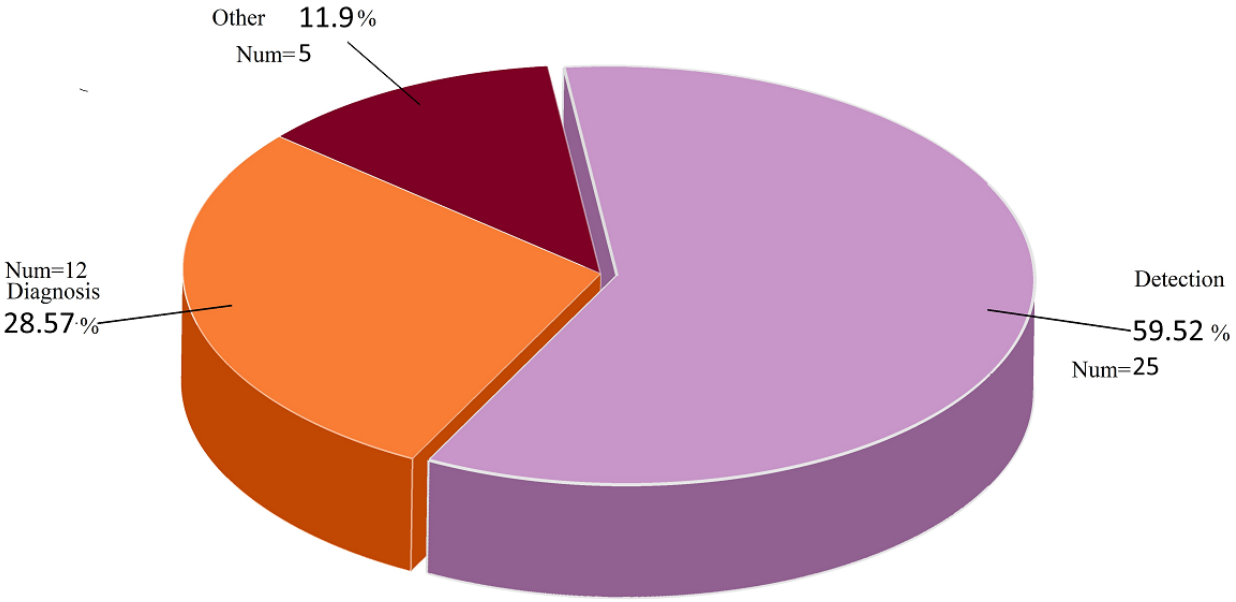
The taxonomy presented in this research classified the studies conducted in line with the investigation into 2 branches: detection and diagnosis. In the field of detection, the AI method was used more, which included traditional ML algorithms, such as supervised, unsupervised, semisupervised, and reinforcement learning; however, deep learning (DL) dealt with images and sounds. In the field of diagnosis, rule- and guideline-based techniques were mainly used to diagnose COVID-19 with mobile apps.

Detection vs Diagnosis of COVID-19 Using Mobile Apps

The terms "detection" and "diagnosis" were used interchangeably in many of the studies, but they differed in meaning and usage. These 2 terms are used differently in different settings. In clinical settings and diagnostic laboratories, the term "diagnosis" is used, while in computer vision and pattern recognition, observing the first definite signs in determining the status of a disease is called "detection." By examining the differences between these 2 terms in the dictionary and by inquiring from clinicians, a 2021 study found that detection identifies diseases in a set of patient and nonpatient cases. In detection, the disease is distinguished from other conditions, such that other cases may or may not have a disease-free status. However, the precise level and type of disease are completely specified during diagnosis. In the diagnosis concept, different cases might have a disease status or belong to other classes of abnormality or nonhealth, which can be determined [4,13-17].

Accordingly, detection was used for studies that distinguished cases of COVID-19 from healthy and normal cases. In contrast, diagnosis was used for studies that distinguished COVID-19 from other infectious pulmonary diseases (eg, different types of pneumonia). Detection makes sense in sets where other conditions (not infected with COVID-19) are specified, and COVID-19 can be distinguished with certainty from types of pneumonia or other coronaviruses [4,13,14]. By reviewing the 42 extracted papers, we found that 25 (59.5%) papers used DL to detect (identify) COVID-19, whereas 12 (28.6%) studies used it to diagnose and distinguish COVID-19 from other diseases. In addition, 3 (7.1%) studies did not precisely mention that diagnosis was their objective, while in 2 (4.8%) studies, the goal was to diagnose and detect. Figure 3 shows the amount of research performed to detect and diagnose COVID-19.

Figure 3. Aim of studies on the analysis of COVID-19 data in mobile applications.



Overview of the Role of Smartphone Apps in the Diagnosis of COVID-19

The apps were classified into the following 6 categories by reviewing all the studies conducted on mobile technologies and apps in line with our research objectives: contact tracing, data gathering, data visualization, AI-based diagnosis, rule- and guideline-based diagnosis, and data transformation.

Mobile Apps for Contact-Tracing Analysis

One of the main uses of apps during the COVID-19 pandemic was for contact tracing to diagnose and classify COVID-19. Thus, smartphones were used to diagnose patients with COVID-19 who had been in contact with people with infection. Many of the studies used mobile apps to trace people via trackers, geofencing, and GPS.

Mobile Apps for Gathering Data From Users

The sole purpose of some mobile apps was to collect data for processing. These apps received data through a standard smartphone from mobile devices as input devices in perception layers and sent them to the edge and cloud layers, where processing took place. In this case, the mobile apps sent data from the output of biosensors to higher-level systems for processing.

Mobile Apps for Data Visualization

Mobile apps were used to visualize the data received from biosensors or other data collection tools in many of the studies. After data were received, they were displayed to users via statistical charts. Smartphones carried out this task as the first step in data processing, which means gathering data and visualizing these data for COVID-19 diagnosis. In the next stage, these data were transferred to higher levels of processing, such as cloud and fog spaces.

Mobile Apps Used to Analyze COVID-19 Data Based on AI Algorithms

One of the most frequently used mobile apps for COVID-19 diagnosis was an AI-based application in which learning occurred. Studies used different clinical data, sounds, and radiology images. Data were collected in 2 ways: by mobile app designers and developers and by clinical app users using mobile apps.

Since most mobile apps processed and predicted COVID-19 infection, they incorporated different AI algorithms that involved 2 types of methods: methods based on traditional ML algorithms and those based on DL algorithms.

Mobile Apps Used to Analyze COVID-19 Data Based on Guidelines and Rules

A notable study on COVID-19 diagnosis using mobile phones involved ontologies, clinical guidelines, and rules. Due to COVID-19 diagnostic guidelines in health care centers, guideline- and rule-based methods for COVID-19 diagnosis are expected to be popular among clinicians and physicians. By incorporating these guidelines and rules into mobile apps, clinicians and stakeholders can see the process as more tangible and acceptable.

Mobile Apps as a Platform to Transform Messages and Data

Another application of mobile phones for COVID-19 diagnosis was processing keywords related to COVID-19 in social media using smartphones or analog messaging methods. In this method of COVID-19 diagnosis, the main terms representing COVID-19 diagnosis were counted and the COVID-19 diagnosis was made based on the number of uses of these words and their relationship with pronouns and sentence components.

Data Used in Mobile Apps for COVID-19 Detection and Diagnosis

A wide range of data were used in mobile apps, and according to specialty domains, different scientific disciplines made the initial diagnosis of COVID-19 differently. Mobile apps used a range of data for collection, classification, analysis, transfer, and visualization. These apps dealt with various data, including nasal swap samples, personal clinical data, signs and symptoms, voice and sounds, radiology images, and words and terms in media.

Several of the studies used a combination of data types. Some others used subjective clinical data and symptoms. Moreover, some apps used a variety of radiology images and patients' voices (cough).

Table 2 lists 11 (26.2%) studies on mobile apps for diagnosing COVID-19. This table includes the study, data, the application method, the mobile role, and the evaluation output.

Table 2. Studies (n=11) evaluating mobile apps used for COVID-19 diagnosis (or a goal similar to diagnosis).

Study	Data	Goal	Method	Mobile role	Evaluation output
Bindra et al [18]	Symptoms, clinical and bibliography data	COVID-19 risk prediction	ML[a]	Platform for the applied model to calculate risk prediction	N/A[b]
Sharma et al [19]	Sound	Diagnosis	ML	Platform for analysis; speech and sound analysis	N/A
Nema et al [20]	Symptoms	Diagnosis	Rule-based reasoning	Gathering symptoms and receiving alerts (SMS)	N/A
Quer et al [21]	Smartwatch, activity tracker data, symptoms, testing results	Differentiating COVID-19–positive status	Single decision threshold	Data collection	Accuracy=83.3%
Elagan et al [22]	Heart rate, blood cell counts, temperature	Diagnosis	Sending patient data to a physician and receiving output from the physician	Estimating the heart rate, receiving data from wireless sensors used to measure white blood cells (WBCs) and red blood cells (RBCs), and estimating air temperature	N/A
Imran et al [23]	Cough sounds	Diagnosis	DL[c]	Receiving cough sounds and analyzing them using a designed app	N/A
Mukhtar et al [24]	Cough, SpO_2[d], temperature	Diagnosis	Rule-based reasoning	Collecting data, sending data, showing the assessment	N/A
Koshti et al [25]	Symptoms	Diagnosis	ML	App platform	Accuracy=99%
Ertuğrul et al [26]	Personal data, observed symptoms (images, sounds)	Prediction	Ontology and rules	App platform	N/A
Maghded et al [27]	CT[e] scan, cough, voice, breath sounds, fatigue	Diagnosis	DL	App platform	N/A
Rangarajan and Ramachandran [28]	CT images	Diagnosis	DL	App platform	N/A

[a]ML: machine learning.

[b]N/A: not applicable.

[c]DL: deep learning.

[d]SpO_2: saturation of peripheral oxygen.

[e]CT: computed tomography.

There are several mobile apps available to detect COVID-19, as shown in Table 3. An overview of 31 (73.8%) studies is provided in the table, which includes the study, data, the application method, the mobile role, and evaluation results.

Table 3. Studies (n=31) that used mobile technologies to detect COVID-19.

Study	Data	Goal	Method	Mobile role	Evaluation output
Gökcen et al [29]	Cough	Detection	DL[a]	Platform for applying a COVID-19 detector via cough sounds	Accuracy=79%; F_1-score=80
Mao et al [30]	Wastewater sample	Detection	Biosensor analysis	Interface to send data	N/A[b]
Stasak et al [31]	Speech voice	Detection	ML[c]	App platform	Accuracy>82%-86%
Alkhodari and Khandoker [32]	Breath, cough, voice	Detection	DL	App platform	Accuracy=94.5% and 92.1%
Al-zubidi et al [33]	Blood index	Detection	ML	App platform	Accuracy=89%
Abdulrazaq Al-shekhly et al [34]	Thermal images and location	Detection	Thermometer and Send location	API[d] to calculate and send data	N/A
Berquedich et al [35]	Contact tracing	Detection and Management	Guideline based	App platform to prescribe drugs and send an alarm	N/A
Karataş et al [36]	Cough, voice	Detection	ML	App platform	Accuracy=96.5%
Awasthi et al [37]	Ultrasound images	Detection	DL	App platform	Accuracy=83%
Tawfik et al [38]	Cough sounds	Detection	ML and DL	App platform	Accuracy=98%
Krisnanik et al [39]	Symptoms	Detection	Rule-based reasoning	App platform	N/A
Ponomarchuk et al [40]	Breath and cough sounds	Detection	DL	App platform	N/A
Shreyas et al [41]	X-ray images	Detection	DL	App platform	Accuracy=98.4%
Mohsin et al [42]	Symptoms	Detection	Rule-based reasoning	App platform	N/A
Sanjeev et al [43]	Cough and clinical data (SpO_2[e] level, body temperature, heart rate, symptoms)	Detection	ML	App platform	Accuracy=85%
Ponomarchuk [40]	Breath and cough sounds	Detection	DL	App platform	N/A
Bushra et al [44]	X-ray images	Detection	DL	Platform to trace and analyze keywords	Accuracy=98.6%
Verde et al [45]	Cough	Detection	ML	Platform to analyze cough sounds	Accuracy=82%
Stanciu et al [46]	Bluetooth data	Virus Detection	Contact management	Contact tracing	N/A
Han et al [47]	Nasal swab sample	Virus Detection	Fluorescent aptasensors	Data visualization	N/A
Fozouni et al [48]	Nasal swab sample	Detection	RNA analysis	Data visualization	Sensitivity in less than 30 minutes
Coppock et al [49]	Audio and sound	Detection	ML	Platform to install an app	N/A
Wong et al [50]	Symptoms	Detection	Medical protocol	Receiving data and analysis using a designed app	N/A
Hijazi et al [51]	Heart rate, feeling features, blood pressure	Detection	ML	Collecting data from users	Mean accuracy= 83.3% (SD 1.6%)
Echeverría et al [52]	Sounds, symptoms	Early detection, management of close contacts	Guidelines	Gathering signs and symptoms	N/A
Verma et al [53]	CT[f] scan	Detection	DL	Process unit and platform for applied model	Accuracy=99.6%; F_1-score=99.6
Chen et al [54]	Spike protein, nucleocapsid protein	Detection	Data transfer	Receiving, gathering, and transmitting data in edge layers	N/A

Study	Data	Goal	Method	Mobile role	Evaluation output
Chen et al [55]	Temperature, heartbeat	Detection	Comparing received data with normal data	Receiving data from a sensor and sending it to the database	N/A
Wang et al [56]	Keywords on social media	Detecting the SARS-CoV-2 outbreak	Analysis of emerged keywords	Platform to install WeChat to trace and analyze keywords	N/A
Udhaya Sankar et al [57]	Speech, voice	Detection	Computational audit techniques	Data collection	N/A
Sun et al [58]	Horse nasal swab samples	Detection	ML	Smartphone-based collection and visualization of data	Results achieved in approx. 30 minutes

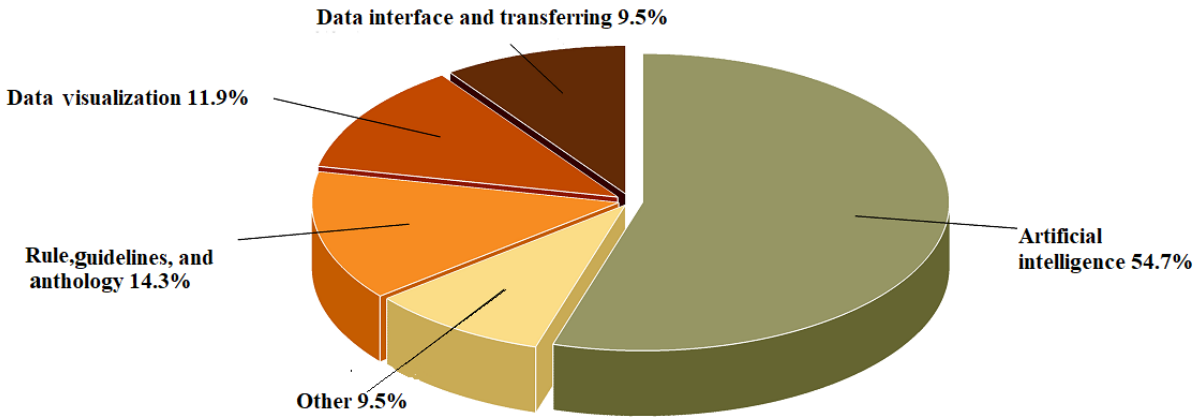
[f]CT: computed tomography.

Having thoroughly scrutinized the particulars of the investigations delineated in Tables 2 and 3, the methodologies implemented therein, the scholarly community involved, and the significance of mobile apps in the detection of COVID-19, we were equipped to provide answers to the AQs.

To answer AQ1, although different apps were used, the main apps belonged to 6 functional domains: contact tracing, data gathering, data visualization, AI-based platform to analyze data and signals, rule- and guideline-based methods for decision-making, and data transformation. Contact tracing is a critical application and a strength of this technology for the timely diagnosis of COVID-19 due to its high availability, serving as a module for accessing GPS satellites, determining people's positions, and accessing higher data transaction layers, such as cloud and fog spaces. Berquedich et al [35] adopted a model for contact tracing and designed technology to reduce hospital visits and alert people who were in contact with patients to seek health care. Some domains, such as the processing of patients' voice and audio data for COVID-19 detection, received more attention, whereas biosensor data visualization apps were less frequently designed and presented. Figure 4 depicts the 6 functional dimensions of smartphones for COVID-19 diagnosis.

Figure 4. Areas of application of mobile technology for the diagnosis of COVID-19. AI: artificial intelligence.



As can be seen in Figure 4, AI-based methods formed a large part (about 54.7% of the methodologies at the core of smartphones to diagnose COVID-19). It is believed that the researchers' focus was on mobile phones as on-site processing tools for faster detection of COVID-19. However, the mobile apps that embedded guideline- and rule-based techniques in their processing core to analyze biomarkers are powerful tools for processing all kinds of numerical data and present them to users as a piece of point-of-care equipment. These aspects of mobile apps have been of great importance for researchers due to the ease of faster analysis of input data and the data input gates of mobile phones for more immediate identification of patients. More than 14% of the mobile apps analyzed all kinds of biomarkers using guidelines and rules to access a model in the field of COVID-19 diagnosis by classifying input data. A large number of mobile apps also focused on visualizing (11.9%) and transferring (9.5%) data.

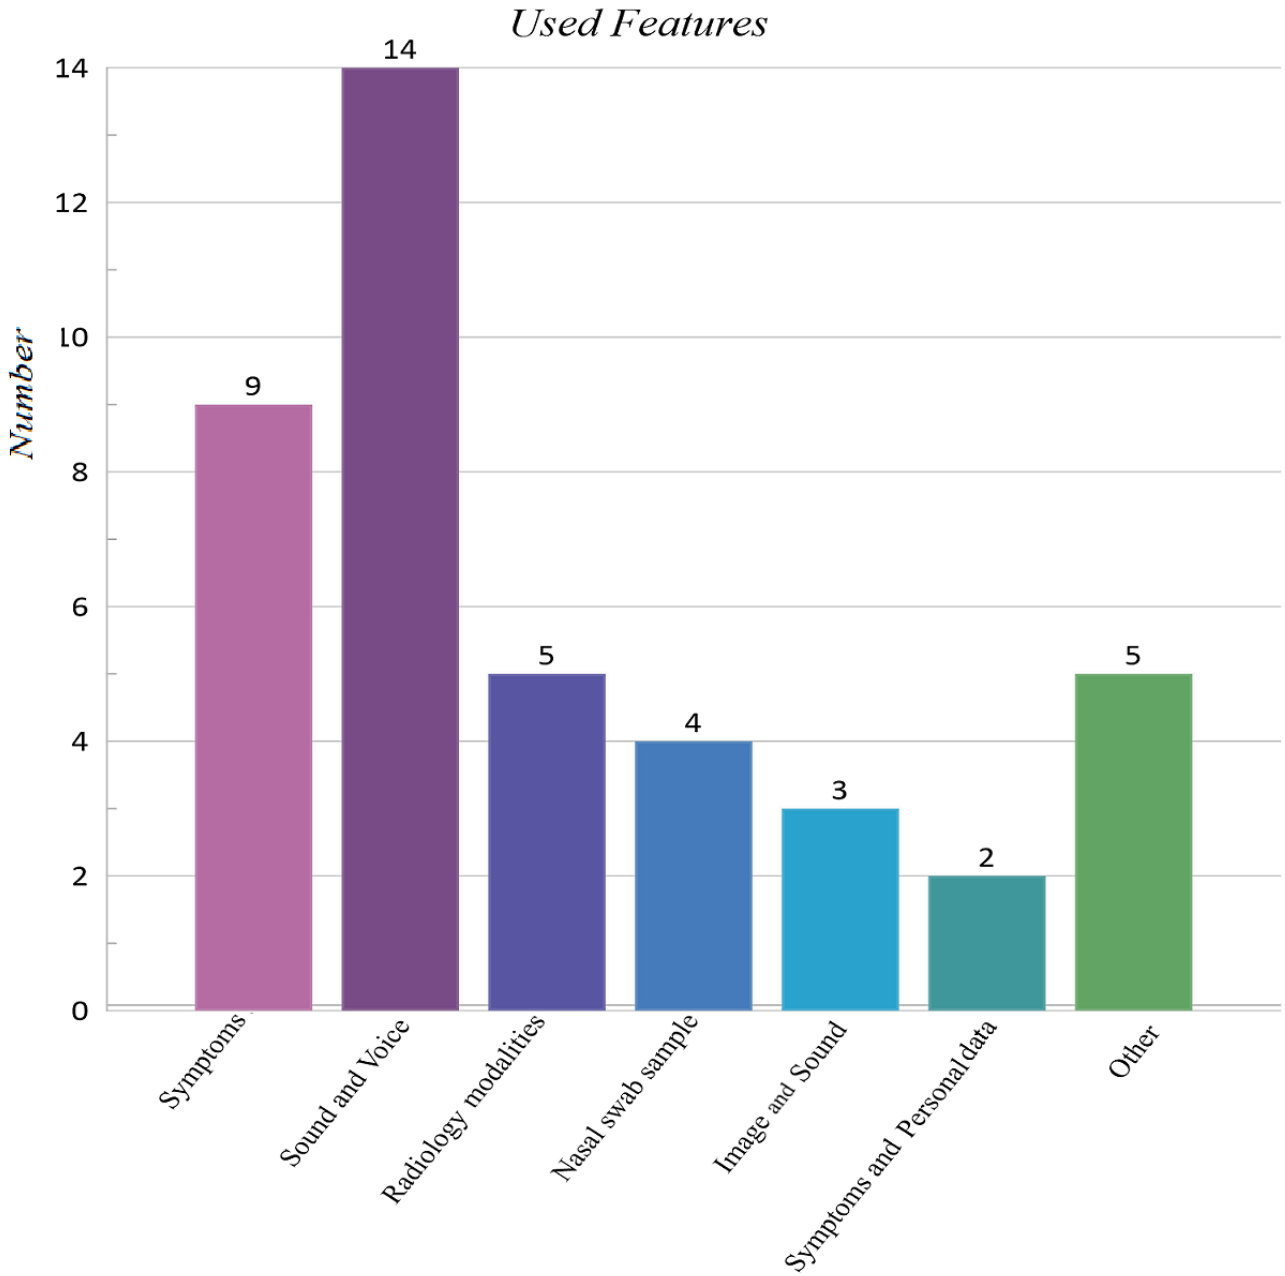
One of the strengths of mobile technology in identifying and diagnosing diseases, especially infectious diseases, is the visualization of the data received from internet of things (IoT) technologies and biosensors. After analyzing the data with

hardware chips and equipment or nucleic acid analysis, the signals are transferred to the mobile app for visualization through various means, such as IoT and Bluetooth. In these studies, blood, serology, and saliva data analysis results, after DNA and amino acid analysis, were sent by biosensors to mobile apps for visualization [27,28,47,52].

In some other studies, one of the most influential features of smartphone technology that had a significant impact on COVID-19 diagnosis and detection was the receiving and collection of data from people suspected of having COVID-19. These data included saliva samples, clinical signs and symptoms, vital signs, demographic information, cough sounds, and medical history. The data were obtained with mobile phones, the equipment connected to and embedded in them (eg, chemical sensors), and the recording of vital and clinical signs was stored in the mobile phones or moved to the cloud, allowing other computing devices to access this information. Some studies dealt with using smartphones for collecting patient data; for computation, they provided the data in a centralized space to specialists or decision support systems [21,22,25,26,32,53].

We observed many features to answer AQ2. The design and development of mobile apps for COVID-19 detection and diagnosis were commensurate with the frequency of COVID-19 diagnosis data. In other words, for frequent data, such as coughs, apps that used this type of data to diagnose COVID-19 were the most frequent. Figure 5 presents the usage of data types in mobile apps.

Figure 5. Data used in the detection and diagnosis of COVID-19.



Several laboratory biomarkers, diagnostic tests, biographical data, histories of diseases, and the voices and cough sounds of patients were used as input features for mobile apps based on methodology. According to Figure 5, it seems that the amount

of research using these features has a linear relationship with the diagnostic methods of COVID-19, as most mobile apps used the features of signs and symptoms as well as the patients' voices and cough sounds. In many apps designed to increase the accuracy of disease diagnosis, a combination of these features was used. Since mobile devices can receive and save sounds, these apps used this feature significantly.

For the analysis of nasal swab samples, apps that used biosensor technology incorporated multidisciplinary knowledge and used additional hardware. Following the sample analysis, the resulting data were transferred to the mobile apps via Wi-Fi or Bluetooth and were then used to automatically diagnose COVID-19. As a notable study, one can mention aptamers as a robust molecular tool for COVID-19 diagnosis [12]. The findings revealed that mobile technologies in pandemic control and prevention were a hot research topic and an exciting and trendy approach.

To answer AQ3, the notable use of smartphone apps in COVID-19 prevention assisted clinicians with the timely diagnosis of COVID-19. AI methods, such as ML and DL algorithms, achieved remarkable results in COVID-19 diagnosis. Many researchers [8,10,13,27,35] who used clinical data, such as serology data, vital signs, and symptoms, adopted ML algorithms. These features were received from users and applied to the ML model to diagnose COVID-19. Different ML algorithms were used for this purpose.

Since the main symptoms of COVID-19 diagnosis are cough sounds, the type of coughs, and respiratory sounds, many researchers adopted ML methods and algorithms, such as support vector machines, to identify patients' sound patterns [10,20,40,48]. Sound feature extraction was carried out based on mathematical algorithms. Using mobile apps to classify these features led to the automatic diagnosis of COVID-19.

Due to the complexity of detecting the pattern of cough sounds, several of the studies required more efficient and voluminous methods, so they used DL algorithms. After training with more significant data and obtaining a more efficient model on systems with more powerful processing units, such as graphics processing units (GPUs), these algorithms were applied to smartphone operating systems with the cough sounds of people suspected of having COVID-19. The methods in this category differentiated infected from noninfected cases by receiving patients' sounds with higher accuracy and precision [9,30]. Tawfik et al [38] used ML and DL methods simultaneously and achieved 98% accuracy.

Radiographic images offered another facility for rapid diagnosis of COVID-19 and, thus, pandemic control. DL methods and the convolutional neural network (CNN) algorithm were also used in studies using these images in mobile technologies. These models were optimally designed by training on radiology images using concepts such as transfer learning. At the point of care (PoC), they helped clinicians diagnose and detect new cases. These mobile apps demonstrated optimal performance and achieved an accuracy of >92%. By automatically extracting the features using manual feature selection, the bias in the results of diagnostic models was eliminated [18,29,45,46].

AI algorithms were used in various techniques in mobile phones, and the developers attempted to enhance their efficiency by adjusting the parameters of these algorithms [59-62]. Some of the studies used no performance evaluation index to determine the success rate of these apps (to answer AQ4). Regarding apps that used AI methods, the studies used the metrics in the confusion matrix. For different AI methods, different levels of accuracy were obtained. Upon evaluating the efficacy of ML and DL approaches in the identification and diagnosis of COVID-19, our analysis revealed that the accuracy of ML methods ranged from 83% to 99.5%, while DL algorithms exhibited accuracy rates within the range of 91% to 99.6%.

Studies that used all kinds of numerical variables as features, such as signs and symptoms, selected ML methods, while studies that used features such as sounds and images as recognition features, selected DL methods due to their high efficiency.

By calculating the approximate average accuracy of AI-based models in the detection and diagnosis of COVID-19, we concluded that ML algorithms used in mining COVID-19–related data achieved good results. In addition, in analyzing sound data, radiology, or their combination, DL methods achieved high accuracy; in many cases, this accuracy was reported to be >95%. As shown by the accuracy rates presented above, the findings demonstrate the acceptable results of AI methods. In addition, studies using apps to visualize RNA and DNA analysis tests detected cases of COVID-19 in a shorter time due to their sensitivity.

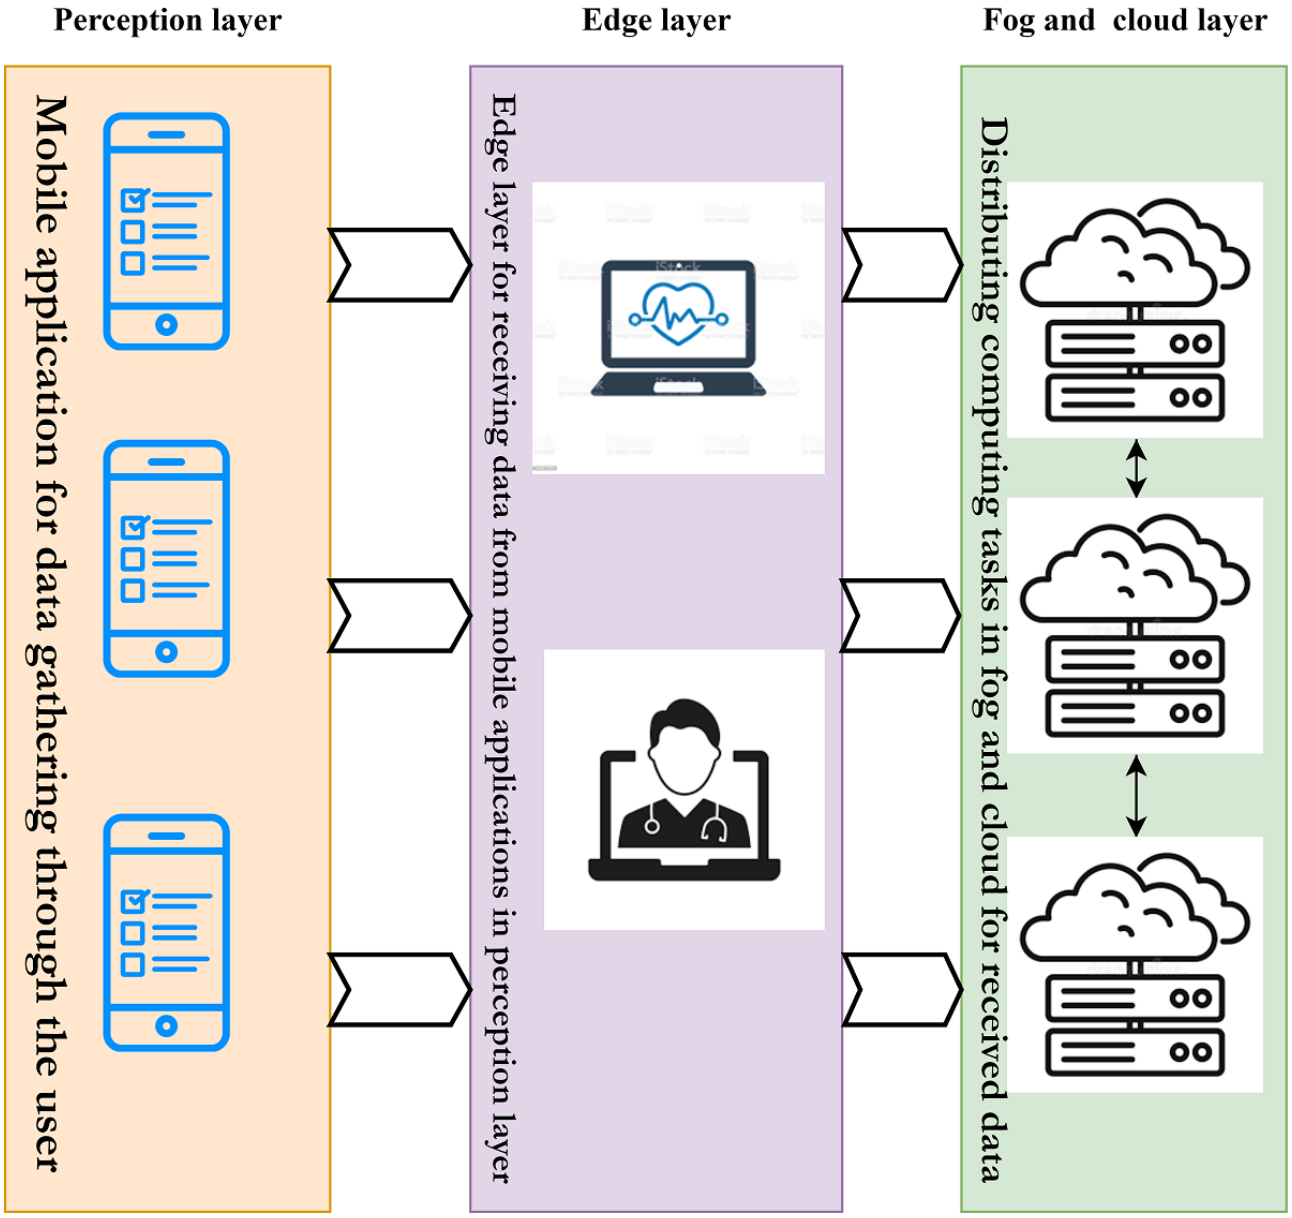
Discussion

Principal Findings

In this study, after reviewing all the research conducted on mobile apps for the diagnosis of COVID-19, several research questions that may have arisen for researchers and health care app development companies were answered. This section provides an answer to the remaining AQ by analyzing and evaluating the data entrance, technological method, and performance metrics of the methodologies outlined in the main tables.

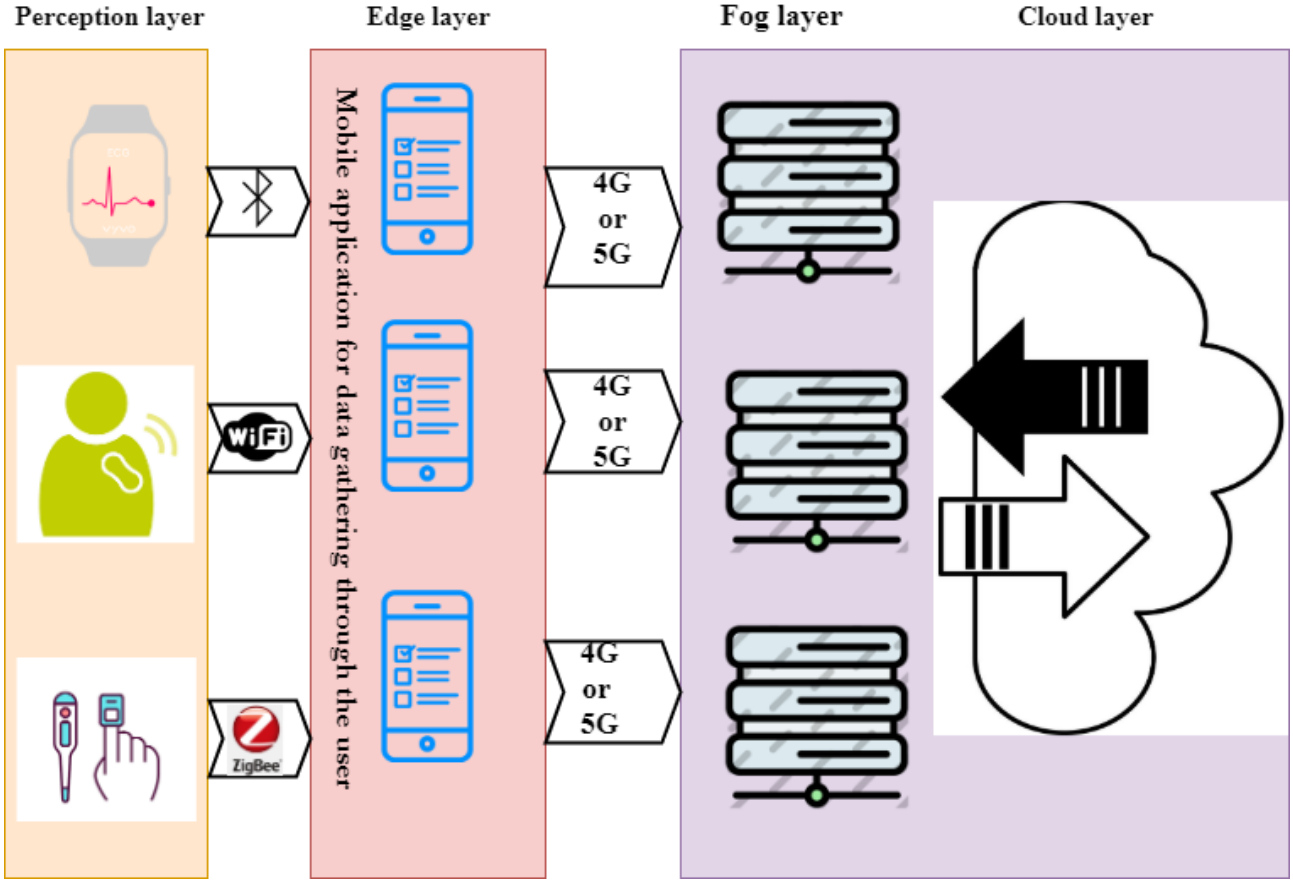
To address AQ5, we recommend using mobile apps for gathering data from PoCs obtained from individuals, monitoring devices, or clinical data generators. In modern techniques, edge layer devices are used in the health care devices layer. Therefore, it is strongly advised to incorporate higher-level technologies, such as fog and cloud spaces, for computing processes or computational units in distributed data clusters. Figure 6 illustrates a model of this mobile app for diagnosis.

Figure 6. Suggested model for mobile applications for gathering data from smartphones.



In the case of mobile apps that are used as data transmitters at the perception level, we suggest using 5th-generation (5G) instead of 4th-generation (4G) technology in centers and geographical areas that have access to this technology to transfer structured and unstructured data to a higher layer. Using this technology, and transferring health care data to the fog and cloud spaces, distributes computing and data processing. The model in Figure 7 is proposed for mobile apps with the purpose of data collection from sensors, biosensors, and monitoring equipment.

Figure 7. Suggested model for mobile applications for transmitting data from health sensors, biosensors, and monitoring devices. 5G: 5th generation.



We compared the 42 studies in terms of the requirements for AI methods. In using AI algorithms, the volume of the data set, overfitting prevention methods, and method lightness (for use in mobile phones) are the parameters for analyzing the quality of studies incorporating AI methodology in mobile phones. Since the included studies did not mention these cases, future studies should adopt methods to prevent overfitting when using ML methods. In ML algorithms, it is advised to use 3 methods: early stopping, dropout, and cross-validation. In addition to the mentioned methods, data augmentation techniques should be used in DL methods so that the resulting model is free of any overfitting.

Studies using DL algorithms in smartphones should carefully consider the following points:

- Data preprocessing plays a vital role in model convergence and speed [54]. It is recommended that future studies use data preprocessing techniques, especially for images.
- Model parameters must be optimized to develop a robust and valid model. Future research should adopt the concept of transfer learning and pretrained networks, and these networks should be customized to the investigation.
- Mobile phones have a limited processing unit. As a result, it is suggested that the models be designed using cutting-edge techniques. It is preferred to use lightweight pretrained CNN networks, such as MobileNet, MobileNetV2, and Efficient, to obtain lightweight models that efficiently run on smartphones.
- In studies using mobile phones for data collection and visualization, we recommend using cloud storage and 5G technologies that significantly contribute to the comprehensiveness of the data and image visualization.

Conclusion

Mobile technology, including various apps, can help with COVID-19 diagnosis and detection and play a vital role in controlling COVID-19 outbreak. Contact tracing can prevent additional contacts during an epidemic or pandemic outbreak of any disease. Thus, on the front lines of outbreak control, healthy people can be separated from people with infection and be alerted through their mobile phones. In the second step, mobile app technology, biosensors (for rapid diagnosis), and AI methods (for diagnosis in the early and acute stages of the disease) can reduce high mortality rates and minimize the consumption of hospital resources. In the third step, mobile technology as a powerful tool can help clinicians form repositories of clinical data and signs and symptoms and collect data from individual smartphones to create such repositories and big data. This can shed more light on COVID-19, its symptoms, the prognosis, and treatment outcomes. In this and future pandemics, smartphones and their apps can be an integral part of controlling the disease and improving patients' survival.

Abstract

Background: Physical activity has well-known and broad health benefits, including antidepressive and anxiolytic effects. However, only approximately half of Americans meet even the minimum exercise recommendations. Individuals with anxiety, depression, or related conditions are even less likely to do so. With the advent of mobile sensors and phones, experts have quickly noted the utility of technology for the enhanced measurement of and intervention for physical activity. In addition to being more accessible than in-person approaches, technology-driven interventions may uniquely engage key mechanisms of behavior change such as self-awareness.

Objective: This study aims to provide a narrative overview and specific recommendations for future research on smartphone-based physical activity interventions for psychological disorders or concerns.

Methods: In this paper, we summarized early efforts to adapt and test smartphone-based or smartphone-supported physical activity interventions for mental health. The included articles described or reported smartphone-delivered or smartphone-supported interventions intended to increase physical activity or reduce sedentary behavior and included an emotional disorder, concern, or symptom as an outcome measure. We attempted to extract details regarding the intervention designs, trial designs, study populations, outcome measures, and inclusion of adaptations specifically for mental health. In taking a narrative lens, we drew attention to the type of work that has been done and used these exemplars to discuss key directions to build on.

Results: To date, most studies have examined mental health outcomes as secondary or exploratory variables largely in the context of managing medical concerns (eg, cancer and diabetes). Few trials have recruited psychiatric populations or explicitly aimed to target psychiatric concerns. Consequently, although there are encouraging signals that smartphone-based physical activity interventions could be feasible, acceptable, and efficacious for individuals with mental illnesses, this remains an underexplored area.

Conclusions: Promising avenues for tailoring validated smartphone-based interventions include adding psychoeducation (eg, the relationship between depression, physical activity, and inactivity), offering psychosocial treatment in parallel (eg, cognitive restructuring), and adding personalized coaching. To conclude, we offer specific recommendations for future research, treatment development, and implementation in this area, which remains open and promising for flexible, highly scalable support.

Introduction

Background

In the 21st century, anxiety and depression have been among the top 25 causes of global disease burden [1]. The COVID-19 pandemic has only intensified the rising prevalence as well as the personal and societal impacts of these disorders [2,3]. As there are simply not enough mental health professionals to meet this need [4,5], alternative interventions—both preventive and curative—are urgently needed. Targeting physical activity is a clear opportunity. Before the pandemic, more than 1 in 4 adults reported sitting for >8 hours per day [6], and this number rose to >40% during the pandemic [7]. Both of these statistics are likely underestimated [8]. Prolonged sedentary behavior, or extended time spent awake with minimal energy expenditure [9], is associated with more severe anxiety and depression as well as higher odds of developing related disorders [10-14]. In contrast, decades of research have demonstrated that regular physical activity is associated with numerous positive psychological outcomes [15-17]. Cross-sectionally, individuals who engage in regular exercise—a subset of physical activity that involves planned, structured, and repetitive bodily movement intended to improve or maintain fitness [18]—report fewer and less severe symptoms of anxiety and depression [19,20], greater positive affect and well-being [21], less stress [22], and lower rates of anxiety and depressive disorder diagnoses [23-25]. At the individual level, people report feeling better on days when they exercise [26-28].

Exercise as an Intervention for Depression and Anxiety

Prospective data support regular exercise as a potent population-level *prevention* tool, significantly lowering the risk of developing anxiety and depressive disorders [25,29,30]. Encouragingly, even small amounts of physical activity may have an enormous impact on mental health [31,32]. For example, an estimated 12% of new cases of depression could be prevented if the entire population exercised for just 1 hour per week [33]. In addition, among individuals presenting with diagnosable levels of symptomatology, systematically increasing exercise behavior is therapeutic [33-36].

Exercise appears to enhance emotional flexibility, or a person's ability to self-regulate under stress [37-40]. Physiologically, individuals who exercise more regularly show faster heart rate recovery following stressors than their peers who exercise less, and individual bouts of exercise can mitigate the hypothalamic-pituitary-adrenal axis, heart rate, and blood pressure reactivity to acute stress [39,41-43]. Physical activity can also increase the production of brain-derived neurotrophic factors, which are neurobiological changes that are understood to increase resilience [44]. These effects are mirrored in reports of exercise bolstering emotional recovery following stressors, enhancing coping self-efficacy, and mitigating the impact of rumination and other emotion regulation deficits on prolonging distress [34,39,42,45,46]. Furthermore, exercise benefits physical health targets that share bidirectional relationships with mental health, such as better sleep and cardiometabolic health [47-51]. Critically, positive treatment effects have been found for directly alleviating anxiety [52-55] and depressive [56-58] disorders as well as related and frequently comorbid conditions such as posttraumatic stress disorder [59] and obsessive-compulsive disorder [60,61]. Importantly, research has replicated the benefits of physical activity (ie, reducing psychiatric symptoms) in samples of people with severe mental illness, such as schizophrenia [62]. Similarly, physical activity and other health-related behaviors (eg, sleep hygiene) are considered to be an integral component of treatment for bipolar disorder [63]. Exercise has also been successfully used to augment the effects of other validated psychosocial treatments such as cognitive behavioral therapy (CBT) [64-67].

Despite the broad knowledge that regular physical activity is physically, cognitively, and emotionally beneficial, only approximately half of Americans meet even the minimum exercise recommendation of 150 minutes per week of moderate-intensity or equivalent physical activity [68]. Individuals with anxiety, depression, or related conditions are even less likely to do so [69,70]. They are also more likely than peers without mental health disorders to exhibit elevated sedentary behavior [71,72]. Thus, although acceptable and efficacious tools exist to help individuals meaningfully change their behavior and improve psychiatric symptoms, there is a large gap between the evidence and real-world implementation. Few clinicians include physical activity as an explicit treatment target or use it as an intervention tool [73-75]. Moreover, the larger barriers to treatment within our health care system remain, including the inaccessibility of treatment due to the acute shortage of qualified clinicians; stigma; and patients' difficulty with travel, timing, and the cost of regular appointments [76].

Promise of Digital Platforms for Promoting Physical Activity

With the advent of mobile sensors and phones, experts have quickly noted the ability of technology to expand the reach of evidence-based psychiatric care; overcome the aforementioned barriers by providing treatment flexibly; and begin reducing long-standing disparities in treatment access, response, and dropout [77-79]. This could also be an efficient, scalable method of promoting increased physical activity among adults with or at risk of anxiety and depressive disorders.

Digital solutions show strong early benefits for activity measurement and intervention in nonpsychiatric populations. In fact, leveraging technology to measure and increase physical activity was an official recommendation from the National Heart, Lung, and Blood Institute and National Institute on Aging "Influences on sedentary behavior/Interventions to reduce sedentary behavior" joint workshop [80]. First, measuring behavior via mobile sensor is validated and widely used [81-84]. Similarly, people's tendency to carry their phones with them throughout the day allows for more accurate monitoring of physical activity and related progress. The ease of use and, therefore, precision of such technologies (wearable and smartphone-based sensors) is an important boon for research and treatment as self-report measures of activity typically result in underreporting [81-84].

Second, delivering treatment in part or fully via mobile phones is effective in increasing physical activity in nonpsychiatric populations [85-87]. This parallels broader findings that apps

can effectively promote other health behaviors (eg, improved nutrition, smoking cessation, and medication adherence) [88,89]. Currently, 97% of Americans have a mobile phone, and an estimated 85% have a smartphone [90]. Although these numbers are lower in certain populations, such as those with serious mental illness (wherein an estimated 85% own a mobile phone and 60%-70% own a smartphone), the ubiquity of smartphones allows for the promotion of behavior change in real time and with a wider array of individuals [91-94]. Inactivity frequently occurs out of conscious awareness or choice due to people's attention being fixated elsewhere (eg, watching television or taking the elevator at work). As such, personal devices can unobtrusively enhance awareness of behavior, which itself can promote increased activity [95]. Furthermore, technologies can deliver notifications in the moment to interrupt passive episodes while also providing tools to increase activity when individuals are most likely to take action [96]. Mobile app–based physical activity interventions can also gamify exercise to enhance enjoyment, which is a key mechanism for long-term engagement in physical activity [97,98]. In-the-moment enjoyment not only promotes regular exercise but is also in itself beneficial for mental health, contributing to the success of broader interventions such as behavioral activation. Overall, digital interventions are promising as they are low risk (ie, typically focus on reducing sitting and increasing light activity), can be deployed without a clinician, and can be used in the context of a patient's daily life. Ultimately, research conducted thus far in the general population supports mobile technologies as valid, accessible, and effective methods of promoting physical activity and reducing sedentary behavior.

Current Objective

Although it is reasonable to extrapolate that physical activity interventions could be implemented via smartphone in a similarly feasible, acceptable, and effective manner in psychiatric populations or for psychiatric targets, this remains an open question. High-quality trials of in-person exercise programs for mental health often unintentionally include components beyond the activity itself that are potentially therapeutic, such as regular, structured, and supervised sessions [65]. In other words, as part of most exercise programs, participants also receive regular social engagement or support, face-to-face time with a professional, instruction and demonstration of target behaviors, and guidance with behavioral scheduling or activation, all of which may enhance the therapeutic benefits of physical activity. However, the remote and asynchronous nature of technology-based interventions may provide a different experience from that of in-person programs, and thus, the impact may also differ. On the other hand, the aforementioned benefits of digital interventions, such as their ability to increase accessibility, lower logistical barriers to engagement, and enhance self-awareness while also promoting behavior change in real time, may boost response and, thus, lead to comparable—or even stronger—effects than face-to-face trials. As a result, it cannot be assumed that face-to-face physical activity programs or digital programs designed for other populations (eg, medical) will translate when delivered via smartphone or to a new population.

In this study, we explored the potential of physical activity interventions, as delivered (at least in part) via smartphone, to improve mental health in psychiatric populations. As this topic remains relatively new, we also considered available evidence on these tools to address mental health symptoms in nonpsychiatric populations. Specifically, we highlighted in which populations these tools have been tested; what outcomes have been evaluated (eg, acceptability, behavior change, and symptom change); and how strategies and tools have (or have not) been tailored to individuals with depression, anxiety, or related concerns. The goal was to provide a narrative overview and specific recommendations for future research on smartphone-based physical activity interventions for psychological disorders or concerns.

Methods

Literature Search

To provide a narrative overview of this emerging research area, we searched for articles that (1) described or reported an intervention intended to increase physical activity or reduce sedentary behavior; (2) included an emotional disorder, concern, or symptom as an outcome measure; (3) described or reported an intervention delivered entirely or in part via a smartphone app; and (4) were published in English and in peer-reviewed journals. Example search terms include "smartphone," "smartphone application," "mobile application," "mobile app," "digital mental health," "app-based," "app-assisted," "mobile phone," "ehealth," "digital," "mobile," "exercise," "physical activity," "sedentary," "sedentary behavior," "physical inactivity," "depression," "dysthymia," "mood," "anxiety," "phobia," "trauma," "posttraumatic stress," "obsessive compulsive disorder," "post-traumatic stress," "obsessive-compulsive disorder," "stress," "emotional disorder," "emotional problem," "well-being," "wellness," "affective disorder," "OCD," "PTSD," "MDD," "GAD," "mental health," and "mental illness." Web-based database (PubMed, Google Scholar, and Cochrane) searches and additional manual searches (eg, searching the reference sections of articles identified through database searches) were conducted up to March 2022. Records were initially reviewed by one coauthor; in cases of uncertainty about appropriateness for this review, records were reviewed in full by 2 additional coauthors and discussed until a consensus was reached.

Data Review

We attempted to extract the following information, where available, from each paper: sample size, inclusion criteria, demographics of the sample, primary aim, trial design (eg, randomized controlled trial), treatment duration, technology used, other interventions used (ie, in addition to physical activity), outcome measures (eg, primary and secondary measures of physical activity), results, treatment components or behavior change strategies, adaptations for mental health, and inclusion of coaching.

Results

Overview

In taking a narrative lens, we drew attention to the type of work that has been done and used these exemplars to discuss key directions to build on. Table 1 provides a summary of the included articles.

Table 1. Summary of studies investigating the impact of digital physical activity interventions on mental health symptoms.

Study, year	Sample size, N	Population studied	Intervention used	Duration	Physical activity outcome	Primary psychiatric outcome	Primary medical outcome
Aguilera et al [99], 2020[a]	N/A[b]	Adults with diabetes and a score of >5 on the PHQ[c]	Apps: DIAMANTE to track data and deliver adaptive learning algorithm (active only) and HealthySMS to send messages (active and control)	6 months	Steps	Depressive symptoms (PHQ-8[d])	HbA_{1c}[e] levels (blood glucose)
Broers et al [100], 2019	557	Adults diagnosed with hypertension, symptomatic heart failure, or coronary artery disease	Wearable (Fitbit) activity tracker, wearable (Beddit) sleep tracker, app (Moves) GPS tracker, app (Careportal) home monitoring system	6 months	Steps; physical activity level (combined length of active periods and step count)	Anxiety (GAD-7[f]) and depression (PHQ-9[g])	N/A
Damschroder et al [101], 2020	357	Web-based confirmation of veteran status	App (Stay Strong) and wearable (Fitbit Charge 2)	12 months	Active minutes per week; steps	N/A	N/A
Edney et al [102], 2020	444	Adults currently completing <150 minutes of MVPA[h] per week	App (Active Team) and wearables (pedometer and Zencro TW64S)	3 months	Daily minutes of MVPA	Symptoms of anxiety, depression, and stress (DASS-D[i])	N/A
García-Estela et al [103], 2021[a]	N/A	Spanish-speaking adults with MADRS[j] score of >1	App (IDEApp) and wearable (smartband)	8 months	SIMPAQ[k]; functional exercise capacity (6MWT[l] and 1-min sit-to-stand test); short Borg CR-10[m] Scale	Depressive symptoms (PHQ-9); well-being (WHO-5[n])	Global functioning (SF-36v2[o])
Guo et al [104], 2020	300	Adults who are HIV-seropositive with elevated depressive symptoms	App (WeChat) and Run4Love program (adapted CBSM[p] course and physical activity promotion) delivered through the WeChat app	3 months	Chinese version of the GPAQ[q]	Depressive symptoms (CES-D[r])	N/A
Haufe et al [105], 2020	314	Adults with metabolic syndrome	Wearable (activity monitor; Forerunner 35; Garmin)	6 months	Freiburger Questionnaire on Physical Activity; steps	Anxiety severity and depression severity (HADS[s])	Change in metabolic syndrome severity; health-related quality of life (SF-36[t])
Kim et al [106], 2021	21	Adults aged >46 years diagnosed with PD[u] or atypical parkinsonism conditions and regular participation in a PD exercise program at least once a week	App (researcher-created physical activity app)	8 weeks	Total exercise calculated by multiplying the frequency and duration for all exercises; subjective exercise scale (Borg 6-20 scale); IPAQ[v]	Depression (Geriatric Depression Scale–Short Form)	PDQ-39[w]
Lin et al [107], 2020[a]	N/A	Physically inactive adults with a musculoskeletal diagnosis (*ICD-10*[x]) and in rehabilitation following inpatient clinic treatment	App (MoVo)	12 months	BSA[y], sport activity and movement activity subscales	Depression (PHQ-9); anxiety (GAD-7)	Brief Pain Inventory

Study, year	Sample size, N	Population studied	Intervention used	Duration	Physical activity outcome	Primary psychiatric outcome	Primary medical outcome
Ma et al [108], 2015[a]	N/A	Adult participants who were obese and experiencing depression	Wearable (Fitbit) and app or website (MyFitnessPal)	12 months	Minutes of physical activity logged on MyFitnessPal	Depression (SCL-20[z])	Changes in BMI
Nadal et al [109], 2021[a]	N/A	Adult users with mild to moderate depression who were assigned to iCBT[aa] treatment for depression	Wearable (smartwatch; Mood Monitor watch app)	8 weeks	Smartwatch activity data	Depression (PHQ-9), anxiety (GAD-7), and functional impairment (WSAS[ab])	N/A
Park et al [110], 2021	60	Adults with a history of cardiovascular disease who were within 2 weeks of completing cardiac rehabilitation	Wearable (Fitbit Charge 2) and apps (Movn and Fitbit)	2 months	Steps; 6MWT; self-reported physical activity	Quality of life (QLESQ[ac]); depression (PHQ-9)	N/A
Puszkiewicz et al [111], 2016	13	Adults with a diagnosis of breast, prostate, or colorectal cancer who had finished primary curative treatment	App (GAINFitness)	6 weeks	Physical activity (GLTEQ[ad])	Health and quality of life outcomes (EQ-5D); well-being (FACT-G[ae]); anxiety and depression (HADS)	Cancer-related fatigue (FACIT[af]); sleep quality (PSQI[ag])
Puterman et al [112], 2021	334	Adults with a score of 1-3 on the L-CAT[ah] who were cleared to exercise	App (Down Dog suite of apps—HIIT[ai] and yoga)	6 weeks	Sessions of yoga or HIIT completed; minutes of yoga or HIIT completed	Depressive symptoms (CESD)	N/A
Skrepnik et al [113], 2017	172	Adults with osteoarthritis eligible to receive the hylan G-F 20 injection	Wearable (Jawbone UP24) and app (OA GO)	90 days	Steps	VAMS[aj]	Changes in sleep captured by the wearable activity monitor
Stephens et al [114], 2022	15	Youth (aged 11 to ≤18 years) with MS[ak] and a disability rating of <4 on the EDSS[al] and attending a pediatric MS and neuroinflammatory disorder clinic	App (Atomic)	12 weeks	Physical activity measured via accelerometry; time spent in MVPA and sedentary activities; aerobic fitness, musculoskeletal strength, and walking endurance	Depression (CES-DC[am])	N/A
Teychenne et al [115], 2021	62	Mothers 3-9 months post partum, insufficiently active, and experiencing heightened depressive symptoms	App (smartphone app and web forum)	12 weeks	Self-reported physical activity; accelerometer-assessed physical activity and sedentary behavior	Depressive and anxiety symptoms (unstandardized questionnaires)	N/A
Wilczynska et al [116], 2020	N/A	Adults with or at risk of type 2 diabetes	App (eCoFIT)	20 weeks	N/A	Depressive and anxiety symptoms (PHQ-9 and GAD-7)	Social support, self-efficacy, nature relatedness, and perceived sleep quality

Study, year	Sample size, N	Population studied	Intervention used	Duration	Physical activity outcome	Primary psychiatric outcome	Primary medical outcome
Wong et al [117], 2021	79	Adults with moderate depressive symptoms	App (Lifestyle Hubl)	8 weeks	Physical activity level (IPAQ)	Depressive and anxiety symptoms (PHQ-9 and GAD-7)	Insomnia (ISI[an]); health-related quality of life; health-promoting behaviors (HPLP-II[ao]); functional impairment (SDS[ap])

[a]Published protocol.
[b]N/A: not applicable.
[c]PHQ: Patient Health Questionnaire.
[d]PHQ-8: Patient Health Questionnaire-8.
[e]HbA_{1c}: hemoglobin A_{1c}.
[f]GAD-7: Generalized Anxiety Disorder-7.
[g]PHQ-9: Patient Health Questionnaire-9.
[h]MVPA: moderate to vigorous physical activity.
[i]DASS-D: Depression Anxiety Stress Scales: Depression Subscale.
[j]MADRS: Montgomery–Åsberg Depression Rating Scale.

Who Was Included in This Work?

Overall, a review of the literature revealed that little work has been done to test the impact of smartphone-based physical activity interventions on increasing physical activity or reducing mental health symptoms in psychiatric or at-risk populations. Most related trials with clinical populations have been conducted in the area of medicine, with studies investigating the effects of physical activity—encouraged through smartphone- and wearable-based interventions—on physical health conditions (eg, diabetes [99,116], obesity [86,108], cancer [111,118], cardiovascular issues [100,110], and multiple sclerosis [114]). Physical activity is well established as a means of facilitating rehabilitation following serious illness or injury, as well as mitigating the progression of chronic health conditions [119-121]. For example, adults with Parkinson disease who used a minimally supported, customizable home-based exercise app for 8 weeks doubled their amount of weekly exercise (minutes) while also increasing the intensity of such exercise [106]. Similarly, engagement with smartphone-based physical activity interventions led to increased strenuous exercise among adults with cancer [111] as well as increased step count for those with cardiac issues [100,110] and for youths with multiple sclerosis [114]. These changes are noteworthy as medical illness or disease can serve as a barrier to engaging in health-promoting behaviors [122] despite the knowledge that such behaviors can stabilize or even improve such medical conditions [123].

In contrast, the practice of formally integrating exercise into *mental* health care is relatively new and not established in current standards of care. This is mirrored by the disproportion of extant research examining digital tools for increasing physical activity in medical versus psychiatric populations. When mental health targets were examined, they were largely included as secondary or exploratory outcomes and frequently framed in relation to coping with the medical concern of interest [99,100,104-108,110,111,113,114]. We only identified 16% (3/19) of the studies that specifically recruited individuals with psychiatric symptoms, and all (3/3, 100%) were focused on individuals with depressive symptoms [103,109,117]. The most common mental health outcomes were depression, anxiety, general quality of life, and emotional well-being [99,100,102-110,112,114-117]. Specifically, subclinical depressive concerns were the most frequently investigated psychiatric target, followed by subclinical anxiety [100-105,112,115-117].

The impact of smartphone-based physical activity interventions is yet to be investigated explicitly for individuals diagnosed with depressive or anxiety disorders, let alone other mental health conditions, including serious mental illness. Furthermore, although wide age brackets were represented across the studies, with average ages ranging from teenagers to older adults, men and non-White individuals were underrepresented. As research progresses in this space, it will be imperative to include the experiences and perspectives of adults with clinical levels of psychiatric concerns as well as diverse backgrounds and identities.

Do Smartphone-Based Physical Activity Interventions Benefit Mental Health?

Owing to the limited available data; small samples comprising mostly White Western, educated, industrialized, rich, and Democratic women with subclinical depression or anxiety; and heterogeneity of outcomes measured, it is difficult to conclude whether and to what extent existing smartphone-based physical activity interventions benefit mental health. However, with these caveats in mind, we aimed to synthesize the available evidence in the following sections.

Feasibility and Acceptability

There is encouraging evidence that smartphone-based physical activity interventions could be feasible and acceptable for psychiatric populations. However, supporting data were primarily collected in samples of individuals with elevated depressive symptoms or who were at risk of depression rather than in explicitly clinical samples or among individuals with other prominent mental health concerns. One study of postnatal women at risk of depression found *low* engagement with the digital aspects of a 12-week multicomponent physical activity intervention (home exercise equipment and a physical logbook combined with a motivational smartphone app and a web-based social support forum) [115]; however, other studies reported more positive participant response and engagement. For example, retention in smartphone interventions for physical activity tended to be high compared to that in other types of digital health interventions—one systematic review found that completion rates of digital mental health interventions ranged from 1% to 28% [124]. In a study of adults with diabetes, retention in a 20-week digital physical activity intervention (an app that allowed participants to use workout circuits, set goals, monitor progress, and learn cognitive and behavioral strategies) was of >70% [99]. Similarly, compliance with a suite of high-intensity interval training (HIIT) and yoga apps during a 6-week intervention was strong in a community sample with elevated depressive symptoms. More than half of the participants in the yoga and HIIT+yoga group and 40% in the HIIT group continued completing the recommended 4 sessions per week by the end of the trial [112]. Compliance and satisfaction ratings were comparably high when physical activity promotion was combined with cognitive behavioral stress management via a WeChat intervention in a group of adults with HIV and elevated depressive symptoms [104].

These findings are consistent with those of the larger literature showing that digital physical activity interventions tend to be well received by participants [85,125,126]. Public interest is already high, with physical activity and fitness apps dominating the mobile health space. Notably, a 2018 systematic review of the experience of adults who used mobile interventions to promote physical activity highlighted important themes to be considered for future design—self-reported engagement was most enhanced by the availability of social features, prompts, goal setting, personalization or customization, and gamification but was limited by low technological literacy, preference for coached apps, and a desire for social support [127].

Change in Psychiatric Symptoms

The impact of smartphone-based physical activity interventions on psychiatric symptoms was far more mixed. Some studies observed resultant improvements in symptoms. In one study that included patients specifically recruited for having elevated symptoms of depression and anxiety, patients experienced a reduction in depression and anxiety scores following a 6-month exercise intervention (150 minutes of moderate physical activity per week with individual recommendations given via a smartphone app) as compared to a waitlist control. However, it is notable that this intervention did not test a smartphone-based physical activity intervention in isolation but, instead, combined it with nutritional counseling and the option of receiving exercise recommendations through personal meetings or by phone instead of an app [105]. Among adults from the general population with low physical activity scores, using a publicly available suite of exercise apps for 6 weeks significantly improved depressive symptoms compared to a waitlist control [112]. Psychiatric improvements were also observed in patients with medical comorbidities. For example, in a study of adults with obesity using a smartphone-based physical activity app (eCoFIT), depression symptom severity improved after 20 weeks [116]. Finally, in a study of older adults with Parkinson disease, using a mobile app to access and customize a home-based exercise program for 8 weeks led to reduced depression symptoms and improved quality of life [106].

However, other studies reported null effects. For example, among patients with a history of cardiovascular disease, a smartphone-based intervention including motivational prompts and educational messages did not yield significant changes in depressive symptoms from baseline to 2 months [110]. Furthermore, a trial of patients with cancer using a tailored physical activity smartphone app (which included workout videos, spoken instructions, and push notifications) did not observe changes in depression, anxiety, or quality of life after 6 weeks [111]. In a study testing an app-based physical activity program for youth with multiple sclerosis (including personalized coaching and promotion of aerobic fitness, musculoskeletal strength, and walking endurance), there was no change in depression levels over 12 weeks [114]. Furthermore, a meta-analysis of studies examining digital physical activity interventions in cancer survivors found that none of the included studies were successful in improving depression or anxiety [118]. In the general population, one study similarly did not find significant differences in depression, anxiety, stress, or well-being after 3 or 9 months of using an app (Active Team) and wearable pedometer [102].

These results should be interpreted cautiously for 2 reasons. First, there is the confound of potential floor effects—as none of these trials were designed to address questions about mental health, symptom levels at study start were typically already low, thus reducing investigators' abilities to identify possible effects. In addition, studies varied widely in their evidence of behavior change, including outcome measures (eg, minutes of activity, number of sessions completed, exercise intensity, and fitness level; see Table 1 for detailed information on this variance) and the use of objective versus subjective reports, which are known to be discrepant [82-84]. In other words, if an intervention did not produce meaningful physical activity changes, it would be unlikely that downstream emotional changes would occur.

How Have Smartphone-Based Physical Activity Interventions Been Tailored to Individuals With Depression, Anxiety, or Other Psychiatric Concerns?

To date, interventions generally have not been tailored to the specific needs or presentations of individuals with mental health concerns. This is unsurprising as most technology-based physical activity trials have not been designed to target mental health. However, some studies have integrated components that specifically address psychological well-being. One adaptation that is low effort but high return is adding psychoeducation about the relationship between physical activity and mental health. For example, a recent trial for adults with mild to moderate depressive symptoms devoted the first in-person group session to discuss the relationship between depression and exercise to complement the personalized exercise program, smartphone app, and wearable device they received [103].

The second adaptation observed in the literature is offering concurrent psychotherapy-based tools. In some cases, psychotherapeutic content was interspersed with the physical activity intervention; for example, in a trial for adults living with HIV and depression in China, both an exercise promotion intervention and cognitive behavioral stress management course were delivered as multimedia messages through the WeChat app [104]. Relatedly, in a study of the eCoFit app for adults with or at risk of type 2 diabetes, short cognitive behavioral tasks ("FitMind Challenges") were integrated throughout the program [116]. Examples of FitMind Challenges included motivational strategies, relaxation, cognitive restructuring, social support, and problem-solving. In other cases, the approaches were delivered in parallel. In one trial, adults who were overweight and experiencing depression received a 7-step problem-solving therapy via a workbook in addition to live lifestyle coaching, at-home video lessons, the MyFitnessPal app, and a Fitbit for monitoring [108]. In another study, SilverCloud's guided internet-based CBT program for depression was the primary intervention, with smartwatch-based monitoring of sleep, steps, and mood added to promote greater awareness of the relationship between health behaviors and mood, thereby independently encouraging positive lifestyle changes [109].

A third but largely unexplored avenue is the inclusion of personalized or tailored messaging. This is an opportunity for coaches or other support persons to address barriers that may be specific to the experience of someone with mental health concerns (eg, navigating social anxiety to go to the gym and restructuring depressive thoughts). In one open trial of a physical activity app for youth with multiple sclerosis, coaches were trained in social cognitive theory for behavior change as well as motivational interviewing [114].

Although few digital physical activity interventions have been designed or modified to specifically affect mental health, many have been designed using evidence- and theory-based behavior change strategies that are ripe for implementation in psychiatric contexts. Indeed, the most successful interventions are based

on behavioral theory [73,127]—explicitly stated or not—such as the transtheoretical model [128], the theory of planned behavior [129], self-determination theory [130], and social cognitive theory [131]. Social cognitive theory is most often cited given its emphasis on internal, external, and social factors that reinforce learning and contribute to sustained change [131]. Targeting self-efficacy, self-regulation, and social support to engender meaningful, lasting behavior change aligns strongly with principles of psychotherapy as well. Digital physical activity interventions have also experimented with numerous evidence-based behavior change techniques, including goal setting and review, action planning, regular feedback, self-monitoring of behavior, instruction and demonstration of how to perform a new behavior, graded tasks, prompts and cues, and social rewards, to name a few [132-134]. Interventions integrating multiple behavior change strategies are more successful than those that rely on one (eg, self-monitoring or reminders alone [133]). Considering how such strategies could be adapted for individual presentations (eg, those with clinical levels of dysregulation) should be a priority for future iterations of these programs.

Furthermore, technology-driven techniques may uniquely (or at least more strongly than traditional treatments) engage key mechanisms of behavior change. For example, these tools can promote self-awareness. As people tend to keep their devices close to them throughout their daily lives, wearable and mobile platforms can provide objective, continuous monitoring and feedback related to behavioral patterns such as physical activity [102,108]. In addition, these approaches can enhance a person's likelihood of changing their behavior by lowering the cognitive burden involved in initiating physical activity. Strategies include delivering content more flexibly (eg, when it is most convenient for a participant to engage or in doses of their choosing); modeling target behavior via written, image, or video instructions that can be reviewed on demand or infinite times; or tailoring activity suggestions to a person's present context (eg, suggesting at-home activities on rainy days). This may be particularly meaningful for psychiatric audiences as depression and anxiety are associated with attention and memory deficits that can interfere with information processing and learning [135-138]. In addition, in-the-moment rewards and other gamification or reinforcement features could be particularly useful early on [139,140] as individuals with depression and anxiety may not experience initial sessions of exercise as intrinsically gratifying or mood boosting as others do; for example, depression is characterized by deficits in reward processing and motivation [141], and anxiety sensitivity and social anxiety can blunt positive responses or promote avoidance [142,143].

Finally, personal devices may allow for more consistent, flexible social support throughout an intervention. Social support is an established, evidence-based behavior change technique that promotes physical activity [126,144-146]. Smartphone-based physical activity interventions provide a range of avenues for social connection, such as texting with a coach [101,107], access to an web or app-based discussion forum [115], and creation of virtual "teams" [102]. Critically, although social media has been frequently incorporated as a means of facilitating connection, participant reactions have been mixed, and it may not be optimal for psychiatric populations [126]. In general, social support appears to boost engagement when it is perceived to facilitate emotional support, provide tips from peers, enhance motivation, foster social comparison or competition [126,147,148]. How to best leverage social support and social media for psychiatric populations requires nuanced future study.

Discussion

Principal Findings

The primary aim of this narrative synthesis was to examine the status of smartphone-based physical activity interventions for mental health and understand how they have and have not been tailored to or evaluated in psychiatric populations. Ultimately, the literature is limited and difficult to synthesize owing to the high heterogeneity across the studies in terms of sample selection; study design; outcomes of feasibility, acceptability, and efficacy; and degree of tailoring. To date, mental health outcomes have typically been secondary or exploratory within trials focused on medical outcomes (eg, diabetes management) and, when included, have had a narrow focus on measures of depression, anxiety, and general well-being in nonclinical populations. As a result, this review relied significantly on research focusing on medical populations to explore how smartphone-based physical activity interventions could be used to impact mental health outcomes and to infer how they may be used in psychiatric populations. Furthermore, although extant studies have included diversity of age, the samples in the included studies comprised mostly White and female individuals, thus reducing the generalizability of the already limited findings.

The feasibility and acceptability of these interventions for subclinical and at-risk populations are encouraging and suggest that digital physical activity programs may be similarly well received among individuals above diagnostic thresholds. The available data on psychiatric outcomes were mixed. However, it is difficult to draw meaningful conclusions given the limited data; high heterogeneity of intervention approach and target behavior; and lack of standardization in measurement and reporting of use, engagement, and behavior change, as well as the elevated risk of floor effects given the subclinical samples. These inconclusive psychiatric outcomes may also be related to a lack of tailoring of smartphone-based physical activity interventions to the specific needs of those presenting with mental health concerns. The existing tailoring included basic psychoeducation about physical activity as a treatment, adding concurrent psychotherapy-based tools, and including personalized or tailored messages. There was no standardization or evidence base for how this tailoring was applied. The upshot is that many of the papers included in this review presented interventions that were already built around established, evidence-based behavior change strategies, which suggests that psychotherapeutic tailoring could be efficiently integrated into existing smartphone-delivered physical activity interventions. In general, effective physical activity interventions use many of the same fundamental behavior change strategies commonly found in psychotherapy, such as education, goal setting,

self-monitoring, graded tasks, engaging social support, and motivational interviewing [149,150].

Taken together, the primary barrier to advancing the use of smartphone-based physical activity interventions in mental health care is the absence of evidence. The need for research in this area has been highlighted in other reviews as well [151,152]. To construct a more consistent, evidence-based foundation for intervention development, we outline several avenues for future research.

Recommendations for Tailoring Physical Activity Interventions to Psychiatric Populations

More research is needed to better understand *how* existing smartphone interventions can be tailored to fit the needs of psychiatric populations. The following are example adaptations rather than an exhaustive list. One likely critical step is to provide users with psychoeducation early on about the ways in which physical activity can be used to affect psychological health, such as improving mood and reducing anxiety. This should involve making explicit connections between health behaviors (eg, exercise), mental health symptoms, and emotion regulation so that users can better appreciate the bidirectional links between these areas of well-being. Including even a brief text summary of the literature or treatment rationale could likely augment the effects [153,154]. In fact, there is evidence with depression treatment that physical activity interventions lacking such psychoeducation or treatment rationale do not lead to robust clinical changes and can worsen dropout rates [155]. In contrast, attending to the mental and emotional benefits of exercise, particularly the acute or immediate impact on affect or resilience, can further enhance mood and motivation to continue exercising [35,156]. Highlighting these benefits and encouraging users to monitor such positive changes could improve sustained engagement and clinical response. Technology may be particularly helpful for this; apps, for example, can provide in-the-moment reminders through push notifications to attend to one's affect or visual feedback of a user's pretest-posttest change in self-reported mood with exercise. Furthermore, digital tools could provide information about the impact that mental health symptoms may have on program engagement. This can help users recognize that it is normal and expected for symptoms such as fatigue, anxiety sensitivity, or low motivation to serve as barriers to physical exercise and can proactively help users engage in related problem-solving.

Another compelling feature to test is the incorporation of modules or content that specifically address mental health concerns or symptoms. For example, technology-based physical activity interventions aimed at improving anxiety symptoms would benefit from including evidence-based skills such as cognitive restructuring and exposure practices. These approaches can be used to identify and challenge maladaptive beliefs that anxiety symptoms such as a racing heart are dangerous (known as anxiety sensitivity [157]), design a more graded exercise plan, and use activity as an interoceptive exposure by allowing patients to experience and tolerate those feared sensations [158]. Furthermore, CBT skills can be incorporated to address exercise-related social anxiety, such as integrating exposures (eg, walking with a friend or going to a gym first at off-peak hours) and challenging associated negative expectations (eg, "I won't be able to keep up with my friend and they will judge me"). Meanwhile, a digital physical activity intervention aimed at helping people with depression could include skills consistent with behavioral activation, such as tracking the relationship between mood and activities (including physical activity); intentionally adding new behaviors such as gardening, walking, or going to the gym to their weekly schedule; and generating more flexible approaches to regular movement. Furthermore, cognitive skills can be used for participants to identify and evaluate negative thoughts about themselves or the program (eg, "I can never stick to my goal of going for walks, so what's the point") in terms of their accuracy or utility. In this vein, equipping coaches with some knowledge of common mental health symptoms to look out for, destigmatize, and address could enhance outcomes.

In addition, coaches are understood to bolster digital interventions in general by providing further psychoeducation or resources, personalizing content or skill use, and answering questions. Given the known relationships between mental illness and both inactivity and chronic medical conditions, even with basic mental health knowledge, coaches could perform these roles better. It is also important to recognize that digital or physical activity interventions may not be the appropriate or most effective level or type of care for all individuals experiencing mental health concerns. As such, tools should include information for users on the signs or symptoms that may indicate that pursuing psychotherapy could be beneficial as well as resources for doing so.

Finally, physical activity promotion tools could be integrated to augment existing treatments. Currently, there are a number of well-established treatments for psychiatric disorders, such as CBT and mindfulness. CBT has extensive research support as the gold-standard treatment for a range of disorders, including depression and anxiety [159]. This treatment integrates both behavioral and cognitive skills, such as tracking and scheduling activities as well as evaluating and challenging maladaptive thoughts, to reduce the severity and impact of symptoms. Mindfulness—or the purposeful, nonjudgmental awareness of the present moment [160]—is increasingly included in "third wave" interventions to reduce psychiatric symptoms [161] as well as increase well-being, such as positive affect and quality of life [162,163]. Recently, a dominant focus of digital mental health innovation has been translating these gold-standard psychotherapies to digital platforms. There is now a strong foundation of evidence supporting the feasibility, acceptability, and efficacy of delivering these treatments through both face-to-face and digital means [164-166].

Thus far, the development of digital interventions for physical activity and for mental health has largely occurred separately. However, their concurrent delivery provides promising initial evidence [111,118]. This parallels in-person trials demonstrating that increasing physical activity strengthens psychotherapy outcomes [167,168]. The next step in this line of research is to more formally integrate the 2 or even develop technologies in which both sets of skills are delivered within a single coherent platform. For example, in a study conducted by Wilczynska et al [116], adults with diabetes used the eCoFit app, which

integrated guided workouts, goal setting, and cognitive behavioral skills. Some of the commercially available apps targeting mental health have already begun moving in this direction as well. The mindfulness-based app Headspace has recently incorporated a suite of video- and audio-guided exercises that help users engage in activities such as stretching, dancing, and yoga. Within these integrated platforms, it will be important to explicitly link the mental health and physical activity content rather than presenting them side by side as distinct intervention pathways.

Recommendations for Developing and Testing Physical Activity Interventions for Populations With Psychiatric Disorders

Overview

More research is also needed to understand *to what degree* smartphone interventions require tailoring and for whom. Given the wide range of possibilities, an important step in the development process is to have focus groups with the goal of hearing from individuals with lived experience about their wants and needs. Through pilot-testing, intervention design and refinement can be an iterative process wherein individuals of the target audience engage with the program, feedback is elicited, and changes are made in response to that feedback. This user-centered approach fits well within the larger preparation phase of a Multiphase Optimization Strategy. Following such development, digital tools should be scientifically tested and optimized, leading to a randomized controlled trial to examine their efficacy in achieving the outcomes of interest (eg, reduction in depression symptoms). This testing phase is necessary to establish a program as evidence-based, which would allow it to stand out in an otherwise large pool of digital applications that are not backed by research.

Leveraging New Trial Designs

New trial designs, such as sequential multiple-assignment randomized trials, microrandomized trials, and factorial designs, will be useful in intermediate stages to parse issues such as dosing, sequencing, and personalization. For example, research shows that at least 6 weeks are required for new physical activity habits to form [169]; thus, interventions that are, on average, 8 weeks long lead to more lasting changes than shorter ones [169]. Moreover, it remains unclear whether longer treatments, such as ≥24 weeks, have a greater impact on the general population [170]. It is unknown what duration would be sufficient for various clinical populations to observe changes in both the target behavior and in downstream symptoms and for whom extended support would be necessary. Individual components such as the aforementioned tailoring elements or the inclusion of coaching can also be efficiently tested using these new study designs [170].

Understanding the Role of Human Support

Previous work has shown that supervised exercise tends to have a larger impact on anxiety outcomes than unsupervised prescriptions [171]. This parallels guidance from experts in digital mental health that including human support (eg, a lay coach or therapist) alongside internet- or app-based cognitive behavioral and other therapies should enhance retention, engagement, and outcomes. Possible explanations could be greater accountability, the presence of social support, clearer guidelines, opportunities to ask for clarification, in-the-moment personalization, problem-solving, direct affirmation or reinforcement, and a more regular routine. However, guidance does not unilaterally improve outcomes for all digital interventions or all patients [164,172]. There are currently no evidence-based guidelines for implementing human support in digital interventions (ie, when, how often, how much, by whom, and for which users), let alone a nuanced understanding of *how* coaches can effect positive change in adherence or response [173]. Understanding the mechanisms of action would allow developers to maximize automation and most efficiently deploy human support when needed. As human support is the most expensive and scarce resource in digital health solutions, it will be critical to determine how to automate some of these supportive pathways and how to most efficiently identify who needs human support and at what dose.

Considering Individual Factors

Across intervention types, we must also consider the individual factors that may serve as facilitators of or barriers to engagement and success. This is doubly important for smartphone-based physical activity interventions as there are potential barriers inherent in both smartphone use and physical activity uptake.

Barriers to Physical Activity

Research examining barriers to physical activity in those with mental health conditions suggests that individuals with high symptom severity and low self-efficacy may be particularly disinclined to pursue physical activity–based interventions [174,175]. Lack of social support, lack of available time, and fear of injury were also frequently mentioned barriers in a sample of adults with anxiety and depression [174]. In addition, individuals with higher or lower levels of baseline physical activity or fitness may face different barriers and have different needs. A qualitative review suggested that those with lower baseline physical activity wanted an app that had more of a coaching role, whereas those with a higher baseline physical activity preferred an app that helped them intensify or optimize their current physical activity level [126]. In addition, developers should consider the accessibility of exercise suggestions; for example, exercise prescriptions that necessitate equipment, a gym membership, or access to a safe outdoor space may not be generalizable to many otherwise well-suited recipients.

Barriers to Digital Mental Health Use

A recent review by Borghouts et al [176] examining barriers to and facilitators of user engagement found that scoring high on neuroticism and agreeableness was associated with greater interest in using smartphone apps to reduce stress, whereas scoring high on extraversion was a predictor of preferring in-person services to web-based options [177]. The severity of baseline symptoms—both psychiatric and comorbid medical concerns—may also play a role in engagement and adherence. Most smartphone-based digital physical activity interventions have been investigated in those with mild to moderate symptoms, which can hamper engagement with apps [178,179].

Some studies suggest that those with mild depression may actually be at an even greater risk of dropout than those with moderate depression [178,180]. Researchers should also be cautious about potential iatrogenic app components. For example, the tracking components inherent in many smartphone-based physical activity interventions, particularly those related to physical health and tracking activity, run the risk of becoming compulsive or rigid. This could pose an issue for individuals with obsessive-compulsive, anxiety, and related disorders that are often characterized by perfectionism or inflexibility. Furthermore, peer support groups within apps, although often helpful, could also lead to negative social comparisons, thus exacerbating depression.

A possible mitigating approach to this would be to introduce smartphone-based physical activity interventions through a stratified care model in which individuals are allocated to different levels of an intervention depending on their clinical needs. In this model, providers could use patient-level data to decide whether an individual would benefit from the smartphone tool as a stand-alone intervention, as a coached version integrated with another level of care (eg, psychotherapy with a clinician), or delivered after progress with another intervention has been made (eg, medication stabilization).

Barriers Related to Technology

For many, significant barriers may include technology literacy and access. Multiple studies have identified technology literacy as an obstacle to digital physical activity intervention uptake [126,181] and for digital mental health use [178,180]. This, coupled with the lack of technical support provided by many apps, means that individuals who may be motivated to engage with smartphone-based physical activity interventions are stymied by the inability to navigate the app or seek help when issues arise. This necessitates a user interface and navigability features that can be understood or customized by a range of age groups and technological ability levels, and furthermore, it emphasizes the importance of accessible, embedded technical support tools for those who need them. Coached or guided tools may be helpful in mitigating this literacy issue but still require users to have the basic skills needed to contact their coaches or guides for help. In addition, there is still a subset (15%) of the US population that does not own a smartphone, many of whom represent communities that could benefit the most from flexible, low-cost, and accessible support options [182]. An even greater percentage of Americans lack a stable internet connection; this statistic is highly stratified along racial lines—8 in 10 White adults report having a broadband connection at home, whereas only 71% of Black adults and 65% of Hispanic adults report the same [183]. This suggests a need for digital physical activity interventions that can be accessible from communal settings, such as local community centers or publicly available fitness facilities.

It should be acknowledged that the vast majority of digital mental health interventions are designed—intentionally or not—with primarily White, Western, educated, industrialized, rich, and Democratic populations in mind. Research investigating the efficacy of both in-person and digital physical activity interventions also suffers from similarly nonrepresentative samples, calling into question which validated strategies are universally beneficial. For example, there is compelling research that physical activity interventions (both in person [184,185] and virtual [186]) are effective for health behavior change in Black Americans; however, other studies investigating the perspectives of Black Americans suggest that many in this community face unique social and structural barriers to physical activity that may not be considered by extant programs [187,188]. Thus, engagement in smartphone-based physical activity interventions by marginalized populations might be impacted by both the perception and reality that many of these apps are not designed with their community or culture in mind. Future research should engage with a range of underserved populations in qualitative research to understand the community and cultural values surrounding physical activity and technology use. This information should then be used to collaboratively design new programs or features or culturally tailor existing tools to meet the needs of a broader audience.

All these limitations support the importance of qualitative work as a future direction when building smartphone-based physical activity interventions for mental health. The research synthesized by Carter et al [126], for example, presents valuable insights into individual-level concerns and emerging trends in patient preferences for components and design of apps. In particular, their identification of 2 key mechanisms through which mobile health use facilitates physical activity (strengthening motivation and changes in self-awareness and strategizing) is an important step in boosting engagement and exploring the mechanisms by which these apps function. Engaging qualitatively with a broad spectrum of stakeholders would also be foundational in improving the issue of representation, thereby supporting the goal that smartphone-based physical activity interventions for mental health are acceptable and efficacious for all.

Practical Considerations

The unfortunate reality of scientifically validated digital mental health products is that the vast majority do not move beyond their success in the laboratory [173], and those that do make it to market face fierce competition, flagging engagement rates, and a lack of financial means to scale the project. Thus, in developing and testing these promising digital mental health–focused physical activity tools, investigators should integrate elements essential for successful dissemination. One proposed pathway for improving the dissemination and ultimate success of digital mental health tools is to connect consumers through employers or public and private insurance companies, who have indicated a growing interest in expanding services to cover digital mental health. To illustrate, Blue Shield of California is now offering the mindfulness meditation app Headspace to subscribers [189]; Cigna offers the mental health app Ginger as part of its service package [190]; and Kaiser Permanente supports the use of Ginger, Calm, and MyStrength [191]. Physical activity technologies that track and manage exercise and step count are even more prevalently covered by insurance. Blue Cross Blue Shield, United, and others have partnered with Fitbit to offer low-cost wearable devices and use of their apps to promote health behavior change. Aetna and Cigna offer similar programs and occasional incentives to people who use health-tracking apps and devices. Taken together, the

enthusiasm for apps and devices promoting physical health, as well as the recent foray by insurers into the digital mental health space, suggests that smartphone-based physical activity interventions for mental health may be prime for scalable coverage. This also means that academics developing such tools should be mindful when designing research studies to collect outcome data relevant to insurers and other payers, such as outcomes related to health care costs (reduction in insurance claims and physician or therapist visits), disability-adjusted life years (reduction in overall illness burden), adoption and engagement rates, and user data such as acceptability and fidelity (whether people use the tools as intended). In addition, investigators and designers should carefully consider the costs inherent to their interventions, such as relying on "off-the-shelf" versus research-grade devices and other platforms, the extent to which an intervention relies on human support to be administered, and the broader infrastructure required for implementation and sustainment, all of which will alter accessibility and scale. By designing research studies on smartphone-based physical activity interventions with true scalability in mind, researchers will be better poised to expand their intervention beyond academia and better achieve the goal of connecting evidence-based interventions with those who need them.

Conclusions

Physical activity has well-known and broad mental health benefits. However, a minority of at-risk individuals or those with mental disorders meet even the minimum exercise recommendations. Smartphones may bridge this gap given their pervasiveness in daily life, capacity to help concurrently manage multiple dimensions of personal health, and ability to engage key mechanisms of behavior change. Although early data for smartphone-based physical activity interventions reducing psychological symptoms are encouraging, overall, surprisingly little work has been done in this area. Therefore, there is untapped potential for developing and disseminating accessible, beneficial tools that can have a great public health impact.

Acknowledgments

During the preparation of this manuscript, EEB and BMH were supported in part by the Hope Fund, an internal fellowship at Massachusetts General Hospital provided through the generosity of an individual donor to support early-career investigators.

Conflicts of Interest

Abstract

Background: Wearable devices, mobile technologies, and their combination have been accepted into clinical use to better assess the physical fitness and quality of life of patients and as preventive measures. Usability is pivotal for overcoming constraints and gaining users' acceptance of technology such as wearables and their companion mobile health (mHealth) apps. However, owing to limitations in design and evaluation, interactive wearables and mHealth apps have often been restricted from their full potential.

Objective: This study aims to identify studies that have incorporated wearable devices and determine their frequency of use in conjunction with mHealth apps or their combination. Specifically, this study aims to understand the attributes and evaluation techniques used to evaluate usability in the health care domain for these technologies and their combinations.

Methods: We conducted an extensive search across 4 electronic databases, spanning the last 30 years up to December 2021. Studies including the keywords "wearable devices," "mobile apps," "mHealth apps," "physiological data," "usability," "user experience," and "user evaluation" were considered for inclusion. A team of 5 reviewers screened the collected publications and charted the features based on the research questions. Subsequently, we categorized these characteristics following existing usability and wearable taxonomies. We applied a methodological framework for scoping reviews and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist.

Results: A total of 382 reports were identified from the search strategy, and 68 articles were included. Most of the studies (57/68, 84%) involved the simultaneous use of wearables and connected mobile apps. Wrist-worn commercial consumer devices such as wristbands were the most prevalent, accounting for 66% (45/68) of the wearables identified in our review. Approximately half of the data from the medical domain (32/68, 47%) focused on studies involving participants with chronic illnesses or disorders. Overall, 29 usability attributes were identified, and 5 attributes were frequently used for evaluation: satisfaction (34/68, 50%), ease of use (27/68, 40%), user experience (16/68, 24%), perceived usefulness (18/68, 26%), and effectiveness (15/68, 22%). Only 10% (7/68) of the studies used a user- or human-centered design paradigm for usability evaluation.

Conclusions: Our scoping review identified the types and categories of wearable devices and mHealth apps, their frequency of use in studies, and their implementation in the medical context. In addition, we examined the usability evaluation of these technologies: methods, attributes, and frameworks. Within the array of available wearables and mHealth apps, health care providers encounter the challenge of selecting devices and companion apps that are effective, user-friendly, and compatible with user

interactions. The current gap in usability and user experience in health care research limits our understanding of the strengths and limitations of wearable technologies and their companion apps. Additional research is necessary to overcome these limitations.

Introduction

Background

Wearable technology, also known as *wearable devices*, includes smart electronic devices worn in close proximity to the surface of the human body. These devices can detect, analyze, and transmit information concerning body signals such as vital signs and physiological data, including step count and heartbeat [1-3]. Smart wearable technologies and their high-performance microsensors are of growing importance for patient health monitoring and are being widely accepted into clinical use and trials [4-7]. These technologies have the capability to amplify personal wellness and raise awareness in the spectrum of preventive health care. Consumers continue to rely on smart devices such as mobile phones and smartwatches to engage in healthy behavior [8-10]. They also assist in the self-management of chronic conditions, preventive measures, and aftercare, for example, diabetes monitoring [11], rehabilitation [12-14], fall detection [15,16], wound healing [17], and even monitoring symptoms of long-term illness [18-20]. Wearable technology further enhances the continuum of care within interdisciplinary communication and improves individuals' health and well-being, all in their natural mobile environment [3,21].

Commercial Wearables Versus Medical Wearables

The growing demand for health care technology, particularly wearable devices, has led to the proliferation of various medical and smart health care wearables. However, there is ambiguity in distinguishing between commercial consumer wearable devices and wearable medical devices. The European Union regulations [22] define medical devices as those intended for medical purposes such as disease diagnosis, monitoring, treatment, injury management, and physiological process modification; however, this scope does not include wearable technologies, such as smartwatches, smart bands, and mobile phone–based devices, designed primarily to provide users as tools for health monitoring and management. Fotiadis et al [23] defined wearable medical devices as self-contained, noninvasive devices with specific medical functions. Although a clear definition of wearable medical wearables remains elusive, these devices serve as a convergence point for both conventional medical device manufacturers and consumer-oriented companies aiming to enter the profitable medical market. The traditional distinction between medical and consumer-grade devices relies on the primary intention; however, we found that many commercial devices are being used opportunistically in health care and clinical trials.

Despite the expanding scope of wearable devices, unresolved concerns persist among general consumers regarding the safety, security, and usability of these devices [24-28]. Therefore, ensuring the fit-for-use of these technologies for specific users in clinical settings must be ascertained. The assessment of the usability of these technologies is critical to the success and adoption of wearable and mobile technology or the combination thereof. The identification and consideration of the appropriate attributes and methods for the measurement of usability as early on in the product development process can increase productivity, reduce errors, reduce user training and user support, and improve efficacy, thereby further broadening the acceptance of wearable and mobile technology by users [29-31].

Definition of Usability

In the literature, the definition of *usability* varies, with some studies equating it to assess a device's functionality, whereas others focus on aspects such as feasibility or performance. This ambiguity highlights the need for a comprehensive approach in measuring usability, considering users, devices, environment, and the actions users perform. The International Organization for Standardization (ISO) 9241 clarifies usability as "the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [32]. It is important to recognize that usability extends beyond the immediate outcomes of use. Established standards such as ISO 9241 or other regulatory frameworks primarily view usability as a result of use, emphasizing attributes such as effectiveness, efficiency, and satisfaction. However, a holistic evaluation of usability attributes that goes beyond immediate outcomes contributes to a deeper understanding of user interactions with these technologies and their acceptance in everyday use.

For better adoption of wearables in combination with their companion mobile health (mHealth) apps in clinical settings, usability needs to be considered to safeguard the effectiveness, functionality, and ease of use of these technologies. Concerning the acceptance of wearable technologies, it has been advocated that the devices must be easy to wear, affordable, possess suitable functions, and be appealing to users [33-35]. In such circumstances, designers, developers, and interdisciplinary researchers need to consider the development and use of such devices in a user-centered manner [36-38], thereby affirming that wearable technology is relative to the requirements of the users as it is a vital factor in the adoption of digital health apps and devices because it can be challenging for users owing to their health conditions. Furthermore, usability testing of these technologies allows researchers to understand how the wearable being developed meets users' requirements before being used in health interventions.

Exploring Key Attributes of Usability

Previous scientific literature disclosed the measurements of usability using different entities. These entities are defined as

dimensions, components, scales, or factors of usability. According to Folmer and Bosch [39], these terms are analogous and hold the same meaning. Therefore, as defined by Wixon and Wilson [40], the term usability attribute is the characteristics of a product that can be measured. The most consistently reported usability attributes are effectiveness, efficiency, and satisfaction, which are part of the usability definition of ISO 9241-11:2018 [32,41]. Existing reviews have focused on reporting the usability attributes of mobile apps in health care; however, the shortcoming of applicable attributes for wearables and their companion app poses a challenge in assessing the usability of these technologies.

Exploring Evaluation Methods of Usability

Usability assessment is instrumental in determining how well users learn and use technology to meet their goals. This includes the effectiveness and efficiency of a device and how satisfied the users are with the process. Therefore, different usability evaluation methods should be used to gather this information. Existing literature shows that different methods have been used for the testing of wearables such as field studies and laboratory experiments [42-44]. Although laboratory experiments, field studies, and hands-on measurement are some of the most commonly used methodologies, these are sometimes difficult to apply and have drawbacks. The prevailing usability methods assess different facets of usability, each providing different data. Accordingly, the selection of methods plays a pivotal role in evaluating the desired attributes of usability. Previous reviews have investigated the usability of wearables [45-47] and mHealth apps independently [41,48-50]. These reviews examined the usability assessment of wearables or mobile apps according to specific use cases in the health care domain [51-57]. Moreover, evaluation studies on the combination of the aforementioned devices were not taken into consideration. Research in this area continues to be fragmented, which demonstrates the importance of exploring further the requirements, functionalities, and capabilities of such wearable devices to enhance our comprehensive understanding of their use and acceptance.

Objectives

This study aims to survey the existing literature in the field of medicine and health care that reports on the usability of wearable technology, mHealth apps, or their combination. Our scoping review seeks to analyze the literature in three ways: (1) type (commercial or medical) and category (stand-alone or paired) of wearable devices and their frequency of use in studies; (2) medical use cases; and (3) usability evaluation of these technologies, specifically usability attributes, methods, and frameworks.

Methods

Framework

This study uses the framework developed by Arksey and O'Malley [58] for reporting on scoping reviews, following the recommendations for enhancement of this approach by Levac et al [59]. We followed the five stages of the framework: (1) identifying the research question (RQ), (2) identifying relevant studies, (3) selecting studies, (4) charting the data, and (5) summarizing and reporting the results. In addition, the review followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist to report the study selection process of the scoping review (Multimedia Appendix 1) [60,61].

Stage 1: Identifying the RQs

For our scoping review, we used the PICO (Population, Intervention, Comparison, and Outcome) model [62,63] shown in Table 1 to help us regulate our RQs, outline the search strategy, and identify relevant studies within the health care domain. However, for our scoping study, the control or comparison aspect of the PICO methods was eliminated because our focus was not on comparative studies or controlled exposure.

Table 1. The PICO (Population, Intervention, Comparison, and Outcome) method applied to our review.

Aspect	Description	Our review
Patient, population, or problem	Problem to be addressed	• Wearables • Fitness trackers • Physiological data
Intervention, prognostic factor, or exposure	Situation or condition or a characteristic of a patient (technology savvy). Exposure to be considered in treatments and tests	• Mobile devices or smartphones • Mobile apps
Control or comparison	Control or comparison intervention treatment or placebo or standard of care	• Comparison is eliminated as the focus is not on comparative studies or controlled exposure
Outcome to measure or achieve	Outcome of interest—what can be accomplished, ensured, improved, or affected?	• Usability and human factors

This scoping review aims to accomplish its objectives by answering the following RQs:

1. RQ1: What type (commercial or medical) and category (stand-alone or paired) of wearable devices and their companion mHealth apps were implemented and how frequently were they used in the studies?
2. RQ2: What medical use cases and medical data were reported?
3. RQ3: What usability methods, frameworks, and attributes were used for the usability evaluation?

Stage 2: Identifying Relevant Studies

The focus of the second stage of the Arksey and O'Malley framework [58] was to find the relevant studies that match the RQs and the purpose of the scoping review. We began the review with an extensive search using keywords related to the PICO model. However, this raised questions about the sensitivity and specificity of the articles, that is, retrieving and identifying relevant research topic publications. Therefore, redefining the search terms after the initial search added the advantage of prioritizing the sensitivity of the relevant article.

We conducted our search in 4 electronic databases, including ACM Digital Library, IEEE Xplore, PubMed, and Web of Science (Clarivate Analytics), resulting in relevant studies covering the last 30 years up to December 2021. Relevant additional literature was also identified through other resources such as citations and expert recommendations. The search strategy was developed in association with the university librarian at the Medical Faculty Mannheim, Heidelberg University. The search integrated both search terms and Medical Subject Headings associated with the topics of health care, wearables, mHealth apps and terms used under the umbrella term *user experience*. The search strategy for the respective databases can be found in Multimedia Appendix 2.

Stage 3: Study Selection

For our scoping review, all types of articles ranging from journal articles to conference papers were considered, without restrictions on the period of publication. In line with the systematic review methodology, we formulated inclusion and exclusion criteria for this scoping review. The inclusion and exclusion criteria are provided in Textbox 1. This allowed us to reduce the number of papers that were included in the screening of titles and abstracts. Citavi (version 6; Swiss Academic Software GmbH) was used for the collection of the articles.

Textbox 1. Inclusion and exclusion criteria for the scoping review.

Inclusion criteria

- Language: English
- Papers focused on wearables or a prototype of wearables that have used usability testing for their evaluation, where methods such as questionnaires, observations, experimental testing, or surveys were used
- Papers focused on a mobile health (mHealth) app or a prototype of the mHealth app that used usability testing for its evaluation, where methods such as questionnaires, observations, experimental testing, or surveys were used
- Papers that use either a wearable, an mHealth app, or both in a medical use case, for example, chronic diseases
- Papers that use a user-centered design approach for developing wearables or mHealth apps

Exclusion criteria

- Inclusion criteria not fulfilled, for example, papers not written in English or not matching any of the secondary inclusion criteria
- Papers with the theme or topic of augmented reality and virtual reality, which may also include usability studies (eg, Google Glass)
- Papers that have only used audio and visual wearable aids (ie, without additional support from smartphones)
- Papers purely focused only on the technical aspects, technical descriptions, or features of wearables or mobile apps or PDAs in the development and testing processes of materials; self-developed sensors; or wearable sensors such as accelerometers, gyroscopes, or inertial measurement unit
- Papers that are focused mainly on medical professionals rather than patients, for example, describing algorithms or methods used for the optimization of viewing medical data (such as electrocardiogram and electroencephalogram)

We followed the recommendations from Daudt et al [64] for interdisciplinary teamwork in scoping reviews: we incorporated reviewers from different disciplines and backgrounds such as health services research, usability engineering, and medical informatics. The reviewers were divided into 2 groups such that each group had members with diverse backgrounds and expertise. Furthermore, an expert not involved in the screening reviewed mismatched publications from the groups and made discrete decisions for the inclusion and exclusion of articles. Each team member independently reviewed the titles, abstracts, and full text of the publications assigned to them. Studies were considered for the full-text reading if the inclusion criteria were met and cross-verified among team members.

Stage 4: Charting the Data

At this stage, the data from the included studies were extracted. The review team collectively designed a structured data-charting format aligned with the RQs of the scoping review. Each team member individually extracted relevant characteristics from the included studies and adapted them to the data-charting format. Disagreements between the reviewers were resolved through discussions and feedback. The characteristics extracted from the included studies that are associated with the aim of this scoping review are as follows: (1) classification of wearable devices and mHealth apps (only wearables or paired); (2) type of wearable devices; (3) type of mHealth app (stand-alone or interactive); (4) medical use cases (if wearables or mobile apps or combination of both were used in a specific medical use case); (5) physiological data; (6) type of connections between wearables and apps (Wi-Fi or cables); (7) duration of usability studies; and (8) usability evaluation—usability attributes, frameworks, and methods. Excel (Microsoft Corp) was used to facilitate this process.

Stage 5: Summarizing and Reporting the Results

To effectively summarize and organize the extracted data, a comprehensive search of the relevant literature was conducted to identify suitable articles to structure the examination and analysis. Two relevant literature sources were identified to fulfill our objectives. We aimed to find a suitable classification system that could effectively categorize various wearable devices. The classification proposed by Seneviratne et al [65], which provides a comprehensive survey of commercial wearable products grouped into 3 categories—accessories, e-textiles, and e-patches—served as a helpful tool for our analysis. In addition, we used the usability taxonomy hierarchy proposed by Alonso-Ríos et al [66] for our analysis. This taxonomy provided a comprehensive framework for organizing usability attributes in a logical and meaningful order.

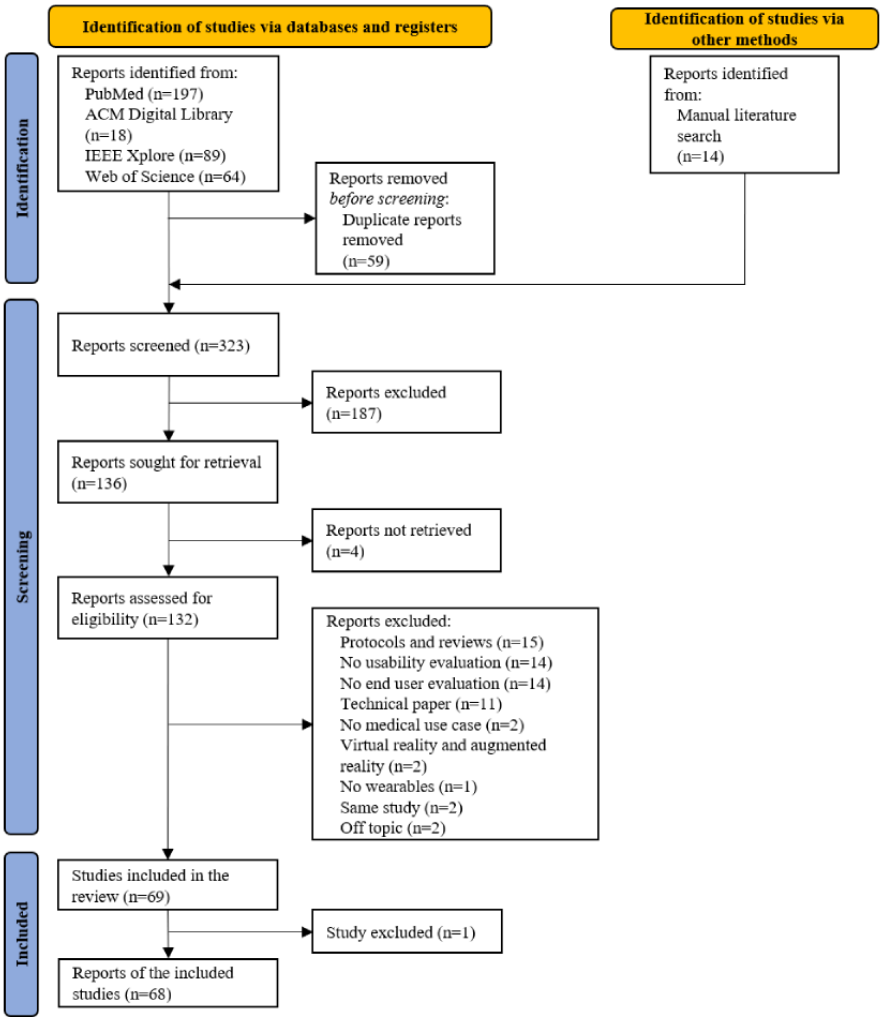
We present our findings by integrating descriptive tables and graphical illustrations of the outcomes. These figures and graphics helped our analysis to directly connect the findings to the objectives of our review and identify the gaps in the literature. In our study, we illustrate the frequencies and percentages of the findings in coherent data visualizations, emphasizing the analysis and reporting of data and giving them a comprehensive meaning.

Results

Eligible Studies

Our search yielded 382 records, including articles about wearables, mHealth apps, or their combination; research about the implementation of these technologies in medical use cases; and evaluations of their usability. Overall, 323 records were evaluated for the initial screening of titles and abstracts after eliminating duplicates. From these, 132 full-text papers were found, of which 62 were excluded, resulting in 69 studies whose data were charted per the study questions. Following the final text reading, a single study had to be excluded from this scoping review because it did not meet the predefined inclusion criteria, despite the presence of relevant keywords in the paper. The process of selection of articles for the scoping review can be seen in the PRISMA-ScR diagram shown in Figure 1.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram of the selection process for the scoping review.



Wearable Devices and Their Frequency of Use

Most studies (57/68, 84%) used a combination of wearables and mobile apps. Overall, 12% (8/68) of the studies used wearables in conjunction with other technological devices such as smartphones, computers, recording devices, or PDAs; however, these devices were used independently from the wearables. Furthermore, the data extraction indicated that two-thirds of the studies (45/68, 66%) used commercially available wearables for their evaluation studies, of which approximately half of the studies (21/45, 47%) used Fitbit (Fitbit Inc.) devices as their source of data tracking and collection. Our data further showed that only 11% (5/45) of the studies used wearable devices that were certified as medical devices. In addition, only 18% (12/68) of the studies used a self-developed wearable prototype and a mobile app for data tracking and monitoring.

From the included studies, 9% (6/68) of the studies reported using only wearables in their studies. Of these 6 studies, 5 (83%) used commercially available wearable devices such as Fitbit and Samsung Gear S3 (Samsung Electronics Co, Ltd), whereas 1 (1%) study reported using a self-developed wearable prototype. However, 7% (5/68) of outliers were detected where 60% (3/5) of the studies mentioned using only a mobile app; 20% (1/5) of the studies reported using only a smartphone; and in 20% (1/5) of the studies, smartphone was used as a wearable device by attaching a 3D-printed phone holder around the user's neck [67]. Although this is typically not defined as a wearable, the outcome of this study proved imperative in determining the different devices and variables used for evaluation. We used a classification system consisting of 6 distinct groups to categorize the diverse use of wearable technologies and mobile apps (with, without, or a combination thereof). They are (1) only wearables (eg, stand-alone wearables such as Fitbit and Garmin [Garmin Ltd]), (2) wearables+companion apps (eg, Garmin tracker+corresponding Garmin mobile app), (3) smartphone as wearables (eg, smartphone used in close proximity to the skin to track physiological data), (4) wearables+connectivity (not companion) apps (eg, wearables paired with connectivity apps for Bluetooth connection and not for presenting data), (5) wearables+other technologies (eg, Garmin+laptops, recording units, and PDAs), and (6) others (only smartphone or only app). The specified categories and the corresponding studies included in this review are presented in Table 2.

In most studies, the validation, accuracy, and certification of the used wearables were not thoroughly discussed, despite these aspects being considered essential in good research practices. Although some studies briefly touched upon validation or accuracy, they did not necessarily indicate that the wearables had undergone certification, such as Food and Drug Administration approval or Conformité Européenne mark. Authors of the included studies often omitted reporting the inaccuracies and validation limitations of consumer-grade wearables, particularly when usability was of significant importance. Instead, the accuracy of wearables was often assumed based on the authors' validation of wearables' selection through peer-reviewed research and their alignment with traditional instruments for measuring health data. The list of included studies along with the extracted information can be found in Multimedia Appendix 3 [43,67-133].

Most of the wearables (35/68, 51%) covered in the review were wrist worn, such as wristbands or smartwatches. However, only 9% (6/68) of the studies used multiple wearables, such as a smartwatch and chest belt or multiple wrist-worn wearables. Table 3 presents the data on the different categories of the types of wearable devices extracted from the included studies. More than half of the studies (48/68, 71%) deployed stand-alone mobile apps, which implies that users or patients collected health information using wearables and apps without sharing it with their professionals. Overall, 68% (46/68) of the studies determined that Bluetooth connections were the primary means of connectivity for wearables and the mobile apps that accompanied them. Data from the extracted studies revealed no linkage between the technologies; hence, outliers (4/68, 6%) were also recognized.

Table 2. Wearable devices, mobile apps, and their combination along with their frequency of use in studies (n=68).

Category of wearable devices and mobile apps	Frequency of use in studies, n (%)	References
Only wearables	6 (9)	[68-73]
Wearable devices+companion apps	49 (72)	[43,74-121]
Wearable devices+connected with apps (not companion app)	5 (7)	[122-126]
Wearables+other technologies (eg, laptops, recording units, and PDAs)	3 (4)	[127-129]
Smartphone as wearables	1 (1)	[67]
Others	4 (6)	[130] (smartphone only), [131-133] (app only)

Table 3. Categorization of the type of wearable devices according to the classification of wearable devices by Seneviratne et al [65] ordered by their frequency of use in studies (n=68).

Categorization of the type of wearables	Description	Devices	Studies, n (%)
Wrist worn	Wrist-worn devices with fitness tracking capabilities or other functionalities, generally without a touchscreen	Wrist bands	26 (38)
Wrist worn	Wrist-worn devices with a touchscreen display	Smartwatches	9 (13)
>1 wearable device in the study	Study includes >1 wearable device (any type)	Wrist bands, Upper arm bands, e-Patches, Sensor patches	6 (9)
Other accessories	Chest straps, belts, upper arm bands (in contrast to wrist-worn bands), or knee straps equipped with sensors for health tracking or other functionalities	Straps	5 (7)
e-Textiles	Main clothing items that also serve as wearables, such as shirts, pants, and undergarments	Smart garments	5 (7)
Hearables	Fits in or on an ear that contains a wireless link	Hearing devices	4 (6)
Other accessories	Clip-on	Clip-on	3 (4)
e-Patches	Sensor patches that can be adhered to the skin for either fitness tracking or haptic applications	Sensor patches	3 (4)
Outliers	Does not fit the categories	Wrist bands, Upper arm bands, e-Patches, Sensor patches	3 (4)
e-Textiles	Shoes, socks, insoles, or gloves embedded with sensors	Foot or hand-worn	2 (3)
Other accessories	Jewelry designed with features such as health monitoring and handless control	Smart jewelry	1 (1)
e-Patches	Tattoos with flexible and stretchable electronic circuits to realize sensing and wireless data transmission	e-tattoo or e-skin	—[a]
Head-mounted devices	Spectacles or contact lenses with sensing, wireless communication, or other capabilities	Smart eyewear	—
Head-mounted devices	Bluetooth enables headsets or earplugs. Sensor-embedded hats and neck-work devices are also found in research products	Headsets or earbuds	—

Medical Use Cases and Reported Data

Our data showed that approximately half of the studies (32/68, 47%) focused on participants with chronic illnesses or disorders, indicating the importance of wearable technologies in managing and monitoring chronic conditions. The remaining 53% (36/68) of the studies encompassed various other medical use cases such as wellness, mental health, rehabilitation, sleeping disorders, otolaryngology, and preventive measures.

Most studies (40/68, 59%) routinely collected physiological data from users or patients. The most commonly collected health data revolved around physical activity, encompassing metrics such as steps taken, stairs climbed, and inertial measurement units. Approximately 35% (24/68) of the health data gathered in the studies focused on cardiac measurements, including electrocardiogram, heart rate variability, heart rate, or blood pressure. In addition to physical activity and cardiac measurements, other data types were also collected, albeit to a lesser extent. Sleep data accounted for 25% (17/68) of the collected information, and brain activity data, such as electroencephalogram recordings, constituted 4% (3/68) of the data. Furthermore, biosignals, including measurements such as skin conductance and respiration rate, were captured in 18% (12/68) of the studies. Other health data and observations such as acoustics, posture, blood glucose, and weight were also monitored in approximately 21% (14/68) of the cases, indicating the broad range of parameters that wearables can track and analyze.

In addition to physiological data, a small proportion of the studies (4/68, 6%) included in our analysis also collected nonphysiological data that were not directly linked to health parameters. These data contained various variables such as the number of cigarettes consumed per day, location data, and dietary intake. Although not directly related to traditional health measurements, the inclusion of such data provides a broader context and enables a more holistic understanding of individuals' behaviors and lifestyle factors.

Usability Attributes

The studies included in this review used various terms such as *usability characteristics* and *attributes*, which we consider to be synonymous. Therefore, we applied the usability attributes from the extracted data to the usability taxonomy [66]. We found that satisfaction (34/68, 50%), ease of use (27/68, 40%), user experience (16/68, 24%), perceived usefulness (18/68, 26%), and effectiveness (15/68, 22%) were the most commonly used attributes for assessing usability. Although user experience is acknowledged as the overarching term encompassing

usability, conceptualizing user experience as a facet of usability captures the comprehensive perception arising from interactions with devices. This extends beyond the mere use of the device, encapsulating the entirety of the experience or the anticipated use of the technologies. Furthermore, we identified 32% (22/68) of the studies that simply reported usability or perceived usability. Moreover, our findings further indicate that out of the 29 identified usability attributes, 6 (21%) can be classified as quality attributes. Table 4 shows the mapping of the attributes identified in the review to the attributes defined in the usability taxonomy. These particular usability characteristics possess qualities that are directly related to the overall quality and performance of the technologies used in the studies. Table 5 presents the quality and product attribute matrix of the attributes ascertained in the review and the defined attributes from the ISO norm 25010 [134]. A detailed explanation of the different attributes in Tables 4 and 5 can be found in Multimedia Appendix 4 [66].

Table 4. Matrix mapping of the attributes identified in the scoping review and the usability taxonomy [66][a].

Usability attributes from scoping review	Usability taxonomy						
	Knowability	Operability	Efficiency	Robustness	Safety	Subjective satisfaction	Number of studies, n (%)
Accuracy		✓					5 (7)
Aesthetics						✓	7 (10)
Attitude						✓	4 (6)
Attractiveness						✓	2 (3)
Clarity	✓						1 (1)
Cognitive load			✓				2 (3)
Controllability		✓					1 (1)
Data quality		✓					1 (1)
Ease of use or perceived ease of use (effort expectancy, easiness, self-descriptiveness, and self-efficacy)	✓						27 (40)
Effectiveness (user errors, ease of executing a task, task completion, and task completeness)		✓					15 (22)
Efficiency (task time)			✓				6 (9)
Engagement						✓	7 (10)
Error tolerance				✓			1 (1)
Functionality		✓					7 (10)
Hedonic motivation						✓	2 (3)
Learnability	✓						4 (6)
Likes and dislikes						✓	1 (1)
Perceived usefulness (usefulness, utility, performance expectancy, and system usefulness)	✓						18 (26)
Satisfaction (subjective app quality, survey and ratings, positive and negative feedback, opinions and reactions, and participants' experience)						✓	34 (50)
Technical difficulties				✓			2 (3)
Trust					✓		1 (1)
User control		✓					1 (1)
User experience (experience, overall subjective quality, and user-friendliness)						✓	16 (24)

[a]The rows list all the usability attributes identified in the scoping review and the columns list the first-level usability attributes from Alonso-Ríos et al [66], with each checkmark symbol indicating a match based on their description and their sublevel attributes. The last column lists the number of studies using the term from that row.

Table 5. Quality and product attributes identified in the scoping review that match the attributes from the International Organization for Standardization (ISO) norm ISO/International Electrotechnical Commission (IEC) 25010 [134][a].

Attributes identified in the scoping review	Quality attribute					Product attribute								
	Effectiveness	Efficiency	Satisfaction	Safety	Usability	Functional suitability	Performance efficiency	Compatibility	Usability	Reliability	Security	Maintainability	Portability	Number of studies (%)
Comfort			✓											8 (12)
Design—app interface and design and interface quality									✓					3 (4)
Effectiveness[b]	✓													15 (22)
Efficiency[b]		✓					✓							6 (9)
Facilitating conditions								✓						1 (1)
Information quality							✓							3 (4)
Interface quality									✓					2 (3)
Reliability										✓				1 (1)
Trust[b]				✓										1 (1)
Satisfaction[b]			✓											34 (50)

[a]The rows list all the attributes identified in the scoping review and the columns list the quality and product attributes from ISO norm 25010 [134], with each checkmark symbol indicating a match based on the description of the attributes. The last column lists the number of studies using the term from that row.

[b]Overlapping attributes also identified as usability attributes.

In addition, during the data extraction process, we obtained insights into the elements and factors that affect the evaluation of usability. Among the 68 included studies, 52 (76%) reported these elements and factors, which played a crucial role in shaping and guiding the measurement of usability. Notably, acceptance (21/68, 31%) emerged as the most commonly used element or factor in assessing usability, indicating its significance in understanding users' acceptance and adoption of wearable technologies.

Usability Evaluation Methods and Frameworks

Only 12% (9/68) of the studies outlined using some sort of framework for usability evaluation. User- or human-centered design (7/68, 10%) was the most commonly used framework. Our findings revealed that more than half of the studies (37/68, 54%) collected data using the mixed methods approach. Only 15% (10/68) of the articles used only qualitative methods. These data collection methods included interviews, focus group discussions, thinking-aloud protocols, cognitive walkthroughs, open-ended discussions, Wizard of Oz, and free-text writing. Approximately two-thirds of the studies (21/68, 31%) used quantitative approaches for data collection during evaluation studies. The System Usability Scale (SUS) outnumbered other usability questionnaires (17/68, 25%) such as the Mobile Application Rating Scale, Net Promoter Score, Single Ease Question, NASA Task Load Index, and Technology Acceptance Model. However, a large percentage (21/68, 31%) of the articles used self-developed surveys or self-reporting questionnaires. Only one-fourth of the articles (16/68, 24%) further implemented statistical analysis including task completion, number of errors, descriptive statistics, or Google Analytics for the assessment of usability. Consequently, only a small proportion (3/68, 4%) of the included studies performed heuristic evaluation as a form of expert evaluation.

Discussion

Principal Findings

Our data suggest that the evaluation of wearables for medical purposes was largely conducted without direct integration with mobile apps. Although some studies used smartphones as a means of connecting with the wearables, users were not assigned companion apps for data viewing. This limits the analysis and data visualization capabilities of the data collected within the studies. Wrist-worn devices were the most common type of wearables identified in the studies, indicating the convenience

of using this type of wearables for measuring physical activities in a research setting. We also found that most studies (21/68, 47%) reported the use of consumer-grade fitness and activity trackers from Fitbit, and only a handful of the studies (5/68, 7%) implemented medical-grade wearable devices. A small number of the studies (10/68, 15%) investigated the data collection and use of the wearable in the aspects of aftercare of patients, wellness, and rehabilitation.

We noted the absence of standards or guidelines to facilitate the analysis of the usability of wearables, mobile apps, or their combination. Although user- and human-centered design frameworks were mentioned in a few studies (7/68, 10%), they are guiding the design and development of systems and devices focusing on users and their needs but not the usability of these devices. Despite the fact that many wearable technologies were included in the study, no usability evaluations of multiple devices, the combination of devices, or multidevice interfaces were reported.

Only a little more than one-third of the included publications (22/68, 32%) in our review explicitly reported the measurement of usability or perceived usability. Some studies (8/68, 12%) primarily focused on assessing the measurement of *usability* or *perceived usability* as user perceptions of the devices, attitudes, and compliance using different qualitative or quantitative methods [71,89,91,95,97,98,102,129]. However, it is worth noting that these studies encountered a challenge in clearly differentiating the evaluation of the usability of the wearable device from that of the accompanying mobile app. Consequently, the intended purpose of the evaluation may have been limited in these studies. Therefore, we address the term *usability*, a broad term that encompasses various factors including technology and user acceptability. Studies might have reported on usability alone either due to missing expertise or due to a high-level summarization of various aspects they investigated. To help mitigate this, we incorporated and synthesized a set of attributes or subattributes to measure the capability and performance of a system based on the extracted data.

Our analysis showed that a subset of usability studies lacked testing with the intended target group and instead relied on healthy adults as participants. Despite the absence of explicit acknowledgment of this limitation in the included studies, it raises concern regarding the extent to which the devices and apps under investigation adequately address the unique needs and requirements of the target users, particularly individuals with chronic health conditions. This observation is in line with the findings reported in previous studies [135-144], emphasizing the concern regarding the devices and apps under investigation that adequately meet the unique needs and requirements of the target users.

Comparison With Prior Work

Wearables

Most of the studies (45/68, 66%) in our review used consumer-grade wearables. This matches the observations of other studies [145-150] that investigated commercially available wearables and reported a wide variety of purposes, ranging from digital diagnostic tools to sports tracking to remote monitoring. Niknejad et al [151] and Ferreira et al [152] reported that consumer-grade wearables have been used to foster self-awareness among users. In contrast, we observed that the studies using consumer-grade wearables in our corpus focused on their use for monitoring chronic conditions such as diabetes, obesity, cardiology, and cancer.

We found that wearables are gradually being used more widely in health care and clinical settings. As stated in the previous paragraph, this is true for consumer-grade wearables such as Fitbit, Jawbone, Apple, and Garmin [153-157]. However, concerns about the safety, reliability, and accuracy of these devices persist. In their work, Piwek et al [146] raised concerns about wearables in terms of user safety, emphasizing the need to better address the reliability and security of the data collected from these devices. Considering the inherent lack of emphasis on user safety in consumer wearables, it is imperative to acknowledge the importance of adhering to standard safety and privacy protocols. This includes ensuring ethical transparency and providing appropriate education to users regarding the privacy and information security risks they may encounter when using such devices [24,158,159]. In addition, the use of consumer wearables in health care settings remains somewhat ambivalent at present [160,161]. Although our review did not specifically address these concerns, we acknowledge that these factors significantly affect the usability of wearable technologies, whether used independently or with companion mHealth apps. Similar to Piwek et al [146], who pointed out acceptance challenges of wearables concerning safety and security, we believe that a structured framework with clear definitions and well-defined methods would allow bringing wearables into more diverse practices in the health care system, encouraging a broader adoption and implementation of use cases with high and tested usability.

Studies by Niknejad et al [151], Dimou et al [162], and Yang et al [163] proposed different categorization approaches for wearables, considering factors such as industry relevance (eg, health care or fashion) or wearable placement on the body. However, owing to the wide variety of wearables available in the market, establishing a standardized classification or hierarchy for these different types of wearables becomes challenging. Thus, to help designers and developers, a standardized classification or hierarchy would be helpful when selecting wearables for specific use cases.

Usability Attributes

Many studies in our corpus did not explicitly state the usability attributes they evaluated. Some mentioned generic terms such as *usability* or *user experience*, but did not define them further for their specific cases. As we have argued, more specific usability attributes can facilitate the development of more appropriate requirements and clearer identification of problems in usability studies. This matches observations in related areas. Meyer et al [164] analyzed usability evaluation practices in wearable robotics and recommended better distinguishing between the different usability dimensions and including qualitative measures for identifying a wider range of usability issues. Chiauzzi et al [139] examined the use of wearable

devices for long-term chronic disease management. Patient concerns regarding technical difficulties and the appeal of the devices were identified, but their investigation did not address usability attributes such as device comfort and usefulness. Furthermore, the authors emphasized the importance of wearables being perceived as usable and generating comprehensible data to facilitate wider adoption among patients.

Among the 29 identified attributes in our review, 6 (21%) attributes were found to be more suitable for capturing the quality or product-related aspects of the technologies investigated in this study (Table 5). However, determining the most appropriate attributes for wearables and their associated mobile apps can be challenging because of the potential overlap between the product and inherent attributes, such as effectiveness and satisfaction (Table 5). This finding is consistent with Bakhshian and Lee [165], who argued that consumers' attitudes and purchase intentions toward wearable technology are influenced by both product attributes and inherent attributes, including functional, expressive, and esthetic characteristics. In contrast, other studies have explored the design attributes and their influence on user interactions and acceptance of different types of wearables for specific use cases, such as electroencephalogram systems [166], autism spectrum disorders [167], sports applications [168], and haptic feedback wearable robots [169]. The importance of assessing usability based on user interactions with wearable devices and their associated app remains crucial, amid the emphasis on the design and quality attributes of wearables.

Our data highlight the importance of considering supplementary attributes such as wearability, perceived usefulness, and connectivity when evaluating individual wearables and companion mobile apps. Consistent with our findings, the existing literature also emphasizes the significance of incorporating auxiliary attributes beyond the conventional usability factors such as effectiveness and satisfaction to enhance the acceptance of wearable devices. The aforementioned supplementary attributes identified in the literature include characteristics such as comfort, user-friendliness, affordability, useful features, and appealing design [33-35,136]. It is imperative to incorporate these attributes into the evaluation process to ensure comprehensive assessments of usability and user acceptance in both wearables and companion mobile apps. Although a few studies provide a general overview of wearable attributes related to design and product quality, there is limited research that specifically focuses on the usability attributes of wearables. Although some reviews have identified specific usability attributes for mHealth apps used in various use cases [41,170-176], these are insufficient when evaluating the combined use of wearables and companion apps because of the complex and multifaceted features and interactions involved.

Our results revealed diverse informal terminology used to describe usability, performance, and quality aspects of the technologies examined in the studies. This variability in terminology posed challenges in accurately distinguishing and classifying the terms based on their usability characteristics. We adopted an existing usability taxonomy from the literature to address this issue and ensure consistency in data interpretation [66].

Usability Evaluation Methods and Frameworks

Our analysis revealed that only 9 studies incorporated the user- and human-centered design framework in the design and development of prototypes. These studies specifically targeted specific user populations and assessed usability attributes such as satisfaction, ease of use, and effectiveness as part of their evaluation process. Although usability frameworks are available individually for the design and development of wearables and mobile apps [32,177-182], a usability evaluation framework for the combination of these technologies or multi-interface devices is unavailable.

In our scoping review, most of the included studies (57/68, 84%) used qualitative methods, with interviews being the primary method. This corresponds with other studies reporting on evaluation methodologies [183-185]. A survey on the evaluation of physical activity apps highlighted that a substantial number of studies specifically used a mixed methods approach, including randomized controlled trials, to assess the acceptability and evaluate the usability of wearable technologies, with or without companion mobile apps [186]. This approach has gained popularity because of its comprehensive nature and ability to capture diverse perspectives. Among the combinations of methods used, questionnaires and interviews have emerged as commonly used techniques [75,187-189].

Among the 68 studies included in our review, only one-third (20/68, 31%) used a standardized usability questionnaire to evaluate perceived usability. These questionnaires comprise a predefined set of questions presented in a specific order and format, with established scoring rules based on respondents' answers [190]. The SUS questionnaire [191] was used most frequently among the studies analyzed. Although SUS was originally designed as a generic tool for usability assessment across a broad range of digital interfaces and software apps, it may not include items tailored to the specific characteristics and challenges posed by wearable technology. Wearables often involve prolonged and continuous interaction with the user, making aspects such as device comfort and user experience crucial; however, these aspects are not comprehensively addressed by the SUS. Researchers have proposed different adaptations of usability questionnaires tailored to assess the usability of wearables or mobile apps [192-194]. Although this helps to better evaluate the particularities of wearables and mobile apps, they lack items assessing novel usability considerations such as ergonomics, comfort, real-time data feedback, and interaction with the wearable independently or combined with their associated mobile app, which has been identified as important factors by studies [33,73,195,196]. The investigation of these aspects, which are crucial for most systems and apps, has been limited and partial. These observations may be attributed to various factors, including inadequate awareness of available usability questionnaires, the perception that these questionnaires do not align with their specific study, or the belief that the items or constructs within the questionnaires do not adequately reflect the purpose of their evaluation.

Concluding Analysis

We have shown that health care professionals and the medical technology industry acknowledge the importance of high or

adequate usability in new medical equipment, including wearables and mobile apps. In addition, our results highlight the shortcomings in the evaluation and reporting of usability for wearable technologies, necessitating further research on human factors and usability. Literature reviews emphasize concerns regarding the lack of standardized study methodology reporting, guidelines for evaluating usability, and the absence of frameworks or theories for designing comprehensive usability assessments [151,197-199]. According to the reviews conducted by Khakurel et al [27] and Keogh et al [144], the current literature lacks a comprehensive usability evaluation method that effectively addresses usability issues throughout the entire life cycle of a wearable device, from the early development stages to product release. Considering the significance of reliability and wearability in wearable devices, it is imperative to establish traceability in the usability evaluation process. Although researchers are actively engaged in assessing usability, further research is required to identify potential usability attributes, develop suitable evaluation methods and frameworks, and successfully integrate these effective assessments into practice.

Limitations

The goal of this scoping review was to investigate wearable devices and their frequency of use in studies as well as their combination with mHealth apps within the medical domain. Our findings may not completely capture the breadth of usability attributes and their effectiveness in wearables across different contexts. Wearables and their companion apps have demonstrated utility in various use cases and recreational activities, including industrial settings, gaming, museums, and entertainment. By limiting our search to health care–related keywords, we may have excluded valuable insights and perspectives from these alternative domains. Future research could broaden the search criteria to include diverse contexts and use cases beyond health care. This will allow for a more holistic exploration of the potential and effectiveness of usability attributes across different industries and settings.

This study did not aim to synthesize evidence on the effectiveness of usability evaluation methods. Instead, it focused on capturing the diversity of the available literature, encompassing various objectives, critical usability measures, and methods. Consequently, this study primarily serves as an exploratory investigation and provides suggestions for future research in the field.

Conclusions

Our scoping review sheds light on the types and categories of wearable devices, frequency of wearables used in the medical context, their use cases, and the evaluation of their usability. With a wide array of wearables and mHealth apps available, health care providers and manufacturers face the challenge of selecting devices and apps that are effective and user-friendly. The evaluation of usability is crucial for ensuring user engagement and the success of these technologies. As our scoping review shows, there is a lack of standardized frameworks for classifying usability attributes and their subattributes as well as structured evaluation guidelines for wearable technologies. This gap in usability and user experience research hinders the understanding of strengths and limitations in the field of wearable technologies. Therefore, further research is needed to address these limitations and enhance the comprehension of researchers in this field.

Acknowledgments

The authors would like to thank Thomas Ganslandt for his early support and initiation of this scoping review. The authors would also like to thank Fabian Siegel for his support in the execution of this review. The library at the Medical Faculty Mannheim of Heidelberg University played a vital role in assisting with the development and implementation of the search strategy for this scoping review. The extensive knowledge and access to resources of the library staff greatly facilitated a thorough and systematic exploration of the relevant literature for our study. The authors extend their gratitude to the librarian Maurizio Grilli for his valuable support, as it made a substantial contribution to the success of this research. In addition, for the publication fee, the authors acknowledge the financial support from Deutsche Forschungsgemeinschaft within the funding program, Open Access Publikationeskosten, and from Heidelberg University.

Authors' Contributions

PM proposed the idea for this review. PM developed the search strategy, and the strategy was approved by LW, LS, CS, BS, and JM. PM performed the search screenings. LW, LS, CS, BS, and JM screened the titles and abstracts and determined the eligibility of the studies based on full-text examination. PM contributed to the screening process and the full-text examination. LW, LS, CS, BS, and JM extracted data from the included studies. PM proposed the framework for the review, and TN approved it. PM wrote the first draft of the manuscript, and LW, LS, CS, BS, JM, and TN contributed to the drafts of the manuscript. All authors approved the final version of the manuscript.

Abstract

Background: The opioid crisis continues to pose significant challenges to global public health, necessitating the development of novel interventions to support individuals in managing their substance use and preventing overdose-related deaths. Mobile health (mHealth), as a promising platform for addressing opioid use disorder, requires a comprehensive understanding of user perspectives to minimize barriers to care and optimize the benefits of mHealth interventions.

Objective: This study aims to synthesize qualitative insights into opioid users' acceptability and perceived efficacy of mHealth and wearable technologies for opioid use disorder.

Methods: A scoping review of PubMed (MEDLINE) and Google Scholar databases was conducted to identify research on opioid user perspectives concerning mHealth-assisted interventions, including wearable sensors, SMS text messaging, and app-based technology.

Results: Overall, users demonstrate a high willingness to engage with mHealth interventions to prevent overdose-related deaths and manage opioid use. Users perceive mHealth as an opportunity to access care and desire the involvement of trusted health care professionals in these technologies. User comfort with wearing opioid sensors emerged as a significant factor. Personally tailored content, social support, and encouragement are preferred by users. Privacy concerns and limited access to technology pose barriers to care.

Conclusions: To maximize benefits and minimize risks for users, it is crucial to implement robust privacy measures, provide comprehensive user training, integrate behavior change techniques, offer professional and peer support, deliver tailored messages, incorporate behavior change theories, assess readiness for change, design stigma-reducing apps, use visual elements, and conduct user-focused research for effective opioid management in mHealth interventions. mHealth demonstrates considerable potential as a tool for addressing opioid use disorder and preventing overdose-related deaths, given the high acceptability and perceived benefits reported by users.

Introduction

Overview

Since the COVID-19 pandemic, the incidence of opioid overdose has increased significantly among young adults [1,2]. According to research conducted in Canada, there was a 135% increase in opioid overdose–related deaths per week in Ontario during COVID-19 in comparison to prepandemic times [2]. Excess levels of opioids may lead to respiratory depression and cardiopulmonary failure, resulting in loss of consciousness and death [3,4]. It is treated with naloxone, an antagonist that prevents opioid-related fatalities [5,6]. Thus, it is essential to find ways to manage opioid use disorder (OUD) and prevent overdose. A study reviewing smartphone apps that were commercially available until 2019 found that there was a lack of evidence on their ability to be useful for monitoring OUD [7]. The study's authors also reviewed interventional studies involving mobile health (mHealth) for opioid use; most of the reviewed studies included smartphone apps or personal digital assistants, and only a minority of those devices had a wearable biosensor [7]. The authors concluded that there is a gap in the literature and that more studies are needed to address OUD [7].

Since that study was published, there have been technological developments in this area to meet the pressing need that arose during the COVID-19 pandemic. Specifically, new wearable sensors have been developed that monitor sweat, heart rate, and temperature and that predict overdose in patients [7-13]. Several studies have evaluated the application of wearable opioid sensors for detecting overdose by detecting changes in temperature, movement, respiratory rate, heart rate, and electrodermal activity [8,11-17]. Most of the studies involved a wrist-worn biosensor, usually the Empatica E4 biosensor and Q sensor, which integrate a machine learning algorithm. A few studies found that wearable technology can detect changes in skin temperature, notably a temperature rise during opioid intake and overdose [8,12-14,16,17]. Carreiro et al [14] found that the mean skin temperature increase after opioid intake was 2.62 °C and that differences in body temperature before and after intake were significant (P<.01). In addition to temperature changes, several studies found reduced movement or locomotion by evaluating triaxis acceleration data [8,11,13,14,16,17]. Notably, local extremities, such as the fingers, had reduced motion or there was less "fidgeting" after opioid intake. In 1 study, fidgeting was observed more in heavy opioid users than less heavy users [14]. Emerging research also suggests that these devices may be valid for detecting opioid intake and overdose [8,11,16]. For example, Mahmud et al [11] found that the Q Affectiva sensor had an accuracy of 99% for detecting opioid intake in users.

Although emerging technological research in the wearables and mHealth domain suggests that these devices may be promising for detecting opioid overdose and assisting with OUD, little is presently known about the acceptability of this form of monitoring from the patients' perspectives. In other words, a review of qualitative studies on consumer perspectives has not been undertaken. While a device may work in theory, it may fail to be an effective intervention and be implemented within the community care setting if the technology is not acceptable for opioid users or if they do not adhere to the technological intervention. While the quantitative efficacy of these devices has been established in a past review [7], there is a need to understand how usable these devices are for patients. Often, many patients with substance use disorders are difficult to reach and treat due to marginalization or stigma [18-20], making them resistant to accessing medical help [21]. Thus, there is a compelling research interest to determine how patients and opioid users feel about the emerging technological developments that may assist them in managing their substance use and preventing overdose fatalities.

Aims

This study aimed to undertake a review of opioid users' perspectives on mHealth and wearable technology for OUD and overdose management, with a focus on the latest technology developed over the last 5 years. We aimed to better understand whether users found the technology acceptable to use and helpful. We also aimed to better understand the perceived barriers as well as the benefits of using wearables for OUD and opioid overdose management among opioid-using populations. This study focused on qualitative research in order to better understand consumer experiences with wearable technology for OUD, with the overarching goal of making recommendations for future technological development and intervention design.

Methods

Study Guidelines

A scoping review was performed to summarize the use of wearable devices in managing OUD to better understand the key benefits, preferences, and barriers of use. The guidelines of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [22] were followed.

Search Strategy and Study Eligibility

The PubMed (MEDLINE) and Google Scholar databases were searched for all studies published until July 2022 using the search strategy in Textbox 1.

Textbox 1. The search strategy used to search for studies.

"Wearable Electronic Devices"[Mesh] OR wearable*[tiab] OR "Smart Band*"[tiab] OR "Smart Watch*"[tiab] OR mHealth OR "mobile health" OR app OR application OR wristband OR ((sensor*[tiab] OR sensing[tiab] OR biosensor*[tiab]) AND (wear*[tiab] OR worn[tiab]))

(("Analgesics, Opioid"[Mesh] OR "Analgesics, Opioid" [Pharmacological Action] OR Opiate*[TIAB] OR Opioid*[TIAB] OR "fentanyl"[tiab] OR "hydromorphone"[tiab] OR "meperidine"[tiab] OR "morphine"[tiab] OR "oxycodone"[tiab] OR "pentazocine"[tiab] OR "sufentanil"[tiab] OR "tramadol"[tiab] OR "morphine"[MeSH Terms] OR "hydrocodone"[MeSH Terms] OR "hydrocodone"[tiab] OR "buprenorphine"[MeSH Terms] OR "buprenorphine"[tiab] OR "codeine "[MeSH Terms] OR "fentanyl"[MeSH Terms] OR "hydromorphone"[MeSH Terms] OR "meperidine"[MeSH Terms] OR "oxycodone"[MeSH Terms] OR "pentazocine"[MeSH Terms] OR "sufentanil"[MeSH Terms] OR "tramadol"[MeSH Terms] OR OxyContin[tiab] OR Vicodin[tiab] OR "Codeine"[Mesh] OR codeine[tiab] OR morphine[tiab]) AND ("substance use disorder"[tiab] OR "substance abuse"[tiab] OR disorder[tiab] OR abuse[tiab] OR use[tiab])) OR "Opioid-Related Disorders"[Mesh] OR "Opiate use disorder"[tiab] OR "opioid use disorder"[tiab] OR "opiate dependence"[tiab] OR "opioid dependence"[tiab] OR "opiate abuse"[tiab] OR "opioid abuse"[tiab]

Inclusion and Exclusion Criteria

All qualitative studies that evaluated opioid users' perspectives on the latest mHealth wearable devices or portable mHealth devices (including apps and SMS text messaging–based interventions) for monitoring opioid use were included in the review. Quantitative studies were only included if they had a qualitative component or if they had collected more detailed information on acceptability, benefits, and barriers associated with use. The technology must have been emerging and recently developed (within the past 5 years, with a focus on technology during the pandemic). Web-based interventions were excluded if they did not include a wearable or mHealth element.

Data Screening and Extraction

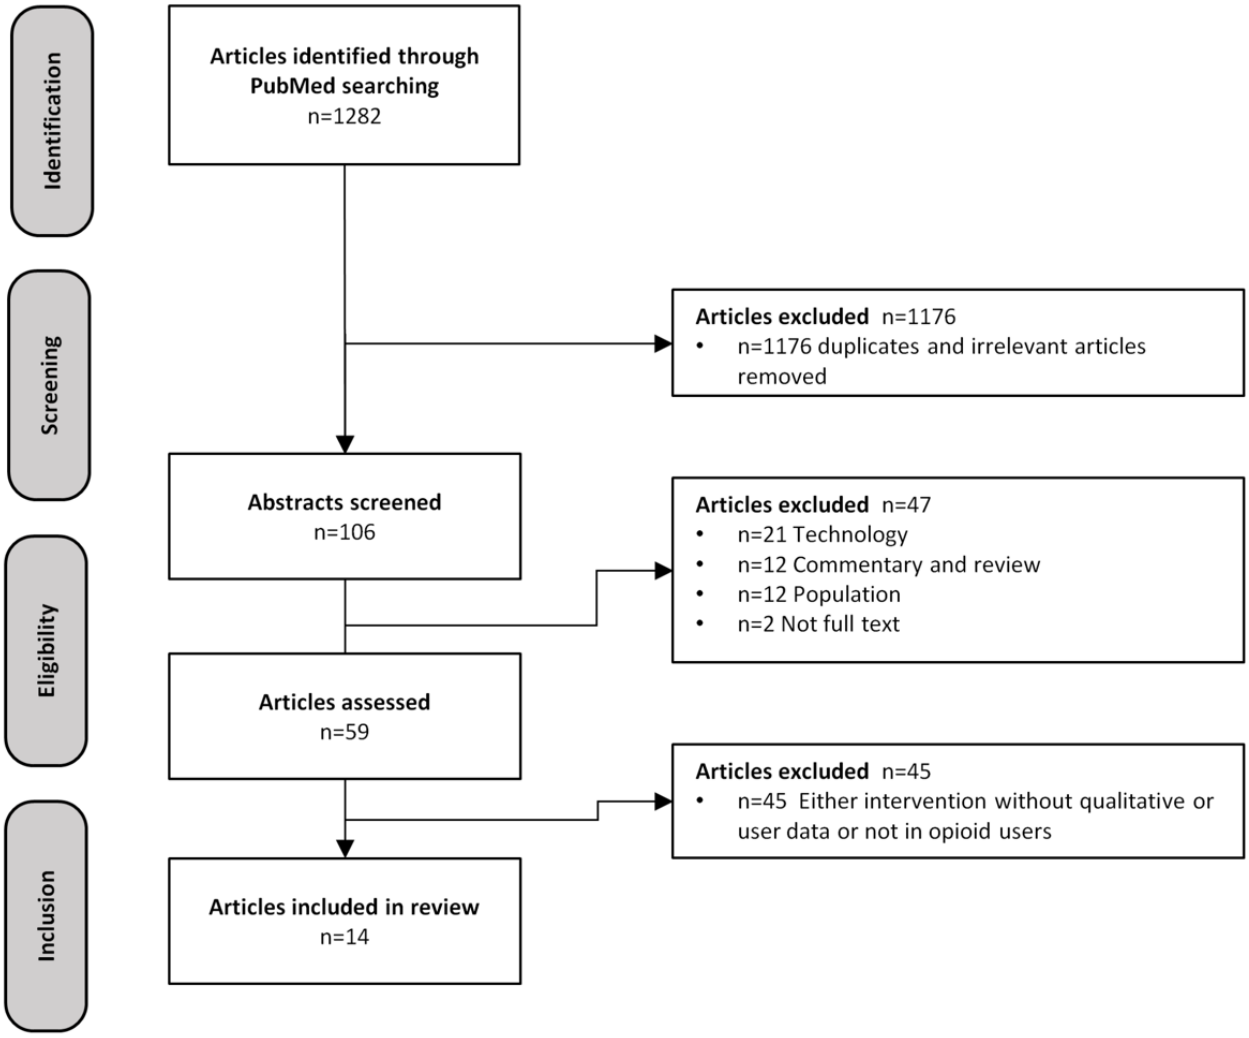
Data were screened according to titles, and abstracts, and followed by full texts of articles meeting inclusion criteria. The 2 reviewers, LNL and ME, screened the articles for inclusion and met when there was disagreement. Data on user perspectives, including benefits, barriers, and preferences, were extracted and summarized in tabular format. General study characteristics, including location, methods, participant age, and gender, as well as the type of technology, were also extracted.

Results

Overview

A total of 14 studies met the criteria and were included in the review [9,23-35]. Details of the search and stages of selection are outlined in Figure 1. Most of the studies were undertaken in the United States. One study was undertaken in Singapore and another in Canada. Most of the studies were relatively evenly distributed by sex, and most participants were middle-aged.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of the study.



Usability, Feasibility, and Acceptability

Overall, the studies that explored the usability and acceptability of mHealth technology for opioid monitoring found relatively high usability and acceptability among the participants. A summary of the key issues and perspectives raised by the participants with OUD is described in Table 1. In Waselewski et al's [34] study, the mean useability score was 86.9 in the participants using opioids; in health care providers, the score was also high at 83.3. Another study found that 71% of the patients had a high level of satisfaction when using a mobile app with telemedicine built-in videos to monitor medication use [23]. In that study, the usability was also high; 93% of the patients did not report having had any technical issues, and 72% submitted their videos using the app [23]. Similarly, a wearable biosensor for overdose monitoring also had a high level of support from participants and a willingness to wear it [25]. Although the study by Hawk et al [24] had a high initial survey response rate (95%), which highlights interest among opioid users, completion of the surveys declined over the course of 1 month, from 97% at baseline to 42% at 4 weeks. Kanter et al [9] found that patients were willing to wear the device to monitor opioid overdose all the time (76%). Most patients were willing to share personal data on their opioid intake [24,31]. For example, in 1 study, 81% of the patients were willing to use the mHealth device to help them taper off opioids [31]. Comfort was also identified as an important factor in determining acceptability and wearability for participants in 2 studies [9,24].

Table 1. Study characteristics.

Study; country; type of study	Number of participants (M%[a] and F%[b]); Age	Technology	Procedure and measures	Results
Waselewski et al (2021) [34]; United States; 6-month pilot with qualitative interview	25 (52% and 48%); mean 33.7 (SD 8.1) years	Hope app for opioid user disorder	Feasibility, usability, and acceptability	• Patient Usability: mean score 86.9 (SD 10.2) • Providers: mean 83.3 (SD 12.8) • Patients liked self-monitoring, enhanced support, communication, and contact with providers
Godersky et al (2020) [23]; United States; N/A[c]	14 (86% and 14%); 18-65 years	mHealth[d] app for opioid and telemedicine (observation of buprenorphine intake) use in the office	Feasibility and acceptability	• 93% had no problems with using the app to share videos • Adherence= 72% • High satisfaction= 71 % of users • Pros: simplicity of use, structure, and personal accountability • Cons: self-portrayal when recording

Hawk et al (2021) [24]; United States; pilot feasibility	101 (43.7% and 57.3%); mean 38.4 (SD 10.25) years	mHealth platform reporting patient outcomes	Feasibility and acceptability	• Registration=95%
				• Declining rate of completion of surveys over time:
				  • Day 1=97%
				  • Day 3= 49%
				  • Month 1=42%
				• Willingness of patients to share data on medication, visits, substance use.
				• Barriers: Wi-Fi connection and access to technology
				• Email retention issues
				• mHealth log-in information retainment
				• patient factors: comfort
				• Privacy is a concern in a minority

Kanter et al (2021) [9]; United States; cross-sectional study with semistructured interviews	97 (57% and 43%); mean 41 (range 37-49) years	Wearable device for opioid detection, overdose, and treatment	Acceptability or likability and willingness to use (usability)	• Theme: privacy or discreetness is important • Theme: comfort when wearing it • Theme: a device that tracks and helps with overdose is needed • Willingness to use an mHealth device for opioid overdose=76% • Wear device continuously=75.5% • Vital sign monitoring=77% • Alerts others of overdose=63% • Watch type of bracelet design preferred=77% • Necklace=51% • Advised giving this to the hardest to reach and treat (eg, opioid intolerant or homeless)
Magee et al (2021) [31]; Australia; N/A	21 (48% and 52%); N/A	mHealth SMS text message supportive intervention	Qualitative acceptability and willingness to use	• Willingness of patients to engage with SMS text messaging to help curtail opioid use (from prescriptions)=81% • App-based support=71% • Desire for education and social support (socioeconomic support) • Barriers: internet; access to technology; visual problems; phone signal strength; poor self-assurance for knowledge around technology such as apps • Adherence could be improved through greater integrated medical or physician care, flexibility with dosing, and regular replies • Pain management advice • Need for support from a person as well • Need for encouragement and motivation
Marcu et al (2020) [32]; United States; N/A	19 (53% and 47%); 18-36 years	Smartphone app for opioid overdose	Acceptability or likability and user perspective	• Positive: mHealth can increase accessibility to care including medical supportive therapy for preventing overdose fatalities • Negative: privacy concerns, geolocation tracking of apps, and theft, and private data in apps

Study; country; type of study	Number of participants (M%[a] and F%[b]); Age	Technology	Procedure and measures	Results
Ahamad et al (2019) [25]; Canada; N/A	1061 (63.1% and 36.9%); median 44.2 years	Wearable opioid biosensor	Factors linked with willingness to wear the device	• Barriers: homelessness • High willingness to wear the opioid sensor • Predictors of openness to try the sensor: Higher in women (aOR[e]=1.41; 95% CI 1.09-1.84) • Those who were on methadone treatment regimes (aOR=1.86; 95% CI 1.45-2.40) and history of overdose (aOR 1.39; 95% CI 1.06-1.83)
Eaves et al (2022) [26]; United States; N/A	27 (0% and 100%); N/A	mHealth app for substance abuse (general opioid and polysubstance abuse, alcohol)	Qualitative 5 focus groups	• Desire to access social services: housing and counseling parenting help • Respectful safe environment • Supportive tone in SMS text messages, connect with social support (peers) and health professionals • Did not want the app to feel like a chore (eg, points earned)
Flickinger et al (2022) [27]; United States; N/A	28 (52% and 48%); mean 33.7 (SD 8.1) years	Hope app and community message board	User engagement and conversation in the app	• Opioid users exchanged supportive messages with one another and physicians through the app • They asked for medical advice=52% • Social support subjects=8% • App related interaction=45%
Glass et al (2021) [28]; United States; N/A	14 (71% and 29%); mean 40.1 (19-65) years	mHealth apps (opioid and cannabis users)	Semistructured interviews	• Apps should be a part of the primary care encounter and communication • Endorsement from medical professionals • Support and interaction with physicians, instructing them • SMS text messaging and professional health support through phone • Convenience • Minimize hassle • Trust essential
Hodges et al (2022) [29]; United States; pilot study	25 (52% and 48%); mean 34 years	Hope app	Self-efficacy and engagement	• Loss to follow-up a problem due to distance • mHealth app usage continued • Reported increases in self-efficacy to abstain
Tofighi et al (2022) [33]; United States; N/A	50 (48% and 52%); mean 44.1 (SD 11.8) years	SMS text message through texting software (ApToto)	Analysis of text messages	• Desire for personally tailored messages • Frequency according to risk profiles • Professional health support • Video-based content and advice • 6% opted out of messages • Reply to SMS text message over month=88% • Buprenorphine advice=2% messages • Cognitive behavioral therapy–based replies=13.8% • Appointments=6.1%
Zhang et al (2019) [35]; Singapore; N/A	30 (66.7% and 33.3%); mean 47.9 (SD 11.8) years	mHealth smartphone intervention for polysubstance (opioid, cannabis)	Thematic analysis and surveys	• App was liked and motivating=54% • Self-efficacy or confidence=33% • Interactive=77% • Easy=100%
Langdon et al (2021) [30]; United States; N/A	24 (50% and 50%); mean 38.9 years	Digital health interventions, computer, and SMS text message–based opioid users	Semistructured interviews on preferences	• Motivational element is essential • Distress tolerance • Assists with learning • Reduces stigma or being judged • Automated and tailored messages • Frequency=2-3 messages per day • Engaging use of media, videos (links), emojis, and GIFs

Perceived Benefits

The synthesis of qualitative research reveals shared advantages among participants regarding mHealth technologies for opioid management. Accessibility stands out as a key benefit, with an emphasis on the pivotal role of behavior change. For example, 1 theme was that the opioid mHealth wearable tracker could provide enhanced access to care, which was perceived to be needed [31,32,34]. This included greater contact with health care services and medical providers [32,34]. These trackers, particularly wearable forms such as bracelets, wristbands, and necklaces, were favored for their noninvasive nature, as mentioned in Kanter et al [9]. Participants in 2 studies recognized a clear need for an opioid monitoring device that would help prevent overdose and fatalities [9,32], echoing the sentiment for an effective opioid monitoring tool. For example, the study by Kanter et al [9] found that 77% of patients reported that wearables were beneficial for monitoring vital signs, while 63% saw their value for alerting bystanders of an overdose. Self-monitoring and accountability were brought up as benefits in 2 studies [23,34]. Convenience and ease of use were also identified as benefits of using wearables for opioid use management [23,28,35]. A total of 2 studies found that a mHealth intervention increased the self-efficacy of opioid users and polysubstance users to overcome substance abuse [29,35], and motivation was brought up as a benefit as well [30,35]. These findings collectively underscore the value of mHealth apps in supporting individuals with OUD through various practical and psychological avenues.

Perceived Barriers

The research across various studies delineates several challenges in the adoption and continuous use of mHealth technologies for opioid management. Privacy stands out prominently as a concern. The apprehension over safeguarding personal health information was paramount, particularly with wearables that track opioid use. Protecting privacy and personal information was one of the main concerns participants had with tracking opioid use through wearable devices [9,32]. Privacy was mainly related to protecting personal and private health information. This included geolocation tracking as well as theft of the device if the patient was unconscious from an overdose [32] as well as concerns with the privacy of electronic health records and log-in information retention [24].

The visibility of the device and the need for it to be inconspicuous during use were significant factors in Kanter et al's [9] study, while Godersky et al [23] identified discomfort with self-viewing during video recordings as a deterrent. These issues underscore the need for privacy in both data handling and physical device usage.

Technological barriers also emerged, with several studies pointing to issues such as unreliable phone reception, limited access to necessary hardware, and inconsistent Wi-Fi connections, as indicated by Hawk et al [24]. These issues are compounded by the digital literacy required to effectively use such apps, with some users lacking the confidence to navigate mHealth technology, as might be inferred from some studies [24,31].

Visual difficulties in interacting with devices were also noted as a hindrance in 1 study [31]. Ahamad et al [25] report that homelessness can be a substantial obstacle to the effective use of wearable biosensors for overdose monitoring. Moreover, Kanter et al [9] suggest that interventions should aim to reach the most vulnerable populations who stand to benefit significantly from mHealth solutions.

The importance of human support in conjunction with technological aids was also mentioned, indicating that personal interaction may bolster adherence to using mHealth apps, a sentiment that could be associated with the insights from Magee et al [31]. These findings highlight the multifaceted nature of the barriers faced and the need for a holistic approach to mHealth implementation for OUD management.

Preferences

The research presents a range of preferences by participants when engaging with mHealth technologies for opioid management. Central to these preferences is the desire for behavior change facilitation through various techniques. The main behavior change techniques (BCTs) that were preferred by participants across the studies included encouragement or motivation [30,31], social and personal support [26,27,31,34], professional support [28,31], education [31,35], and personal tailoring [30,33]. Most notably, participants expressed a desire to have contact with a health care professional and to receive encouragement and educational, motivational, socioeconomic, and social support [26,31,33]. With regard to professional help, some participants wanted to have more medical professionals on board with the app rather than requiring users to navigate the app without professional support [26,28]. Integrated medical care from providers when using the wearables was preferred by participants in 5 studies [26,28,31-33]. For example, the study by Glass et al [28] found that participants preferred to have conversations with their medical providers about mHealth apps as part of their treatment plan. Another study found that 52% of users asked for medical advice from health practitioners while using the app [27].

In addition to this, peer social support was highlighted as being important in 2 studies [26,27], with app-based support being preferred by 71% of participants in another study [31]. Participants in 1 study wanted the mHealth app to integrate social assistance, housing services, counseling, and medical and peer support into the application and treatment regime [26].

Tone was also brought up as a theme in 1 study. Specifically, participants preferred to receive messages with a supportive and respectful tone; moreover, they wanted the technology to feel safe to use [26]. Integration of visual elements, including emojis, video links, and memes, was identified as being important in 1 SMS text messaging study [33]. Trust was an important factor in 2 studies [26,28]. Discreetness was essential, as was the need for mHealth to reduce the stigma associated with substance use [30,32]. In addition to automated messages, personally tailored messages were preferred by the participants

in 2 studies [30,33]. The need for motivation and encouragement was brought up as an important theme in 2 studies [30,31].

Additionally, 2 studies found that participants desired the app to be hassle-free or to not feel like a tiresome exercise to complete [26,28]. The personalization of messages and ease of use are underscored, with participants favoring tailored communication as seen in studies [30,33], and a seamless, nonburdensome interaction with the technology as suggested in 2 studies [26,28]. These preferences highlight the need for mHealth interventions to be user-centered, providing not only the technology but also the necessary human and educational resources to support individuals with OUD.

Discussion

Overview

This study aimed to better understand the perspectives of consumers of wearable technology and mHealth apps for detecting opioid intake and overdose in patients with OUD. Overall, it appears that patients are open to using mHealth technology and wearable devices to help manage opioid-related substance use and detect overdose. The common themes around the ability of technology to save lives and increase access to health care were a benefit that was noted in a few studies. Comfortable wearable sensors also appeared to be important as was technology that protected the user's privacy. Special attention must be paid to protecting the privacy of opioid users, as this was brought up as a concern and a potential disadvantage of the emerging technological interventions. Indeed, patient privacy and data protection are key hallmarks of the ethical principles surrounding modern health technology. Privacy must be protected to prevent unauthorized access to sensitive and personal information.

To manage the technological barriers associated with mHealth apps and wearable devices, users should be trained and reassured of their safety. This will increase their confidence in their ability to use this type of technology to manage their substance use condition. As users in 1 study wanted encouragement and motivation, these BCTs [36] should be incorporated in future interventions [31]. Other BCTs that may be considered include integrating social and professional health support and sending reminders and prompts [37]. Since access to health professionals was identified as being important [31], combining technological interventions with access to physicians and other health care professionals may be desirable. It may also be relevant to integrate theory-informed psychological interventions to increase the users' self-efficacy and motivation to change, such as implementing the Theory of Behavior Change, the Transtheoretical Model of Health Behavior Change, and implementation intentions [38-40]. It would also be relevant to study the stage of change (eg, preparedness vs denial) patients are in and to tailor the interventions accordingly [40]. It would also be interesting to evaluate opioid users' adherence to behavioral changes in a tailored intervention according to their stage of change, their motivation, and their self-efficacy levels.

The technology holds potential given the high usability and willingness of participants to try these wearables and apps. However, future studies should aim to address some adherence issues surrounding completion rates and reaching out to the most vulnerable groups. The decline in survey completion rates over time, as reported by Hawk et al [24], highlights a challenge in maintaining user engagement, and the issue of homelessness, as discussed by Ahamad et al [25], raises concerns about the reach of such interventions among the most vulnerable populations.

Strengths and Limitations

This review is important as it explored user perspectives on mHealth for opioid use management and overdose prevention, providing new insights into consumer acceptability in a newly developing field. We focused on emerging wearables and apps that were evaluated over the past 5 years. A limitation is that we did not explore older devices, but our aim was to focus on the latest technology. It should be noted that the findings of this review are limited by the few studies that have been undertaken on the population with OUD during this period. It is necessary to better understand this population's needs to develop technologically tailored interventions that may best maximize the benefits of assisting with the disorder and preventing fatalities while limiting barriers to using mHealth apps and wearables. More studies are needed to explore future consumer perspectives on mHealth apps for opioid use management. Another limitation is that we did not focus on commercially available apps if they were not evaluated in peer-reviewed medical literature for consumer perspectives. However, our focus was to better understand user experiences; hence, reviewing commercial applications that were not evaluated was not our goal. We also did not focus on efficacy, something that should be further explored alongside mixed methods qualitative research in order to make the best future recommendations.

Here is a list of recommendations for moving this technology forward:

1. Ensure robust privacy measures to address data security concerns, including geolocation tracking and device theft.
2. Provide thorough user training for confident and safe use of mHealth apps and wearables.
3. Integrate more BCTs to potentially increase engagement and positive opioid use management.
4. Provide health care professionals and peer support for enhanced mHealth intervention outcomes.
5. Deliver tailored messages considering participants' needs and preferences for increased intervention effectiveness.
6. Incorporate behavior change theories for enhanced motivation and self-efficacy.
7. Evaluate participants' needs and tailor interventions accordingly.
8. Design stigma-reducing mHealth apps and wearables to promote acceptance and help-seeking.
9. Investigate user perspectives to develop tailored mHealth interventions for effective opioid management.

Conclusion

In conclusion, while mHealth apps and wearables show potential for adoption among patients with OUD, there is a scarcity of studies on consumer perspectives. More research is required to

address the specific needs of this population. Common themes in the reviewed studies highlighted the benefits of using mHealth technology to prevent fatalities and improve accessibility to care. However, participants expressed concerns about data privacy and faced technological challenges. To advance mHealth technology for managing OUD, future development should focus on reducing technical barriers, prioritizing patient privacy, and enhancing access to health care professionals. By implementing our 10 recommendations, we can drive progress in health technology, ensuring user-centered design, increased engagement, and improved outcomes for individuals seeking support in managing their OUD.

Abstract

Background: The COVID-19 pandemic has significantly reduced physical activity (PA) levels and increased sedentary behavior (SB), which can lead to worsening physical fitness (PF). Children and adolescents may benefit from mobile health (mHealth) apps to increase PA and improve PF. However, the effectiveness of mHealth app–based interventions and potential moderators in this population are not yet fully understood.

Objective: This study aims to review and analyze the effectiveness of mHealth app–based interventions in promoting PA and improving PF and identify potential moderators of the efficacy of mHealth app–based interventions in children and adolescents.

Methods: We searched for randomized controlled trials (RCTs) published in the PubMed, Web of Science, EBSCO, and Cochrane Library databases until December 25, 2023, to conduct this meta-analysis. We included articles with intervention groups that investigated the effects of mHealth-based apps on PA and PF among children and adolescents. Due to high heterogeneity, a meta-analysis was conducted using a random effects model. The Cochrane Risk of Bias Assessment Tool was used to evaluate the risk of bias. Subgroup analysis and meta-regression analyses were performed to identify potential influences impacting effect sizes.

Results: We included 28 RCTs with a total of 5643 participants. In general, the risk of bias of included studies was low. Our findings showed that mHealth app–based interventions significantly increased total PA (TPA; standardized mean difference [SMD] 0.29, 95% CI 0.13-0.45; *P*<.001), reduced SB (SMD –0.97, 95% CI –1.67 to –0.28; *P*=.006) and BMI (weighted mean difference –0.31 kg/m^2, 95% CI –0.60 to –0.01 kg/m^2; *P*=.12), and improved muscle strength (SMD 1.97, 95% CI 0.09-3.86; *P*=.04) and agility (SMD –0.35, 95% CI –0.61 to –0.10; *P*=.006). However, mHealth app–based interventions insignificantly affected moderate to vigorous PA (MVPA; SMD 0.11, 95% CI –0.04 to 0.25; *P*<.001), waist circumference (weighted mean difference 0.38 cm, 95% CI –1.28 to 2.04 cm; *P*=.65), muscular power (SMD 0.01, 95% CI –0.08 to 0.10; *P*=.81), cardiorespiratory fitness (SMD –0.20, 95% CI –0.45 to 0.05; *P*=.11), muscular endurance (SMD 0.47, 95% CI –0.08 to 1.02; *P*=.10), and flexibility (SMD 0.09, 95% CI –0.23 to 0.41; *P*=.58). Subgroup analyses and meta-regression showed that intervention duration was associated with TPA and MVPA, and age and types of intervention was associated with BMI.

Conclusions: Our meta-analysis suggests that mHealth app–based interventions may yield small-to-large beneficial effects on TPA, SB, BMI, agility, and muscle strength in children and adolescents. Furthermore, age and intervention duration may correlate with the higher effectiveness of mHealth app–based interventions. However, due to the limited number and quality of included studies, the aforementioned conclusions require validation through additional high-quality research.

Introduction

Background

The COVID-19 global pandemic has had adverse effects on the physical fitness (PF) and mental health of children and adolescents [1]. Before the COVID-19 pandemic outbreak, only approximately 30% of children and adolescents worldwide could meet the recommended levels of physical activity (PA) [2,3]. However, the COVID-19 pandemic has exacerbated this issue by decreasing their levels of PA, increasing sedentary behavior (SB), and leading to a decline in their PF [4]. A recent study in the United Kingdom discovered that children exhibited lower performance scores on the seated forward bend and 20-meter shuttle run test and higher BMI values in 2020 than in 2019 [5]. PF is a crucial determinant of children's and adolescents' health status [6], which can be influenced by various factors, including genetic, environmental, and PA-related factors [7]. Epidemiological studies have established a "dose response" relationship between PA and PF, which showed that increased PA levels and reduced SB were positively associated with improved PF in adolescents [8]. Therefore, the way to increase PA and improve PF is still one of the most important social problems to be solved for children and adolescents.

The rapid advancement of intelligent technology has increased the use of smartphones among young generation and the wide use of mobile health (mHealth) technologies [9,10]. At present, mHealth technologies, including wearable devices, smartphones, tablets, mHealth apps, smartwatches, and pedometers, are commonly used in the field of health care [11]. Recently, 2 systematic reviews have investigated the impact of mHealth-based interventions on behavioral changes, including PA and SB, in children and adolescents [12,13]. However, these reviews primarily concentrated on specific mHealth technology interventions, including SMS text messaging, wearable devices, web-based interventions, and others. Moreover, these systematic reviews exclusively focus on one or more behavioral changes, encompassing physical inactivity and SB, and the overall quality of the evidence is deemed low [13]. Current research indicates that app-based interventions on smartphones may represent the most effective strategy [13]. mHealth app–based interventions are among the most commonly used methods within the realm of mHealth technologies. Among these technologies, mHealth apps have been extensively used in the fitness and medical fields due to their affordability, personalization, and diverse features [14]. mHealth apps can provide quantitative visual feedback regarding the health behaviors of users, such as their PA; meanwhile, users upload their personal information to app databases, and apps facilitate personalized, long-distance, and low-contact training to improve the healthy development of users [15]. In recent years, mHealth app–based interventions have shown significant promise in promoting healthy behaviors, including increased PA and reduced SB, among children and adolescents. Nevertheless, there is a lack of systematic reviews comprehensively summarizing the impacts of stand-alone mHealth apps or concerted interventions using apps as one of the multiple components (eg, behavioral counseling combined with app interventions) on various health behaviors, including PF. In addition, studies in this domain have been predominantly centered on adults, with a noticeable dearth of pertinent research within populations such as children and adolescents [16].

Studies have demonstrated that mHealth app–based interventions can lead to effective outcomes in improving the PA behavior of users [17]. However, another study [18] found that such intervention has indicated only small effects on PA and is likely related to potential influencing factors. Furthermore, the efficacy of mHealth app–based interventions on PF is inconsistent. One study linked lower BMI and higher motor competence to the frequency and type of mHealth app use [19], while another study indicated that mHealth app–based interventions were ineffective in improving PF among adolescents, which is possibly due to the characteristics of the intervention [20]. The use of theory-based mHealth app interventions may also be more advantageous in increasing PA and enhancing PF in children and adolescents [21]. Several theoretical paradigms, including self-determination theory (SDT), the transtheoretical model, the health belief model, the theory of planned behavior, and social cognitive theory (SCT), have been used in mHealth app–based interventions [22]. The number and type of behavior change technique (BCT) clusters may also play a significant role in the effectiveness of mHealth app interventions. Michie et al [23] provided a standardized taxonomy of BCT that categorizes them into 16 clusters, such as feedback and monitoring, reward and threat, goals and planning, shaping knowledge, social support, and comparison of outcomes. This taxonomy aids in identifying which BCT clusters are more effectively applied to apps, thereby enhancing PA promotion and PF improvement. In conclusion, various factors, including the type of mHealth app, intervention characteristics, theoretical paradigms, and BCT clusters, are important considerations in the effectiveness of mHealth app interventions. Despite the increasing number of articles summarizing interventions based on mHealth apps, a noteworthy research gap persists. Most of these articles concentrate on interventions using commercially available mHealth apps that lack evidence-based behavior change strategies. Nevertheless, a significant proportion of users and patients rely on commercially available app-based mHealth interventions that lack empirical evaluation and rarely incorporate evidence-based behavior change strategies. Furthermore, current research predominantly highlights the intervention effects of mHealth apps on health-related outcome

measures. However, there is a notable deficiency in evidence-based mHealth apps intervention programs and studies that integrate various target behaviors.

Objectives

The first objective of this systematic review aims to evaluate the effectiveness of mHealth app–based interventions in promoting PA and improving PF among children and adolescents. The second objective is to specifically assess moderating effects (eg, age, types of apps, theoretical paradigm, BCT clusters, and intervention duration) on the effectiveness of mHealth app–based interventions in subgroups within these studies. Unlike previous studies, our review contributes evidence-based, high-quality content for potential mHealth app interventions addressing PA and PF. This contribution results from a meticulous evaluation and meta-analysis of relevant randomized controlled trials (RCTs). In addition, we conducted an extensive analysis of key moderating variables using subgroups and meta-regression, encompassing theoretical paradigms, BCT clusters, intervention duration, and more. This comprehensive approach enhances our understanding of the factors influencing intervention effects and facilitates the precise quantification of the intervention program. Our endeavors significantly expand the research scope beyond previous reviews.

Methods

Registration and Approval

The systematic reviews were registered on the PROSPERO (CRD42023426532). The literature search, reporting guidance, and implementation process of the study followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [24].

Search Strategy

Several databases were searched, including PubMed, Web of Science, EBSCO, and Cochrane Library, to identify relevant RCTs published until December 25, 2023. The search strategy involved a Boolean search using a combination of subject-related words and free words. The following search terms were used: (Child OR Preschool OR Adolescent), ("Mobile health application*" OR "mHealth app*" OR "Portable Software Application*" OR "Mobile Application*" OR App*), and ("Physical Activity" OR PA OR MVPA OR "sedentary behavior" OR SB OR "Physical Fitness"). A detailed search strategy for Web of Science is presented in Multimedia Appendix 1. We opted to update the searches in the same databases used for the initial search to refine the results for this study. In addition, we examined the references cited in previous reviews to identify additional relevant literature. Concurrently, we reached out to authors of potentially eligible studies to obtain complete data. If >2 attempts were made to contact authors without receiving a response, the study was excluded. The literature search was not restricted by language.

Inclusion and Exclusion Criteria

Inclusion Criteria

The following criteria were included for inclusion in the literature review: (1) The study comprised children and adolescents, aged 3 to 18 years, with the majority falling within this range. Participants did not exhibit physical dysfunction, and overweight or obesity, among other factors, were not exclusionary criteria. Children and adolescents were categorized into 3 groups: preschoolers aged 3-6 years; children aged 7-12 years; and adolescents aged 13-18 years. (2) Interventions using smartphone-based and tablet-based mHealth apps may involve either stand-alone apps (ie, solely apps) or concerted intervention (ie, apps combined with another intervention). The control group comprised genuine controls, such as no interventions, waitlist conditions, and usual clinical care. In addition, active controls, including interventions via apps, were considered. Studies using placebo and sham apps also met the inclusion criteria. (3) The study design was an RCT. (4) Primary outcome measures included PA, SB, performance-related PF (eg, coordination and balance), health-related PF (eg, cardiorespiratory endurance, muscle strength, and body composition), and physiological function (eg, body shape and metabolism).

Exclusion Criteria

The exclusion criteria were as follows: (1) articles written in languages other than English and Chinese; (2) repeated published studies, basic studies, observational studies, reviews, and case series articles; (3) studies for which full text was unavailable or data were incomplete; and (4) mHealth apps that only used SMS text messaging interventions or were incompatible with smartphones or tablets.

Study Selection

After the literature search, the initial search results were imported into EndNote 20 (Thomson ResearchSoft) to remove duplicate articles. Predefined inclusion and exclusion criteria were applied to the literature. Two authors (ZZ and ZS) initially screened the titles and abstracts. Articles meeting the criteria were downloaded, and 1 author (ZZ) thoroughly evaluated the full text based on the inclusion and exclusion criteria, while the other author (ZS) conducted a randomized assessment. Another author (JF) was involved in resolving discrepancies between 2 independent reviewers to determine if a study met the inclusion criteria.

Data Extraction

The included literature was independently extracted by 2 researchers (YJ and ZLG). The extracted information included basic details (eg, authors, publication year, country, and study type), characteristics of the study population (eg, age, gender, and sample size), characteristics of mHealth apps (eg, name, type, theoretical paradigm, and number or type of BCT clusters), intervention characteristics, outcome measures, and indicators related to risk of bias assessment. Two authors (YJ and ZLG) assessed the use of BCT in apps using the taxonomy by Michie [23]. Relevant information was primarily extracted from the study descriptions; in cases of incomplete data, the original apps were consulted. Disputes were resolved through third-party consultation (WDC).

Risk of Bias Assessment

Two independent (YJ and ZLG) investigators assessed the risk of bias using the Cochrane Working Group's tool [25]. Any disagreements were resolved by a third independent researcher (WDC) through consultation. Each study underwent evaluation in 7 domains, and the risk of bias was categorized as unclear, low, or high.

Statistical Analysis

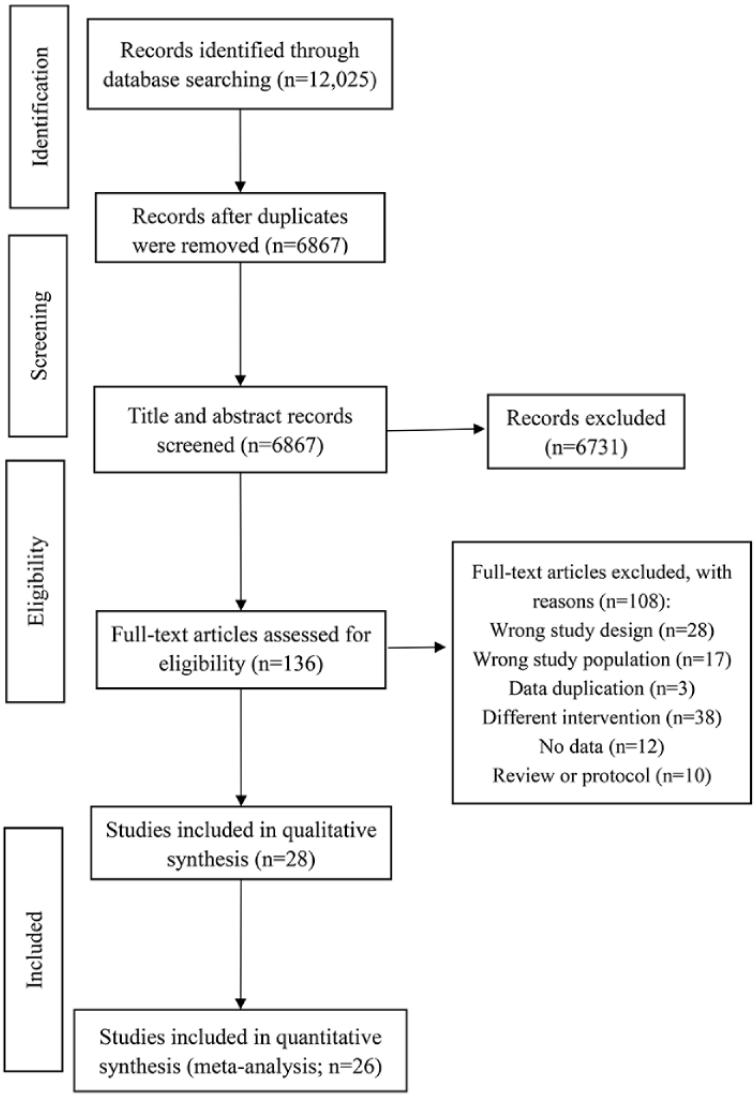
If the number of included papers was <3, then a systematic review was conducted. When a sufficient number of included studies were available for a meta-analysis, we used Revman 5.4 (Nordic Cochrane Center) and Stata 16.0 (StataCorp) to estimate effect sizes, conduct subgroup analysis, and sensitivity analysis. Weighted mean difference (WMD) and 95% CI were used as effect measures when the same measurement method was used. When measurement methods were consistent, the standardized mean difference (SMD) and 95% CI were used. The magnitude of SMD was interpreted as follows: SMD<0.2, negligible; 0.2≤SMD<0.5, small; 0.5≤SMD<0.8, medium; and SMD≥0.8, large [26].

The study indirectly mentioned the mean and SD, and the MD and SMD were calculated as the postintervention mean and SD based on the Cochrane Handbook [27]. The study examined the magnitude of heterogeneity using I^2 and P values. If I^2≤50% and P≥.10, a fixed-effect model was used for data analysis. On the contrary, if I^2>50% and P<.10, a random effect model was used for meta-analysis [27]. The sources of heterogeneity were identified by subgroup analyses and meta-regression analysis based on type of apps, theoretical paradigm, age, and BCT clusters. The robustness of each study was evaluated using sensitivity analysis, and publication bias was assessed with funnel plots and the Egger test. Results

Study Selection

A total of 12,025 relevant articles were retrieved from PubMed (n=69), Web of Science (n=11,033), EBSCO (n=217), and Cochrane Library (n=706). Duplicate references were removed, which resulted in 6867 articles. Following an initial screening by abstracts, 136 articles were identified, which were then assessed by reading the full text. Finally, 28 articles were chosen for inclusion (Figure 1).

Figure 1. Flowchart of the study selection.



Characteristics of the Included Studies

This study included 28 publications, all of which were RCTs published between 2014 and 2023 [20,26,28-49]. The sample size included 5643 subjects, ranging from 12 to 1392 participants per study. As shown in Table 1, the included studies have the following basic characteristics. The age of the participants varied from 3 to 18 years with 5 (18%) of the 28 studies involving preschool children [26,44,46,48,50], 8 (29%) studies involving children [28-31,33,36,37,51], and 15 (53%) studies involving adolescents [20,32,34,35,38-43,45,47,49,52,53]. The objectives of the studies differed, and the selection criteria for the target population varied inconsistently. Most studies (16/28, 57%) focused on healthy children and adolescents; however, of the 28 studies, 9 (32%) included participants with overweight and those with obesity [29-31,35,36,39,43,45,52], 2 (7%) involved children with cancer [34,53], and 1 (4%) enrolled youth with congenital heart disease [40]. Of the 28 studies, 8 (29%) were conducted in Asia [31,36,37,39-41,44,45], while the remaining studies were performed in Oceania (7/28, 25%) [29,30,35,38,46,50,53], North America (5/28, 18%) [28,33,34,43,51], and Europe (8/28, 29%) [20,26,32,42,47-49,52].

This review encompassed 28 studies that used 14 different mHealth apps. These included 9 commercial apps [20,31-33,35,38,41,47,49] and 14 research apps [28-30,39,40,42-46,48,51-53], and 5 mHealth apps did not provide the corresponding information [26,34,36,37,50]. The type of intervention used in 15 studies was stand-alone apps [20,26,28,32,33,40,41,43-47,49-51], and 13 studies used concerted intervention [29-31,34-39,42,48,52,53]. Participant engagement with the intervention was mentioned in 28 studies, 8 studies focused on parent-centered [26,31,36,37,44,46,48,50], the remaining studies were child centered. The mHealth apps were based on various theoretical paradigms, including self-regulation theory (SRT), SDT, and SCT. Different numbers or types of BCT clusters were identified, and they ranged from 1 to 7 clusters. Examples of BCT clusters used included goal setting and planning, feedback and monitoring, and behavioral comparison. Interventions duration lasted 2 to 48 weeks (Table 1). The primary and secondary outcome measures included total PA (TPA), moderate to vigorous PA (MVPA), SB, cardiorespiratory fitness (CRF), BMI, waist circumference (WC), muscle strength, agility, flexibility, muscular power, and endurance.

Table 1. Summary of the intervention characteristics of the included studies.

Study	Participants or population	Age (years)	Sample size（treatment/control）	Interventions	Comparator	Type of mobile health apps	Theoretical paradigm	BCT[a] clusters	Duration（weeks）	Outcomes
Direito et al [20]	Insufficiently active healthy young people	15.7 (+1.2 or –1.2)	32/17	Group 1: immersive app *Zombies Run;* group 2: nonimmersive app *Get Running*	No interventions	Commercial apps	SRT[b]	Feedback and monitoring	8	CRF[c], TPA[d], SB[e], and MVPA[f]

Risk of Bias Assessment

Overall, of the 28 studies, 11 (39%) were classified as having a low risk of bias [20,26,28,29,34,35,37,39,51-53], and a high risk of bias was identified in 17 (61%) studies [30-33,36,38,40-50]. The methods for random sequence generation were adequately reported in 28 studies, and 14 (50%) of the 28 studies described allocation concealment protocols [20,26,29,31,35,37,39,43,46,48,50-53]. Of the 28 studies, blinding of participants and personnel was unclear in 17 studies [20,28-33,38-41,43-45,47,49,51], high risk of bias was identified in 7 (25%) studies [26,34,35,37,50,52,53], and blinding of outcome assessment was unclear in 18 (64%) studies [18,28-34,38,40,41,44,45,47-51,53]. Four studies provided data regarding subjects lost to follow-up [30-32,34], while one study had unclear information on this aspect [51]. None of the 28 studies were found to have selective outcome reporting, and other aspects of bias were evaluated mainly in terms of baseline data and conflicts of interest (Figure 2 [20,26,28-53]).

Results of the Meta-Analysis

Effects of mHealth App–Based Interventions on PA

Of the 28 studies, 21 (75%) were examined to assess the impact of mHealth app–based interventions on TPA. The heterogeneity test indicated a substantial level of heterogeneity among the studies (I^2=75%; P<.001), which led to the adoption of a random effects model for the analysis. The meta-analysis results indicated that the intervention group exhibited higher TPA (SMD 0.29, 95% CI 0.13-0.45; P<.001; Figure 3 [20,28,30,35,37,38,40,41,43,46,47,49-51]), but the effect size was small.

Of the 28 studies, 14 (50%) reported the impact of mHealth app–based interventions on SB levels. Heterogeneity tests revealed homogeneity between the studies (I^2=98%; P<.001), which required analysis using a random effect model. Meta-analysis found that mHealth app–based interventions significantly reduced SB (SMD –0.97, 95% CI –1.67 to –0.28; P=.006; Figure 4 [20,26,29,30,32,34,35,43,44,46,48,53]).

Of the 28 studies, 14 (50%) investigated the impact of mHealth app–based interventions on MVPA levels. The heterogeneity test indicated homogeneity among the studies (I^2=67%; P<.001), which allowed for analysis using a random effect model. There were no significant differences between the control and intervention groups (SMD 0.11, 95% CI –0.04 to 0.25; P<.001; Figure 5 [20,26,29,30,33,34,37,38,41,46,48,53]).

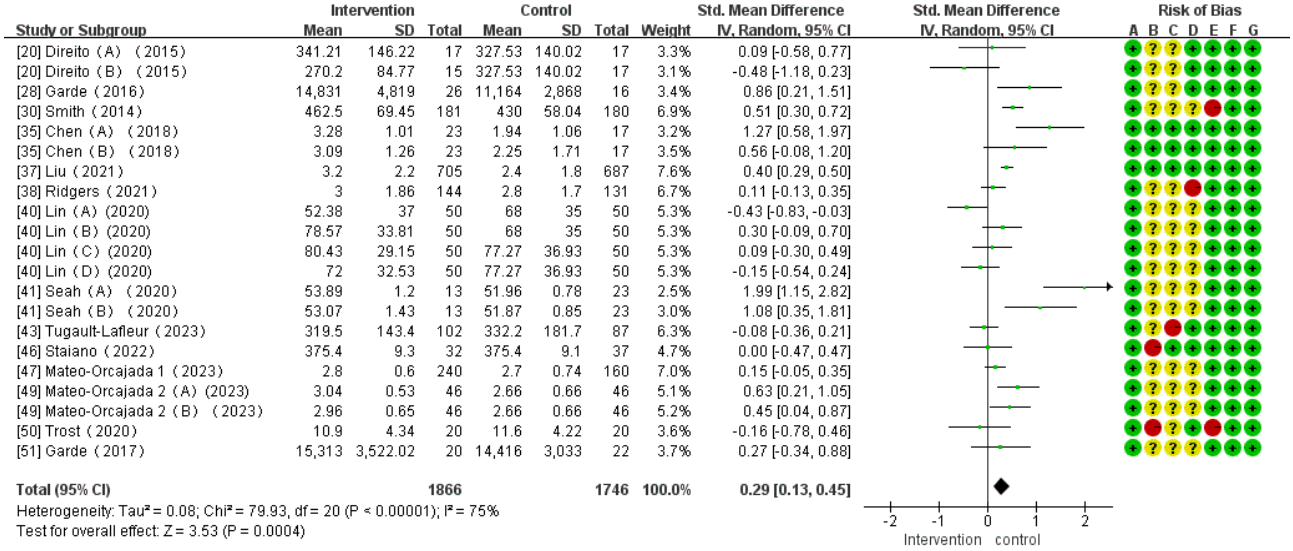

Figure 4. Forest plot of the effect of mobile health app–based interventions on decreasing sedentary behavior.

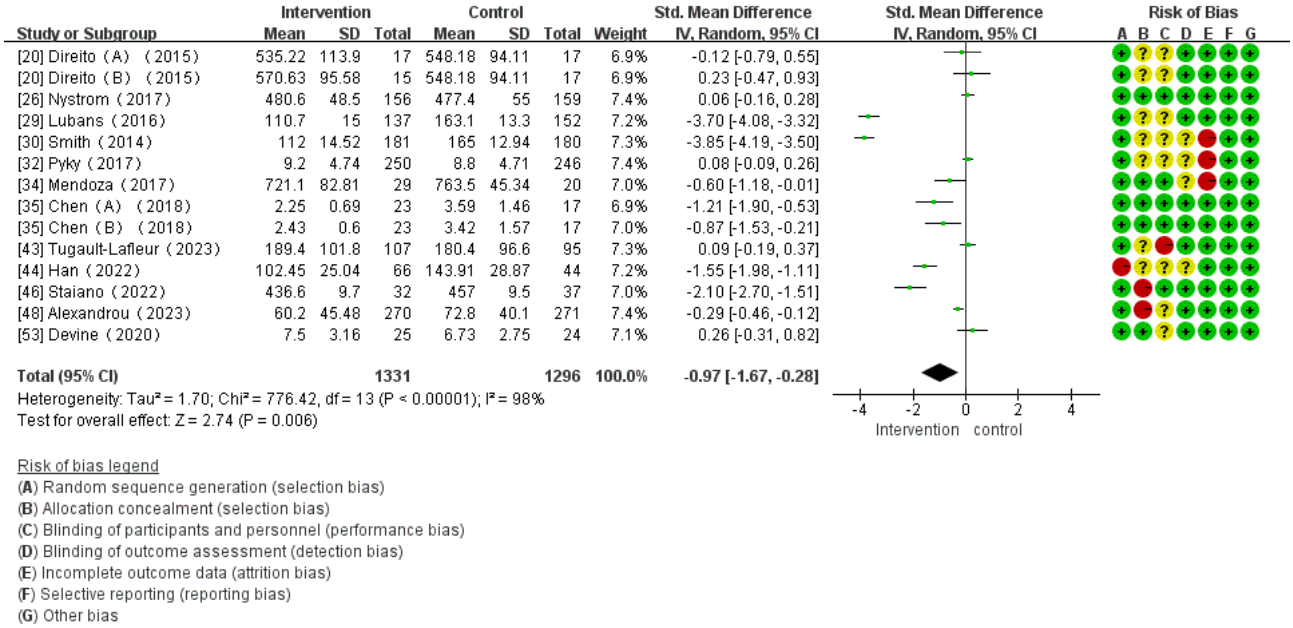

Figure 5. Forest plot of the effect of mobile health app–based interventions on increasing moderate to vigorous physical activity.

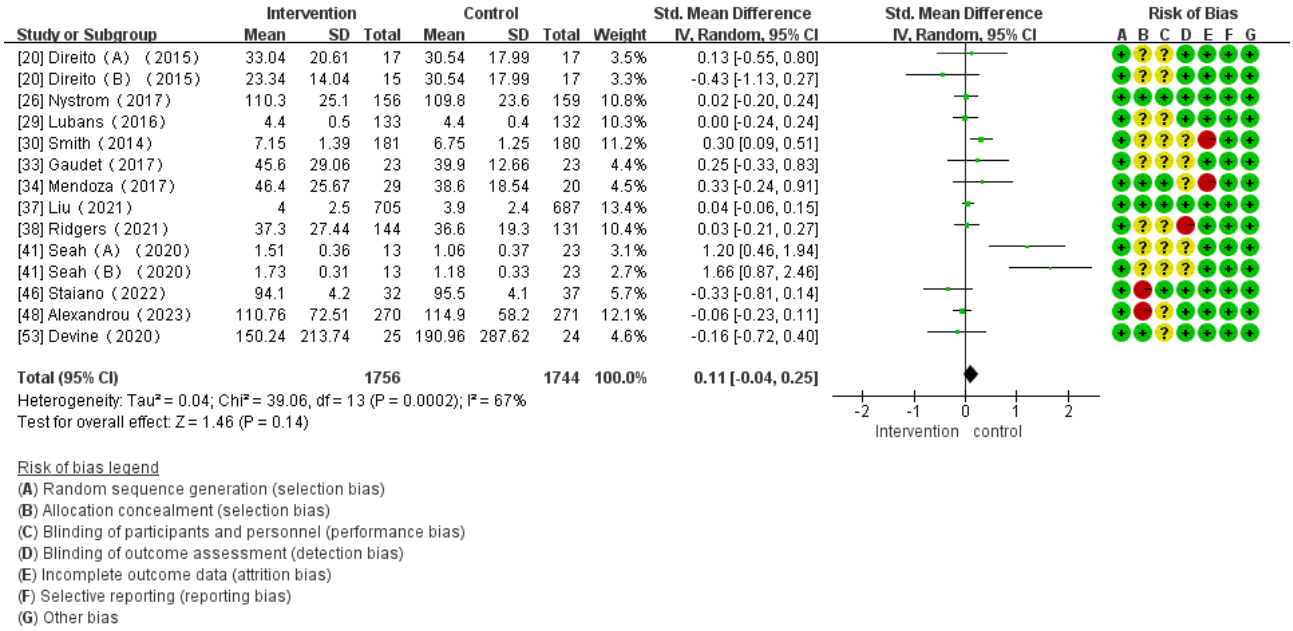

Effects of mHealth App–Based Interventions on BMI and WC

Of the 28 studies, 13 (46%) investigated the effects of mHealth app–based interventions on BMI. Of these 13 studies, 2 (15%) did not directly conduct changes in outcome indicators before and after interventions [31,52] and were only included in systematic reviews. The heterogeneity test demonstrated homogeneity among the studies (I^2=32%; P=.12), which enabled analysis using a fixed-effect model. Meta-analysis found that mHealth app–based interventions significantly reduced BMI (WMD –0.31, 95% CI –0.60 to –0.01; P=.12; Figure 6 [29,30,35-37,39,45,47,49,53]). The 2 other studies on BMI reported a significant reduction in BMI among obese children with mHealth app–based interventions [31,52], which is consistent with the meta-analysis results.

Of the 28 studies, 9 (32%) reported the effect of mHealth app–based interventions on WC. The heterogeneity tests showed homogeneity among the studies (I^2=54%; P=.02), which allowed for analysis using a random effect model. There were no significant differences in WC between the intervention and control groups (WMD 0.38 kg/m^2, 95% CI –1.28 to 2.04 kg/m^2; P=.65; Figure 7 [29,37,39,42,47,49,53]).

Figure 6. Forest plot of the effect of mobile health app–based interventions on BMI.

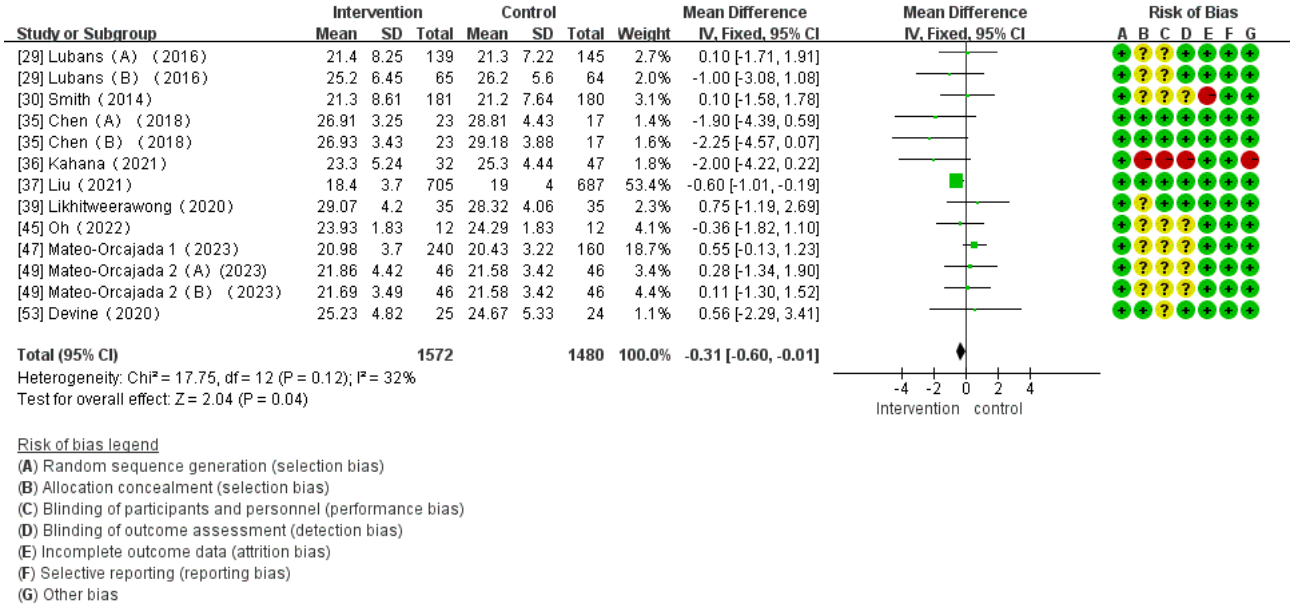

Figure 7. Forest plot of the effect of mobile health app–based interventions on waist circumference.

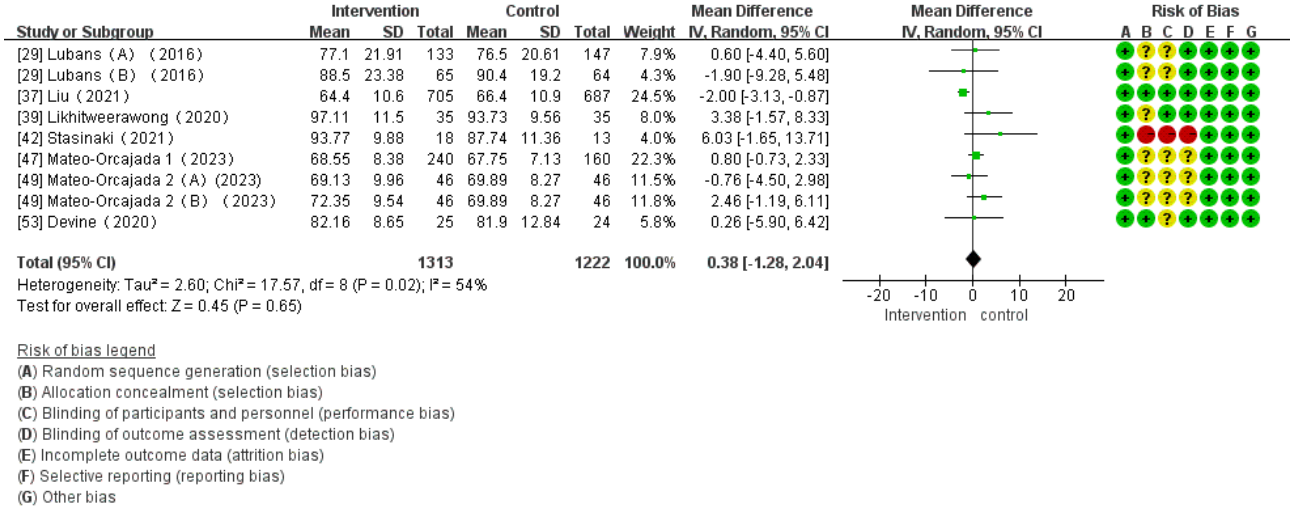

Effects of mHealth App–Based Interventions on PF

Of the 28 studies, 7 (25%) studies investigated the impact of mHealth app–based interventions on CRF. Heterogeneity tests showed homogeneity among the studies (I^2=66%; P=.007) and were conducted using a random effect model. No significant differences were found between intervention and control groups in CRF (SMD –0.20 cm, 95% CI –0.45 to 0.05 cm; P=.11; Figure 8 [20,37,42,45,47,53]).

Of the 28 studies, 6 (21%) reported the impact of mHealth app–based interventions on muscle strength. Heterogeneity tests revealed homogeneity in the studies (I^2=99%; P<.001) and were conducted using a random effect model. Meta-analysis found that mHealth app–based interventions significantly increased muscle strength (SMD 1.97, 95% CI 0.09-3.86; P=.04; Figure 9 [29,30,36,44,47,53]).

Of the 28 studies, 5 (18%) investigated the impact of mHealth app–based interventions on muscular power. The heterogeneity test indicated homogeneity among the studies (I^2=45%; P=.12), which allowed for analysis using a fixed-effect model. There were no significant differences between the control and intervention groups (SMD 0.01, 95% CI –0.08 to 0.10; P=.81; Figure 10 [36,37,42,44,47]).

Of the 28 studies, 5 (18%) examined the impact of mHealth app–based interventions on muscular endurance. The heterogeneity test indicated a substantial level of heterogeneity among the studies (I^2=98%; P<.001), which led to the adoption of a random effects model for the analysis. The meta-analysis results indicated no significant difference in muscle endurance between the intervention and control groups (SMD 0.47, 95% CI –0.08 to 1.02; P=.10; Figure 11 [29,36,37,42,47]).

Of the 28 studies, 3 (11%) investigated the impact of mHealth app–based interventions on agility. The heterogeneity test indicated homogeneity among the studies (I^2=0%; P=.87), which allowed for analysis using a fixed-effect model. Meta-analysis found that mHealth app–based interventions significantly improved agility (SMD –0.35, 95% CI –0.61 to –0.10; P=.006; Figure 12 [36,42,44]).

Of the 28 studies, 3 (11%) reported the impact of mHealth app–based interventions on flexibility. Heterogeneity tests revealed homogeneity in the studies (I^2=52%; P=.12) and were conducted using a random effect model. There were no significant differences in flexibility between the control and intervention groups (SMD 0.09, 95% CI –0.23 to –0.41; P=.58; Figure 13 [42,44,47]).

Sensitivity Analysis

In this study, Stata 16.0 was used to conduct sensitivity analyses on TPA, SB, MVPA, and BMI for evaluating the robustness and reliability of the results. The sensitivity analysis results demonstrated that excluding any single study did not impact the effect size of the mHealth app–based intervention in outcomes such as TPA, SB, and MVPA (Multimedia Appendices 2-4), which indicates the robustness and reliability of the study results. In terms of BMI, sensitivity analyses identified 1 study as an outlier [37] (Multimedia Appendix 5). Removing this study altered the overall effect size, indicating that the study results were not sufficiently robust (SMD 0.03 cm, 95% CI –0.41 to –0.46 cm; *P*=.90) and should be interpreted with caution.

Subgroup Analyses

Overview

Subgroup analyses were conducted to investigate the potential sources of heterogeneity and moderating effects, which considered factors such as age, types of apps, theoretical paradigm, number or type of BCT clusters, and intervention duration. The primary outcome indicators included TPA, BMI, SB, and MVPA. Sensitivity analysis, subgroup analysis, and assessment of publication bias were not conducted for the remaining outcome indicators due to the limited number of included studies.

Subgroup Analyses on the Effect of mHealth App–Based Interventions on TPA

The results of subgroup analyses investigating the impact of mHealth app–based interventions on TPA are presented in Multimedia Appendix 6. Subgroup analyses indicated no significant difference in types of intervention, theoretical paradigm, and the number of BCT clusters concerning the improvement in TPA in children and adolescents.

Age-based subgroup analysis revealed significant positive effects of interventions for children in the 7-12 years group (SMD 0.42) and adolescents in the 13-18 years group (SMD 0.29) but negligible effect for the preschool children in the 3-6 years group (SMD –0.06).

Subgroup analysis based on types of apps revealed a significantly greater effect size for the commercial apps (SMD 0.51) compared to the research apps intervention (SMD 0.13). Substantial heterogeneity existed between these 2 groups (I^2=75%; *P*<.001), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analysis based on intervention duration revealed a significant increase in TPA for the 2- to 4-week intervention (SMD 1.01) and 8- to 12-week intervention (SMD 0.23). Heterogeneity was observed between the 2 groups (I^2=75%; *P*<.001), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup Analyses on the Effect of mHealth App–Based Interventions on SB

The results of subgroup analyses on SB are presented in Multimedia Appendix 7. Subgroup analyses showed no significant difference in intervention duration regarding the reduction of SB in children and adolescents.

Age-based subgroup analysis unveiled a notably larger effect size for interventions directed at children aged 7-12 years (SMD –3.78) compared to the group of preschool children aged 3-6 years (SMD –0.92). Heterogeneity was evident among the 2 groups (I^2=99%; P<.001), and the 95% CI for the effect size between the 2 groups did not overlap.

Subgroup analysis based on the types of apps demonstrated a significantly stronger effect size for research app interventions (SMD –1.38) than for commercial app interventions (SMD –0.35). Heterogeneity was observed between the 2 groups (I^2=98%; P<.001), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analysis based on types of intervention revealed a significantly greater effect size for the concerted intervention (SMD –1.47) compared to the stand-alone apps intervention (SMD –0.45). Substantial heterogeneity existed between these 2 groups (I^2=98%; P<.001), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analyses based on the theoretical paradigm showed a greater effect size for interventions based on the SCT (SMD –0.64) than for interventions based on combination of SCT and other theories (SMD –2.18) and interventions solely based on SRT (SMD 0.05). Substantial heterogeneity existed between these 2 groups (I^2=98%; P<.001), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analysis based on the number of BCT clusters demonstrated a significant reduction in SB for interventions based on 7-10 BCT clusters (SMD –1.03) and interventions based on 4 BCT clusters (SMD –1.36), and the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analysis based on intervention duration revealed a significant reduction in SB for the 20- to 48-week intervention (SMD –1.42) but had a negligible effect at the 8- to 12-week intervention (SMD –0.63).

Subgroup Analyses on the Effect of mHealth App–Based Interventions on MVPA

The results of subgroup analyses on MVPA are shown in Multimedia Appendix 8. Subgroup analyses revealed no significant difference in type of apps, types of intervention, and the number of BCT clusters in improving MVPA in children and adolescents, which were not moderators of the effect of mHealth app interventions.

Age-based subgroup analyses unveiled a notably larger effect size for interventions directed at adolescents aged 13-18 years (SMD 0.42) compared to the group of preschool children aged 3-6 years (SMD –0.05) and children aged 7-12 years (SMD 0.11). Heterogeneity was evident among the 2 groups (I^2=68%; P<.001), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analyses based on theoretical paradigm demonstrated a significant increase in MVPA for SDT-based intervention (SMD 1.03), while no significant effect was observed for SCT (SMD –0.06), combination of SCT and other theories (SMD 0.12), and SRT (SMD –0.14).

Subgroup analysis based on intervention duration revealed a significant increase in MVPA for the 2- to 4-week intervention (SMD 1.42) but negligible effect for the 8- to 12-week intervention (SMD –0.01) and 20- to 48-week intervention (SMD 0.05).

Subgroup Analyses on the Effect of mHealth App–Based Interventions on BMI

The results of the subgroup analyses based on BMI are shown in Multimedia Appendix 9. Subgroup analyses revealed no significant difference in type of apps, theoretical paradigm, and the number of BCT clusters in decreasing BMI in children and adolescents.

Age-based subgroup analysis revealed a significant decrease in BMI for interventions targeting children aged 7-12 years (WMD –0.59), but no significant difference was observed for adolescents aged 13-18 years (WMD 0.03).

Subgroup analysis based on types of intervention revealed a significantly greater effect size for the concerted intervention (WMD –0.59) compared to the stand-alone apps intervention (WMD 0.34), but the 95% CI for the effect size between the 2 groups overlapped.

Subgroup analysis based on intervention duration revealed a significant reduction in BMI for the 20- to 48-week intervention (WMD –0.57) and the 8- to 12-week intervention (WMD 0.33), and the former showed a clearly superior effect.

Meta-Regression

We conducted meta-regressions for TPA, BMI, SB, and MVPA, focusing on statistically significant moderators identified in the subgroup analyses. The results of the meta-regression for TPA (P=.03, 95% CI –1.127 to –0.082) and MVPA (P=.045, 95% CI –2.052 to –0.033) revealed that intervention duration had a potential moderating effect on high heterogeneity; no statistical differences were found for other variables acting as moderators. In the case of BMI, meta-regression results indicated that age (P=.04, 95% CI 0.041-1.473) and types of intervention (P=.02, 95% CI –1.648 to –0.205) could be potential moderators for high heterogeneity, whereas other factors did not significantly contribute to explaining high heterogeneity.

Reporting Biases

Funnel plots were used to assess publication bias in the effects of mHealth app–based interventions on TPA, SB, BMI, and MVPA in children and adolescents. The funnel plots exhibited mostly symmetrical patterns in the 4 studies (Multimedia Appendices 10-13). In addition, Egger test was performed for TPA (t_{20}=0.01; P=.99), SB (t_{13}=–0.135; P=.20), MVPA (t_{13}=1.22; P=.25), and BMI (t_{12}=–0.07; P=.95), and the results

suggested no significant publication bias (Multimedia Appendices 14-17).

Discussion

Principal Findings

We conducted a systematic review and meta-analysis to assess the effectiveness of mHealth app–based interventions in promoting PA and enhancing PF in children and adolescents. This study also examined the potential moderators that may influence the efficacy of these interventions. The findings of this study suggest that mHealth app–based interventions may yield positive effects on TPA, SB, BMI, agility, and muscle strength in children and adolescents. However, no significant effects were observed for MVPA, WC, CRF, muscular power and endurance, and flexibility. Age, theoretical paradigm, BCT clusters, types of intervention, types of apps, and intervention duration were identified as significant moderating factors associated with the increased effectiveness of mHealth app interventions on PA and PF, but the impact on effect size is not entirely consistent.

Overall Effect

PA Levels

The findings of this study indicated that mHealth app–based interventions increased TPA and reduced SB among children and adolescents but had no significant effect on MVPA. Our research findings represent a valuable expansion of recently published systematic reviews; however, they do not entirely align with the results of previous studies. A prior systematic review reported that mHealth-based interventions increased TPA levels and addressed physical inactivity in children and adolescents but did not lead to reduced SB and improved MVPA [12,13]. The inconsistency in the findings may be attributed to the cointervention effect of technologies such as SMS text messaging, wearable devices, web-based interventions, and smartphone apps [13]. Among these, smartphone app–based interventions might be the most effective strategy. The use of apps may contribute to increased SB time. Nevertheless, results of this study indicate that mHealth app–based interventions can effectively reduce SB in children and adolescents. Distinguishing whether the effect is from stand-alone app interventions or other strategies within concerted interventions is challenging. Subgroup analyses in this study demonstrated the superiority of concerted interventions over stand-alone app interventions. In conclusion, mHealth app–based interventions serve as a valuable adjunct in reducing SB in children and adolescents. Further concerted interventions, such as combining educational policies with mHealth apps interventions, are recommended.

The effectiveness of mHealth app–based interventions was influenced by age and intervention format. Notably, these interventions were more effective in improving PA levels among adolescents compared to children, and greater effects were observed when using mHealth apps than when using only SMS text messaging interventions [35,50]. These findings support the conclusions of this study, but some researchers hold differing views. The study by Trost and Brooks [50] indicated that an 8-week intervention with Moovosity apps (Kinetica Group Pty Ltd) improved proficiency in fundamental movement skills (FMS) but did not increase PA levels. The phenomenon may be associated with the types of design and goal setting of the apps. The apps in the study were primarily used to increase the FMS of children, which may have resulted in the activity of FMS replacing the original PA. As a result, the TPA of children was unchanged. Another study [35] identified that targeted app interventions would be effective in reducing SB in adolescents, which must be based on certain theoretical paradigms and BCT clusters. Gamification-based app interventions are also more favorable for increasing TPA and reducing SB levels in children and adolescents and must be combined with the theoretical paradigm, intervention duration, and features of apps [55]. In conclusion, the reasons for inconsistent intervention results may be related to population characteristics, types of apps, theoretical paradigm, BCT clusters, and intervention duration. Moreover, further research is needed in the future.

PF Levels

Another significant finding of the meta-analysis was that mHealth app–based interventions decreased BMI and improved muscle strength and agility among children and adolescents. However, no significant effects were observed for WC, CRF, muscular power and endurance, and flexibility. These findings are not entirely aligned with the results of previous studies. For example, a previous study reported an increase in PA levels among adolescents and significant reductions in sugary drink consumption and BMI following a 3-month intervention using Fitbit Flex apps (Fitbit, Inc) [35]. Meanwhile, a different study [29] indicated that an 18-month app intervention did not lead to significant reductions in BMI and WC, but it improved exercise capacity and reduced screen time. Several potential factors may contribute to the inconsistent results. First, the choice of outcome measure could be a contributing factor. BMI and WC may indicate distinct aspects of obesity; although BMI primarily assesses body size and shape, WC is a measure of abdominal obesity, leading to a weak correlation between the two [56,57]. Moreover, BMI tends to underestimate overweight prevalence when abdominal obesity is considered [57]. Hence, although mHealth app–based interventions show minor effects on BMI in children and adolescents, they might not induce significant changes in WC. Nonetheless, such interventions can still yield favorable outcomes. Another possible reason for the inconsistency in interventions could be related to the age of the population under study. Some studies have shown that mHealth app–based interventions are effective in reducing body weight and BMI in individuals aged ≥45 years, but they are less effective in children and adolescents [58]. In addition, our meta-regression analysis revealed that age significantly influences the effectiveness of app-based interventions. This result could be attributed to the fact that children and adolescents are in a period of rapid growth and development, and the effects of the interventions may be masked by the significant changes in height and weight during this stage.

In terms of muscular strength, power, and endurance, previous studies have shown that a 6-month intervention using mHealth apps and trackers resulted in increased muscle strength among children and adolescents but did not have a significant effect

on CRF [53]; Stasiak et al [42] discovered that a daily conversational agent intervention, using a mobile app for adolescents with obesity, enhanced subjects' muscular fitness, with no discernible difference between the intervention and control groups. Conversely, other studies have indicated that interventions using AIMFIT apps can positively impact maximal oxygen uptake [20]; Mateo-Orcajada et al [47] found that a 10-week after-school intervention for adolescents using mobile step-tracking apps significantly enhanced subjects' upper limb strength, hamstring and lower back flexibility, explosive power of the lower limbs, as well as abdominal muscular strength and endurance. Various factors can influence the effectiveness of interventions, including subject characteristics, intervention dosage, engagement levels, and willingness to use apps. Some of the studies included in this work involved participants who were patients with cancer [53] or children with overweight and obesity [42], and this factor may have influenced the outcomes of the intervention. Furthermore, low user willingness to engage with apps may reduce PA engagement, which consequently impacts the effectiveness of the intervention. Finally, insufficient dosage of mHealth app–based interventions has been associated with a small effect size on TPA in children and adolescents and has shown no increase in MVPA levels. This insufficiency in dosage may explain the lack of intervention effects observed in children.

Moderating Variables on the Effects of mHealth App–Based Interventions for PA and PF

Age

The study results revealed that age moderates the effects of mHealth app interventions on TPA, MVPA, SB, and BMI. Subgroup analysis indicated that mHealth app–based interventions significantly increased TPA and MVPA and reduced SB in children and adolescents aged 7-18 years; increased TPA and MVPA in adolescents aged 7-18 years; and only reduced SB in children aged 3-6 years. It is noteworthy that previous studies have indicated that mHealth app–based interventions did not effectively decrease SB in children and adolescents. This observation may stem from the fact that the use of apps may result in increased SB time, consequently reallocating the time resources of children and adolescents [12]. However, the findings of this study do not support this conclusion. A separate study reported that the intervention using Fit Survivor apps on SB in adolescents was ineffective, which is possibly due to the characteristics of the population; notably, most participants in these studies had cancer, which may require a longer period of SB to observe significant changes [53]. The findings regarding BMI indicate that parent-focused mHealth app–based interventions have not been successful in reducing BMI among children and adolescents [29], somewhat not entirely consistent with the findings of this study. Our meta-regression analysis revealed that age significantly influences the effectiveness of app-based interventions.

This phenomenon may be closely associated with willingness of users and their behavioral intention to use apps. Individual differences, such as age and gender, play a crucial role in moderating willingness and intention of users. In general, behavioral habits and expected performance serve as predictors of willingness and intention of users [59], and age can increase the frequency of use by moderating behavioral habit and performance [60], which in turn have an influence on SB. In addition, most of the app intervention is parenting-focused intervention among preschoolers [61]. The successful implementation of interventions relies on parental involvement, thus parental attitudes significantly influence the participation of preschoolers aged 3-6 years, potentially impacting the efficacy of mHealth app interventions [13]. In the case of children and adolescents aged 7-18 years, increasing age correlates with improved expected performance [62]. In adolescents, this performance expectation is closely linked to user intention, bolstering their willingness to engage with apps. However, older adolescents, who prioritize academic achievement, may exhibit reduced effectiveness in app interventions [63]. In conclusion, the effects of mHealth app–based interventions may vary across different age groups. However, only 4 studies included subjects aged 3-6 years, potentially affecting the generalizability of the findings. Therefore, further validation through a larger number of high-quality studies is warranted to strengthen the conclusions.

Types of Intervention

Concerning types of interventions, there is a lack of systematic reviews analyzing the impacts of stand-alone apps and concerted interventions on PA and PF, including their distinctions. Subgroup analysis revealed that concerted interventions significantly increased TPA and reduced SB and BMI in children and adolescents, whereas stand-alone app interventions had only a modest positive effect on TPA with a small effect size. The findings diverge somewhat from prior research. Some studies indicate that interventions using COOL Passport apps or a combination of COOL Passport apps and game-based interactive platforms do not enhance PA in youth with congenital heart disease [40]. Conversely, other studies suggest that mobile apps can increase TPA while decreasing SB and BMI in youth [46,47]. This phenomenon may be associated with behavior change interventions. Effective behavior change interventions can enhance health status and reduce health care spending, with theory-based interventions often yielding superior results [64]. Hence, interventions based on the high-scoring theoretical paradigm, or in combination with other specific high-scoring strategies, are more likely to yield positive outcomes [65]. In summary, interventions integrating apps with high-scoring strategies are probably more effective than stand-alone apps, although the optimal number and type of strategies remain undetermined.

Theoretical Paradigm

Effective behavior change interventions can improve health status and reduce health care spending, and theory-based interventions generally yielded superior results [64]. Currently, mHealth app interventions use multiple types of BCT that have been shown to be effective in influencing intervention outcomes [21]. Of the 28 studies, 8 (29%) did not use theoretical frameworks in their mHealth app interventions [31,36,37,45,47,49,50,52], while the remaining 20 (71%) studies were grounded in theoretical paradigms such as SCT, SDT, and SRT.

The most commonly used theoretical paradigms in the research are SCT and SDT, and interventions based on these frameworks have demonstrated positive effects on TPA, MVPA, and SB in children and adolescents. Subgroup analysis revealed that interventions based on SDT significantly increased TPA and MVPA in children and adolescents, while interventions based on SCT significantly reduced SB in this population. Previous studies have consistently shown that interventions based on SCT effectively improve PA among adolescents, which aligns with the findings of this study [54]. SCT is commonly used to elucidate the mechanisms underlying the improvement in PA through behavior change interventions. SCT posits that PA is influenced by personal, social, and environmental factors. Personal factors, including self-efficacy, self-management, and expected performance, play a crucial role in enhancing PA and reducing SB. mHealth apps can effectively promote the increase in PA and the reduction in SB by modifying these factors [66].

SDT is frequently used to account for variations in individual behavior resulting from differences in intrinsic and extrinsic motivation. Intrinsic motivation, which is a crucial predictor of PA levels, is lacking in approximately 40% of Europeans; this situation leads to failure to meet the recommended PA levels [67]. In contrast to extrinsic motivation, intrinsic motivation drives the initiation and sustained engagement in individual behaviors. Thus, interventions grounded in SDT can effectively enhance leisure-time PA and PA in physical education classes and reduce SB among adolescents by fostering intrinsic motivation [68]. Furthermore, interventions using mHealth apps based on the health belief model and theory of planned behavior may yield positive effects on increasing PA in children and adolescents. However, which theory yields optimal intervention effects requires further investigation. In conclusion, interventions based on SCT or SDT within mHealth apps may likely yield more effective results. However, due to the limited number of included studies, further validation through a larger volume of high-quality research is necessary to bolster these conclusions.

BCT Clusters

BCT clusters represent specific implementation strategies in behavior change interventions. Previous studies have demonstrated that interventions incorporating a specific number of BCT clusters are more effective in promoting the PA of users. However, further investigation is needed to determine the optimal combination of the number and type of BCT clusters to achieve optimal intervention effects [69].

The BCT clusters that emerged frequently in this study were feedback and monitoring (n=22), goals and planning (n=19), shaping knowledge (n=12), and social support (n=11). A previous study [70] focusing on app interventions targeting PA and SB in adults also identified feedback and monitoring as well as goals and planning as the most commonly used BCT clusters. Another study [16] also highlighted the positive effects of mHealth app–based interventions on PA and SB, particularly when specific BCT clusters such as goals and planning, feedback and monitoring, and social support were implemented. Consequently, specific BCT clusters, including goals and planning, feedback, and monitoring, play a crucial role in influencing the effectiveness of mHealth app–based interventions, ensuring increased TPA, decreased SB, and reduced BMI by enhancing the willingness and engagement of users [71].

Limited research exists on the impact of varying numbers of BCT clusters implemented on PA and PF in children and adolescents. In this study, we discovered that mHealth app–based interventions incorporating 4 and 7-10 BCT clusters resulted in a significant reduction in SB among child adolescents, and the latter showed a greater effect size than the former. Conroy et al [72] reported a mean of 4.2 for the use of BCT in app. The number of studies included in the analysis varies, and most studies used 4 BCT clusters, which is slightly lower than the number of BCT used in previous studies. This discrepancy may be attributed to the characteristics of the subjects [73]. Moreover, more BCT clusters in mHealth apps do not necessarily lead to better outcomes. Excessive use of BCT can decrease the willingness of users and their frequency of app use [74]. Thus, further research is needed to determine the optimal number of BCT clusters.

This phenomenon appears to be strongly associated with the willingness of users and their engagement in using apps. Feedback and monitoring, which involves design patterns enabling users to track their performance or status, play a crucial role in enhancing the trust, motivation, and engagement with the app of users. Consequently, this situation leads to the effective promotion of PA levels and reduction in BMI [75]. Similarly, goals and planning, which involve planned behaviors and the conversion of the intentions of users into actionable steps through self-regulation and self-efficacy, have been shown to improve PA and reduce BMI [76].

Types of Apps and Intervention Duration

The available evidence suggests that commercial apps did not yield improvements in PA or reductions in SB among children and adolescents [20,31-33,35]. However, Jasmine et al [77] found that integrating commercial apps with web-based social networking platforms was effective in improving PA. However, a certain use frequency was needed, and a significant correlation between frequency of use and PA was observed. Our study discovered that research apps significantly reduced SB, while commercial apps increased TPA in children and adolescents, but the effect size was small. However, the effect size was small for commercial apps, which contrasts with our expectations. This discrepancy may be attributed to the design and characteristics of the apps. Commercial app developers often prioritize user interface simplification and the inclusion of complex features to enhance app engagement. However, they may overlook incorporating theoretical frameworks and BCT clusters that are closely associated with intervention effectiveness [78].

An intriguing finding emerged regarding the duration of the interventions. The 2- to 4-week and 8- to 12-week interventions significantly increased TPA, but the former demonstrated superior effectiveness to the latter; 8- to 12-week interventions significantly increased MVPA. Furthermore, the 20- to 48-week intervention significantly reduced SB and BMI in children and adolescents. This finding aligns with the results of previous

studies that short-term mHealth app interventions effectively increased the PA of children, while longer interventions yielded diminished outcomes [40,51]. The results of this study support the notion that intervention effects are closely linked to the willingness of participants to engage. The reason is that shortly after engaging in an mHealth app–based intervention, children and adolescents will experience a sensitive attraction period [79]; prolonged interventions may lead to diminished interest and compliance, thereby weakening the impact. Another plausible explanation is that behavior change interventions rooted in theoretical frameworks yield better outcomes, but they require sufficient time for users to develop habitual behaviors conducive to lasting positive changes, and interventions targeting SB and BMI take even longer. In addition, our meta-regression analysis revealed that intervention duration significantly influences the effectiveness of app-based interventions.

Limitations

This study has several limitations. The search was restricted to English literature, which may introduce language bias and affect the reliability of the findings. Only a limited number of published articles were included, which potentially omit unpublished manuscripts and other sources (eg, conference papers and dissertations) that could contribute to publication bias. The outcome measures used in this study had inconsistent units, and the interpretation of the results using SMD as effect indicators requires caution. PF encompasses multiple dimensions, and different studies focused on various subdimensions.

Most studies (21/28, 75%) encompassed multiple metrics, and some studies (11/28, 39%) were not primarily designed to enhance PA and PF. These factors could have biased the results, potentially limiting the effect sizes and hindering a full reflection of the true effects in this study. Despite our extensive meta-regression and subgroup analyses, only age and intervention period demonstrated significant associations. Heterogeneity for some outcome metrics remained high, and the 95% CIs for the effect size overlapped between groups. Consequently, caution is advised when interpreting partial conclusions from subgroups. Our findings indicate heterogeneity in some studies, and the source of this heterogeneity remains unclear. The effectiveness of mHealth app–based interventions may vary among children and adolescents based on demographics (eg, ethnic backgrounds, regions, genders, and BMI), economic levels, intervention models (parent centered vs child centered), and the degree of app individualization. These factors could contribute to the observed heterogeneity. However, due to limitations stemming from the number and characteristics of included studies, these factors were not analyzed in this study. In conclusion, the findings of this systematic review and meta-analysis should be interpreted cautiously.

Conclusions

The findings from a systematic review and meta-analysis indicate that mHealth app–based interventions hold significant potential as a therapeutic strategy for increasing TPA levels, reducing BMI and SB, and improving agility and muscle strength among children and adolescents. However, these interventions insignificantly affected MVPA, WC, CRF, muscular power and endurance, and flexibility, which are crucial for promoting PA and enhancing PF. Age, app types, types of intervention, theoretical paradigms, BCT clusters, and intervention duration emerged as important moderating variables that influence the effectiveness of mHealth app–based interventions. These moderating effects should be considered during the design, preparation, and promotion of interventions.

Considering the potential benefits of using mHealth apps, future research should explore the combination of different types and quantities of mHealth app–based interventions to determine the optimal approach for increasing PA levels and improving PF in children and adolescents. Furthermore, future studies could investigate the impact of additional influences on the intervention effectiveness of mHealth app interventions, such as demographics characteristics, economic levels, and intervention models.

Acknowledgments

The authors would like to thank the staff and faculty at the Institute of Sports Medicine and Health at Chengdu Sport University, which offered the funding support and the place to conduct the study. This study was funded by the National Social Science Fund (grant 22BTY063), the Key R&D Projects of the Sichuan Provincial Science and Technology Plan Project (grant 2022YFS0053), the Soft Science Project of Sichuan Provincial Department of Science and Technology (grant 2022JDR0314), the Key Project of Sichuan Provincial Philosophy and Social Science Foundation (grant CJJ23ND77), the Sports Medicine Key Laboratory of Sichuan Province and Sports Medicine Key Laboratory of State Sport General Administration (grant 2024-A002), and the “14th Five Year Plan” Scientific Research and Innovation Team of Chengdu Sport University (grant 23CXTD02).

Authors' Contributions

JWW designed the study protocol and drafted the report; ZZ, ZS, and JF searched the literature, analyzed the data, and interpreted the results; YJ, ZLG, and WDC contributed to the study protocol and reviewed the manuscript; and XL reviewed and revised the manuscript.

Abstract

Background: Motion tracking technologies serve as crucial links between physical activities and health care insights, facilitating data acquisition essential for analyzing and intervening in physical activity. Yet, systematic methodologies for evaluating motion tracking data, especially concerning user activity recognition in health care applications, remain underreported.

Objective: This study aims to systematically review motion tracking in daily living and physical activities, emphasizing the critical interaction among devices, users, and environments from a design perspective, and to analyze the process involved in health care application research. It intends to delineate the design and application intricacies in health care contexts, focusing on enhancing motion tracking data's accuracy and applicability for health monitoring and intervention strategies.

Methods: Using a systematic review, this research scrutinized motion tracking data and their application in health care and wellness, examining studies from Scopus, Web of Science, EBSCO, and PubMed databases. The review used actor network theory and data-enabled design to understand the complex interplay between humans, devices, and environments within these applications.

Results: Out of 1501 initially identified studies, 54 (3.66%) were included for in-depth analysis. These articles predominantly used accelerometer and gyroscope sensors (n=43, 80%) to monitor and analyze motion, demonstrating a strong preference for these technologies in capturing both dynamic and static activities. While incorporating portable devices (n=11, 20%) and multisensor configurations (n=16, 30%), the application of sensors across the body (n=15, 28%) and within physical spaces (n=17, 31%) highlights the diverse applications of motion tracking technologies in health care research. This diversity reflects the application's alignment with activity types ranging from daily movements to specialized scenarios. The results also reveal a diverse participant pool, including the general public, athletes, and specialized groups, with a focus on healthy individuals (n=31, 57%) and athletes (n=14, 26%). Despite this extensive application range, the focus primarily on laboratory-based studies (n=39, 72%) aimed at professional uses, such as precise activity identification and joint functionality assessment, emphasizes a significant challenge in translating findings from controlled environments to the dynamic conditions of everyday physical activities.

Conclusions: This study's comprehensive investigation of motion tracking technology in health care research reveals a significant gap between the methods used for data collection and their practical application in real-world scenarios. It proposes an innovative approach that includes designers in the research process, emphasizing the importance of incorporating data-enabled design framework. This ensures that motion data collection is aligned with the dynamic and varied nature of daily living and physical activities. Such integration is crucial for developing health applications that are accessible, intuitive, and tailored to meet diverse user needs. By leveraging a multidisciplinary approach that combines design, engineering, and health sciences, the research opens new pathways for enhancing the usability and effectiveness of health technologies.

Introduction

Daily Living and Physical Activity in Health Care

Motion tracking data are pivotal for understanding physical activity in hospitalization and rehabilitation [1,2]. However, the procedures for investigating motion tracking data have not yet been systematically reported, especially in the context of user activity recognition in health care application studies. Several findings indicate that living patterns, such as daily activity trajectories, physical activity, and dietary behaviors, are associated with the initial stages of disease development [3-5]. Inadequate daily physical activity exacerbates symptoms of mental distress and contributes to medical illnesses, including cardiovascular and kidney diseases [6,7]. Conversely, regular physical activity can enhance wellness by activating the immune system and reducing inflammation [8,9]. Monitoring activities of daily living (ADLs) [10] is vital for self-care and long-term health [11,12], making the analysis of daily living and physical activity data crucial for disease prevention and promoting a healthy lifestyle.

A comprehensive analysis of motion tracking data in daily living and physical activities scenarios is essential for delving into human activity patterns and behavior intentions. Research shows that activity patterns are linked to behavior intentions [13,14], and motion data help uncover these patterns, improving diagnostic efficiency [15]. The motion data of ADLs represent activity patterns [16,17], while the formation of these patterns is multifaceted [18], with external influences playing a role [19]. Accumulated movement behaviors, when stimulated by the environment, become habitual actions [20,21]. By analyzing the motion data of ADLs, researchers have found that the formation of activity patterns is attributed to individuals' cognitive representations [22] and environmental factors, such as sedentary behaviors in working and learning spaces [10,23], as well as daily routines at home [24]. Thus, motion tracking data, enriched by environmental context, effectively represent and interpret human behaviors across different settings.

When applied as representations of ADLs, motion data can facilitate behavioral change through interventions. The analysis and visualization of motion data concerning ADLs can potentially enhance mutual understanding between physicians and patients in medical education and remote clinical consultations [25,26]. Patients' trajectories of past daily activity and medical histories are essential indicators for physicians to understand symptoms [27]. Human physical activity patterns can reflect the formation of disease and aid in the prevention and management of illness conditions [28,29]. In addition, many researchers have devised human activity interventions and suggested that early care physical activity interventions are feasible for promoting healthy lifestyles [30,31].

Motion Tracking Technology

The evolution of motion tracking technologies in health care has transitioned from basic motion detection systems aimed at rehabilitation to artificial intelligence (AI)–enhanced wearable sensors for personalized care. Early systems focused on simple motion detection, primarily for rehabilitation [1]. Advancements led to the inclusion of wearable sensors and AI for personalized health care [32]. Recent developments have embraced Internet of Things (IoT) frameworks for more comprehensive health monitoring [33]. In addition, the shift toward patient-centered care has been facilitated by technologies that assess and support daily activities and physical functions [11,34]. The integration of machine learning and sensor data fusion has further enhanced the ability to monitor and analyze patient movement in real time, contributing to preventive health care and improved treatment outcomes [12,35]. Researchers in health care and computer science have discussed the possibility of using motion tracking. Data classification, precision, validity, and diagnostic prediction in activity recognition are popular areas of investigation [36,37]. Several studies have also discussed how collecting voluminous data might contribute to personalized health surveillance systems [32,33]. Furthermore, scholars in computing have claimed that high-quality data would enhance data-driven AI processing [38,39]. IoT, with motion tracking techniques (eg, inertial measurement unit, smartphone, smartwatch, Mocap system, etc) [40,41] and AI processing (eg, human activity recognition, positioning system, etc) [35,42], have been widely used. It is anticipated that AI processing using high-quality motion tracking data would provide accurate and timely health information. For instance, smartphones with built-in motion-tracking sensors can record activity trajectories and routine data to identify activity types and patterns [43]. Studies have also found that motion data can be used to learn about humans' typical behaviors and identify any outlier activities [44,45]. Moreover, it can boost individuals' likelihood of engaging in physical activity over the long term, which is associated with habit formation [46,47].

However, the data interpretation of human activity trajectories, environment, and process has not been discussed as extensively as technology. Conversely, several studies have reported that learning from health information could promote health literacy [48,49]. Yet, the public has a long-standing misunderstanding of technology [50,51]. The technology-based health information needs to be in readable language [52,53]. In the meantime, the foundational criteria (ie, ease of use, usefulness, and enjoyment) of the technology acceptance model (TAM) provide insights to evaluate human-technology interaction [54,55]. TAM exemplifies the 3 needs of humans in interpreting technology-based health information.

The Usability of Motion Tracking Data

Designers play a key role in making data legible, efficiently transmitted, and actively engaging for users [56-58]. To optimize the utility and interpretability of motion tracking for both professionals and users, designers should gather health information needs from the user's cognitive standpoint, thereby refining the functionality and analytical clarity of motion-tracking systems [59,60]. The adoption of data-enabled design (DED) [61-63] in health care emphasizes continuous data refinement and context-specific design. On the basis of these, health care–related applications, as intelligent solutions [62], should integrate data, users, and environments to optimize the transmission of health information and the intelligent ecosystems. Scholars asserted that design studies could illuminate the nature of nonsocial entities, such as data, to create durable systems [64,65]. This approach has been implemented

in designing health interventions [66,67]. It overcomes the barrier between people and technology, offering guidance for enhancing the sustainable hybridization of the social and the technical entities.

Motion tracking serves as a bridge, delivering activity data to health care professionals and users. Understanding data collection and analysis is vital, involving motion data (eg, trajectories and durations) and environmental elements in physical settings. Analysis entails identifying and classifying activities. Yet, interactions among researchers, participants, devices, and environments are seldom explored. Therefore, it is critical to methodically study these interactions within health care applications and their environments.

Integrating Actor Network Theory in Research

In health care application research on ADLs, interactions occur between participants, sensors, cameras, and scenario objects. The actor network theory (ANT) has been instrumental in analyzing these interactions within a network [68,69], especially in human-computer interaction and design studies [70]. ANT outlines three critical aspects for network analysis: (1) actor-led activities, where initiators, such as individuals or devices, lead activities and interact with others; (2) purpose-oriented interactions, which serve as the guiding principle for activities; and (3) the dynamic interplay between devices, environmental factors, and individuals, shaping the network. Integrating ANT into motion tracking data analysis illuminates the movement trajectories and environmental influences, clarifying human-device-environment relationships.

Objectives

Prior research has thoroughly examined motion tracking in health care, mainly focusing on algorithm validation and technology deployment for rehabilitation and hospitalization [42,71]. Meanwhile, several studies have reviewed the benefits of physical activity for medical purposes [10,26]. However, systematic reviews exploring the use of motion tracking techniques in ADLs and their connection with humans for health care and physical wellness research are scarce. Furthermore, studies investigating the process of analyzing ADLs for health care applications are even rarer. This study shifts focus to motion data, participant engagement, and situational contexts as key components in health care technology. It delves into how participants interact with technology in physical environments, technology adoption, and participant behavior. This systematic review aimed to map and collate literature on the motion tracking data of daily living and physical activities for health care and physical wellness application research. It aimed to evaluate the research landscape, identify literature gaps, and endorse a designer-engaged approach to studying ADLs. The overarching research questions are as follows:

1. How was the motion tracking technique used in ADLs for health care–related studies and physical wellness applications?
2. What are the environmental factors, interactions, and processes of ADLs in health care and physical wellness application research?
3. What is the design opportunity in health care and physical wellness application research?

Methods

Overview

Our research focuses on investigating the motion tracking data, interaction, and process of ADLs in health care and physical wellness applications from the designers' perspective. Owing to the exploratory and descriptive nature of our research question, we opted for a systematic review [72,73], with the aim of compiling and comprehensively summarizing the relevant research. To guarantee rigor and coherence with our research objectives, 2 researchers meticulously screened the studies for inclusion. These 2 researchers independently conducted screening work on the same data set and met weekly for discussions. Following 5 detailed discussions about the screening methodology, centered on eligibility criteria and research focus, we conducted 2 pilot searches to refine our search strategy and ensure the accuracy of our results. In addition, we discussed the framing of questions being addressed with reference to participants, interventions, comparisons, and outcomes (PICO) [74], ensuring a comprehensive and structured approach to our review (Table 1). The overarching goal of the systematic review is to identify and map the available evidence investigating the technology use in everyday health care and physical wellness apps and its relationship with humans and environments. We then applied ANT [68,69] to analyze the interaction in activity scenarios and used design narrative through the lens of DED [62] to analyze the process of motion tracking data in health care and physical wellness application research scenarios.

Given the independent nature of technology, user behaviors, and environments in our research, we developed bespoke criteria for bias assessment. This approach enabled 2 independent reviewers to identify potential biases in study design, execution, and reporting accurately. Discrepancies between reviewers were resolved through consensus, ensuring a balanced evaluation. To further validate our review, we engaged relevant scholars to critique the search strategies of both pilot and final searches stages, substantially enhancing the review's validity and comprehensiveness. Our thorough assessments of potential biases, both at the study and outcome levels, were integrated into our data synthesis, paving the way for a credible interpretation of the evidence (detailed in Multimedia Appendix 1 [75-128]).

Table 1. Search term– and strategy-based participants, interventions, comparisons, and outcomes (PICO) framework and research questions.

Component	Details	Search terms	Search strategies
Population	• General public, including special populations such as children, pregnant women, older adults, people with disabilities, and athletes	N/A[a]	N/A
Intervention	• Use of motion tracking techniques in ADLs[b] and physical activity scenarios	Motion tracking	TITLE-ABS-KEY (“motion capture” OR “MoCap” OR “motion analysis” OR “motion tracking” OR “body positioning” OR “human activity recognition” OR “IMU” OR “dynamometry”)
	• Application of AI[c] processing for activity classification and analysis; or using devices (including sensors, motion capture technology, IoT[d] devices, VR[e], AR[f], and MR[g])	IoT, AI, VR, and AR	TITLE-ABS-KEY (“Internet-of-things” OR “IoT” OR “wearable” OR “virtual reality” OR “augmented reality” OR “mixed reality” OR “machine learning” OR “deep learning” OR “decision making” OR “artificial intelligence” OR “AI”)
Comparator	• Variation in technology use, sensor placement, and participant interaction across different studies	N/A	N/A
Outcome	• Identification and classification of daily living and physical activities within health care and physical wellness applications • Understanding of environmental factors, interactions, and processes in health care and physical wellness applications • Exploration of design opportunities in health care and physical wellness applications	Health and sport application	TITLE-ABS-KEY ([“sport” OR “kinematics” OR “sport analytics” OR “wellness” OR “health”] AND [“smart health” OR “healthcare” OR “health monitoring” OR “health of things” OR “digital health” OR “mobile health system” OR “behaviour change” OR “decision making”])

[a]N/A: not applicable.

[b]ADL: activity of daily living.

[c]AI: artificial intelligence.

[d]IoT: Internet of Things.

[e]VR: virtual reality.

[f]AR: augmented reality.

[g]MR: mixed reality.

Selection Criteria

Study Types

Original research articles published in scientific, technical, and medical journals in English from January 2013 to December 2022 were considered. Reviews, conference abstracts, magazines, and newspaper articles were excluded. We concentrated exclusively on studies encompassing ADLs, specifically within the realms of health care and physical wellness application research, to ensure the relevance of motion tracking technology to real-world health and wellness contexts. Eligibility for inclusion was determined for studies using motion-tracking sensors, motion capture technology, IoT devices, multiple sensors capable of motion tracking, virtual reality (VR) or augmented (mixed) reality, or AI, highlighting our focus on advanced technologies that offer innovative approaches to monitoring and enhancing health-related activities. Eligible populations include the general public as well as specific demographics including children, pregnant women, older adults, individuals with disabilities, and athletes. Exclusions were applied to studies that (1) focused on technology or materials development (ie, technical validation), as our interest was in direct applications of technology in health and wellness, rather than preliminary stages of technological development; for instance, one research focused on preliminary technology validation without applying findings to enhance health-related activities, missing our application-focused criteria, although it mentioned motion tracking, smart systems, inertial measurement unit, and ADLs [129]; (2) presented a data set without further analysis, as our aim was to understand the implications of data on ADLs, necessitating detailed data interpretation; (3) investigated activities in clinical scenarios such as injury, impairments, hospitalization, rehabilitation, etc, because our focus was on everyday activities rather than those strictly within clinical settings; (4) were applied to nonhuman subjects to maintain the applicability of findings to human health and wellness; or (5) did not include any user study results or did not clearly explain their findings, as comprehensible and applicable user data are crucial for informing practical health care and wellness interventions (Textbox 1).

Textbox 1. Eligibility criteria for considering the studies in the review.

Inclusion criteria

- Study types
  - Original research articles published in scientific, technical, and medical journals in English from January 2013 to December 2022
  - Studies that encompass activities of daily living (ADLs) or physical activity within the scope of health care and physical wellness application research
  - Studies using motion-tracking sensors, motion capture technology, internet of things (IoT) devices, multiple sensors capable of motion tracking, virtual reality (VR) or augmented (mixed) reality (A[M]R), or artificial intelligence (AI)
- Population
  - General public, including special populations such as children, pregnant women, older adults, people with disabilities, and athletes
- Materials
  - Research investigating the use of motion tracking for ADLs analysis
  - Studies using motion-tracking sensors, motion capture technology, or multiple sensors for motion monitoring, analysis, visualization, or providing feedback
  - Research integrating a combination of AI processing, IoT devices, or VR (A[M]R) technologies
  - Studies integrating motion tracking data and AI technology for the classification of ADLs
- Comparison
  - Variation in technology use, sensor placement, and participant interaction across different studies
- Research outcomes
  - Measures or indexes describing the activity in health care or physical wellness application research (eg, daily human activities, physical activities, or daily activities of special populations)
  - Studies focusing on the use of motion tracking for monitoring, analyzing, visualizing, or providing feedback
  - Research related to health care or physical wellness system design

Exclusion criteria

- Study types
  - Reviews, conference abstracts, magazines, and newspaper articles
  - Studies focused on technology or materials development (technical validation)
  - Research presenting a data set without further analysis
  - Investigations in clinical scenarios such as injury, impairments, hospitalization, rehabilitation, etc
  - Studies applied to nonhuman subjects
  - Studies that did not include any user study results or did not clearly explain their findings
- Population
  - Investigations in clinical scenarios such as injury, impairments, hospitalization, rehabilitation, etc
  - Studies applied to nonhuman subjects
- Materials
  - Studies not using the described technologies or not focused on the specified applications within health care and physical wellness
- Research outcomes
  - Outcomes not related to the activity in health care or physical wellness application research, or those not providing meaningful insights into monitoring, analysis, visualization, or feedback within these contexts

Materials

Health care or physical wellness application research investigated the use of (1) motion tracking for the analysis of ADLs; (2) motion-tracking sensors, motion capture technology, or multiple sensors for motion monitoring, analysis, visualization, or providing feedback in ADL scenarios; (3) a combination of AI processing, IoT devices, or VR or augmented (mixed) reality technologies; or (4) integrating motion tracking data and AI technology for the classification of ADLs.

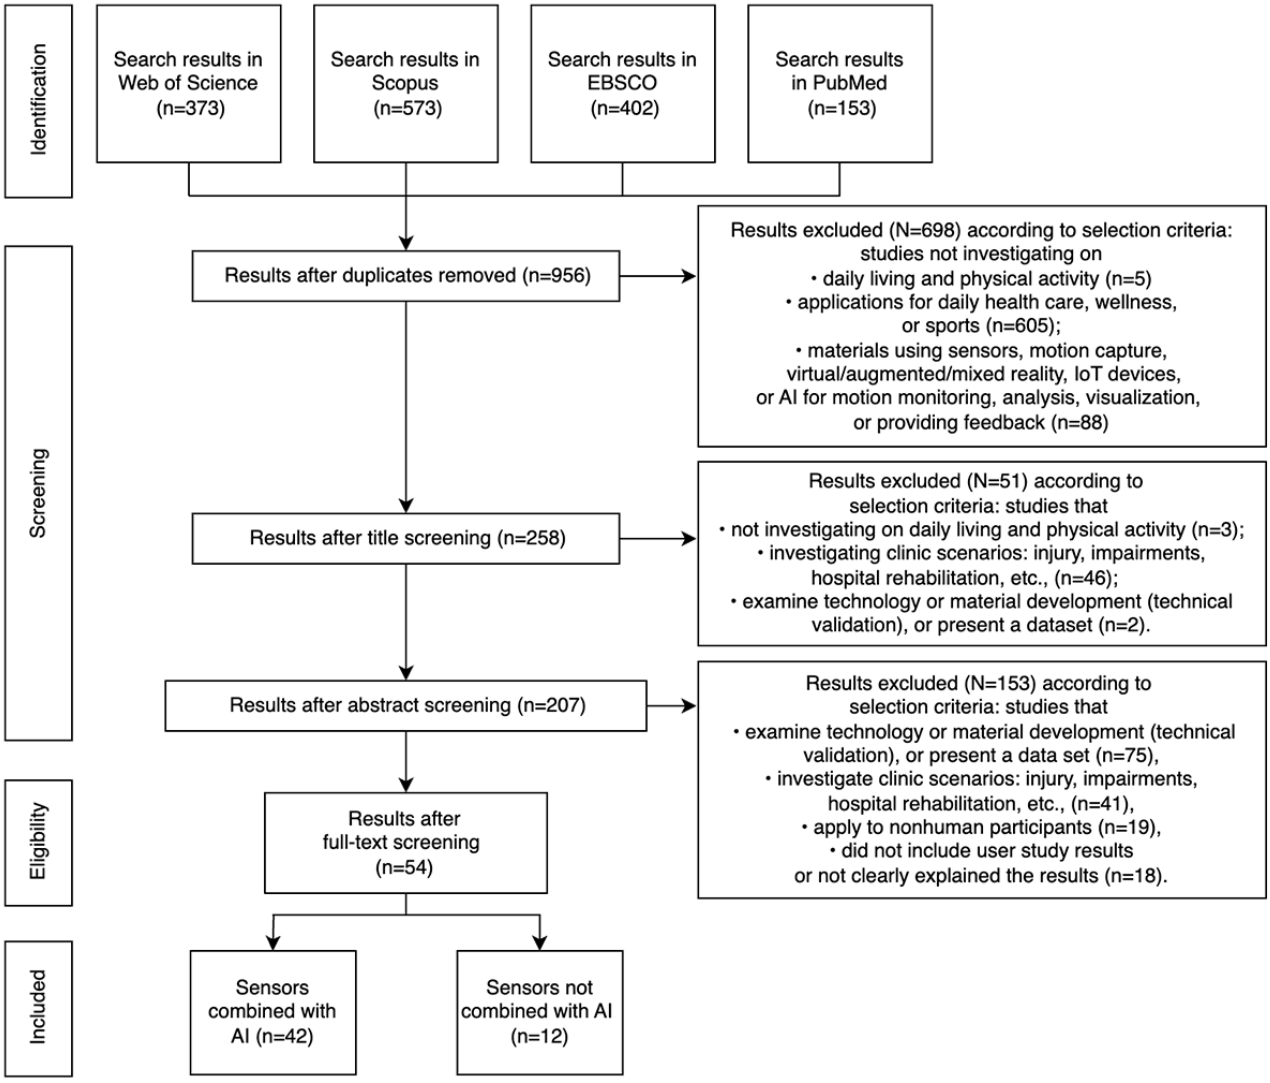
Research Outcomes

Any measure or index that described (1) the activity in health care or physical wellness application research (eg, daily human activities, physical activities, or daily activities of special populations); (2) the use of motion tracking for monitoring, analyzing, visualizing, or providing feedback; and (3) health care– or physical wellness–related system design was included.

Search Strategy

Two pilot searches were conducted using the Scopus and Web of Science electronic databases in August 2022, applying search strategies detailed in Multimedia Appendix 2. The first search yielded an exceedingly limited number of articles, while the second search displayed a broader range. Upon reviewing the titles and abstracts from the pilot search results, we observed that the terms “physical activity” and “daily living activity” might lead to irrelevant research fields, such as heart rate monitoring and step count. In contrast, “motion tracking” and “motion capture” more accurately capture the essence of physical activity within our research context. These terms are commonly used in the field of motion capture technology research. Consequently, we gave these terms precedence in our investigation, which assisted in the strategic identification of pertinent keywords for inclusion. Moreover, from the results of the initial 2 pilot searches, we identified additional keywords related to health care applications, AI, and motion tracking, such as “health of things” and “dynamometry.” Following discussions, we selected these terms for use in our final search queries (Table 1). The search strategy was subsequently refined and executed in September 2022, covering the following 4 databases: Web of Science, Scopus, EBSCO, and PubMed (Figure 1). The titles, abstracts, and index terms were screened to identify the studies that met our stated eligibility criteria as outlined in Textbox 1.

Figure 1. The flowchart of the selection process of articles. AI: artificial intelligence; IoT: Internet of Things.

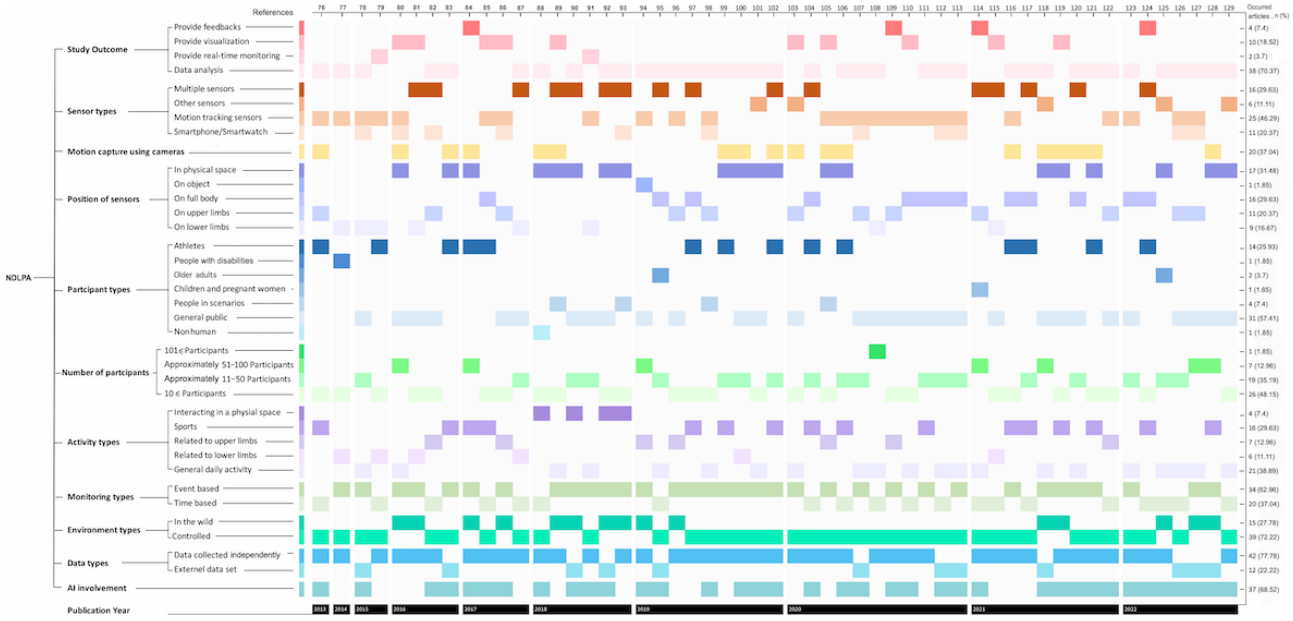


Data Extraction

Drawing from previous research in health care and motion tracking, our study builds upon the insights provided by Straczkiewicz et al [42], who illustrated the relationships among different human activity recognition processing phases through data visualizations. Their approach to data visualization reveals the connections among co-occurring factors identified across the reviewed articles over time. In addition, we also considered the work of van Kollenburg et al [62], who explored design narratives for situated design exploration, thereby enriching our understanding of the data analysis process and its application in health care scenarios [62].

Through the data extraction process from the selected articles, we organized the data into 11 categories: (1) study outcome (subcategories encompassing providing feedback, visualization, real-time monitoring, and data analysis); (2) sensor types (subcategories include multiple sensors, other sensors, motion-tracking sensors, and smartphone or smartwatch); (3) motion capture using cameras; (4) position of sensors (eg, physical space, on object, full body, upper limbs, or lower limbs); (5) participant types (individuals on whom sensors were placed or who were being monitored, including athletes, people with disabilities, older adults, children, pregnant women, people in scenarios, general public, or nonhuman subjects); (6) number of participants (categorized as >101, 51-100, 10-50, or <10); (7) activity types (covering interactions in physical spaces, sports, activities related to upper or lower limbs, and general daily activities); (8) monitoring types (differentiated by event or time-based monitoring); (9) environment types (distinguished as in the wild or controlled); (10) data types (differentiating between data collected independently or from external data sets); and (11) Al involvement. Then, using the timeline and the categories of the included studies, we provided a publication year–based summary that illustrates the Network of Daily Living and Physical Activity (NDLPA) among included studies, as depicted in Figure 2.

Figure 2. The Network of Daily Living and Physical Activity (NDLPA) among included studies. AI: artificial intelligence. For a higher-resolution version of this figure, see Multimedia Appendix 3.



Results

Identification of the Studies

The electronic search yielded 1501 studies. After removing internal duplicates, 956 studies remained. On the basis of the eligibility criteria, 258 articles were chosen through title screening (Figure 1). A total of 54 articles were included for full-text appraisal after the abstract screening process [75-128]. The results from database search indicated that the relevant research from 2013 to 2018 grew steadily, while research articles published from 2019 to 2022, aligning with our interests, experienced a significant uptick and consistently maintained a high volume (Figure 3; Table 2). The findings (Figure 2) revealed that 54 articles used motion tracking data in health care and physical wellness applications, of which 42 (78%) articles used motion-tracking sensors [75-81,84-86,88-97,101,103-116,119,121-123,125,126]. Overall, 70% (38/54) of the articles used AI technology combined with motion tracking data [75,77,79,82-85,87,89-91,93,94,97,99-101,103,105,106,108,109,111-113,117-128]. The role of AI mainly functions for data classification, monitoring, and visualization among the included studies. Furthermore, 80% (43/54) of the studies recruited participants for user study [75,76,78-81,83-88,90,92,93,95-105,107-110,113-116,118-124,127,128]. Twelve articles used public data set [78,82,89,91,94,106,111,112,117,125-127]. Most of the public data set that were used are University of California, Irvine human activity recognition, center of advanced studies in adaptive system, mobile health, University of Milano Bicocca smartphone-based human activity recognition, mobile sensor data anonymization, a large multipurpose human motion and video data set, and wireless sensor data mining data sets.

Figure 3. The distribution of total selection, abstract screening, and included articles based on publication year.

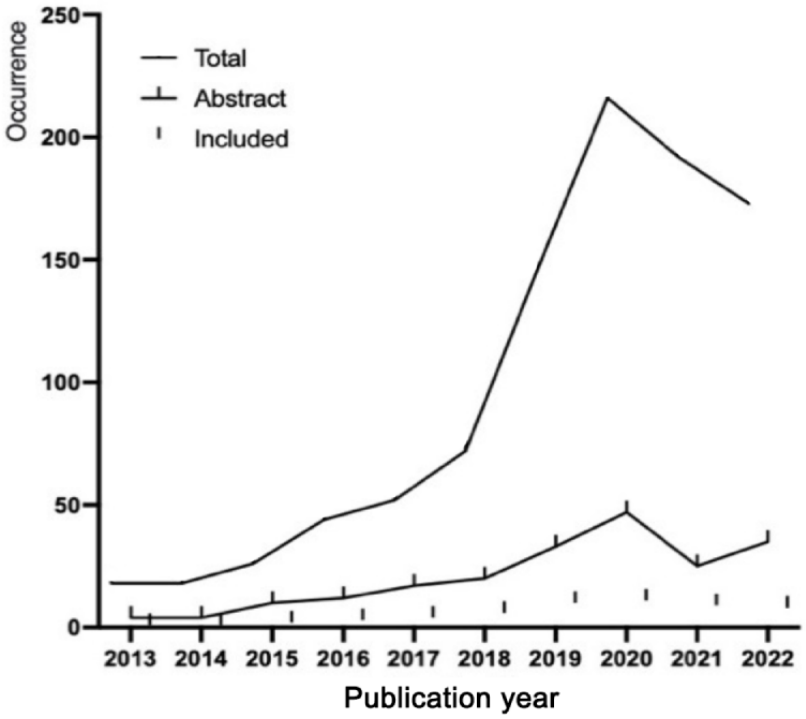


Table 2. The distribution of total selection, abstract screening, and included articles.

Publication year	Total (n=956), n (%)	Abstract screening (n=207), n (%)	Included articles (n=54), n (%)
2013	18 (1.9)	4 (1.9)	1 (1.8)
2014	18 (1.9)	4 (1.9)	1 (1.8)
2015	26 (2.7)	10 (4.8)	2 (3.6)
2016	44 (4.6)	12 (5.8)	4 (7.3)
2017	52 (5.4)	17 (8.2)	4 (7.3)
2018	72 (7.5)	20 (9.7)	6 (10.9)
2019	145 (15.2)	33 (15.9)	9 (16.4)
2020	216 (22.6)	47 (22.7)	11 (20)
2021	192 (20.1)	25 (12.1)	9 (16.4)
2022	173 (18.1)	35 (16.9)	7 (13)

Descriptions of Technology Use, Participants, Activity, and Outcomes

Overview

The contributing studies displayed a broad spectrum of methodologies, participant types, and technology uses. Characteristics of activity varied from studies focusing on lower limb activities to those analyzing full-body movements, using a range of sensors and AI technologies. Most studies used a combination of accelerometers, gyroscopes, and sometimes cameras across diverse settings from controlled environments to in-the-wild scenarios. Participant types ranged from the general public, including specific groups such as athletes and older adults, to nonhuman participants in a few instances.

Technology Use

Most of the included publications (42/54, 78%) used technology based on AI combined with motion tracking techniques or multiple sensors. Among those using sensors, studies incorporating accelerometer and gyroscope sensors formed the core of the investigations (42/54, 78%), including those using a smartphone or smartwatch (11/54, 20%) and those using multiple sensors capable of motion tracking (16/54, 30%). Fewer studies used other types of sensors (eg, temperature sensors, light sensors, etc; 6/54, 11%) or combined them with motion capture using cameras (10/54, 19%). Moreover, 17% (9/54) of the studies exclusively used cameras for motion capture. Details are provided in Figure 2. A combination of accelerometer and gyroscope sensors has been deemed essential for tracking everyday human activity over the past decade. They were used to collect data on typical ADLs, such as standing, walking,

sitting, and jumping, while ambient sensors were used less frequently. Physical activities such as jumping [75,78,98], playing basketball [96,116], soccer [83], baseball [115], running [105], ballet dance [103] skiing [127], karate [84], and Taijiquan [123] were studied. Meanwhile, AI processing in the included articles functions for data extraction and classification to achieve daily living and physical activities recognition.

According to the studies using motion tracking data and classifiers, using a minimal pair of accelerometer and gyroscope sensors to acquire motion tracking data can achieve activity recognition with high precision [75,77,78,81,85,97,107,108,113,121]. Several scholars have suggested that the human activity recognition system has the potential to enhance the efficiency of health care applications using multiple pairs of accelerometer and gyroscope sensors [94,101]. Most studies obtained original motion tracking data of ADLs for evaluating health care systems, whereas fewer studies adopted public data sets for activity recognition applications.

Position of Sensors

The method of sensor placement among the included 54 studies was distributed relatively evenly (Figure 2). The sensor placements in most of the included articles were implemented on the full body (n=16, 30%) and in physical spaces (n=17, 31%), with relatively fewer studies focusing on the upper limb (n=11, 20%) and the lower limb (n=9, 17%). However, 1 (2%) article reported that the sensors were placed on an object. The findings suggest that the placement of sensors is inherently determined by the nature of the activities. ADLs were categorized into lower limb–based activities (eg, walking, standing, sitting, etc); upper limb activities (eg, eating, talking on the phone, washing dishes, cooking, etc); and full-body activities (eg, playing basketball, dancing, skiing, etc). Therefore, sensor placements are specifically tailored to match the inherent types of activities being tracked.

The studies that involved placing sensors on the full body and in environments were widely reported [84,94,96,103,109-112,115,116,119,122,123], and the purposes of using full-body motion tracking are commonly argued for analyzing specific movements or securing the credibility of system evaluations [94,106,110,112,115,116,123]. The investigations involving the placement of sensors in physical spaces mostly use motion capture and image processing techniques [117,119]. Researchers have placed high-speed cameras to capture movements during sports activities [75,82-84,88,98,101,105,115,120,127] and in specialized work situations, such as maritime occupations [104]. One study [93] placed accelerometer and gyroscope sensors on an object, specifically a water container, to determine the frequency and amount of use from the container's motion tracking data. The positioning of sensors has become increasingly precise and intricate over time. Research has primarily targeted the upper limb, full body, or physical spaces.

Participants

The research exploring motion tracking of daily living and physical activities for health care applications has studied a variety of participant types (Figure 2), including the general public (healthy individuals; 31/54, 57%), people in specialized scenarios (4/54, 7%), children and pregnant women (1/54, 2%), older adults (2/54, 4%), people with disabilities (1/54, 2%), and athletes (14/54, 26%) over the past decade. One exception involved using a male cadaver for the analysis of vehicle-cadaver tests. From the results, researchers primarily applied motion capture technology to healthy individuals aged between 18 and 60 years and to athletes. Activities involving healthy individuals can provide representative activity characteristics for training activity recognition models and identifying outliers in activities through activity classification. In the last 3 years, researchers have increasingly prioritized the use of data collected from the public and youths for sports education–related research.

The number of participants recruited varied significantly across the included studies. Approximately half of the selected studies collected data from <10 participants (26/54, 48%), and a smaller number gathered data from 10 to 50 participants (19/54, 35%). Moreover, 13% (7/54) of the studies collected data from 50 to 100 individuals. Half (27/54, 50%) of the studies used 10 to 100 samples from public databases [77,89,94,106,111,112,117,125-127]. Only one study [107] amassed gait data from >1000 healthy individuals. The quantity of the sample size correlates with the types of participants and activities. In sports-related activities, the sample size ranged from 1 to 50 individuals, predominantly involving athletes. For studies on daily living activities, the sample size varied from 10 to 1000s of individuals, primarily focusing on the healthy general public.

Activity

Prior studies have classified activities according to the intensity of exercise [130]. In this study, the activity classification extends the previous categorization and is divided into general daily activity (21/54, 39%; eg, walking, standing, sitting, etc); activities related to the lower limb (6/54, 11%; eg, running, jumping, etc); activities related to the upper limb (7/54, 13%; eg, drinking, writing, cutting, etc); sports (16/54, 30%; eg, playing basketball or baseball, dancing, Taijiquan, etc); and interaction in a physical space (4/54, 7%; eg, living in a laboratory setting house, farming, etc) based on the sensor placements and the purposes of the activities (Figure 2). Most studies (39/54, 72%) specified that they were conducted in laboratory experiment settings and aimed to minimize the intervention of irrelevant environmental factors [75-78,82,84,86,87,90,94,96-116,119-123,125,128]. Each data collection session involved 1 participant, who was pretrained for a few minutes before their data were collected for experimental purposes. Researchers aimed to focus participants' attention on specific movements and perform standardized activities. The results suggest that collecting pretrained ADLs data provides standardized motion data for training ADLs recognition, but this approach might not capture the variety of behaviors necessary to accurately judge specific motion data. Meanwhile, the results also indicate that researchers concentrated on laboratory-based activities for professional use, such as the classification and identification of ADLs and the functionality of joints.

Study Outcome

The included studies (n=54) were all aimed at the identification and classification of activity trajectories (Figure 2). The findings indicate that most included research (n=39, 72%) focused on data analysis. Overall, 2 (4%) studies provided real-time monitoring; 3 (6%) studies offered feedback; and 10 (19%) studies were dedicated to visualization, including 6 studies that visualized original data without AI processing. The purpose of visualization is to provide professionals [88,114] or users [104,118] with the ability to view motion statuses. The visualization of motion data without classification is used in medical research [79,80,88,102,104,114], and the data are intended for use by health care professionals. Excluding the studies using animation and VR techniques, such as the one by Zelck et al [104], who proposed the animation of digital maritime workers' working processes, and another study by Ahmed and Demirel [102], who demonstrated human performance in normal situations and aircraft accidents using VR, and the data from the latter are accessible to the public. Generally, studies focusing on ADLs primarily used data from the healthy public for professional use.

Risk of Bias and Quality Assessment

In conducting a thorough risk of bias and quality assessment of the selected studies, our scrutiny was directed toward several critical dimensions: participant selection transparency, the accuracy and completeness of data acquisition methodologies, the analytical rigor, and the integrity in reporting outcomes. Notably, prevalent biases included selection bias, rooted in participant recruitment strategies; measurement bias, owing to sensor placement inconsistencies or activity categorization; and reporting bias. Studies using public data sets or conducted within laboratory confines typically showed reduced bias risks. In contrast, studies with constrained participant demographics or undertaken in less regulated environments faced heightened bias risks, primarily affecting data representativeness and the influence of external variables on activity assessments.

The included articles variably reported on participants' gender and age specifics—57% (31/54) of the articles provided detailed demographic data [77-79,82,86,89-91,93,94,97-99,101,103,105-107,109-113,115,116,119,122,124-127], while others (22/54, 41%) omitted such specifics [75,76,80,81,83-85,87,88,92,95,96,100,102,104,108,114,117,118,120,121,123,128]. The sensor models used across studies are meticulously documented within the articles and are detailed in the Multimedia Appendix 1. It was observed that the spectrum of daily living activities discussed was somewhat narrow, seldom addressing activities that entail object interaction. The theoretical underpinning, such as that provided by ANT [68,69] and activity classification [130], lends robust support to the motion data analysis, facilitating a nuanced understanding of the data. The selected articles did not address the incorporation of verbal language or cultural customs in the context of data collection or the execution of physical activities. Thus, we consider that the concentration on physical movement to the exclusion of linguistic or cultural contexts likely accounts for the omission of cultural background in the analysis. Data collection in laboratory settings is controlled, thereby eliminating interference from factors such as socioeconomic elements. The physical tasks assigned to participants encompass routine daily movements or activities well-acquainted with athletes, effectively eliminating potential interferences from policy-related factors.

Discussion

Interaction Between Devices, Users, and Environmental Factors

The features of the selected studies were systematically categorized into study outcome, sensor configuration, participant types, activity types, monitoring, environment types, and AI involvement, as illustrated in NDLPA among included studies (Figure 2). This organization was informed by the visualization of Straczkiewicz et al [42], who elucidated the complex interrelations among diverse human activity recognition process phases. Drawing upon the theoretical foundation provided by ANT [64,68,69], our analysis delved into the NDLPA by investigating the dynamics of actor-led activity; purpose-oriented interaction; and interaction among devices, individuals, and environmental factors.

Actor-Led Activity

Overview

Among the 54 articles selected for review, 3 main categories of initiators in health and physical wellness application research were identified: participants (including health information beneficiaries, professionals, caregivers, and interactional factors), researchers in health care, and researchers in computing. According to ANT [68,69], the interaction within the activity network is governed by those who lead the activity. As researchers are the initiators for implementing ADL research, we classified environment types by the extent of the researchers' intervention, namely, controlled and in the wild.

Controlled

In controlled settings, researchers initiated the activity. Participants conducted time- and environment-restricted daily activities following the researchers' activity assignments. Most articles mentioned that participants undergo pretraining before starting data collection to ensure that the data are typical [90,96]. Most athlete participants are in controlled environments. Researchers stated that motion data collection was controlled in specific movements, times, and spaces to guarantee optimal exercise time [81,121]. There is no other human-athlete interaction, except for 1 article using a virtual athlete [96]. This approach ensures the typicality of the data and the precision of the movement trajectories, which are essential for analyzing physical activity.

In the Wild

In uncontrolled or in-the-wild settings, participants are inclined to initiate activities, with interaction between participants and ambiance minimally restricted by researchers. Researchers configure sensors within the range of participants' activities (cameras, smart water meters, pressure mats, etc), allowing participants to produce movement trajectories relating to their intents. Findings include 2 types of in-the-wild activities: one

is video data sets captured in real-world situations, and the other is based chiefly on motion and multiple sensor data (eg, temperature and light use) to infer work and daily routines in living scenarios. The included studies in this review used data from in-the-wild activities, with 11 papers using data from the general population [79,80,85,88,89,91-93,95,118,126] and 1 article using data from older adults [124]. One study mentioned data collected from interactional factors, a water container [93] as the interactional initiator. Placing a motion-tracking device on the container that passively triggers humans' drinking movements may accurately detect the trajectory of upper limb movements.

Generally, most included investigations on everyday living and physical activities have been conducted in controlled settings, where researchers aim to capture accurate and standardized movements for health professionals and activity recognition processing. Although participants receive activity guidance and practice movements before the experiment, inconsistencies in activity objectives among them may arise. Alternatively, research using activity data from in-the-wild settings could provide a more intimate and real-life interaction but generate excess data. Moreover, it can achieve data controllability when the initiators are passive objects.

Purpose-Orientated Network

Overview

The activity initiator guides the purpose. As the research and the content of the activity were led by the researchers, the purpose of the research becomes the purpose of the activity in the network. We consider study outcomes, activity types, and monitoring types as elements forming the purpose of the activity networks.

Study Outcomes

The fields of human activity recognition and motion analysis have consistently been focal points of research, with an increasing volume of publications annually, particularly maintaining a stable high volume over the past 3 years (Figure 3). Studies have primarily focused on data visualization and monitoring, targeting daily activities and local body movements. Studies providing data feedback have addressed movement correction [123], outlier indication [113], and body posture correction [108]. It is noteworthy that outcomes related to feedback provision and data visualization have chiefly used in-the-wild data during the initial 6 years, shifting toward controlled data in the subsequent years, a transition likely influenced by advancements in research methodologies and technological evolution.

Activity Types

Most studies on activity trajectory recognition have focused on whole body movements, with local movements and movements related to environments being rare. Over the past 3 years, researchers have started to shift the target beneficiaries of their sports research to the general public, with physical activity education gradually overtaking professional sports. The dominant type of activities remains predominantly oriented toward daily living, with sports-related activities progressively shifted to ordinary activity.

Monitoring Types

Researchers described the nodes of data acquisition in terms of activity content and duration, and these nodes serve in subsequent data computation and analytical processes. They directed participants to undertake activities conforming to the predetermined criteria associated with these nodes. Moreover, research using in-the-wild data adapt their methodologies to the unpredictable nature of activity content and duration, ensuring a structured approach to capturing motion data despite the inherent variability. This nuanced guidance ensures that even in uncontrolled environments, the collection and analysis of data remain methodically aligned with the research objectives.

Interaction Among Devices, Individuals, and Environmental Factors

Activity trajectory is demonstrated through the interaction between humans, sensors, and environments. Motion-tracking devices, sensor positions, and environments factors are the main features to be evaluated.

Motion-Tracking Devices

Given this study's basis on motion tracking technology and the categorization of sensor types, we divided device types into complex devices (multiple sensors, eg, temperature, lighting, pressure accelerometer, and gyroscope sensors, VR, AR, etc) [91,92,101,113]; portable devices (smartphone or smartwatch) [77,79,81,92]; basic devices (motion-tracking sensors, eg, accelerometer and gyroscope sensors) [78,79,84,90,93]; and environmental devices (other sensors, eg, cameras, radiofrequency ID tags, etc) [100,102,117,124,128]. The configuration of complex devices aims at research related to local motions, complex motions, and environmental interactions. In conditions using complex devices, participants wore portable devices such as smartwatches to record motion data simultaneously with built-in multiple sensors (eg, ambient light sensor, UV light exposure sensor, and skin temperature sensor) [81]. A portable device with built-in accelerometer and gyroscope sensors performed a similar motion tracking task as a basic device. Most of them were used to determine everyday activities' trajectories as they are easy to perform. In conditions using portable and environmental devices, the portable device was placed on the body, and the participant activated sensors placed in the environment. The active and passive motion data form an activity network [92]. Accelerometer and gyroscope sensors were placed on multiple areas of participants' bodies to monitor their full-body motions. However, using cameras to capture athletes' movements and environmental devices (eg, pressure mats, mercury contacts, and float sensors) [91] to record living routine is favored by researchers.

Positions of Sensors

Our study categorizes device placements by areas of the human body and their relative distance from the human body, namely, in physical spaces, on objects, on the full body, on the upper limb, and on the lower limb. The results indicate that sensor placement is related to the study's purpose and the intensity of the activity. Sensors used in physical spaces or on the full body

examined high-intensity activities (eg, professional sports), correlating with accurate data acquisition. High-intensity activities, such as running [105] and throwing darts [110], were primarily studied using devices on local body areas. Devices placed on specific objects received limited daily exercise data but were consistent with the study's objectives. Sensors attached to different areas of the participants' bodies collected data from those areas and integrated with participants' movements. Sensors placed in the environment passively received signals, yet timing and activity patterns could be detected.

Environmental Factors

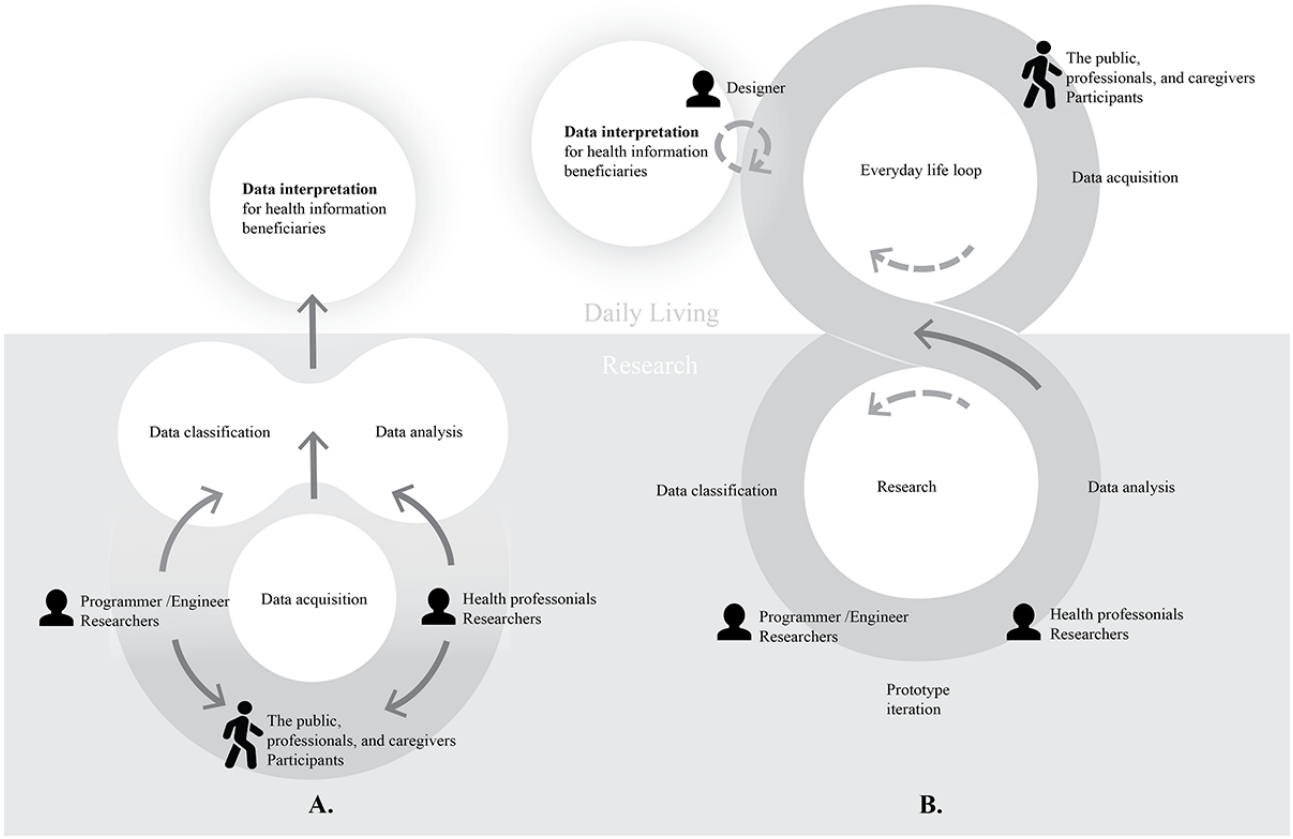
The environments for study implementation were mainly controlled by researchers. The movement trajectory of participants' performance aligned with the research objectives. The content and duration of activities were fixed, and devices were placed according to the research purposes. Participants passively interacted with their surroundings. Performing daily living or physical activities in an experimental setting might influence the participants' intent of the action. In these settings, participants' movements were unrelated to habitual actions. The environment and devices reflected interactions with researchers but did not interact with the participants, leading to a severed connection between the activity network and the participant involved. However, in video recording scenarios, participants performed activities in real-life settings, potentially providing purposeful and personalized movement data for research.

Investigation Process

Activity identification and recognition have been the primary focus of research on ADLs and physical activities in health and wellness applications over the past decade. The fundamental objectives are to enhance the accuracy of motion tracking data recognition and its practical use for health professionals. From the perspective of NDLPA, researchers acted as initiators of activity networks, leading the content and environments of activities in most activity recognition studies. Participants provided standard movement data within a restricted time and environment, lacking personal purpose and awareness of real-life activity. Participants did not fully become the initiators of the activity networks, but real-life activity data could be more complex. The variety of activity scenarios, user-friendly sensor design, data collection at specific time points, and data variances produced by complex activities and various real-life purposes could present research opportunities for studying daily living and physical activities for health and physical wellness applications. Meanwhile, designers have the opportunity to engage in designing user-initiated activities and collect technology-based motion data for health and physical wellness application research.

According to the descriptions in the included articles, the investigation of ADLs and physical activities in health care applications covers 4 phases: data acquisition, data classification, data analysis, and data interpretation, as shown in Figure 4A. In the process of motion tracking data acquisition, researchers recruited participants and conducted data collection. Participants performed assigned activities under full or partial surveillance by researchers. The data were supervised and categorized into standardized movements corresponding to specific activities. At this stage, the activities varied by different engaged areas on participants' bodies but not by the content of daily living activities. Researchers trained various algorithm models for data classification to achieve high activity recognition accuracy and used different data sets to test the system's validity. In the data analysis stage, researchers identified standardized activities and examined the difference values through motion tracking parameters. Using these parameters, researchers analyzed activity norms and behaviors. This stage is also associated with data monitoring. Data classification and analysis can be combined or conducted independently for different research evaluation purposes. Data interpretation, such as data visualization and feedback provision, was created by researchers from the health, engineering, and computing domains. It interacted with health information beneficiaries (eg, professionals, users, and caregivers). The health information was presented in either video or image forms for visualization or in text forms for feedback to users.

Figure 4. (A) The investigation process of motion data on daily living and physical activity for health care application and (B) a designer-involved investigation process of motion data on daily living and physical activity for health care application based on data-enabled design.



On the basis of the investigation process of ADLs and physical activities in health care applications, participants' involvement occurs at an early stage. However, participants are situated in a controlled environment for experimental purposes, with devices attached to their bodies without active interaction. Although the data are clear for classification and analysis, they rarely explain the diversity of ADLs. In the data interpretation stage, there is a weak connection between the data and the general public owing to the dominant purpose of activity identification research aimed at professional use. Designers can aid in bridging communication between information and the public. As described in the literature in previous sections, human motion data are essential components of activity recognition and analysis [1,2], with the public being the beneficiary of physical activity intervention research [11,12]. We propose that designers, coupled with researchers' guidelines, participate in the investigation and application process, which promises to facilitate data collection and interpretation.

Designer-Involved Investigation Process

The research of health care and physical wellness applications is directed toward professional deployment and public health enhancement. However, it has been observed that there exists a gap between the motion data collected from participants and their applicability to real-life situations. In addition, research in health care applications often fails to encompass the breadth of data diversity; there is a noticeable lack of meaningful engagement between devices and participants, and the process of making data understandable for the public is fraught with difficulties. To address these issues, we advocate for a research methodology that integrates DED framework [61-63], a designer-involved research process of motion data on ADLs and physical activity for health care application research, as illustrated in Figure 4B.

In this proposed methodology, designers collaborate with health care researchers to understand the specific information required for participant recruitment in a given project. They assist health care researchers in designing data collection strategies while considering the daily behavior patterns of the target population, thereby refining the data collection plan. Researchers from computing and engineering fields undertake the collection and categorization of data. These data span various demographics, purposes, devices, and scenarios from designers and are tailored for a multitude of applications. Such research process encompasses a cycle of prototype iterations. Researchers from the health field analyze classified data, identify abnormal motion data, and then provide guidelines for designers. Designers, positioned as intermediaries between users and researchers, leverage these guidelines and their nuanced understanding of human daily experiences including participant involvement and activity motivation [131] to reinterpret professional data into user-friendly formats. Furthermore, designers play a pivotal role in collecting motion data that reflect a diverse array of demographics, intentions, devices, and scenarios. They are able to simplify the data and assist with data interpretation for the recipients of health information.

The integration of design principles into the development of health care applications is key to enhancing user engagement, offering more intuitive interfaces that potentially increase adherence to health interventions through user-friendly designs. Our findings indicate that in intricate settings, standardizing data to mitigate external variables might lead to binary misjudgments. Given that daily activities are influenced by individual attributes, environments, and habits, the role of designers becomes critical in tailoring solutions to meet the varied needs of distinct user groups. They fine-tune the implementation methods and locations for motion-tracking devices, such as using cameras or accelerometer and gyroscope sensors and determining specific areas for deployment, such as full-body tracking or environmental interaction. They also specify the nature of the data to be collected, differentiating between event-driven data, which capture specific actions such as walking across varied material surfaces, and time-sequential data, which records information over continuous periods such as walking at night. This process enhances the accuracy and applicability of collected information, facilitating the development of data-driven products that reflect real user experiences. During the experiment, the dialogue between users and designers' aids in identifying actual and hidden needs, thus refining information precision and application. Upon analyzing the data, health care researchers collaborate with designers to reformat health information into accessible, engaging formats on digital interfaces, using techniques such as digital twins, animations, visualizations, and gamification. This method enhances user engagement, elicits valuable feedback, and fosters ongoing improvement in data accuracy, thus promoting a cycle of continuous information enhancement.

In addition, designers can assist engineers in designing user-friendly devices and facilitate actuator developments to provide users with timely feedback. The iterative refinement of technology that monitors ADLs and physical activity motion data in health application research is driven by the diversity of the population, necessitating continuous optimization. Design's contribution is pivotal in promoting effective communication, nurturing relationships, and pursuing sustainable innovation. By involving designers in the process, the development of activities initiated by users and the creation of user-friendly motion-tracking sensors are significantly improved. This, in turn, supports the cyclical development of health and physical wellness applications [64,65], ensuring that they are more aligned with real-world needs and contexts. Thus, in the sphere of health care and physical wellness application research, the involvement of designers is crucial for the effective acquisition and interpretation of data, ensuring that the data are relevant and beneficial in everyday scenarios.

Designers' involvement is essential in shaping design and implementation strategies, ensuring that technology solutions are tailored to meet the inherent human needs for interpreting health-related information. This approach is instrumental in improving the monitoring and management of health conditions, thereby improving patient outcomes. This not only improves usability but also ensures that technologies are perceived as useful and enjoyable, mirroring the foundational criteria of the TAM [54,55]. However, potential challenges include ensuring effective communication and collaboration across multidisciplinary teams, aligning different objectives and methodologies, and the complexity of translating complex health data into accessible and actionable information for users.

Limitations and Future Directions

This review process identified key limitations and future research directions in the use of motion tracking technologies for health care. It pinpointed risks of selection and measurement biases due to participant recruitment strategies and inconsistencies in sensor placement or activity categorization. Highlighting the inadequate exploration of feedback mechanisms, this review emphasized the necessity for future studies to optimize user communication. The use of sensors for motion data collection offers a method to preserve privacy, contrasting with cameras or recorded videos, which might inadvertently compromise it. One included study introduced a Kinect and smartwatch system, focusing on health care professionals' privacy and showcasing a strong commitment to privacy and ethical considerations in system design [79]. The minimal focus on privacy protection in other included studies indicates a potential research gap. Furthermore, this review underscored the unexplored potential of integrating geolocation data into physical activity interventions, proposing future research to delve into scenario-based health care applications. The investigation did not fully address the influences of cultural, socioeconomic, and policy-related factors on physical activity, or the budget constraints that may have curtailed the exploration of these dimensions. Moreover, it acknowledged the potential publication bias and the influence of study quality on the findings, especially given researchers' inclination to report positive outcomes of health care application development. Although the search included major databases, there is a possibility that relevant studies in other databases were overlooked. In addition, database search confined to English language might have excluded pertinent non-English studies. These areas present fertile ground for future research to ensure a more holistic understanding and application of motion tracking technologies in diverse settings.

Implications

This study significantly contributes to future research by demonstrating the importance of a multidisciplinary approach in health care application development, particularly in the integration of design principles with engineering and health sciences. It lays a foundation for further exploration into how designers can enhance the usability and effectiveness of health applications through user-centric design and data interpretation. Future studies can build on this framework to investigate specific design strategies and their impact on user engagement, adherence, and overall health outcomes, potentially leading to more personalized and effective health interventions. For real-world applications, this approach could fundamentally transform the development of health care apps, making them more accessible, intuitive, and tailored to individual needs, ultimately leading to improved health outcomes and patient engagement.

Conclusions

The study systematically reviewed the implementation of motion tracking in health care application research, revealing a discrepancy between the data collection and its effective application in real-world scenarios. Informed by ANT, we explore the dynamics of actor-led activities and purpose-oriented interactions, focusing on participants, sensors, cameras, and environmental factors in health care research concerning ADLs. The guiding roles of activity initiators significantly influence the phases of data acquisition, classification, analysis, and interpretation, underscoring the potential to enhance the accuracy of motion tracking and activity recognition when considering contextual factors. By advocating a designer-involved research process of motion data on ADLs and physical activity for health care application research, this study emphasizes the essential role of incorporating design principles via a DED framework in developing health care applications. This integration is crucial for aligning motion data collection with practical, real-life applications. By adopting a multidisciplinary approach and combining insights from design, engineering, and health sciences, the research demonstrates potential pathways for making health applications more user-friendly and effective. It underscores the necessity of engaging designers in the research process to ensure that health technologies are accessible, intuitive, and tailored to meet the diverse needs of users. Designers play a key role in customizing the deployment and data collection methods of motion-tracking devices, which improves the relevance and accuracy of collected data, leading to better-informed health applications. The iterative dialogue between users and designers during development refines the precision of information and its application, fostering a cycle of continuous improvement. By transforming complex health data into engaging, understandable formats, designers help translate user needs into actionable health solutions, promoting better monitoring and management of health conditions. The study advocates for further research to explore and refine these integrations, offering a direction that promises to transform health care monitoring and interventions, ultimately enhancing patient outcomes and engagement.

Acknowledgments

The authors would like to acknowledge the Hong Kong Polytechnic University for funding this research. This research was supported by the School of Design Collaborative Research Fund (P0035075), Strategic Importance Fund at the Hong Kong Polytechnic University (P0036851), and projects of Research Institute for Intelligent Wearable Systems (P0039255).

Authors' Contributions

LW developed the research framework, identified the research scopes, conducted data collection, screened articles, analyzed the data, and was responsible for writing and revising the manuscript. SJW conceptualized and designed the study, managed project administration, screened articles, provided supervision, contributed to reviewing and editing the draft, supplied resources, and acquired funding. Both authors reviewed and edited the manuscript and approved the final version.

Abstract

Background: Unaddressed early-stage mental health issues, including stress, anxiety, and mild depression, can become a burden for individuals in the long term. Digital phenotyping involves capturing continuous behavioral data via digital smartphone devices to monitor human behavior and can potentially identify milder symptoms before they become serious.

Objective: This systematic literature review aimed to answer the following questions: (1) what is the evidence of the effectiveness of digital phenotyping using smartphones in identifying behavioral patterns related to stress, anxiety, and mild depression? and (2) in particular, which smartphone sensors are found to be effective, and what are the associated challenges?

Methods: We used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) process to identify 36 papers (reporting on 40 studies) to assess the key smartphone sensors related to stress, anxiety, and mild depression. We excluded studies conducted with nonadult participants (eg, teenagers and children) and clinical populations, as well as personality measurement and phobia studies. As we focused on the effectiveness of digital phenotyping using smartphones, results related to wearable devices were excluded.

Results: We categorized the studies into 3 major groups based on the recruited participants: studies with students enrolled in universities, studies with adults who were unaffiliated to any particular organization, and studies with employees employed in an organization. The study length varied from 10 days to 3 years. A range of passive sensors were used in the studies, including GPS, Bluetooth, accelerometer, microphone, illuminance, gyroscope, and Wi-Fi. These were used to assess locations visited; mobility; speech patterns; phone use, such as screen checking; time spent in bed; physical activity; sleep; and aspects of social interactions, such as the number of interactions and response time. Of the 40 included studies, 31 (78%) used machine learning models for prediction; most others (n=8, 20%) used descriptive statistics. Students and adults who experienced stress, anxiety, or depression visited fewer locations, were more sedentary, had irregular sleep, and accrued increased phone use. In contrast to students and adults, less mobility was seen as positive for employees because less mobility in workplaces was associated with higher performance. Overall, travel, physical activity, sleep, social interaction, and phone use were related to stress, anxiety, and mild depression.

Conclusions: This study focused on understanding whether smartphone sensors can be effectively used to detect behavioral patterns associated with stress, anxiety, and mild depression in nonclinical participants. The reviewed studies provided evidence that smartphone sensors are effective in identifying behavioral patterns associated with stress, anxiety, and mild depression.

Introduction

Background

Digital phenotyping is "the moment-by-moment quantification of the individual level human phenotype in situ using data from personal digital devices" [1]. Digital phenotyping applies the concept of phenotypes, in other words, the observable characteristics resulting from the genotype and environment, to conceptualize observable patterns in individuals' digital data. In the last decade, digital phenotyping studies have been able to compare typical and atypical patterns in daily activities to correlate atypical behavior with negative emotions [2,3]. Behavioral patterns include variations in mobility, frequency of being in various locations, and sleep patterns. In smartphones, user data can be stored, managed, interpreted, and captured in enormous amounts [1,4,5]. This can be done actively or passively. Active data collection requires the user to self-report and complete surveys, whereas passive sensing collects data automatically without user input [5]. Most studies combine active and passive sensing to more accurately detect and predict behavioral abnormalities. Modern smartphone analytics can be used for the discovery of commonalities and abnormalities in user behavior. The ease of using passive sensing makes it an ideal data gathering method for mental health studies [6-8] and an ideal technique for assessing mental health [9].

Digital phenotyping has been successful in the early detection and prediction of behaviors related to neuropharmacology [10]; cardiovascular diseases [11]; diabetes [12]; and major severe injuries, such as spinal cord injury [13], motivating further adoption. Digital phenotyping has also proven useful for the detection of severe mental health issues, such as schizophrenia [14,15], bipolar disorder [16], and suicidal thoughts [17]. Digital phenotyping has been so successful for specialized, clinical populations that it is increasingly considered for mass market use with nonclinical populations. Digital phenotyping applications and software tools have been used to capture employee information, such as their screen time and clicking patterns [18]. However, there are not many digital phenotyping studies that have specifically examined the detection or prediction of stress, anxiety, and mild depression.

Individuals with stress, anxiety, and mild depression can develop chronic mental health symptoms that impact their mobility, satisfaction with life, and social interaction [19,20]. When these symptoms are not detected early, they worsen, and the impact is more significant [21-23], increasing the need for medication and hospitalization. This makes mild mental health symptoms a valid target for digital phenotyping, as its goal is to enable early detection and, subsequently, early treatment. Smartphones are increasingly ubiquitous [24], which makes them an optimal platform for digital phenotyping. We constrained our systematic literature search to the more challenging problem of the detection of mild mental health symptoms using only smartphone sensors and excluded studies that used additional wearable sensors. In general, we believe that additional wearables might increase the effectiveness of digital phenotyping in detecting stress, anxiety, and mild depression. Given the ubiquity of smartphones, we aimed to answer the following question: what is the effectiveness of digital phenotyping using smartphone sensors in detecting stress, anxiety, and mild depression?

Objectives

The objective of this systematic literature review was to better understand the current uses of digital phenotyping and results of using digital phenotyping for the detection and prediction of mild behavioral patterns related to stress, anxiety, and mild depression. The 2 research questions this review sought to answer were as follows:

1. What is the evidence of the effectiveness of digital phenotyping using smartphones in identifying behavioral patterns related to stress, anxiety, and mild depression?
2. In particular, which smartphone sensors are found to be effective, and what are the associated challenges?

For these research questions, we considered statistically significant associations between sensor patterns and behavioral patterns as evidence of effectiveness.

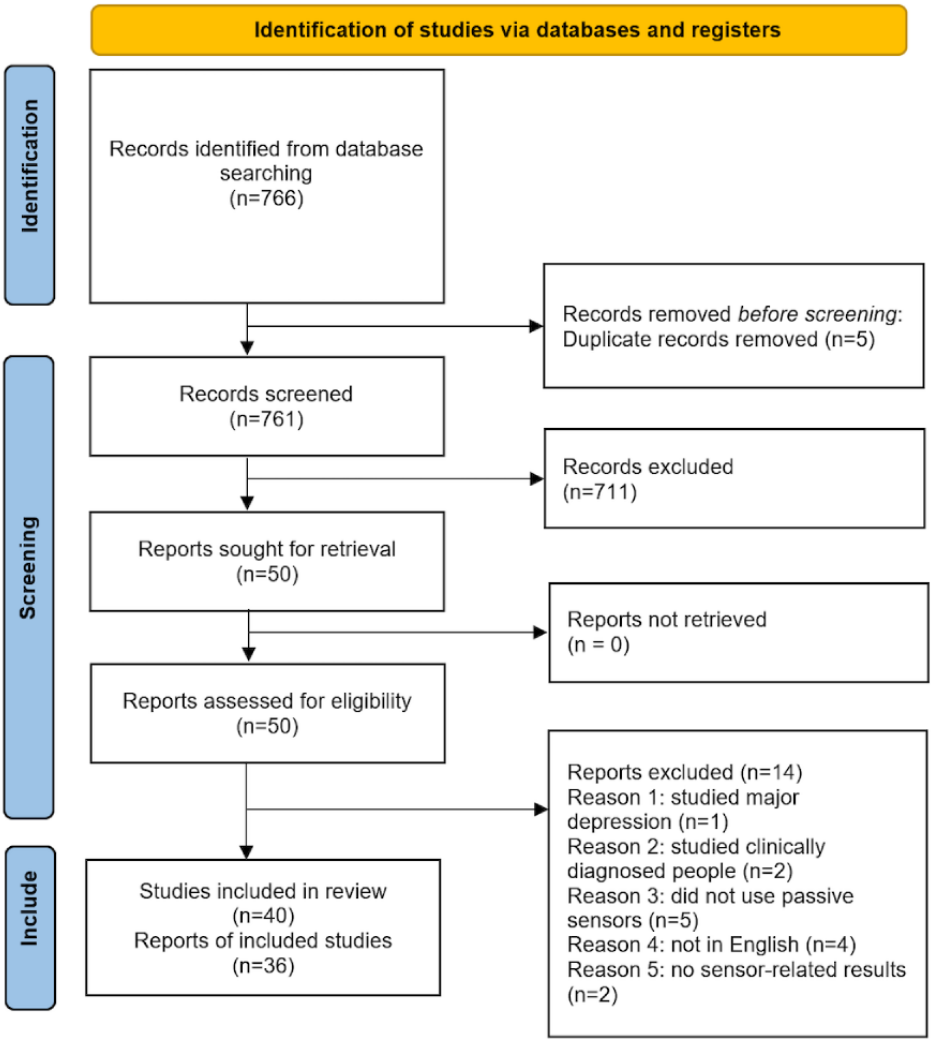
Methods

Type of Studies

This review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [25] (Multimedia Appendix 1). Figure 1 shows the reviewing process and search results. In the first round of screening studies, 1 author excluded studies that were not relevant to the research questions. Another author reran the queries for confirmation. Studies were included in this review if they were conducted to measure and detect stress, anxiety, or mild depression, even if they included other variables, such as job performance, promotion, or discrimination. We included studies in which data were collected through smartphones with an iOS (Apple Inc) or Android (Google LLC) operating system. Data collected through wearable devices were excluded. We included studies in which the participants were adults aged ≥18 years and were from a nonclinical population. Studies conducted with nonadult participants (eg, teenagers and children) were excluded. Given our research questions, if the studies' participants had or had had any severe mental health disorder, such as schizophrenia, bipolar disorder, or psychosis, they were not included. We also excluded personality and character measurement and phobia studies. The primary research language was English. The studies included were conducted from September 2010 to September 2023. Peer-reviewed conference articles and journal articles were included. The data we wished to extract were the study aim, data collected, operating system in the smartphone used for data collection, behavioral patterns identified, surveys used for verification, and sample size. A total of 3 authors reviewed the studies independently to extract data and confirm the extracted data. After the first round of data extraction, 1 author re-examined the studies to extract the predictive modeling used. These data are presented in the *Results* section. We noticed that participants in the included studies fell into 1 of 3 major groups (ie, students, adults, and employees). We refer to the participants of the studies that recruited adults enrolled in universities as "students," participants of the studies that recruited adults

unaffiliated to any particular organization as "adults," and participants of the studies that recruited adults employed at a particular organization as "employees."

Figure 1. Systematic literature reviewing process and search results with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram.



Search Strategy

A total of 3 databases were queried: Web of Science, ACM, and PubMed. PubMed is a medicine-based database, ACM is a technology-based database, and Web of Science is a cross-domain database. The search query was the same for the 3 platforms: "digital phenotyping" OR "passive sensing" AND (stress OR anxiety OR ((mild OR moderate) AND depression)).

Results

Duration

The study length varied from 10 days [26] to 3 years [27]. One study [28] conducted in-depth interviews with students lasting an average of 4.5 hours per person, and another study was a controlled laboratory study [29]. These 2 studies are not presented in Table 1. In the studies conducted with students, a semester or spring or winter term was a common duration. The studies with general nonclinical adult populations were typically longer than those with students.

Table 1. Duration of the reviewed studies (N=38; 2 studies are excluded, as 1 [28] is interview based and the other [29] is a controlled laboratory study).

Number of Participants

The number of participants ranged from a minimum of 7 adults [26] to a maximum of 18,000 adults [27]. Apart from the 3-year longitudinal study with 18,000 participants [27], the average number of participants was 129.4 (SD 184.01). We observed a pattern of attrition, where the number of participants who completed the study was lower than the number of the

participants recruited. The number of participants reported in this review is the final sample size. For example, one of the studies [52] recruited 112 participants, of whom 84 (75%) completed the study. In the study by Pratap et al [55], there was a drastic drop in participants, with only 359 (30.42%) of the 1180 enrolled participants completing the study. Another significant drop was seen in the study by Nepal et al [40], where 750 participants were interested in the research, whereas only 141 (18.8%) of them completed the study. Some studies were less affected; for example, 86 participants started the study by Rhim et al [49], and 78 (91%) completed it.

Publication Years of the Studies

Although the query started with the year 2010, the earliest publication was from 2014 [26], extending to articles published as of April 2023 [35]. Over the years, the interest in detecting and predicting stress, anxiety, and mild depression in the nonclinical population has increased (Table 2).

Table 2. Number of reviewed reports (N=36) by year.

Year	Publication, n (%)
2014	1 (3)
2016	1 (3)
2017	3 (8)
2018	4 (11)
2019	10 (28)
2020	6 (17)
2021	6 (17)
2022	2 (6)
2023	3 (8)

Studies With the iOS and Android Operating Systems

The Android operating system was more common than iOS. Among the 40 included studies, only 2 (5%) were compatible with only iOS [29,51]. A total of 27 (68%) studies were available for both iOS and Android [26,28,30,34,35,37-42,45-47,50,53-61]. A total of 11 (28%) studies were for only Android users [27,31-33,36,42-44,48,49,52]. The reasons identified for the use of the Android operating system were that it has more freedom to capture more modalities, such as keyboard typing and use of apps, and that Android devices enable apps to run more easily in the background [49].

Studies With Students

Table 3 presents the data extracted from the studies that were conducted with student populations. The average length of the studies with students was 158.6 (SD 176.4) days. The average number of participants was 137.3 (SD 152.1). There were significantly more studies with students than studies with employees or general adults. The sample sizes of the studies with students were similar to those of the studies with adults but smaller than those of the studies with employees. In the studies with students, various passive sensors were used, and some were found to be effective for detection, prediction, or both.

Of the 28 studies with students, 23 (82%) used machine learning models for prediction. A total of 12 studies (43%) [30,31,33,37,38,44,46,47,54] used decision tree–based methods, and 9 studies (32%) [37,39,42,49-51,57,58] used regression-based methods. A total of 3 (11%) studies conducted in recent years [43,60,61] used deep neural networks because of their enhanced ability to discern underlying patterns in large unstructured data sets. Tree-based models have the best performance when trained with structured data, and the reported studies mostly used tree-based models and structured data. Among the 28 studies, 2 studies [57,60] conducted in 2023 addressed the generalizability of their proposed detection method and verified its applicability across students from various years, classes, and institutions. Two (7%) studies [42,43] in Table 3 used the StudentLife data set [62]. Each study contributed substantial original analyses including different behavioral patterns and was considered a “study” in this systematic review. Entries with “N/A” in the predictive modeling column indicate that the study did not involve any attempts to predict future occurrences. However, these studies may still contain statistical analyses as part of their research approach. Overall, students who experienced depression, anxiety, and stress visited fewer locations [39,44,50,58-60] and were more sedentary [47,50,58-60]. Depression was also associated with shorter or irregular sleep [35,46,47,50,52,59,60] and accrued phone use [46,47,50,51,58-60].

Table 3. Summary of the reviewed studies with student participants.

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Huckins et al [58], 2020	Understand how students' behavioral health and mental health are affected by the COVID-19 pandemic	GPS, accelerometer, phone lock and unlock, and light sensor data	iOS (Apple Inc) and Android (Google LLC)	At the start of the COVID-19 pandemic, students were more depressed and anxious, used their phones more, visited fewer locations, and spent more time sedentary. Depression and stress were associated with increasing COVID-19–related news coverage.	Linear regressors were used to inspect how behavioral changes were affected by COVID-19 news reports.	PHQ[a]-4	217 students
Melcher et al [35], 2023	Understand how behavioral patterns correlate with mental health for students during the COVID-19 pandemic	GPS, accelerometer, call log, and phone use data	iOS and Android	Individuals with more irregular sleep patterns had worse sleep quality and were experiencing more depression and more stress than those with consistent sleep patterns.	N/A[b]	PHQ-9, DASS[c], SIAS[d], GAD-7[e], PQ[f], PSS[g], PSQI[h], BASIS[i], SF[j]-36, SFS[k], Flourishing Scale, CGI[l], HDRS[m], CAS[n], HAI[o], and UCLA[p]-Loneliness Scale	100 students
Jacobson et al [33], 2020	Predict social anxiety symptom severity and discriminate between depression, negative affect, and positive affect	Accelerometer, call log, and SMS text message data	Android	Measures of SMS text message and call response time discriminated among depression, negative affect, and positive affect. Accelerometer patterns suggested that persons with low social anxiety walked at a steady pace, whereas persons with high social anxiety walked more quickly with more irregularity.	XGBoost[q] with LOOCV[r] was used to predict social anxiety symptom severity.	SIAS, DASS-21, and PANAS[s]	59 students
DaSilva et al [39], 2019	Predict stress	GPS, accelerometer, phone lock and unlock, microphone, and light sensor data	iOS and Android	Students with stress were more likely to spend less time in campus food locations and more time in schoolwork locations. Students with stress traveled less, engaged in fewer conversations, and were in quieter environments during evenings.	Penalized generalized estimating equations were used to prune features and fit a marginal regression model to predict stress.	MPSM[t]	94 students
Acikmese and Alptekin [43], 2019	Predict stress level	Accelerometer, microphone, Bluetooth, light sensor, phone lock and unlock, phone charge, and app use data (GPS and Wi-Fi data were collected but not used)	Android	Students were successfully categorized as stressed or nonstressed using the measured sensors.	LSTM[u], CNN[v], and CNN-LSTM were used to classify stress, with LSTM yielding the best accuracy.	Self-reported stress	48 students

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Rooksby et al [28], 2019	Understand students' perspectives about digital phenotyping	GPS, phone lock and unlock, phone charge, battery, microphone, Bluetooth, light sensor, SMS text message, email, app use, call log, camera, and keyboard data	iOS and Android	None of the results related sensors to symptoms of depression or anxiety. Students have privacy concerns regarding the use of app use logs, Bluetooth data, call logs, camera data, keyboard data, and microphone data but not regarding the use of battery, or light sensor. Students had privacy concerns with the use of SMS text message content but not with counts of messages.	N/A	PHQ-9, GAD-7, and WEMWBS[w]	15 students
Chikersal et al [47], 2021	Predict postsemester depressive symptoms	GPS, accelerometer, Bluetooth, Wi-Fi, phone use, call log, and microphone data	iOS and Android	Depression was predicted by participants' social context in the afternoons and evenings, phone use throughout the day, long periods without exercise, periods of disturbed sleep at night, and time spent outdoors.	Trained an ensemble classifier with the outputs from models containing features from 1 sensor, with different setting combinations.	BDI[x]-II	138 students
Morshed et al [42], 2019	Predict mood instability	Accelerometer, microphone, Bluetooth, light sensor, Wi-Fi, GPS, phone lock and unlock, and phone charge data	Android	Mood instability was negatively correlated with the duration of sleep, the number of conversations, the amount of activity, and outdoor mobility.	Ridge regression with regularization was used to infer mood instability score.	EMAs[y], PAM[z], and PANAS	48 students
Zakaria et al [38], 2019	Detect depression and stress	Wi-Fi data	iOS and Android	Students with severe stress spent significantly less time on campus and were less involved in work-related activities than students with normal stress. Students with severe stress were more involved in these activities at the start of the semester, but the involvement decreased over time.	The random forest stress model with domain-specific features achieved the best result, with feature sets changed every 6 days.	PSS-4, PHQ-8, and BFI[aa]	62 students
Zakaria et al [38], 2019	Detect depression and stress	Wi-Fi data	iOS and Android	Same patterns as those mentioned earlier.	The random forest model that excluded domain-specific features achieved the best result, with feature sets changed every 6 days.	PSS-4, PHQ-8, and BFI	11 students
Zakaria et al [38], 2019	Detect depression and stress	Wi-Fi data	iOS and Android	Same patterns as those mentioned earlier.	The best model is a random forest model with the neuroticism score added as an additional feature, with sensor data sets calculated with a 6-day interval.	PSS-4, PHQ-8, and BFI	35 students
Wang et al [50], 2018	Predict depression	Light sensor, GPS, accelerometer, microphone, screen on and off, and phone lock and unlock data	iOS and Android	Students who experienced depression had more irregular sleep patterns, used their phones more at study places, spent more time stationary, and visited fewer locations.	LASSO[ab] regression was used to predict presurvey and postsurvey PHQ-9 scores.	PHQ-4 and PHQ-8	83 students
Exposito et al [29], 2018	Detect stress	Keyboard 3D touch data	iOS	Students' typing pressure increased under stress.	N/A	Self-reported stress	11 students

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Rhim et al [49], 2020	Detect subjective well-being and stress	Accelerometer, GPS, screen on and off, app use, and notification data	Android	Lower subjective well-being was associated with more time spent on campus, more time spent stationary, increased phone use in the evenings, and more expenses.	Hierarchical regression models were used to predict subjective well-being.	COMOSWB[ac], PHQ, SAS[ad], PPC[ae], and BFI	78 students
Sefidgar et al [53], 2019	Detect stress, anxiety, and gender discrimination	Accelerometer, GPS, phone lock and unlock, screen on and off, and call log data	iOS and Android	Students who experienced discrimination became more physically active; their phone use increased in the morning, they had more calls in the evening, and they spent more time in bed on the day of the discrimination.	Linear regression was used to predict long-term changes in mental health states; hierarchical linear modeling was used for short-term prediction.	UCLA Loneliness Scale, SSS[af], MAAS[ag], ERQ[ah], BRS[ai], PSS, CES-D[aj], STAI[ak], and self-reported affect and fairness of treatment	176 students
Cai et al [30], 2018	Detect state affect, stress, anxiety, and depression	Accelerometer, GPS, call log, and SMS text message data	iOS and Android	Negative emotions were related to geographical locations, but this was affected by personal routines and preferences, for example, liking cinema theatres. On Fridays and Saturdays, students reported less negative states.	Compared support vector machine, random forest, and XGboost with LOSOCV[al] and LOOCV to predict negative affect. The best model was support vector machine with LOOCV.	SIAS and self-reported affect (EMAs)	220 students
Boukhechba et al [31], 2018	Predict response rate and latency to EMA	GPS, call log, accelerometer, and SMS text message data	Android	None of the results related sensors to symptoms of depression or anxiety.	Used random forest, support vector machine, and a multilayer perceptron of 1 hidden layer with LOOCV to predict the compliance rate of EMA responses.	Self-reported affect (EMAs)	65 students
Xu et al [46], 2019	Detect depression	Accelerometer, battery or charge, Bluetooth, call log, screen, location, and phone lock and unlock data	iOS and Android	Students who experienced depression had more disturbed sleep patterns and more phone interactions than students who did not experience depression.	AdaBoost[am] with decision tree–based components achieved the best performance when features were hybrid (contextually filtered + unimodal).	BDI-II	138 students
Xu et al [46], 2019	Detect depression	Accelerometer, battery or charge, Bluetooth, call log, screen, location, and phone lock and unlock data	iOS and Android	Same patterns as those mentioned earlier.	AdaBoost with decision tree–based components achieved a similar result to majority-based baseline predictors.	BDI-II	212 students
Boukhechba et al [44], 2017	Predict social anxiety	GPS, call log, and SMS text message data	Android	Students who experienced high social anxiety may be more likely to buy food so they can eat at home; they tended to visit fewer places and had a narrower range of activities.	Decision tree was used to predict SAS.	SIAS	54 students
Rashid et al [37], 2020	Predict social anxiety and evaluate the effectiveness of imputation methods in handling missing data	GPS, pedometer, accelerometer, call log, and SMS text message data	iOS and Android	The level of social anxiety was predicted, but there were no specific patterns relating sensors to symptoms of social anxiety.	Evaluated 7 predictive models: linear regression, decision tree, XBboost, lightGBM[an], random forest, MERF[ao], and CatBoost.	SIAS and self-reported dimensions of social anxiety	80 students

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Mendu et al [54], 2020	Explore the relationships among private social media messages, personality traits, and symptoms of mental illness	Facebook (Meta Platforms, Inc) private messages	iOS and Android	Students who experienced anxiety received responses later, had more night-time communications, talked less about games and sports, and used more plural pronouns.	Used random forest classifier to select features and support vector machine with LOOCV to predict each psychological measure binarily.	STAI, UCLA Loneliness Scale, and TIPI[ap]	103 students
Tseng et al [45], 2016	Detect stress and its relationship with academic performance	Location, activity, step count (iOS only), audio, accelerometer (iOS only), device use, charging event, battery, light (Android only), SMS text message (Android only) and call (Android only) data and data about currently running apps (Android only)	iOS and Android	Students slept less during examination periods and more during breaks; they felt more stressed during the breaks and examination periods; sensor data were able to capture different routines during weekdays, weekends, and breaks.	N/A	PSQI, ESS[aq], MCTQ[ar], PROMIS[as]-10, BHM[at]-20, CD-RISC[au], Flourishing Scale, Perceived Stress Scale, BFI, PHQ-8, and UCLA Loneliness Scale	22 students
Mack et al [59], 2021	Understand the association between behavioral and mental health and the COVID-19 pandemic	GPS, accelerometer, phone lock and unlock, and light sensor data	iOS and Android	During the COVID-19 pandemic, students experienced more depression and anxiety and increased sedentary time and phone use, whereas sleep and the number of locations visited decreased.	N/A	PHQ-4 and EMAs	217 students
Xu et al [60], 2023	Evaluate the cross–data set generalizability of depression detection	GPS, accelerometer, phone lock and unlock, Bluetooth, Wi-Fi, call log, microphone, gyroscope, and light sensor data	iOS and Android	Individuals who experienced depression had shorter sleep duration, had more interrupted sleep, had more frequent phone locks and unlocks, spent more time at home, were more sedentary, had fewer physical activities, visited fewer uncommon places, and had more consistent mobility patterns.	A multitask learning model with the 1D-CNN[av]–based embedding, fully connected layers for reordering and classification.	Weekly surveys on self-reported depression symptoms and affect, BDI-II, and PHQ-4	534 students
Nepal et al [61], 2022	Explore the association between students' COVID-19 concerns and behavioral and mental health	GPS, accelerometer, phone lock and unlock, light sensor, and phone use data	iOS and Android	Heightened COVID-19 concerns correlated with increased depression, anxiety, and stress. No specific results relating sensors to symptoms of depression, anxiety, or stress were observed.	Evaluated different deep learning models in terms of their classification of COVID-19 concerns: CNN, InceptionTime, MCDCNN[aw], ResNet[ax], multilayer perceptron, TWIESN[ay], LSTM, and FCNN[az]; FCNN performed the best, with an AUROC[ba] score of 0.7.	Self-reported affect and PHQ-4	180 students
Currey and Torous [51], 2022	Predict survey results on mental health from passive sensors	GPS, accelerometer, call, and screen time data	iOS	Individuals at higher risks of psychosis spent less time at home. Individuals who were lonelier had longer sleep duration and fewer calls. Individuals who experienced stress or depression had longer outgoing calls.	Logistic regression was used to predict survey scores.	PHQ-9, GAD-7, PSS, UCLA Loneliness Scale, PQ-16, and PSQI	147 students

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Currey et al [57], 2023	Explore the cross–data set generalizability of symptom improvement based on the surveys	GPS, accelerometer, and screen time data	iOS and Android	Logistic regression was able to predict changes in mood across 2 data sets of student participants. No results relating sensors to symptoms of depression or anxiety were observed.	Logistic regression was used to predict weekly score improvement from both active and passive features. Studies With Adults

Table 4 presents the data extracted from the studies conducted with the general adult population. The average study duration was 201.6 (SD 367) days. Apart from a 3-year longitudinal study with 18,000 participants, the average number of participants was 123.4 (SD 139.8). Of the 8 studies with adults, 2 (25%) [32,52] were conducted with the same set of participants. A total of 3 (38%) studies used predictive modeling, with regression-based models being the most common [34,36,52], and 1 (12%) study identified gender differences in behavioral patterns [27]. Overall, the research with adults showed that GPS, accelerometer, ambient audio, and illuminance data related to individuals' emotional state. Adults with depression were less likely to leave home and were less physically active, whereas adults who were socially anxious were more active and left their home more often but avoided going to places where they needed to socially interact.

Table 4. Summary of the reviewed studies with adult participants.

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Di Matteo et al [32], 2021	Understand whether ambient speech correlates with social anxiety, generalized anxiety, and depressive symptoms	Microphone data	Android	Generalized anxiety and depression were correlated with reward-related words. Social anxiety was correlated with vision-related words.	N/A[a]	LSAS[b], GAD-7[c], PHQ[d]-8, and SDS[e]	86 Canadian adults
Di Matteo et al [52], 2021	Predict general anxiety disorder, social anxiety disorder, and depression	GPS, microphone, screen on and off, and light sensor data	Android	Depression and social anxiety were associated with increased screen use. Depression was associated with sleep disturbance and death-related word features.	A total of 3 logistic regression models were used to predict social anxiety disorder and generalized anxiety disorder with repeated k-fold cross validation.	LSAS, GAD-7, PHQ-8, and SDS	84 Canadian adults
Wen et al [34], 2021	Detect impulsive behavior, positivity, and stress	Call log, phone lock and unlock, and phone charging data	iOS and Android	Impulsivity was correlated with increased phone use and screen checking.	Used LASSO[f] regularization to first select features and trained a linear regression model to estimate trait impulsivity scores.	BIS[g]-15, UPPS[h], PAM[i], and self-reported feelings	26 adults
Fukazawa et al [36], 2019	Predict anxiety levels and stress	Light sensor, gyroscope, accelerometer, and app use data	Android	Anxiety was higher from Monday to Thursday than on Friday and Saturday. Increased anxiety was associated with decreased mobility. During mild exercise, anxiety was reduced.	Used linear classifier by LASSO and XGBoost[j] to classify the change of anxiety.	STAI[k]	20 adults
Pratap et al [55], 2017	Detect depression	GPS, call log, and SMS text message data	iOS and Android	None of the results related sensors to symptoms of depression.	N/A	PHQ-2 and PHQ-9	359 Hispanic or Latino adults
Adams et al [26], 2014	Detect stress level	Microphone data	iOS and Android	Stress can be recognized from pitch, speaking speed, and vocal energy.	N/A	PANAS[l], PSS[m]-14, MAAS[n], and self-reported affect	7 adults
Meyerhoff et al [48], 2021	Detect anxiety and depression	GPS, call log, app use, and SMS text message data	Android	Changes in the number of locations visited and social activity duration were associated with depression. Time spent at exercise locations was positively correlated with changes in depressive symptoms.	N/A	GAD-7, PHQ-8, and SPIN[o]	282 adults
Servia-Rodríguez et al [27], 2017	Predict mood	GPS, Wi-Fi, cell tower, accelerometer, microphone, SMS text message, and call data	Android	A strong correlation was identified between daily routines and users' personality, well-being perception, and other psychological variables; the participants who were the most emotionally stable tended to be more active, stayed in more noisy places, and texted less than participants who were unstable.	Used stacked RBMs[p] to classify moods.	Big-5 personality test, self-reported mood, and self-reports of locations	18,000 adults mainly

[a]N/A: not applicable.

[b]LSAS: Liebowitz Social Anxiety Scale.

[c]GAD-7: Generalized Anxiety Disorder Assessment-7.

[d]PHQ: Patient Health Questionnaire.
[e]SDS: Sheehan Disability Scale.
[f]LASSO: least absolute shrinkage and selection operator.
[g]BIS: Barratt Impulsiveness Scale.
[h]UPPS: Impulsive Behavior Scale.
[i]PAM: Patient Activation Measure.
[j]XGBoost: extreme gradient boosting.
[k]STAI: State Trait Anxiety Inventory.

[m]PSS: Perceived Stress Scale.
[n]MAAS: Mindful Attention Awareness Scale.
[o]SPIN: Social Phobia Inventory.
[p]RBM: Restricted Boltzmann Machine.

Studies With Employees

Table 5 presents the data extracted from the studies that were conducted with employees. Among the 4 studies with employees, 1 (25%) study recruited its own participants [56], and the other 3 (75%) studies [40-42] used the Tesserae data set [63]. Compared with students and adults, the employee population was the least studied, with the fewest articles. However, the studies with employees had the largest number of participants, with a mean of 427.3 (SD 280.3). All 4 studies used regression-based predictive modeling, and 2 (50%) of them [40,56] evaluated a variety of models, with logistic regression, support vector machine, and random forest being the most common methods. Detecting and predicting employees' stress in workplaces were examined in tandem with employees' work performance. The research goal for these studies was to understand the underlining reasons for lowered work-related productivity. In contrast to the other 2 populations (ie, students and adults), less mobility was seen as positive for employees because less mobility in workplaces was associated with more positivity and higher performance.

Table 5. Summary of the reviewed studies with employee participants.

Study, year	Aim	Data collected	Operating system	Behavioral patterns	Predictive modeling	Verification surveys	Sample size, n
Mirjafari et al [56], 2019	Predict stress and job performance	Accelerometer, GPS, phone lock and unlock, and light sensor data	iOS and Android	Higher performers unlocked their phone fewer times during evenings, had less physical activity, visited fewer locations on weekday evenings, were more mobile, and visited more locations during weekends.	Evaluated logistic regression, support vector machine, random forest, and XGBoost[a] in terms of employee performance classification; XGBoost was the best model with 5-fold cross validation.	ITP[b], IRB[c], OCB[d], and CWB[e]	554 employees
Nepal et al [40], 2020	Detect stress, well-being, and mood	GPS, phone lock and unlock, accelerometer, Bluetooth, and phone use data	iOS and Android	Promoted employees spent more time on their phones during early mornings and late evenings and had more unlocks during the night time than nonpromoted employees. Women's mobility increased after promotion, whereas men's mobility decreased.	Evaluated logistic regression, support vector machine, Gaussian naive Bayes, random forest, and k-nearest neighbor in terms of their classification between promoted and nonpromoted periods; the best model was logistic regression trained on ROCKET[f]-based features.	CWB, OCB, IRB, and ITP	141 employees
Saha et al [41], 2019	Predict stress and workplace performance	Light sensor, GPS, accelerometer, and phone lock and unlock data	iOS and Android	Stress was higher with increased role ambiguity.	Linear regression was used to predict a well-being score.	IRB, ITP, and OCB	257 employees
Morshed et al [42], 2019	Predict mood instability	Light sensor, GPS, accelerometer, and phone lock and unlock data	iOS and Android	Mood instability was negatively correlated with the duration of sleep, the number of conversations, the amount of activity, and outdoor mobility.	Ridge regression with regularization was used to infer a mood instability score.	EMAs[g], PAM[h], and PANAS[i]	757 employees

[a]XGBoost: extreme gradient boosting.

[b]ITP: Psychological Type Indicator.

[c]IRB: in-role behavior.

[d]OCB: organizational citizenship behavior.

[e]CWB: counterproductive work behavior.

[f]ROCKET: random convolutional kernel transform.

[g]EMA: ecological momentary assessment.

[h]PAM: Patient Activation Measure.

[i]PANAS: Positive and Negative Affect Schedule.

Passive Sensors

Overview

Table 6 provides an overview of the range of sensors used to detect patterns related to mild mental health symptoms and summarizes the evidence of the effectiveness of the various sensors. The first column lists the sensor, and the second column presents how the data from that sensor are interpreted; in other words, it presents the behavior-related information that the sensor data are intended to represent. The third column indicates which articles found significant associations between the specific sensor and stress, anxiety, or mild depression. The fourth column indicates which articles found no significant associations between the specific sensor and mental health outcomes (ie, explicitly stated so in the articles). In the subsequent sections, we discuss the types of activities detected by the sensors.

Table 6. Sensor summary of the reviewed studies.

Sensor	Behavior	Evidence for effectiveness	No evidence
GPS	Location and physical activity	[27,30,35,37,39-42,44-53,56-61]	[28,31,55]
Microphone	Voice recognition, ambient sound, and sleep	[26,27,32,39,42,43,45,48,50,52,60]	[28,41,47]
Light sensor	Time spent in darkness and sleep	[36,39,41,43,45,50,52,56,58-61]	[28,42,48]
Accelerometer	Movement and physical activity	[27,30,35-37,39-43,45-47,49-51,53,56-61]	[31,33]
Phone locks and unlocks	Phone use	[34,35,39,40,43,45-47,50,53,56,58-61]	[28,41,42]
Call logs	Social interaction and incoming and outgoing calls	[27,33,34,37,44-46,51,53,60]	[28,30,31,35,47,48,55]
Bluetooth	Social interaction	[40,42,43,46,47,60]	[28,51]
Wi-Fi	Indoor location	[27,38,42,47,60]	None
Keyboard	Typing patterns and muscle activity	[29]	[28]
SMS text messages and emails	Social interaction and incoming and outgoing messages	[27,32,33,37,44,45,52]	[28,30,31,48,55]
App use	Phone use and social media	[28,35,36,40,43,45,48,49,61]	None
Screen on and off	Phone use	[40,45,46,49,50,52,53,55,57]	[51]
Gyroscope	Orientation of the smartphone	[36,60]	None

Social Interaction: Call and Text Logs, Audio, Microphone, and Bluetooth

The social interaction of an individual is reflective of their current mood and mental state [44,64,65,66]. Individuals with depression and stress may be expected to decrease their social interactions. This is measured through the frequency of receiving texts and calls, how fast individuals respond, and the frequency of being around others. Among the 40 included studies, 18 (45%) [27,28,30,31,33-35,37,44-48,51,53,55,60] examined call logs to understand social interaction patterns, mainly through the number of incoming and outgoing calls, the number of missed calls, and the duration of calls. Individuals who experience depression and stress may engage in longer outgoing calls [51]. Evening communications were predictive of depression [47], anxiety, and loneliness [54]. Students who experienced discriminations [53] and anxious participants had more evening communications [54]. Metadata on SMS text messages were examined in 10 (25%) [27,28,30,31,33,37,44,45,48,55] of the 40 studies, including the frequency of receiving SMS text messages and the average time of responses. People who are socially anxious were found to take different amounts of time to respond to SMS text messages and calls [33]. Increases in the number of calls were associated with increased social anxiety [48]. Those who experienced social anxiety were less likely to call or text in public [44]. For students, fewer conversations were associated with more stress [39] and more mood instability [42]. One of the studies found that more emotionally unstable individuals tended to text more than emotionally stable individuals [27].

Location: GPS, Bluetooth, and Wi-Fi

Location data can provide insights into individuals' mental health state in terms of the normal or abnormal variety and frequency of locations visited [67]. As presented in Table 6, GPS has been one of the most commonly used passive sensors for stress, anxiety, and mild depression research. The findings regarding location consistently demonstrate that students and adults who experienced depression, anxiety, or stress tended to visit fewer places [39,44,50,58-60]. One of the studies [48] found that location data are highly inversely correlated with mild depression severity. The main way in which this is measured is through the frequency of exiting the house, the variety of locations visited, and mobility. The frequency of exiting the house is less for individuals who are depressed, and there is less variety in the visited locations for individuals who are socially anxious. Individuals who are feeling depressed often experience being less energetic [68,69]. Overall, negative emotions were associated with time spent at specific locations, but this is also affected by personal routines and preferences [30]. For students, stress and lower subjective well-being were associated with more time spent on campus [39,49] and less time spent at campus food locations [39]. Students who experienced depression spent more time at home [60], whereas individuals at higher risk of psychosis spent less time at home [51]. Time spent at exercise locations was positively correlated with changes in depressive symptoms [48]. Another study [38] distinguished between students experiencing severe stress and those with normal stress levels, revealing that students with severe stress spent significantly less time on campus and were less involved in work-related activities compared with their counterparts with normal stress levels. As for employees, higher performers were found to visit fewer locations on weekday evenings but more locations during weekends [56].

Voice Recognition: Audio

The microphone is used to measure audio data of speech and ambient noises. One of the studies [26] examined how people with stress speak by analyzing their voice, including the speed of speech, how energetic their vocality is, and the pitch. One caveat is that the study by Adams et al [26] used audio captured within laboratory environments and found that stress could be

recognized from the absence of speech. In variable environments, it will be harder to recognize the changing voice patterns. One study found that generalized anxiety and depression related to reward-related words in ambient speech, and social anxiety related to vision-related words [32]. Another study [52] identified that people with depression tend to speak less and use more death-related words.

Sleep: Accelerometer, Audio, and Illuminance

Sleep is highly correlated with individuals' mental state [26,35,36,42,45-47,59,60]. Among the 40 included studies, 5 (13%) [35,46,52,60] found that more disturbed sleep correlated with more depressive symptoms. However, occasional sleep disturbance is not necessarily predictive. For example, for those with social anxiety, sleep disturbance might be positive because it suggests night-time activity and social interactions. Metadata on the time spent in darkness can be indicative of sleep patterns. The study by Fukazawa et al [36] stated that anxiety levels increase when the time spent in darkness increases. The study by Di Matteo et al [52] found that individuals with symptoms related to social anxiety and depression spent less time in darker environments. Another study [39] stated that stress changed students' sleep patterns, where they became less likely to move around between 6 PM and midnight. Of the 40 studies, 6 (15%) found that shorter sleep duration was correlated with more mood instability [42], more depressive symptoms [59,60], and more stress [36,44]. One of the studies [45] also found that the student population, in general, tended to sleep less during examination periods and slept more during breaks, and they felt more stressed during both breaks and examination periods.

Phone Use: On and Off Screen, Lock and Unlock, and App Use

Today, smartphones are used for self-regulated "distractions," such as the use of social media [38]. This type of self-regulated distraction can temporarily reduce stress. The study by Chikersal et al [47] showed that depression can impact concentration levels, so if distraction by phone can be measured, this could be a potential predictive marker. Several studies found that increasing phone use was correlated with more depressive symptoms [46,47,50,52,58-60], anxiety [52,59], impulsivity [34] and lower subjective-wellbeing [49]. The study by Morshed et al [42] outlined that for postsemester depression, phone use at night is not predictive, whereas another study [47] summarized that phone use during the day is predictive of depression. More frequent phone locks or unlocks correlated with higher levels of depressive symptoms [60] and impulsivity [34]. Higher performing employees tended to unlock their phones less frequently in the evenings [56]. Additionally, individuals who were promoted spent more time on their phones during early mornings and late evenings, with more unlocks occurring during nighttime compared with their nonpromoted counterparts [40].

Physical Activity and Mobility: Accelerometer

According to Table 6, along with GPS, accelerometer is one of the most widely used passive sensors in digital phenotyping research to monitor participant's mobility, activity, and sedentary periods. Increased sedentary time was correlated with increased depressive symptoms [47,48,50,58-60], increased mood instability [27,42], increased stress [36] and decreased subjective well-being [49]. Exercise duration was positively correlated with changes in anxiety [36] and depressive symptoms [48]. The study by Mirjafari et al [56] found that the amount of movement and physical activity was related to employee's stress level and highlighted that if the activity is regular, it should reduce stress. Different occupations require different levels of physical activity, social interactions, and mobility. For instance, developers spend most of their time at their desks, and their tasks might require less social interaction and mobility at work, but this does not mean they are more stressed. Project managers have more mobility during the day, and this may be because they need to move around to meet with the stakeholders [56]. Several studies have observed variations in mobility and gait consistency. The study by Boukhechba et al [44] reported that individuals with high social anxiety exhibited a narrower range of activities, whereas the study by Xu et al [60] revealed that students experiencing depression demonstrated more consistent mobility patterns. Additionally, accelerometer data indicated that individuals with low social anxiety maintained a steady walking pace, whereas those with high social anxiety tended to walk more rapidly and with greater irregularity [33].

Muscle Activity: Keyboard

Stress can cause muscle tension [70,71]. One of the studies [29] collected the data of users with stress via a keyboard in a laboratory environment and found that typing pressure significantly increased under stressful conditions.

Challenges

Digital phenotyping for mild mental health symptoms in nonclinical participants can present ethical challenges, limitations to the research, and technical challenges. We review the challenges that were stated in the literature.

Ethical Challenges

Among the 40 included studies, 7 (18%) specifically mentioned privacy-related ethical concerns [28,31,35,36,40,41,43]. A major concern for participants across several studies was whether authorities, such as employers or teachers, will have access to their data. One of the studies [28] conducted in-depth interviews with 15 students to understand their perspectives on digital phenotyping through app prototypes. They found that the students' core concerns were whether the acquainted university staff had access to the data. They also found that students' acceptability of such apps depends on the perceived relevancy of the data collected and the effects on students' devices. The study by Nepal et al [40] with employees reported a similar privacy concern of whether the employees' data would be leaked to their boss; if the boss is aware of a potential mental health issue, it may impact their work performance ratings.

The methods of collecting and storing passive sensing data also present privacy concerns [28,70,72], particularly when the tracked data involve sensitive topics, such as mental health [72]. Sensors that infer individuals' social interactions provide insights into their mental health status [26,36,53]. However, these types of data were less likely to be shared by participants

because of privacy concerns. In the study by Rooksby et al [28], students identified camera, microphone, call log, and keyboard data as highly unacceptable types of data to capture.

Location data were associated with privacy and security concerns. In the study by Wen et al [34], participants felt uncomfortable with location tracking because it might breach their privacy and were hesitant to log their location when they moved from one place to another. Some studies excluded specific sensors to protect the participant's privacy. Location data were not recorded owing to security concerns, even though they could provide valuable insights into the mental state [36,38]. In the study by Adams et al [26], the microphone was disabled to capture calls and conversations while individuals were talking to their family members. Another ethical concern was regarding the misuse of data. The main focus in studies of digital phenotyping using smartphones was on tracking participants' usual behavioral patterns and identifying whether they behaved unusually. There were concerns regarding secondary uses. For example, participants' leaked data can be used for advertising purposes or to create content [34,41].

Limitations to the Research

Coping mechanisms related to stress and anxiety vary among individuals [22]. Individual differences can make it challenging to label individuals as stressed, anxious, or depressed, particularly nonclinical participants. Certain behavioral patterns can be generally expected; however, not all individuals will follow the same pattern. To make generalizable and powerful analyses and understand behavioral patterns associated with mild mental health concerns, it is recommended to study diverse groups for longer than a 2-week period. Of the 40 included studies, 2 (5%) [33,39] focused on a particular demographic subset, namely, undergraduate students. Therefore, the generalizability of the studies is limited. In the studies by Rooksby et al [28], Exposito et al [29], and Wang et al [50], limited variation in representation was seen as a major limitation. The studies by Rhim et al [49], DaSilva et al [39], and Fukazawa et al [36] stressed the importance of selecting a wider age group, as younger people use their smartphones proactively, whereas older people's behavioral patterns might show differences when they are experiencing mild mental health symptoms. The study by Nepal et al [40] suggested that diverse population testing is required for more reliable results, considering interindividual differences. Furthermore, the accuracy and effectiveness of machine learning models are highly affected by data set quality. We noticed that over the last 4 years [38,46,57,60], there has been increased focus on the generalizability of machine learning models, with the goal of assessing generalizability across students from various years, classes, and institutions.

Technical Challenges

Digital phenotyping studies on mild symptoms related to mental health with nonclinical participants presented technical challenges. A main concern was the accuracy of the sensor data collected from smartphones. The study by Fukazawa et al [36] sought to understand the time spent in darkness and its effects on the relationship between stress and anxiety patterns and sleep. However, when individuals carried their smartphone in their pockets or bags, the smartphone could not detect the darkness of the environment. This presented a challenge because illuminance data were captured even when the phone was not used actively. Similar concerns were raised in the study by Di Matteo et al [52]. The time spent in darkness feature did not distinguish whether the device was in a dark room or a dark location (ie, in the pocket). The study by Melcher et al [35] stated that the captured accelerometer data may not accurately represent daily activity, as not all participants constantly carried their phones throughout the day. In the study by Di Matteo et al [32], environmental audio did not produce clear transcripts in louder environments. This study mentioned that transcripts were produced based on dictionaries, so language analysis of complex speech, such as metaphors and sarcasm, was ignored. Therefore, the entire content of the conversation might not be correctly interpreted. In the study by Di Matteo et al [52], similar challenges were identified, as the speech data produced from smartphones were not clear. The recorded voices of the participants were masked by those of the people around them or even sound from other sources such as television or radio. Moreover, it was not possible to identify whether the death-related words came from the participants or from the people they interacted with.

Another technical challenge identified was battery life [47]. As expected, moment-by-moment data collection requires high power use, which might shorten the battery life. Participants had to charge their phones more often, which was inconvenient, and altered their usual behavior because they could not carry their phones as usual when the phones were charging. The study by Chikersal et al [47] mentioned another technical limitation: the transfer rate was affected if the app stopped working randomly. During these times, data were not transferred or collected. With the increase in the use of 5G technology, Wi-Fi data for indoor locations may cease to be relevant. In the study by Zakaria et al [38], some users were on their 5G indoors rather than their Wi-Fi, and this may point to a future trend of the use of 5G. We now turn to the discussion.

Discussion

Principal Findings

This literature review examined digital phenotyping studies that detected and predicted stress, anxiety, and depression in their mild states in nonclinical populations using data collected from smartphones. The primary objective of digital phenotyping in the context of mild mental health was similar among the 3 participant cohorts: students, adults, and employees. However, notable distinctions emerged among these groups. Among university students, the geographical proximity and relevance of the university campus were discerned as influential factors. Moreover, academic pursuits, particularly coursework and study-related activities, assumed significance within this demographic. Conversely, among employees, work aspects held salience, accompanied by the workplace environment. The remaining studies encompassed a general population cohort, delineated by undisclosed characteristics. Overall, we found that identifying behavioral abnormalities related to stress and anxiety was possible but raised certain challenges. Generalized

stress and anxiety symptoms vary largely among individuals, whereas serious diagnoses, such as bipolar disorder or schizophrenia, have well-documented behavioral changes. Sleep was a strong predictor variable, yet some individuals tended to sleep more while they were stressed, whereas others lacked sleep under stress. This may be one of the reasons why there are fewer studies and reviews completed on stress and anxiety compared with studies on serious conditions such as bipolar disorder, severe depression, and schizophrenia. Another reason is that clinical psychologists and psychiatrists who are familiar with clinical populations are leading the digital phenotyping research.

Studies tended to use self-report to categorize nonclinical populations as stressed, depressed, or anxious. It was not always clear whether the identified patterns of the passive sensor data would effectively discriminate among groups. Most studies used prestudy and poststudy surveys to identify participants' mental state. There were concerns raised regarding the accuracy of the categorization of self-report surveys. For instance, the study by Sefidgar et al [53] stated that students with stress may not report themselves as very stressed. Melcher et al [70] conducted a review and found that students were concerned regarding their professors learning about their data [71]. Thus, the accuracy of self-report remains an issue for passive sensing studies that use self-report labels, especially when there are privacy concerns. This may be related to the high dropout rates in the studies.

Many types of data sensors were used in the reviewed studies. Few articles related sensor patterns to specific symptoms validated by relevant psychological evidence. One of the studies [46] extracted interpretable rules (such as intermittent sleep episodes or number of bouts of being asleep or number of outgoing calls during weekends) through association rule mining to distinguish the behavioral patterns between students who were depressed and students who were not. However, although the behavioral patterns were identified, they were not validated to be exclusive to the addressed mental health issue; for example, high mobility and physical activity do not necessarily mean that the person is not stressed. In the study by Tseng et al [45], students were more mobile during the examination week, despite being under high pressure and stress. In the same study, some students were less mobile when studying for their examinations, which we cannot necessarily be interpreted as being under stress. Of the 40 included studies, 4 (10%) [35,58,59,61] explored the effects of the COVID-19 pandemic on behavioral and mental health. Additional recent investigations, which independently gathered their own data sets during the COVID-19 pandemic, have shown that quarantine measures have influenced individual behavioral patterns. For the purpose of making precise predictions in digital phenotyping, it is imperative to consider contextual and environmental factors.

Privacy and secondary data uses were the main concerns identified for digital phenotyping. Individuals using digital phenotyping systems have the right to provide informed consent. This means that they should be made aware of how all their data will be used, who will have access to their data, where their data will be stored, and for how long their data will be stored, and they have the right to decline to participate. We urge researchers and medical practitioners to carefully consider the system design and requirements because data transferred to the cloud and other services may fall under various service agreements. To empower end users and improve the quality of digital phenotyping systems, we recommend that transparent algorithms and explainable artificial intelligence be combined with user-accessible and understandable displays so that adults can engage in the process of identifying and categorizing patterns related to mild mental health symptoms.

The digital phenotyping research focused on in this review may enable the design of tailored intervention programs for nonclinical participants who are showing symptoms of stress, anxiety, and mild depression. Most of the studies included in this review were conducted within a restricted timeline and limited scope of detection and prediction. Only 4 (10%) of the 40 studies mentioned potential intervention programs upon predicting stress, anxiety, and mild depression [31,38,47,53].

Our review has some limitations. We excluded studies conducted with teenagers, children, and adults who were clinically diagnosed. Thus, we missed studies that focused on the detection and prediction of stress, anxiety, and mild depression in these populations. These populations are likely to show different patterns than those in adults who are not clinically diagnosed. Further, we excluded studies conducted using technologies other than smartphones. We chose this more limited subset of technologies to scope findings related to widely available technologies. The availability of technologies is changing rapidly, and wearables such as smartwatches are becoming more common. As wearable technologies become ubiquitous, we recommend including them in future systematic reviews.

This literature review is unique in that it examines studies focused on the behavioral patterns of nonclinical populations, namely students, employees, and adults who are stressed, anxious, or mildly depressed. We examined each type of sensor and indicated when it was significantly associated with mild mental health symptoms. We identified commonalities in the studies in terms of ethical challenges, limitations to the research, and technical challenges.

Conclusions

This systematic literature review found that digital phenotyping can be an effective way of identifying certain behavioral patterns related to stress, anxiety, and mild depression. A range of passive sensors was used in the studies, such as GPS, Bluetooth, ambient audio, light sensors, accelerometers, microphones, illuminance, and Wi-Fi. We found that location, physical activity, and social interaction data were highly related to participants' mental health and well-being. The surveyed literature discussed the ethical and technical challenges that limit the accuracy and generalizability of results. One of the greatest challenges was privacy concerns, and these were primarily related to camera, location, SMS text message, and call log data. Another challenge was the significant variation among individuals and their unique behaviors related to mental health. Finally, technical limitations have not been fully resolved, with issues such as the sensor for illuminance still capturing data while not in use reducing the accuracy of the

collected data. It is hoped that this overview of digital phenotyping and mental health studies conducted in the last decade, including the common privacy and technical concerns, can help move this area of research forward, ultimately improving the quality of passive sensing, and provide benefits in terms of the early detection of relevant mild mental health phenomena.

Abstract

Background: Hospitalized patients undergoing surgery or procedures may experience negative symptoms. Music is a nonpharmacological complementary approach and is used as an intervention to reduce anxiety, stress, and pain in these patients. Recently, music has been used conveniently in clinical situations with technology devices, and the mode of providing music is an important factor in technology-based music interventions. However, many reviews have focused only on the effectiveness of music interventions.

Objective: We aimed to review randomized controlled trials (RCTs) of technology-based music interventions for reducing anxiety and pain among patients undergoing surgery or procedures. We examined the clinical situation, devices used, delivery methods, and effectiveness of technology-based music interventions in primary articles.

Methods: The search was performed in the following 5 electronic databases: PubMed, MEDLINE (OvidSP), CINAHL complete, PSYCINFO, and Embase. This systematic review focused on technology-based music interventions. The following articles were included: (1) RCTs, (2) studies using interactive technology (eg, smartphones, mHealth, tablets, applications, and virtual reality), (3) empirical studies reporting pain and anxiety outcomes, and (4) English articles published from 2018 to 2023 (as of January 18, 2023). The risk of bias was assessed using the Cochrane Risk of Bias tool version 2.

Results: Among 292 studies identified, 21 met the inclusion criteria and were included. Of these studies, 9 reported that anxiety scores decreased after music interventions and 7 reported that pain could be decreased before, during, and after procedures. The methodology of the music intervention was important to the results on anxiety and pain in the clinical trials. More than 50% (13/21, 62%) of the studies included in this review allowed participants to select themes themselves. However, it was difficult to distinguish differences in effects depending on the device or software used for the music interventions.

Conclusions: Technology-based music interventions could help reduce anxiety and pain among patients undergoing surgery or procedures. The findings of this review could help medical teams to choose a practical methodology for music interventions. Future studies should examine the effects of advanced technology-based music interventions using smart devices and software that promote interactions between medical staff and patients.

KEYWORDS

technology; music intervention; anxiety; pain

Introduction

Over 33 million patients were hospitalized in the United States in 2020 [1]. Previous studies have reported that many hospitalized patients had experienced negative symptoms, such as pain, anxiety, depression, sleep disturbance, stress, and fatigue, or a combination of these due to illness responses, medical procedures, and unfamiliar environments in the hospital [2-4]. This consistent psychological distress and the negative symptoms could cause a delay in recovery, disrupting optimal treatment and increasing morbidity and mortality [5,6].

To mitigate psychological distress and negative symptoms for patients, nonpharmacological complementary approaches have been studied, such as muscle relaxation, massage, aromatherapy, acupuncture, and music [7-11]. Among these interventions, music interventions were reported to be safe complementary approaches for patients. Therefore, music intervention studies were conducted, especially for hospitalized patients, to reduce pain, improve sleep quality, and help with successful mechanical ventilator weaning [10,12,13].

With the recent developments in science and technology, music interventions can be delivered using smart devices, such as smartphones, tablets, PCs, laptops, and apps [14]. These smart devices allow researchers to deliver personalized music and video content in interactive ways. In addition, health care providers often interact with patients to provide music interventions, bringing psychological stability to patients in a hospital environment. It is possible to provide this treatment independent of a therapist, which may provide a convenient intervention without the time restraints associated with waiting on a therapist [15-20].

Several of the studies supporting music interventions have explained the process of providing music genres and songs that reflect the taste and choice of subjects rather than the music selected by the provider and have reported that this approach enhances the effect of the intervention by increasing the interaction between the provider and patient [14,21-25]. This indicates that the provider-patient interaction is a key element of an intervention using smart devices, and the consideration of the process and method of providing music should be prioritized. However, previous reviews have only focused on the effects of music interventions according to medical treatment and environment, including surgery, procedures, and respiratory treatment [9,25,26], and there has been no consideration of the process and method of a technology-based music intervention and its impact on psychological issues such as anxiety and pain.

The purpose of this study was to focus on the methods of technology-based music interventions and examine the effectiveness of the interventions for the anxiety and pain of hospitalized patients undergoing procedures. The research questions were as follows: (1) What are the characteristics of technology-based music interventions in primary articles? (2) In what ways were technology-based interventions effective for the anxiety and pain of patients undergoing procedures?

Methods

Information Sources and Search Strategy

A systematic review of the literature was performed using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [27]. A comprehensive search was completed in January 2023 by 2 authors (SL and JY) using the following 5 electronic databases: PubMed, MEDLINE (OvidSP), CINAHL complete, PSYCINFO, and Embase.

The search keywords were selected from the PICO format (population: adult patients with procedures in the inpatient and outpatient settings; intervention: technology-based music intervention; comparison: standard care or usual care; outcome: pain and anxiety). These included keywords such as (“inpatient*” OR “hospitalization” OR “intensive care unit*” OR “emergency ward*” OR “general ward*” OR “patient*”) AND (“music*” OR “music intervention” OR “music therapy” OR “music medicine” OR “music listen*” OR “music-based” OR “music methods”) AND (“mobile application*” OR “smartphone” OR “telemedicine” OR “tablet*” OR “computer” OR “mhealth*” OR “ehealth* OR “technolog*” OR “cellphone*” OR “internet*” OR “internet-based” OR “mobile-based” OR “technology-based” OR “smartphone-based” OR “mhealth-based” OR “app*” OR “ipad”) AND (“anxiety” OR “pain”). Results were limited to adults (18 years or older), English text, and publication within 5 years (2018-2023).

Inclusion and Exclusion Criteria

This systematic review selected original empirical research studies on technology-based music interventions. The following articles were included: (1) randomized controlled trials (RCTs), (2) studies using interactive technology (eg, smartphones, mHealth, tablets, applications, and virtual reality), (3) empirical studies reporting pain and anxiety outcomes, and (4) English articles published from 2018 to 2023 (as of January 18, 2023). Articles were excluded if they were (1) not full-text articles (eg, conference abstracts and poster abstracts), (2) review articles, (3) study protocols, (4) studies that were not focused on music interventions (eg, therapist-focused), and (5) studies that targeted inpatients and outpatients who were younger than 18 years. We specifically selected the most recent articles published within the last 5 years to ensure the most up-to-date information on technology-based interventions and to improve upon previous systematic reviews [9,25,26,28,29].

Selection Process and Data Items

Database searches were independently carried out by 2 authors (SL and JY) using electronic databases and cross-references in January 2023. Initially, relevant bibliographic details, including article titles, authors, journal names, publication years, keywords, and abstracts, were retrieved from each electronic database. The management of duplications was facilitated through the use of the EndNote program (Clarivate).

Following the deduplication process, the titles and abstracts underwent independent screening by the 2 authors (SL and JY). Any discrepancies encountered during this phase were systematically resolved through consensus-building between

them. Upon the completion of this initial screening stage, the identified primary articles underwent a comprehensive full-text review.

Subsequently, data extraction from the selected studies was conducted with precision to effectively synthesize the study findings. A matrix table employing Excel (Microsoft Corp) spreadsheets was proficiently used throughout the review process to manage and consolidate the extracted data. The extracted information included a comprehensive array of elements, such as authors' names, research objectives, baseline sample characteristics, study designs, intervention modalities related to music, control group specifications, and outcome variables, with a particular emphasis on elucidating findings pertinent to pain and anxiety.

The full-text screening was independently executed by the same 2 authors. In instances where discrepancies arose during this phase, the intervention of a third author (SP) was sought. The role of the third author entailed a meticulous review of the identified articles to ensure the accuracy and consistency of the selection process. Any disparities or ambiguities were meticulously addressed and resolved under the scrutiny of the third author.

Throughout the review process, adherence to academic standards and methodology was paramount. Any disagreements or discrepancies encountered at any stage were effectively addressed through consensus-building, thereby enhancing the reliability of the synthesized evidence.

Study Risk of Bias Assessment

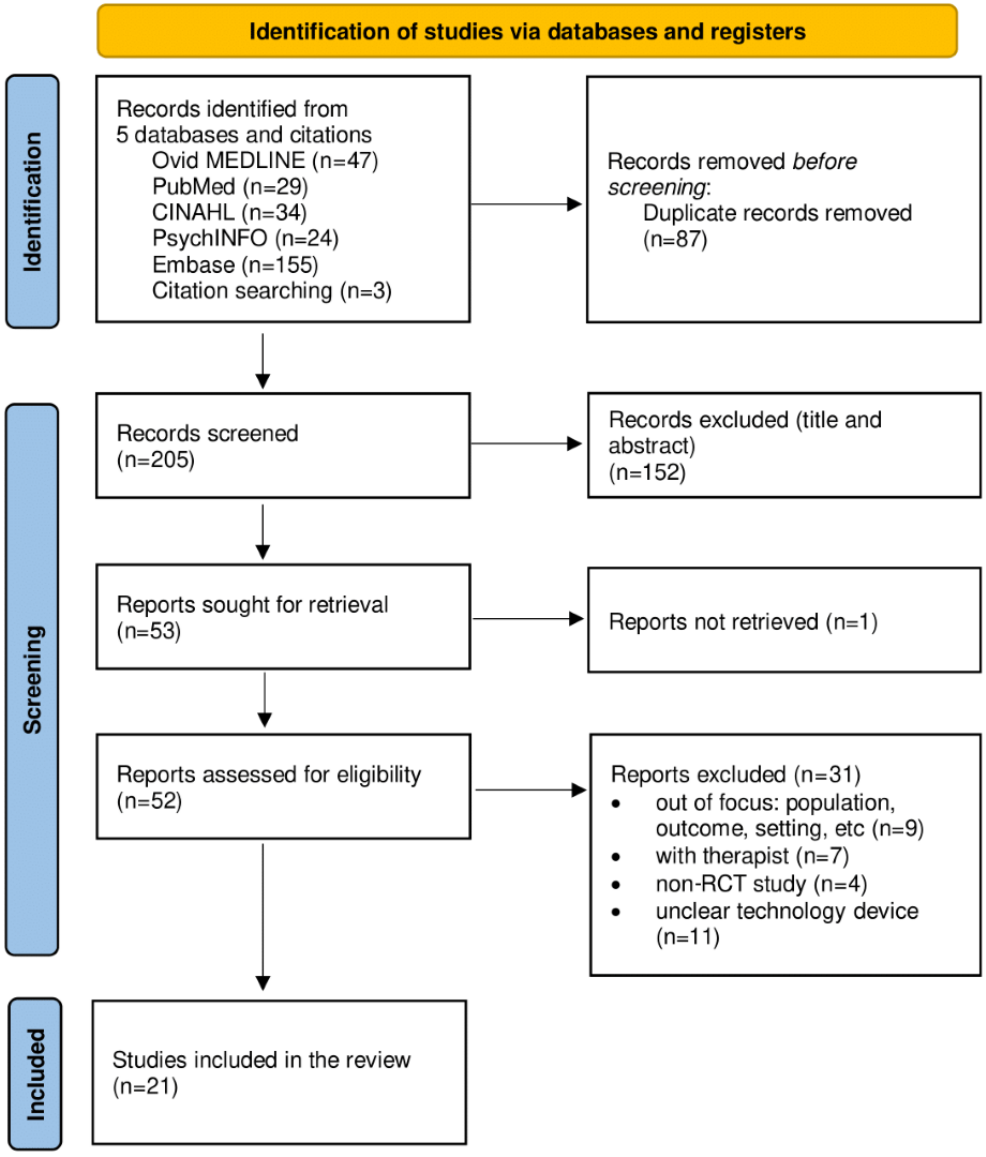
The risk of bias was assessed using the Cochrane Risk of Bias version 2 tool [30]. This tool is used to evaluate the risk of bias for individual RCTs. There are five domains: (1) randomization process, (2) deviations from intended interventions, (3) missing outcome data, (4) measurement of the outcomes, and (5) selection of the reported results. The 3 researchers (SP, SL, and JY) assessed primary articles independently using the Risk of Bias version 2 tool. All disagreements and discrepancies were discussed and resolved through meetings until a consensus was achieved.

Results

Study Selection

Figure 1 shows the flow diagram of the literature search and selection process. A total of 292 articles were identified through 5 electronic database searches. Initially, 87 duplicate articles were eliminated. Subsequently, 205 articles were screened based on titles and abstracts. Among these, 153 articles were excluded due to either irrelevance (n=152) or unavailability of full text (n=1). Following thorough full-text reviews, 31 articles were further excluded for various reasons, including being out of focus (n=9), being therapist-focused (n=7), having a non-RCT design (n=4), and using an unclear technology device (n=11). Consequently, 21 articles met the inclusion criteria for this study.

Figure 1. Study flow chart.



Study Characteristics

The characteristics of the 21 articles included in this study are shown in Table 1. The purpose of all the studies was to examine the effects of technology-based music interventions on patient outcomes, including anxiety and pain. Two studies aimed to examine particularly interactive technology-based interventions [31,32]. Drzymalski et al [31] focused on the impact of self-selected or preselected music, and Anglin et al [32] focused on the effects of a patient's choice. Most studies included male and female participants; however, 6 studies targeted only women [15,20,21,24,31,33]. The sample size ranged from 18 to 330. Most studies had 2 groups (ie, experimental group and control group), except 2 studies [31,33]. The interventions were performed for patients who underwent surgery or invasive procedures. Surgery included gynecologic surgery [20], cardiothoracic surgery [34], cataract surgery [14], orthopedic surgery [35,36], nasal bone fracture reduction [37], and cesarean delivery [21,31]. The procedures included radiation therapy [15], catheter insertion [38], colonoscopy [18], biopsy [24], bronchoscopy [39], steroid injection [40], transvaginal ultrasound-guided oocyte retrieval [33], wound care [16], eye procedures [41], pleural procedures [42], and urologic procedures [32]. The studies were conducted in many countries, including the United States [15,24,31,32,40], France [14,20,38], Hong Kong [18,33], Australia [42], Germany [21], Taiwan [34], India [35,41], Turkey [43], Spain [44], Chile [37], Malaysia [36], Iran [39], and Brazil [16].

Music Intervention Characteristics

Music Playing and Listening Devices

The experimental groups conducted the music intervention using web-based music applications (including QR code access) [14,15,20,24,31,37,38,42], smartphones [20], tablets [14,20], computers [20,42], CD players [20,21,34,43], MP3 players [16,18,33,36,41,44], projectors [39], iPods [31], or personal/cellular devices [32,40] as the music play devices or software. Over 90% (19/21, 91%) of studies used headphones [14,16,18,33-39,41,42,44], earphones [24,43], or speakers [15,21,31,40] for delivery of the intervention.

Music Selection Strategy

In over 50% (13/21, 62%) of studies, participants could select the music theme themselves [14-16,20,24,31,32,36,38-42], and most of the identified music content or genres did not limit the participants' choices [14,15,20,24,31,36,38,40,42]. However, some studies required participants to choose music from playlists available on the music app [38] or select pop-rock, romantic, or religious music [36]. If researchers decided on the music content or genre, there were variations in the selections, such as nature sounds [34], popular songs [18], slow-tempo songs [21,37], relaxation music [35,41,44], folk music [39], piano sonata [31], and regional music [16]. In the experimental groups, music was played before [14,18,20,37,39,41,42,44], during [15,18,21,24,31-33,35,37,38,40,42], or after [16,31,36,37,39,42] the procedure or surgery. The duration was from 10 to 60 minutes [14,16,18,20,36-39,42-44]. Some of the studies did not clearly report the played time and duration. The effect of the intervention was assessed by comparing the experimental group with a no-music intervention group [14,15,31-34,36,37,40-44], standard care group [16,18,21,24,35,38,39], or listening predetermined music group [20].

Effect of the Music Intervention

Anxiety

Seventeen studies employed measures, such as the State-Trait Anxiety Inventory, visual analog scale (VAS), Hospital Anxiety and Depression validated Scale, and Corah dental anxiety scale, to assess anxiety levels. Of these, 13 studies reported a decrease in anxiety scores following music intervention. Out of these 13 studies, 9 (69%) reported a statistically significant decrease in anxiety associated with the use of the music intervention compared to controls [14,21,24,35-37,41-43]. Four studies reported that there were no significant differences between the experimental and control groups, even though there was a reduction in anxiety scores in the experimental group [15,20,31,34]. Studies that reported decreased anxiety scores in the experimental group compared with the control group tended to use music selected by the participants [14,24,36,41,42] and use participants' choices, including classical music [41], traditional music of the nation [43], slow music [21,37], and relaxation music [35,41]. Ten studies assessed music playing during the procedure or surgery [15,18,21,24,31,33,35,37,38,42], and the music playing device or software did not show distinct characteristics (Table 2).

Table 2. Intervention and outcomes of the studies.

Article (author, year)	Music intervention of the experimental group				Comparison or control group	Outcomes (tool)	Key findings
	Music playing device or software	Music selection by participants	Music content or genre	Played time/duration			
Abdul Hamid et al [36], 2022	MP3 with headphones	Yes	Participants' choice: pop-rock, romantic, or religious	After regional anesthesia/30 min	No music	Anxiety (VAS[a], STAI-S[b])	Changes in anxiety from pre- to postoperation were significantly different between the groups (VAS; *P*=.002). Anxiety was higher in the CG[c] than in the EG[d] (STAI-S).
Chen et al [34], 2022	CD player with noise-cancelling headphones	No (nature sounds)	Nature sounds	Not stated	No music	Anxiety (STAI-S, STAI-T[e]); pain (VAS)	Anxiety was not significantly different between the groups (*P*>.05). Reduced postoperative pain and anxiety in cardiothoracic surgery patients, but no significance in the interaction between music intervention and time (*P*=.16).
Jacquier et al [38], 2022	Music Care app with headphones	Yes	Participants' choice: one of the playlists available on the Music Care app	During the procedure/20-60 min	Standard care without music	Anxiety (VAS); pain (VAS)	The music intervention did not reduce patients' anxiety as compared with usual care (anxiety, *P*=.24; pain, *P*=.40).
Kaur et al [35], 2022	Music player with noise-cancelling headphones	Probably no, initial volume setting by participants	Relaxation music	During surgery/not stated	Standard care with a standard operation theater tape sound without music	Anxiety (VAS-A[f])	Anxiety scores were comparable in both groups preoperatively and before anesthesia induction and were lower in the EG intra- and postoperatively (*P*<.001).
Anglin et al [32], 2021	Cellular device	Yes	Not stated	During the procedure/not stated	No music	Pain (VAS-P[g])	Among men, pain scores worsened in both groups (*P*=.38). Among women, changed pain scores significantly differed between the music group and nonmusic group (*P*=.005).
Ferraz et al [16], 2021	MP3 with headphones	Yes	Regional, others	Change of dressing, immediate postoperative period/30 min	Standard care	Pain (NRS[h])	Pain was lower in the EG than in the CG (*P*<.001).
Guerrier et al [14], 2021	Web application–based music (Music Care) with a tablet interface via headphones	Yes	Participants' choice	Before cataract surgery/20 min	Headphones without music	Anxiety (VAS)	Anxiety was lower in the EG than in the CG at the second end point (*P*=.005).
Muddana et al [41], 2021	MP3 with headphones	Yes	Relaxing classical, instrumental, or devotional music	Before surgery/not stated	Headphones without music	Anxiety (State anxiety)	Reduction in self-reported anxiety preoperatively in the EG. A higher proportion in the EG reported feeling not at all or a little anxious compared to the CG peri- and postoperatively (*P*<.05).
O'steen et al [15], 2021	A web-based music application with speakers	Yes	Participants' choice	During radiation therapy/not stated	No music	Anxiety (STAI[i])	Reduction in anxiety scores in the music group relative to the no music group, without statistical significance (*P*=.22).
Reynaud et al [20], 2021	Smartphone, tablet, computer, CD player, or Music Care app (participants' choice)	Yes	Participants' choice, self-selected playlist	One hour before surgery/20 min	Predetermined music using the Music Care app	Anxiety (STAI); pain (NRS)	No significant difference in the reduction of anxiety and pain scores between the groups (anxiety, *P*=.80; pain, *P*=.48).

Article (author, year)	Music intervention of the experimental group				Comparison or control group	Outcomes (tool)	Key findings
	Music playing device or software	Music selection by participants	Music content or genre	Played time/duration			
Bennett et al [24], 2020	A personalized internet radio station (Pandora) via earphones	Yes	Participants' choice	During biopsy/not stated	Standard care without music	Anxiety (STAI)	Anxiety reduction was significantly greater in the EG than in the CG (*P*=.03).
Drzymalski et al [31], 2020	Pandora station broadcast on the iPod with speakers	Yes; EG1=participants, EG2=preselected	EG1=participants' choice; EG2=Mozart piano sonata	Preoperative, during the procedure, and 1 hour after the procedure/not stated	No music	Anxiety (NRS); pain (NRS)	Postoperative anxiety: not different between the EG1 and CG (*P*=.43) and between the EG2 and CG (*P*=.15). Postoperative pain: not different between the EG1 and CG (*P*=.10), but significantly different between the EG2 and CG (*P*=.03).
Li et al [40], 2020	Personal devices with speakers or a radio station (participants' choice)	Yes	Participants' choice	During the procedure	No music	Pain (subjective questionnaire)	The EG had significantly lower postprocedural pain and a decrease in pain compared with the CG (*P*=.03).
Lopez-Yufera et al [44], 2020	MP3 with headphones	Not stated, access volume control	Relaxing music	Before medical intervention/10 min	Headphones without music	Anxiety (HADS[j], Corah dental anxiety score)	No significant differences in anxiety (*P*=.08).
Ko et al [18], 2019	MP3 with headphones	No; adjusted volume by participants	15 easy-listening Chinese popular songs	Before and during the procedure/20 min	Standard care	Anxiety (STAI-C[k]); pain (VAS)	No significant differences between the 2 groups in terms of anxiety (*P*>.05) and pain (*P*=.83).
Ortega et al [37], 2019	Spotify (QR code access) and Bluetooth headphones	No; set music intensity by participants	Rhythmically slow songs	Prior to the intervention, during the procedure, and postoperatively/each 10 min	No music	Anxiety (STAI); pain (VAS)	The EG had significantly lower levels of anxiety (*P*<.001) and pain (*P*<.001) compared with the CG.
Cheung et al [33], 2018	MP3 with headphones	Not stated	EG1=recommended music, EG2=mute music	During TUGOR[l]/not stated	No music	Pain (VAS-P); anxiety (STAI)	Pain in the EG1 was significantly lower than that in the EG2 and CG (*P*=.005). Anxiety was not significantly different between the groups.
Ergin et al [43], 2018	CD player with earphones	No; adjusted volume by participants	Husseini maqam	Not stated/30 min	No music	Anxiety (STAI)	The difference in anxiety in the EG before and after the intervention was statistically significant (*P*<.05).
Hepp et al [21], 2018	CD player using speakers	No	Slow tempo songs	During cesarean delivery/not stated	Standard care without music	Anxiety (STAI, VAS-A)	Significantly lower anxiety levels in the EG by time and group (STAI, *P*=.004; VAS, *P*=.02).
Mackintosh et al [42], 2018	A popular video-sharing website through a laptop computer with ear-bud headphones	Yes	Participants' choice	During the pleural procedure, and 10 min before and after the procedure	No music	Anxiety (STAI)	The EG had significantly improved state anxiety scores between pre- and postprocedure (*P*<.001). However, the pre- and postprocedure trait anxiety scores were not significantly different in both groups (*P*=.80).

Pain

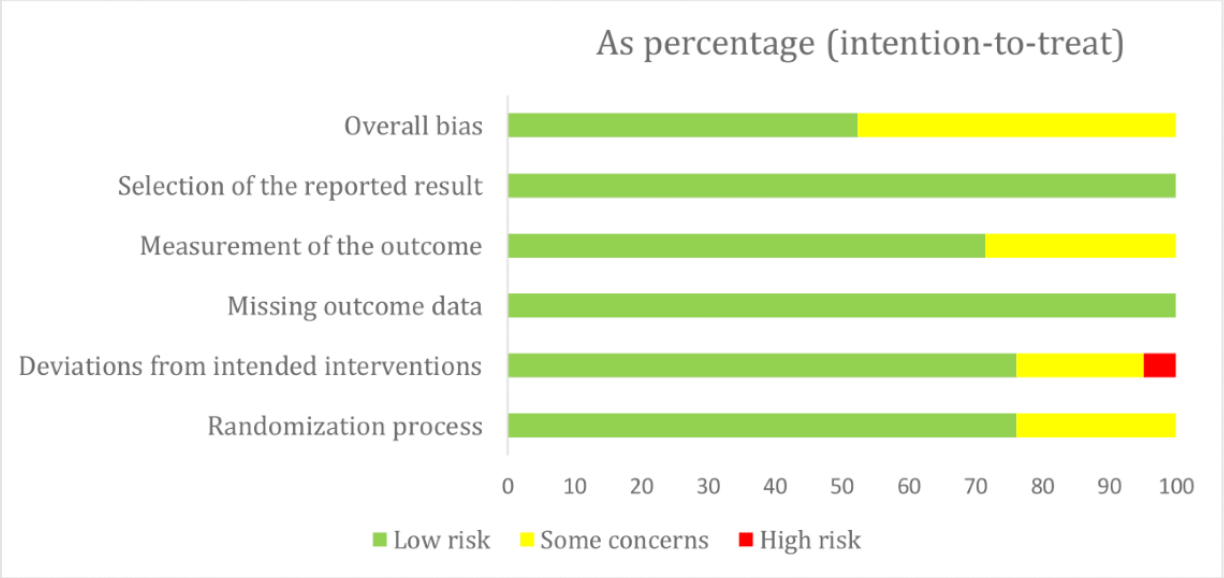
Eleven studies measured pain using the Numeric Rating Scale, VAS, or a subjective questionnaire. All studies reported that pain scores decreased after the music intervention. Among these 11 studies, 7 (64%) reported a statistically significant reduction in pain with the use of the music intervention [16,31-33,37,39,40]. Among them, Drzymalski et al [31] identified significant differences in the effectiveness of the music intervention in only 1 experimental group compared with the control group. Anglin et al [32] reported that male participants showed an overall increase in pain scores, whereas female participants in the intervention group exhibited improvements in pain scores compared with the worsening of scores in the control group. The other 4 articles reported no significant differences between the experimental and control groups, even though there was a reduction in pain scores in the experimental group [18,20,34,38]. Studies that reported decreases in pain in the experimental group tended to allow music selection by participants [16,31,32,39,40]. The played music content or genre varied (eg, slow songs, folk music, participant's choice, and regional music), and the music medium involved a QR code, projector, iPod, MP3 player, or personal or cellular device. Moreover, the timing of the music intervention was before or after the procedure or surgery (Table 2).

Risk of Bias in Studies

The quality assessment of the selected studies was conducted using the Risk of Bias 2 criteria [30]. These criteria provide a more nuanced approach compared to the previous version of the tool, allowing for a more detailed evaluation of bias across different domains of study conduct. This structured assessment helps researchers and readers of systematic reviews to better understand and interpret the quality of evidence presented in the studies. "Low risk" indicates that there are sufficient measures in place within the study design and conduct to minimize bias, thus providing confidence in the validity of the study results. Studies categorized as having low risk of bias are considered to have minimal risk of distorting the intervention effect estimates. "Some concerns" indicates that there are certain aspects of the study design or conduct that raise concerns about the potential for bias. "High risk" indicates that there are significant issues in the design, conduct, or reporting that substantially increase the risk of bias. Studies categorized as high risk of bias are deemed to have limitations that seriously compromise the validity of the findings.

Of the 21 studies, 11 (52%) were classified as having low risk of bias and 10 (48%) were identified as having some concerns. More specifically, in terms of the randomization process, 76% (16/21) of studies were deemed to have low risk and 24% (5/21) were flagged as having some concerns. Regarding deviation from the intended intervention, 76% (16/21) of studies were categorized as having low risk, 19% (4/21) were identified as having some concerns, and 5% (1/21) were categorized as having high risk. In terms of the measurement of outcomes, 71% (15/21) of studies were classified as having low risk and 29% (6/21) were identified as having some concerns. All 21 studies (100%) were rated as low risk for missing outcome data and the selection of the reported results (Figure 2). The evaluation was conducted independently by 3 authors, and any disparities were resolved through discussion.

Figure 2. Risk of bias.



Discussion

Research Trends and Strategies

Many patients undergoing surgical procedures to manage illnesses often endure physical discomfort and psychological strain, which can significantly impact medical expenses and clinical outcomes [45]. Considering these aspects, this systematic review investigated the efficacy of music interventions for alleviating anxiety and pain, drawing insights from recent clinical trials. Specifically, it delves into various methodological approaches, such as employing music-dispensing devices and considering individual preferences regarding music selection and genre. The advent of technological advancements has facilitated the integration of diverse devices for music interventions within clinical settings. These innovations have not only enhanced the accessibility of music interventions in such environments but also empowered patients to personalize their music experiences according to their preferences. This signifies the potential of music interventions in not only mitigating anxiety and pain but also fostering meaningful patient-clinician interactions during the intervention process. Thus, our findings underscore the significance of methodological nuances in music intervention studies, highlighting the pivotal role in yielding favorable outcomes.

A total of 21 studies met the inclusion criteria for this review. Among these 21 studies, 17 addressed anxiety, 11 addressed pain, and 6 addressed both. These studies aimed to identify the effectiveness of music interventions for pain and anxiety among hospital patients. Among the 17 studies on anxiety, 13 reported a significant reduction in anxiety in the experimental group compared with the control group, while 4 studies showed inconsistent results. Similarly, among the 11 studies on pain, 7 reported a significant decrease in pain in the experimental group compared with the control group, while 4 studies showed inconsistent results. These findings support earlier literature that music interventions can be used to manage physical and psychological symptoms [46,47] and can significantly benefit improvements in pain [46-49] and anxiety [46,47,49,50], but they indicated the need for repeated studies.

Previous reviews have underscored the value of music interventions across various patient populations and treatments [46,51], and they have been recommended to decrease anxiety, stress, and postoperative pain [46,47,51]. In this review, music interventions using technology were implemented across a range of medical settings, with experimental groups using diverse music playback devices or software, including web-based music applications (eg, QR code access), smartphones, tablets, computers, CD players, MP3 players, projectors, iPods, and personal or portable devices. However, the findings regarding which device delivered the music intervention better were unclear, and the difference in the effect of the medium on anxiety and pain was not directly discussed. Therefore, these findings indicate that selecting an appropriate device is an important factor in music interventions [52], and the effectiveness of the medium of the music intervention should be further assessed in future studies.

More than 50% (13/21, 62%) of studies included in this review allowed participants to select themes themselves, and of these, more than 70% (10/13, 77%) reported positive effects. Previous studies reported that anxiety and pain reductions were more effective when self-selected music was played [28,29,52,53]. The researchers interpreted that participants' familiarity with self-selected music evoked a sense of pleasure and control that could act to reduce pain [29]. On this basis, this review suggests that the method of the selection of music is also an important factor in a music intervention for reducing anxiety and pain. Some studies required participants to select music from playlists available in music applications, which included pop-rock music, romantic music, religious music, natural sounds, popular songs, slow-tempo music, relaxing music, folk music, piano sonatas, and local folk music. Music content or genre and tempo are important for stimulation and relaxation [51]. Pop, film soundtrack, jazz, classical, folk, and instrumental music are widely used music genres [54]. Moreover, slow-tempo music

(60-80 beats/min) supports relaxation, whereas fast-tempo music can cause discomfort [55]. Hatwar and Gawande [56] reported that consulting an expert while selecting music is beneficial. Yangöz and Özer [47] reported that a music genre should be chosen after consulting with an expert, and the patient or researcher should then select a music playlist. However, in our review, it was unclear whether the music was chosen after expert consultation. Therefore, consultation with experts can be considered in the process of selecting music playlists, and more studies are required to examine the difference between the effects of music selected by oneself and those of music selected by researchers [51]. Although music interventions can be used with individualized interaction, group interaction, or individual listening [47], most of the reviewed literature involved individual listening. Thus, identifying the effect of the music intervention in the context of group interaction in future studies will help implement appropriate music interventions.

Consistently in previous literature [57], the interventions were performed before, during, and after the surgery or procedure, and the duration of playing music varied from 10 to 60 minutes. Music duration is a factor in the intervention's effect on pain and anxiety [52]. Yangöz and Özer [47] reported that music duration ranged from 15 to 180 minutes, and they recommended the duration be restricted to less than 20 minutes because listeners could get bored if the duration is too long. Gillen et al [58] reported that the most common duration for listening to music was 15 to 30 minutes, and Pittman and Kridli [51] found that a duration of 15 to 20 minutes was effective in music interventions. The appropriate playing duration for a music intervention could vary according to the treatment environment (eg, the required time for a surgery or procedure differs). However, studies that determine the appropriate duration for music interventions are limited [51,52].

The risk of bias assessment is an established approach to evaluate the credibility of results at the systematic review level [59]. Nevertheless, the results of this review need to be interpreted with caution. One of the studies included in this review had a high risk of bias in deviations from intended interventions since we could not clarify the interventionist. Given the nature of a music intervention as a therapy, a professional may be required for intervention delivery. However, if researchers perform the intervention, they could be aware of the potential influence on the results. Thus, researchers should design the approach by clearly considering the importance of study quality.

Future studies should examine the effect of advanced technology-based music interventions in the context of interaction using various smart devices and software. Advanced technologies, such as artificial intelligence, robotics, and smartphone apps, are continually evolving for better patient outcomes. More interactive and patient-tailored music interventions using these advanced technologies can be developed and tested to reduce anxiety and pain by allowing to control the type of music and music delivery method. It is also necessary to review the effectiveness of in-patient mobile communication interventions between medical staff and patients, and to promote the development of different field application methods using this technology.

Limitations and Strengths

While our systematic review offers valuable insights, it is important to acknowledge its limitations. Despite our diligent efforts to include comprehensive studies meeting the eligibility criteria, there remains the possibility of incomplete retrieval owing to the search keywords used. Considering the significant evolution in music delivery technology, we decided to include articles published within the past 5 years. Moreover, our search was confined to 5 databases and included only studies written in English, potentially leading to an incomplete list of included studies.

Despite its limitations, our review has significant value as it has conducted an in-depth analysis of the current literature and has provided a lucid summary of intervention protocols and outcomes concerning anxiety and pain. Emphasizing technology use and its outcomes, our findings underscore the critical importance of selecting suitable devices in music interventions, presenting a notable challenge for future intervention development. Notably, our review distinguishes itself with its comprehensive summary of primary articles, intervention methodologies, and outcomes related to anxiety and pain. By highlighting technology use and its outcomes, we offer a global perspective on intervention protocols and the efficacy of technology-based music interventions for alleviating pain and anxiety among hospitalized patients.

While acknowledging the potential impact of a meta-analysis, our review prioritizes elucidating intervention methodologies specific to technology-based music interventions. The diverse array of technologies employed in the included studies can pose challenges in clearly discerning the effectiveness of the used devices. By focusing on methodologies related to technology use, our review underscores significant challenges associated with selecting appropriate devices in intervention protocols aimed at mitigating pain and anxiety in hospitalized patients. This approach can help to lay the foundation for validating the effectiveness of technology-based device use in future studies.

Conclusions

Music interventions are valuable for various patients and treatments and have been recommended to decrease anxiety, stress, and postoperative pain. A music intervention is a nonpharmacological complementary approach and shows a positive effect on patients, and up to 70% of studies reported a positive effect when patients were allowed to select the music themselves. This systematic review provided an in-depth review of the current literature on technology-based music interventions for patients undergoing various procedures. Future studies are needed to examine the effectiveness of interactive technology-based music interventions for reducing anxiety and pain among hospitalized patients undergoing procedures. This review contributes to the research on technology-based music interventions and can help to select a practical methodology for the interventions. Moreover, further meta-analyses should be conducted to enhance statistical power through the combination of studies.

Abstract

Background: Cancer pain remains highly prevalent and persistent throughout survivorship, and it is crucial to investigate the potential of leveraging the advanced features of mobile health (mHealth) apps to empower individuals to self-manage their pain.

Objective: This review aims to comprehensively understand the acceptability, users' experiences, and effectiveness of mHealth apps in supporting cancer pain self-management.

Methods: We conducted an integrative review following Souza and Whittemore and Knafl's 6 review processes. Literature was searched in PubMed, Scopus, CINAHL Plus with Full Text, PsycINFO, and Embase, from 2013 to 2023. Keywords including "cancer patients," "pain," "self-management," "mHealth applications," and relevant synonyms were used in the search. The Johns Hopkins research evidence appraisal tool was used to evaluate the quality of eligible studies. A narrative synthesis was conducted to analyze the extracted data.

Results: A total of 20 studies were included, with the overall quality rated as high (n=15) to good (n=5). Using mHealth apps to monitor and manage pain was acceptable for most patients with cancer. The internal consistency of the mHealth in measuring pain was 0.96. The reported daily assessment or engagement rate ranged from 61.9% to 76.8%. All mHealth apps were designed for multimodal interventions. Participants generally had positive experiences using pain apps, rating them as enjoyable and user-friendly. In addition, 6 studies reported significant improvements in health outcomes, including enhancement in pain remission (severity and intensity), medication adherence, and a reduced frequency of breakthrough pain. The most frequently highlighted roles of mHealth apps included pain monitoring, tracking, reminders, education facilitation, and support coordination.

Conclusions: mHealth apps are effective and acceptable in supporting pain self-management. They offer a promising multi-model approach for patients to monitor, track, and manage their pain. These findings provide evidence-based insights for leveraging mHealth apps to support cancer pain self-management. More high-quality studies are needed to examine the effectiveness of digital technology–based interventions for cancer pain self-management and to identify the facilitators and barriers to their implementation in real-world practice.

KEYWORDS

cancer pain; self-management; mHealth applications; integrative review; cancer survivors

Introduction

Cancer remains a significant health concern in the United States [1]. The cost of cancer health care use in the United States was US $208.9 billion in 2020 and is expected to rise to US $246 billion by 2030 [2]. With advances in cancer diagnosis and treatment and increased survivorship rates, there is a high prevalence of distressing pain, with a pooled prevalence rate of 40% [3]. Cancer pain can persist for months and even years, significantly eroding the quality of life [4-7]. The American Society of Clinical Oncology Practice guideline advocates patient-driven self-management as the primary pain management strategy [8-10]. However, managing cancer pain is a complex and multifaceted experience that poses numerous challenges for patients. These challenges include fear of opioid addiction, insufficient knowledge or skills, and a lack of health care professional supervision [11,12]. In the rapidly advancing digital technology era, it is worth considering leveraging mHealth apps to support patients with evidence-based resources, addressing these concerns, and empowering them with self-management skills to meet personal and social needs [13,14].

The mobile health (mHealth) app is a promising tool for supporting patients in self-managing pain and improving health outcomes due to its popularity, convenience, accessibility, personalization, and cost containment [15,16]. Studies have shown that mHealth interventions could improve medication adherence, self-management engagement, and health outcomes [17-19]. A mixed methods study suggested that individuals with advanced illnesses could greatly benefit from mHealth monitoring systems, which offer continuous patient assessment and critical symptom review information to optimize health outcomes [20]. According to IQVIA's digital health trends report in 2021, over 350,000 health apps were available in app stores, comprising 47% of all apps, with an increase of about 250 apps per day [21]. However, a content review in 2020 identified only 119 designed for patients with cancer among the thousands available in major mobile app marketplaces [22]. Moreover, a review conducted in 2017 identified 46 apps geared toward clinicians for palliative care guidelines, advance care planning, pharmaceutical tools, and sharing the latest news and opinions related to palliative care [23]. However, the same research team identified only 25 palliative care apps designed specifically for patients or families [24]. Another systematic review in 2021 found that only 101 out of 1189 apps included symptom-tracking features for patients with cancer [25]. However, research on mHealth in cancer pain management is limited. To date, only one systematic review has been done to evaluate the effectiveness of mHealth in managing cancer pain [26]. Reviews of acceptability and end users' experiences have not been reported. Therefore, this review aims to bridge the research gap and understand the acceptability, effectiveness, and roles of mHealth apps in supporting cancer pain self-management.

Methods

Theoretical Preparation

An integrative review is a broad review method that includes data from various research designs to comprehensively understand a phenomenon or interest [27]. The conducting of an integrative review involves a broad, flexible, and interpretative approach in six key steps [28,29]: (1) formulate purpose or review questions; (2) systematically search and select qualitative studies, quantitative studies, and mixed methods studies using predetermined criteria; (3) perform quality appraisal of included studies; (4) narratively and interpretively analyze and synthesize findings; (5) synthesize key and themes and offer insights into the broad implications of the findings; and (6) disseminate plans of findings to audience with diverse interests and applications.

Literature Searching Strategies

As indicated in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram, this integrative review identified eligible studies by conducting literature searches in an electronic database and manual reference tracking of eligible articles. With the assistance of librarians, we conducted a literature search using both keywords and controlled vocabulary searches in CINAHL, PubMed, PsycINFO, Scopus, and Embase. Keywords and controlled vocabulary used for the search include "cancer patients" or "oncology patients" or "patients with cancer" or "cancer survivors" AND "mobile application" or "mobile app" or "mHealth app" or "mHealth application" or "eHealth app" or "eHealth application" or mHealth or eHealth or "cellular phone" or "cell phone" or "smartphone" AND "pain self-management" or "pain management" or "pain self-care" or "pain relief" or "pain control" or "pain reduction." Search strategies and results are detailed in 2 appendices (Multimedia Appendices 1 and 2). Upon identifying the included articles, a manual reference tracking method was implemented to identify any additional eligible studies.

Study Selection Criteria

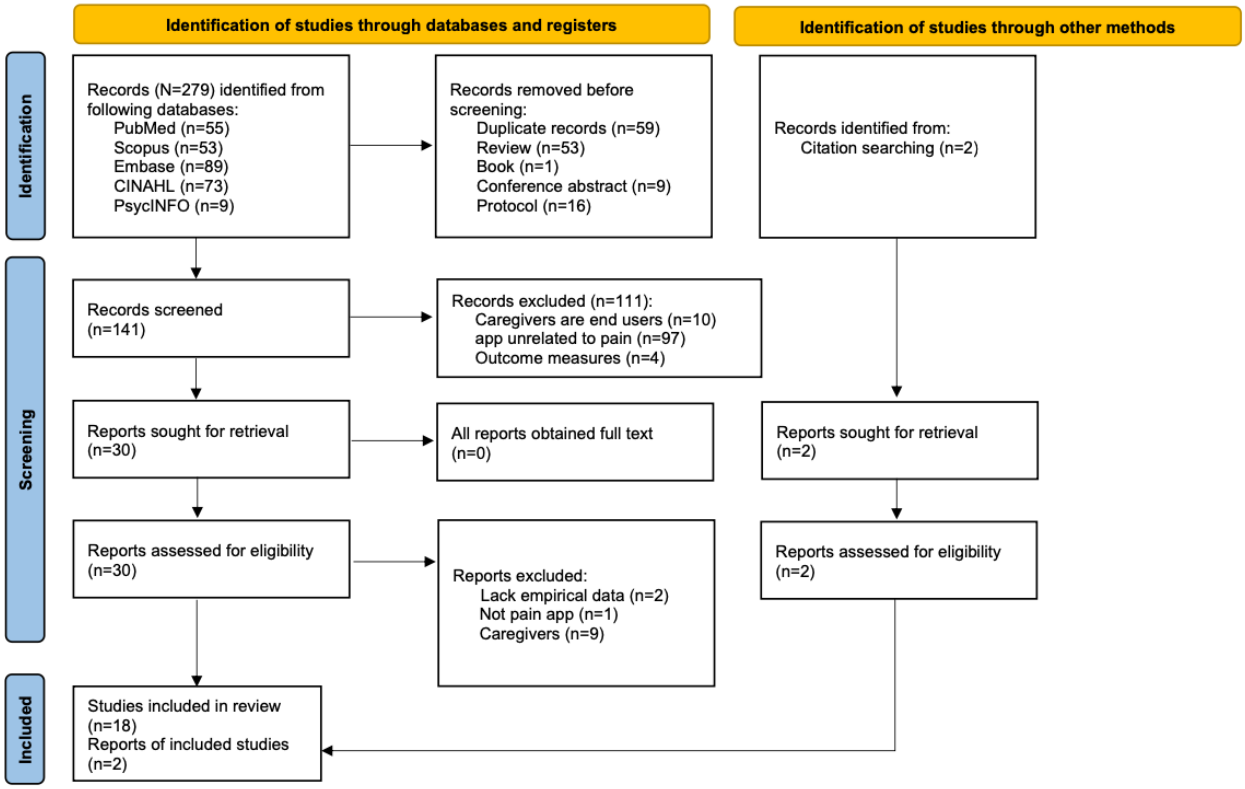
Studies were eligible for inclusion if they met the following criteria: (1) original empirical studies using qualitative, quantitative, or mixed methods design; (2) the study population included individuals of all ages diagnosed with any type of cancer; (3) assessing the effectiveness, acceptability, and cancer patients' experiences of mobile apps in cancer pain assessment and management; (4) primary outcomes focused on pain-related health outcomes, app acceptability, or users' experience; and (5) English-written, peer-reviewed, full-text articles published between 2013 and 2023.

Studies were excluded if (1) apps were exclusively intended for health professionals and caregivers as end users; (2) patients could not use the app independently for pain management; and (3) apps were used solely for delivering interventions, such as videoconferencing apps.

Study Selection Procedure

This integrative review used the PRISMA 2020 flow diagram to report the study selection process (Figure 1). The first author and an experienced librarian conducted the literature search. A total of 279 studies were retrieved by applying the searching strategies as mentioned above. The EndNote program was used to organize the studies and exclude duplicates. Two researchers reviewed the title and abstract of the studies to determine eligibility. The initial screening excluded non-English, nonempirical data, conference abstracts, book documents, reviews, and protocols. Of the 30 remaining papers, 2 researchers did the second round of screening by independently reviewing the full text of each study to determine the eligibility. Discrepancies between reviewers were resolved by discussion and consensus. A total of 18 studies were included after the second-round screening. In addition, 2 studies were identified by tracking the reference lists of included studies, bringing the total number of included articles to 20.

Figure 1. The PRISMA flow diagram. This figure provides the details of (1) identification source (the database searches and reference tracking), (2) the stepwise screening of 281 records (initial screening and abstract, title, and full text), and (3) included 20 records in the review. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Quality Assessment

The quality assessment of 20 included studies was conducted using the Johns Hopkins Research Evidence Appraisal Tool, which is commonly used to appraise the qualities of various study designs [30]. The tool consists of distinct checklists to evaluate the quality of quantitative, qualitative, and mixed methods studies. Each checklist includes questions that facilitate determining the quality rated as A, B, or C (high, good, or low quality) and the level of evidence ranging from I (randomized controlled trial [RCT]) to III (nonexperimental-qualitative). Low-quality studies were excluded. Quantitative studies are assessed by a 14-item checklist based on factors including sample size, result consistency, control measures, conclusiveness, and literature review depth. A low-quality quantitative study refers to little evidence with inconsistent results, an insufficient sample size for the study design, and the inability to draw meaningful conclusions. Qualitative studies are assessed using a 13-item checklist emphasizing transparency, diligence, verification, self-reflection, participant-driven inquiry, and insightful interpretation. Low-quality qualitative studies exhibit a lack of clarity and coherence in reporting, lack of transparency in reporting methods, poor interpretation of data, and offer little insight into the phenomena of interest. Mixed methods studies require separate appraisals of both the quantitative and qualitative components and how well the design addresses the research questions. Low quality in mixed methods studies refers to good to low quality of separate quantitative and qualitative components, low relevance of study design, poor levels of integration of data or results, and no consideration of limits of integration. The first author and corresponding author conducted quality assessments and ratings.

Data Extraction and Synthesis

The authors conducted a comprehensive and iterative review of the included studies to extract overarching findings, and the results were reported following the PRISMA guideline (Multimedia Appendix 3). Table 1 presents the characteristics of the included studies. Due to the heterogeneity of the included studies, a narrative content analysis was conducted to analyze

the extracted quantitative and qualitative data. The synthesis captured the patients' acceptability of mHealth apps, the effectiveness of the targeted outcomes, the features of the apps from the patient's perspective, and how these features are achieved in the apps (Table 2).

Table 1. Basic information of each included study.

Study	Country	Cancer pain context	Cancer type	Age group (years)	Sample size, n
Yang et al [31]	China	Breakthrough pain	General	I[a]: mean 51.10 (SD 8.98), C[b]: mean 53.96 (SD 8.58)	58

Azizoddin et al [44]	Qual	• Review wireframes of the content and its delivery	• Primary themes: (1) clarity, (2) visual appeal, (3) usefulness, and (4) engagement	III	A
Alberts et al [34]	RCT	• Feasibility and acceptability • Pain intensity and interference	• 90.3% (n=28) wore the device >50% of the trial (mean 21.8/30 days [SD 5.9]). 74.2% (23/31) were satisfied with the device. • Average pain relieved but not significant. • Facilitators: easy to use, beneficial, learning new ways, increased awareness, appreciation	I	A
Stinson et al [49]	MMR	• Usability, feasibility, compliance, and satisfaction	• Appealing to adolescents • Endorsed game-based and virtual reward systems • High compliance • Likable, easy to use, not bothersome	III	A

[a]L: the level of evidence ranging from I (randomized controlled trial) to III (nonexperimental-qualitative).

[b]Q: quality rated as A, B, or C (high, good, or low quality).

[c]RCT: randomized controlled trials.

[d]QoL: quality of life.

[e]Quant: quantitative.

[f]QED: quasi-experimental design.

[g]The researcher collected data at four time points: before treatment (T0), and the second week (T1), the first month (T2), and the second month (T3) after the start of treatment.

[h]Qual: qualitative.

[i]MMR: mixed methods research.

Results

Included Studies Characteristics

The characteristics and methodology of the 20 studies were detailed in Tables 1 and 2. The included studies involved quantitative design (RCT (n=4) [31,32,39,49], quasi-experimental (n=3) [34,36,40], prospective (observational, cohort; n=4) [33,35,37,38], cross-sectional design (n=1) [41], qualitative design (n=3) [42,46,48], and mixed methods design (n=5) [43-45,47,50]). The sample sizes ranged from 11 to 234. A total of 12 studies were conducted in North America (US [n=11] and Canada [n=1]), Europe (the Netherlands [n=3], Spain [n=1], and Italy [n=1]), and Asia (China [n=2] and Iran [n=1]).

Quality of Studies

In total, 20 studies included were assessed based on the evidence level and overall quality. Table 2 shows that 4 studies were rated as IA, 3 as IIA, and 8 as IIIA. All of these studies were considered high quality despite different study designs (levels of evidence). In addition, 5 studies were rated as IIIB, which were deemed to be of good quality. No studies were rated as low quality.

Pain Context

As shown in Table 1, 6 studies were conducted to assess pain management experiences in specific cancer subgroups or among patients with similar pain subcategories, such as management of oral pain in head and neck cancer [40], abdominal pain in colorectal cancer [41], lymphedema-related chronic pain in breast cancer [39], advanced cancer pain [48], and breakthrough pain [31,36]. In addition, 8 studies were conducted in specific age subgroups other than adult patients with cancer. These included studies involving children [33,38,45,47], school-age children [44], adolescents [34,42], and adult survivors of childhood cancer [49]. Four studies investigated pain management under specific cancer treatment, such as chemotherapy [44,45,47] or concurrent radiotherapy [40].

App Context

All pain management apps were developed by multidisciplinary teams that consisted of medical oncologists, palliative care nurse specialists, researchers, and app developers. These apps were created in one of 3 formats, that are (1) dedicated pain management apps (n=7), (2) pain management as the primary module in a comprehensive self-care app (n=5), and (3) pain management integrated into an existing app (n=2). For instance, "Pain Buddy" is a dedicated cancer pain app that helps children with pain self-management [33,47]. "ColorectAlong" is a comprehensive self-care app that includes pain management as one of its 8 components [41]. In addition, Villegas et al [36] detailed the integration of pain management features into an existing app.

App Feasibility

Overall, 18 studies assessed the feasibility of using mHealth apps in cancer pain management by evaluating usability, acceptability, fidelity, learnability, satisfaction, and desirability. Results indicated that the real-time pain assessment was efficient, valid, and reliable [33,35-38,42,43,45,46,49,50]. One study reported that the average time to complete the pain assessment was 4.3 (SD 3.5) minutes [46]. Another study observed a moderate to vigorous (0.43-0.68) correlation between weekly pain average ratings recorded on the app and retrospective weekly average pain ratings, indicating a high level of internal consistency over 2 weeks (standard Cronbach α=0.96) [35]. Using mHealth apps to monitor or manage pain was acceptable for most patients with cancer [33,37,38,43,45,49]. In total, 5 studies reported adherence to pain assessment during the trial periods (ranging from 2 weeks to 1 month) and found that 61.9%-76.8% of participants completed daily pain assessment. The remaining participants used the app for a shorter period but for at least half of the trial days (minimum 7 days) [33,37,38,43,45]. One study reported that 81% of participants wore the wearable device throughout the 30-day trial period [49]. Another study showed that 18 participants (45%) continued to complete pain assessments and receive treatment advice beyond the study trial [33]. The overall satisfaction with the apps was high, with an average score of 8.9 out of 10 [38], 8.0 out of 9 [41], 4.8 out of 5 [43], and 85.8 out of 100 [36]. Qualitative studies indicated participants' positive experiences with pain apps, such as likable, enjoyable, easy to use, and not bothersome to complete [42,50].

> *It is really appealing to the eye. The color, the theme, and the font are good. And it's not really that hard to understand. The vocabulary is really straightforward, and all of the things are on it. The multiple-choice questions and the [visual analog scale] sliders are really easy to use.* [42]

Effectiveness of mHealth Apps on Cancer Pain Self-Management

A total of 17 studies demonstrated the effectiveness of the mHealth app in supporting pain outcomes and self-management. Of the 9 studies evaluating the efficacy of pain-related outcomes, 6 reported significant effects of mHealth apps on pain remission (pain severity and pain intensity), improvement in pain medication adherence, reduction of adverse reaction and occurrence of breakthrough pain, and improvement in quality of life [31,34,36,37,39,40]. Two studies observed patterns of pain reduction, although not statistically significant (P>.05) [32,49]. In contrast, 1 study showed no significant difference in average daily pain reduction between the intervention and control groups but noted fewer instances of moderate to vigorous pain in the intervention group [33].

In addition, 8 studies included qualitative data from users' perspectives on cancer pain self-management apps and detailed descriptions of the app. Overall, patients highly valued and emphasized the significant roles of mHealth apps in their daily pain management. A content analysis was conducted to comprehensively understand users' perspectives and how these app features were implemented. The 3 primary features of pain apps in assisting patients with cancer pain self-management were identified and summarized as (1) pain monitoring, tracking, and reminder, (2) pain education facilitation, (3) pain support coordination.

Pain Monitor, Tracker, and Reminder

The primary benefit for patients using mobile apps was monitoring, tracking, and reminding them of their pain management. These apps measured patients' pain in their daily lives and provided continuous real-time monitoring of pain trends, enabling patients to adjust their medication and management plan [42,47].

> *It is helpful when the physician calls. I look at the graph to get a good picture. It also gives justification that I'm not exaggerating my pain* [43]

Pain apps offer various features to assist patients in managing their pain. Three apps provided daily reminders and precisely measured and recorded the cause, severity, intensity, location, nature, type, and duration of pain and the frequency of breakthrough pain, medication taking, and adverse reactions [31,37,40]. The apps used various instruments to assess pain, including the numerical rating scale (NRS) [31,37,45], the Ospedale Pediatrico Bambino Gesù tool [38], the visual analog scale [40,45], the pain diary [37], effective pain descriptors [38], free-text responses [44], and body maps for pinpoint location of pain [31,44,46]. In addition, the app Pain Buddy directed children to pinpoint the pain on an avatar and included a drawing feature to specify the location of the pain in more detail [44].

Pain Education Facilitator

The second common function of the apps was to provide pain education. Patients noted that pain educational modules in these apps improved their awareness and interest in pain management. There were 2 studies that reported 100% of users actively engaging in the learning module [42,43].

> *I thought the pain help ideas were awesome. They would suggest activities like relaxation and breathing. And when you click on it and, there is someone talking to you, walking you through it. Like how to relax* [42]

Most pain apps incorporate psychoeducational modules that focus on promoting comprehensive pain knowledge and self-management skills based on clinical or World Health Organization guidelines [31,32,36,37,39-43,45,47,49]. A total of 3 apps included features to evaluate patients' misunderstanding of pain and offered customized information concerning the fundamental causes of pain and the appropriate treatment methods [31,32,37]. In addition, 7 apps included features for self-management skill training, such as medicine instructions, music relaxation treatment or acupuncture [31,36,41], cognitive and behavioral skills training [47], breathing exercises [49], and step-by-step lymphatic exercises for patients with breast cancer [39]. Children users also found the skills training helpful, with belly breathing and distraction techniques being their favorite skills [47]. The trial results of the app, which focused on educating users about oral mucositis knowledge and care skills, showed that the group with access to these resources experienced significantly lower pain levels [40].

Notably, pain apps served as a distraction for many app users, as reported by participants who found it "fun to do" and a "positive challenge" to monitor their pain without constantly focusing on their pain [43,48]. The efficacy of these apps in providing distraction stemmed from the primary principles of app design, emphasizing the engagement and enjoyment of users while considering the unique characteristics and needs of different age groups. For instance, children found the design of 3D Avatar more attractive and enjoyable and were motivated to earn "coins" to customize the program further [46,47]. Adolescents, on the other hand, may be more inclined to gamification elements, including role-playing, badge acquisition, and point and leveling system [35,46], and were attracted by the "appealing to the eye" elements, such as color scheme, fonts, and graphics used [35,42].

Pain Support Coordinator

Patients reported that pain apps strengthened their partnerships with health care providers [36,41,42,45]. In particular, some apps offered the feature allowing patients to receive direct phone calls from health care providers when they reported experiencing severe pain, and self-management strategies were ineffective [45]. These features permitted direct and effective communication between patients and the health care team and were highly valued among patients [36]. Further, patients found pain apps enabled more efficient conversations with their health care professionals during office visits by providing precise symptom patterns and notes recorded in daily assessments [41,42].

> *We don't want to call the hospital all the time. With the app, you get the sense that pain is being monitored, and they call us when we report high pain scores. That is very comforting. It gives you the sense that you're being taken care of* [45]

Most apps (n=8) allow open dyad access, providing both the patient and their health care provider access to the apps [31,32,36,40,42,43,45,47]. In cases where patients reported a high pain score (over 5/10 or NRS≥4) or moderate to vigorous side effects, the system would automatically remind patients to take medication. One hour later, the system automatically reminded patients to reassess pain [31]. If a high pain score (over 5/10 or NRS≥4) was still reported, an email alert or clinical alarm was sent to clinical professionals to notify the uncontrolled pain condition [36,37]. The medical team could contact the patient directly for alarms when necessary [36,42]. In 2 RCTs, patients assigned to the app group with this alarm feature reported significantly lower frequencies of breakthrough pain and higher medication adherence than the control group and were more likely to promptly detect and address pain exacerbation [31,36]. Clinicians also acknowledged that the app improves treatments' safety, adherence, and effectiveness for managing breakthrough pain [36].

The eConsult module was embedded in several apps, with an email-like format or social network links, facilitating question-and-answer communication between patients and professionals [32,37,40]. Participants who frequently used eConsults found they were beneficial for pain management [37]. For instance, participants could obtain assistance from this module in setting pain management goals, devising action plans, and identifying in-time coping strategies for breakthrough pain when patients reported high scores [31,36,41]. Outpatients, in particular, appreciated the app's therapeutic benefit, as it allowed them to receive real-time support and efficient pain management advice without being constrained by time and space limitations [42,48].

> *It's a fantastic idea. As one who was living in constant pain, I was not the one to call the doctor. If I had this resource available. Things maybe would have changed for me a lot faster than they (doctors) did* [48]

Discussion

Principal Findings

This integrative review synthesizes the current evidence of mHealth apps supporting pain outcomes and self-management of patients with cancer. Overall, mHealth apps offer significant benefits for managing cancer pain and serve as multi-model interventions that provide critical features such as monitoring, tracking, reminders, education facilitation, and support coordination. These findings offer evidence-based insights into effectively leveraging the advantage of mHealth apps in supporting the pain self-management of patients with cancer.

Implications

mHealth apps are effective and acceptable in alleviating pain and supporting self-management, as indicated by participants' feedback and feasibility data. This finding added complementary evidence to systematic reviews that focused exclusively on experimental studies [24,51]. However, integrating these apps into standard clinical care components, such as electronic health records, has posed significant challenges due to factors such as inconsistent app availability [51], standard application programming interface development and adoption in the early stages [52], and security concerns [53]. Despite these challenges, nursing, medical scientists, and other stakeholders have been urged to direct their efforts toward creating a long-term strategic plan for developing and implementing eHealth services, and promoting equitable, accessible, and affordable health care [54]. With the outbreak of COVID-19, videoconferencing apps such as Skype, Zoom, Facebook, 2-way text messages, and other online platforms have played a critical role in transitioning offline health care services to an online format [55]. For example, the electronic patient-reported outcomes (ePROs) system significantly improved health care efficiency, enhanced patient-doctor interaction, and optimized medical resource use [56,57]. Cancer self-management apps have the potential to provide easy access to cancer health care services by eliminating time and space limitations, giving patients greater autonomy and control, and providing more precise or personalized strategies [58]. Further studies are necessary to explore the integration of ePROs into mHealth apps for managing cancer pain.

mHealth apps were promising tools to empower patients with cancer with the necessary knowledge and skills and enable them to manage their pain actively. Patients endorsed and mainly engaged with the educational modules, training programs, and coping strategies offered by pain apps. This finding was consistent with previous studies that patients expressed their educational needs in areas of opioid analgesics, long-term survivorship, and relying on professional service or guidance rather than nonprofessional sources like nonprofessional internet pages or television programs [59,60]. Compared with traditional paper-format educational material, mHealth apps lower the learning threshold and burden while increasing engagement through numerous attractive features such as straightforward, enjoyable, informative, accessible, and personalized designs [61]. Apps can also customize education modules based on patient's health literacy and ability to use the app over time with the advancement of artificial intelligence and big data [58]. Also, mHealth apps have emerged as a promising tool for translating evidence-based practice into the home setting. The included apps in this review reported that all educational modules were developed based on World Health Organization or clinical or evidence-based guidelines. This approach promotes science communication to the public and facilitates more informed decision-making [62].

mHealth apps could also serve as a distraction technique, drawing patients' attention away from the mental processing of pain through attractive features. Patients always viewed their cancer journey as life trauma, especially when accompanied by long-term unpleasant pain experiences [63]. Distraction, a simple nonpharmacological technique, is increasingly being examined as an effective intervention. It is applied primarily in pediatric oncological procedure pain [64], during needle insertion or lumbar puncture [65], or subcutaneous port access [66]. With the advancement of digital technology, virtual reality distraction has shown promise in reducing self-reported pain in patients with breast cancer [67], as well as children and adolescents with cancer [66]. Therefore, the app design should fully consider incorporating engagement techniques, that cater to diverse end users' characteristics, and pain care demands.

mHealth apps had the potential to bridge gaps in health care access and facilitate interaction and communication with health care providers. Previous studies highlighted patients' challenges in accessing professional survivorship care after completing clinical treatment [68,69]. mHealth app serves as an eConsult medical chatbot, allowing patients to seek professional consultation to address daily minor issues or confusion, thus minimizing unnecessary clinic visits [70]. In addition, mHealth apps with alert systems can help identify urgent situations that require immediate health intervention. Implementing ePROs within clinical practice enables remote monitoring and early detection of severe and worsening symptoms [71]. One clinical randomized trial illustrated that web-based ePRO tools are feasible and acceptable among patients with advanced cancer without increasing clinical burden [72]. However, it would be valuable to explore clinical staff's perspectives on whether these applications increase or reduce their workload. Furthermore, with the tracking function of pain apps, patients can precisely describe the trends and characteristics of their pain, enhancing the quality of communication and problem-solving efficiency between patients and professionals in pain management. The findings from another systematic review also supported the idea that practical technology tools can help strengthen communication and partnership between patients and providers [73]. For instance, a 2-way text message strategy has been shown to be effective in improving engagement and adherence in the survivorship management program, although it may require the research team to commit more effort to respond to text messages personally [74,75]. Building effective partnerships with providers is one core skill in promoting successful cancer pain self-management [76]. Further studies are needed to evaluate the cost-effectiveness of such interaction designs within the health care system across different contexts and populations.

Limitations

Several limitations exist in this review that warrant careful consideration. Small sample sizes and short study durations in the preliminary usability testing may limit the generalization of the study findings. There is a risk of a skewed perception of the intervention's success or survivor bias, particularly if individuals who did not adhere to long-term trials or lost interest in the app interventions were not adequately represented in the data. Further research is imperative to establish causality and generalizability of the findings. It is important to note that the review primarily focuses on patients' perspectives. Additional reviews focusing on insights from other stakeholders, such as health care professionals and caregivers, are needed to achieve a more holistic understanding before disseminating findings into clinical practice. The heterogeneity of the included studies,

including varied designs, pain measures, and app functionalities, along with limited evidence from RCTs, inherently constrains the level of analysis and evidence. Despite meticulous search efforts, limitations in search strategy, including search terms, databases used, inclusion and exclusion criteria, and the fast-paced development of technology, could lead to unintentionally omitting relevant new apps. Finally, while the review predominantly draws from academic literature, a more comprehensive understanding could be gained by incorporating insights from market app stores and usage reports.

Conclusion

Overall, mHealth apps are effective and acceptable in supporting the self-management of cancer pain. They offer a promising approach for patients to monitor, track, and manage their pain and receive multimodel interventions to promote pain self-management. These findings provide evidence-based insights for leveraging the features of mHealth apps in supporting cancer pain self-management. More high-quality studies are needed on the effectiveness of digital technology–based interventions for cancer pain self-management and to identify the facilitators and barriers to their implementation in real-world practice.

Acknowledgments

We would like to express our sincere gratitude to all the authors who contributed to this manuscript's conceptualization, methodology, writing, reviewing, and editing. This work was made possible by the Oncology Nursing Foundation, which provided research support through the RE01 grant in 2019. No specific grant number was assigned. The corresponding author, WX, received this research support, which was crucial in conducting this review and would cover potential publication fees.

Abstract

Background: Population studies show that musculoskeletal conditions are a leading contributor to the total burden of healthy life lost, second only to cancer and with a similar burden to cardiovascular disease. Prioritizing the delivery of effective treatments is necessary, and with the ubiquity of consumer smart devices, the use of digital health interventions is increasing. Messaging is popular and easy to use and has been studied for a range of health-related uses, including health promotion, encouragement of behavior change, and monitoring of disease progression. It may have a useful role to play in the management and self-management of musculoskeletal conditions.

Objective: Previous reviews on the use of messaging for people with musculoskeletal conditions have focused on synthesizing evidence of effectiveness from randomized controlled trials. In this review, our objective was to map the musculoskeletal messaging literature more broadly to identify information that may inform the design of future messaging interventions and summarize the current evidence of efficacy, effectiveness, and economics.

Methods: Following a prepublished protocol developed using the *Joanna Briggs Institute Manual for Evidence Synthesis*, we conducted a comprehensive scoping review of the literature (2010-2022; sources: PubMed, CINAHL, Embase, and PsycINFO) related to SMS text messaging and app-based messaging for people with musculoskeletal conditions. We described our findings using tables, plots, and a narrative summary.

Results: We identified a total of 8328 papers for screening, of which 50 (0.6%) were included in this review (3/50, 6% previous reviews and 47/50, 94% papers describing 40 primary studies). Rheumatic diseases accounted for the largest proportion of the included primary studies (19/40, 48%), followed by studies on multiple musculoskeletal conditions or pain sites (10/40, 25%), back pain (9/40, 23%), neck pain (1/40, 3%), and “other” (1/40, 3%). Most studies (33/40, 83%) described interventions intended to promote positive behavior change, typically by encouraging increased physical activity and exercise. The studies evaluated a range of outcomes, including pain, function, quality of life, and medication adherence. Overall, the results either favored messaging

interventions or had equivocal outcomes. While the theoretical underpinnings of the interventions were generally well described, only 4% (2/47) of the papers provided comprehensive descriptions of the messaging intervention design and development process. We found no relevant economic evaluations.

Conclusions: Messaging has been used for the care and self-management of a range of musculoskeletal conditions with generally favorable outcomes reported. However, with few exceptions, design considerations are poorly described in the literature. Further work is needed to understand and disseminate information about messaging content and message delivery characteristics, such as timing and frequency specifically for people with musculoskeletal conditions. Similarly, further work is needed to understand the economic effects of messaging and practical considerations related to implementation and sustainability.

Introduction

Background

Musculoskeletal conditions, those affecting the bones, muscles, and joints, are recognized as a global public health problem, although the prevalence and burden of healthy life lost are difficult to estimate with certainty because population studies are few [1]. Where representative studies have been conducted, they have consistently shown high prevalence of musculoskeletal conditions that increases with age and has a greater burden on female than male individuals [2-5]. In the *Health Survey for England* 2018, a total of 17% of adults reported having a long-term musculoskeletal condition (19.5% female vs 14.2% male), with prevalence increasing with age (4.7% at the ages of 16-24 years vs 39% at the age of ≥85 years). A total of 80% of people who reported having a long-term musculoskeletal condition also reported chronic pain (pain for >3 months), with 34.8% reporting pain that highly interfered with their life activities [4,5]. The Australian *National Health Survey* 2017 to 2018 reported that 29% of Australians were living with a chronic musculoskeletal condition (age standardized; adults aged ≥45 years: 51%; 55.3% female vs 47.3% male) [3]. musculoskeletal conditions were the second leading contributor to total burden of healthy life lost, equal to the burden of cardiovascular disease (13% of total burden in disability-adjusted life years), second only to cancer (18% of total burden) [2]. Prioritizing the delivery of effective treatments is necessary to address the substantial burden of musculoskeletal conditions.

With the ubiquity of consumer devices such as smartphones and tablets, technology may have a useful role to play in the management and self-management of musculoskeletal conditions; potentially improve accessibility of health care; and, in some circumstances, ease health system pressures. The use of technology for providing health-related activities is typically described as “digital health” and, more specifically, “mobile health” (mHealth) when referring to the use of mobile devices. While still a relatively new field, mHealth already has a considerable literature base, with examples of its use across most health disciplines and across the continuum of care from health promotion and prevention [6,7] to screening and diagnosis [8,9], therapy [10,11], and self-management [12,13] to cancer survivorship and palliative care [14,15]. While mHealth shows promise in improving aspects of health care, evidence to date is mixed, and caution is needed in interpreting the clinical value of mHealth for patients [16].

In this review, we focused on the development and use of mHealth for individuals with musculoskeletal pain conditions and specifically on health-related interactions that use text messaging as the delivery mechanism (SMS text messaging or messages provided via app-based push notifications), either alone or alongside another intervention. As one of the mobile technologies that have been established for longer, text messaging is familiar, easy to use, convenient, low cost, and available to anyone with a mobile device [17]. Messaging can be used as a vehicle to promote behavior change and guide self-management through prompts, reinforcement, reminders, activity recording, feedback, and adaptivity to the individual [17,18]. The effectiveness of messaging interventions has been assessed for a wide range of health problems, such as medication adherence and lifestyle change in diabetes; encouraging abstinence in smoking cessation; and, more recently, to encourage prevention behaviors during the COVID-19 pandemic [17,19-21].

In total, 2 previous reviews have explored the effectiveness of text messaging–based interventions for musculoskeletal conditions [22,23]. In a broad review of 19 randomized controlled trials (RCTs; 1086 participants) [23], 5 studies involved aspects of messaging [24-28], with 4 studies reporting improvements in pain [25-28] and functional disability [24-27] favoring digital interventions but not specifically favoring the messaging components [23]. A second review focused specifically on the effectiveness of text messaging–delivered interventions included 11 RCTs (1607 participants) [22]. Of the included studies, 5 assessed text messaging as an adjunct to usual care on treatment adherence and found improvements favoring text messaging [29-33]. In a further 5 RCTs, the effectiveness of text messaging as 1 component of a complex intervention was assessed [34-38], finding small but inconsistent effects on pain, functioning, adherence, and quality of life. In 1 RCT, text messaging was compared to telephone counseling, and similar effects on functioning were reported [39].

Objectives

These previous reviews focused on intervention effectiveness and synthesized data from RCTs only. The findings of observational studies have not been synthesized, and these studies may contain useful information to inform and, ultimately, improve the effectiveness and adoption of future musculoskeletal interventions delivered using text messaging. Furthermore, important characteristics of interventions, such as the configuration of digital content, method of presentation, dose, frequency, and preferences, have not been synthesized. Consequently, to inform the design, development, and evaluation of future messaging interventions for people with musculoskeletal pain, we need to explore the literature using a wider lens. Therefore, in this study focused on individuals with musculoskeletal pain conditions, we had three aims: (1) to map the literature related to the use of mobile messaging; (2) to identify information that could be useful in the design of future messaging interventions; and (3) to explore and summarize the findings on efficacy, effectiveness, and economics derived from previous experimental and observational messaging studies.

Methods

We designed and conducted this review according to a preregistered and published protocol [40] developed using the *Joanna Briggs Institute Manual for Evidence Synthesis* [41] and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [42] guidelines. The methods are described in full in the published protocol and summarized in brief in the following sections.

Review Questions

Research question (RQ) 1 was as follows: In the context of musculoskeletal pain conditions, for which individuals, with which problems, and for what purpose, has messaging on mobile devices been used (eg, medication reminders, alerts, education, motivation, prevention, and data collection)?

RQ 2 was as follows: What information exists to guide the development of mobile messaging for musculoskeletal pain conditions (eg, frequency of messages, length of messages, duration of the intervention, and theoretical basis)?

RQ 3 was as follows: How have patients' preferences been included in the design of a study, and how have their preferences been assessed?

RQ 4 was as follows: What methods have been used to evaluate the use of mobile messaging for musculoskeletal pain conditions (eg, how were outcomes assessed and what processes were involved)?

RQ 5 was as follows: Does the literature support the efficacy, effectiveness, and economics of messaging on mobile devices for individuals with musculoskeletal pain conditions?

Inclusion Criteria

Participants

We included studies on adult participants with acute or chronic musculoskeletal pain conditions.

Concept

The concepts of interest were the development or evaluation of patient-focused health-related messaging (eg, SMS text messaging and app push notifications) provided on mobile devices such as smartphones and tablets.

Context

We included articles that described messaging used in any setting either as a primary intervention or as an adjunct to other interventions. We excluded studies focused on spinal cord injury, traumatic brain injury, moderate to severe orthopedic injuries, surgical patients, and conditions related to mobile phone overuse. We also excluded studies focused on health conditions primarily unrelated to the bones, muscles, and connective tissue (eg, diabetes, asthma, cancer, and stroke).

Data Sources

We searched PubMed, CINAHL (via EBSCOhost), Embase, and PsycINFO (via APA PsycNET) using a strategy that combined controlled-vocabulary and free-text search terms related to messaging and musculoskeletal concepts. Because of resource limitations, we were unable to include gray literature in our searches.

Search Strategy

The search strategy is described in detail in the published protocol [40], and the search queries are provided again in this paper in Multimedia Appendix 1. The search strategy was developed through discussion among the team and an iterative process of pilot searches. The final searches were conducted by SSR. Because of resource limitations, we restricted our searches to articles published in English, and because the area of digital health is a rapidly changing field, we limited our searches to articles published in the previous 10 years.

Study Selection

We exported search results to EndNote (version X9; Clarivate Analytics) and Covidence (Veritas Health Innovation) [43] for duplicate removal and to manage the screening, selection, and record-keeping processes. We conducted study selection in 3 phases. First, using the predefined inclusion and exclusion criteria, 2 independent reviewers (from a pool of 7; SSR, JL, CEE, RE, CR, SR, and NA) screened the titles and abstracts to identify candidate articles for inclusion and to discard irrelevant articles. Second, 2 reviewers from the same pool reviewed the full text of each candidate article. Third, we searched the reference lists of the included papers to identify any further articles. At all stages, conflicts were resolved using a third reviewer from our pool.

Data Extraction

Data were extracted by one reviewer (JL) and independently confirmed by 2 others (NA and CEE). Data were extracted using predefined extraction forms, as described in the protocol [40].

Synthesis and Reporting

We described the results of the study selection process using a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [44], with findings reported in accordance with the PRISMA-ScR checklist [42]. For each

of our 5 review questions, we structured our findings using tables adapted from the Joanna Briggs Institute manual [41] refined as necessary at synthesis stage [40]. We then developed a narrative summary of the evidence for each of our review questions.

Protocol Deviations

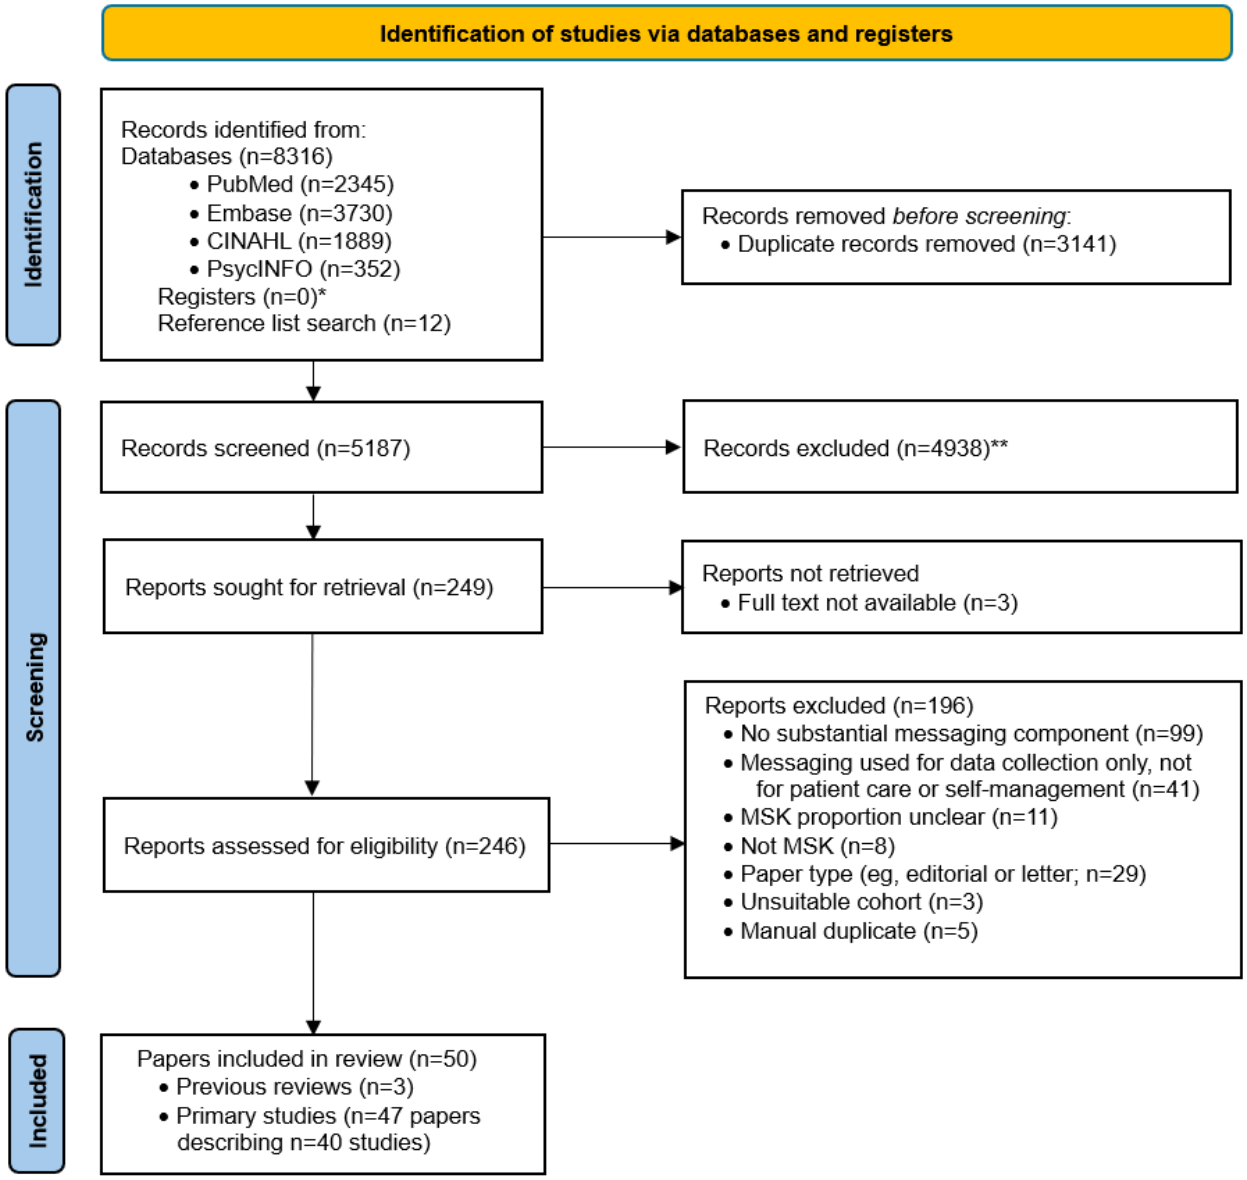
There were 4 minor protocol deviations. First, we excluded studies that described the use of mobile messaging to collect data in cases in which those data were not subsequently used to inform care or self-management (eg, studies that simply tested the feasibility of using text messaging to collect data and studies that used text messaging as a data collection method to model recovery trajectories). Second, we included study protocols associated with evaluation studies if they provided useful information about messaging design and development. Third, we classified the level of development of the country in which the study was conducted using the Human Development Index (HDI) [45]. Finally, we reran our searches in 2022 and, therefore, included studies from a 12-year period rather than the originally specified 10 years.

Results

Overview

Literature searches were conducted in August 2020 and repeated in May 2022. In this section, we present the combined results of both searches. We identified a total of 8328 papers (published in 2010-2022) for screening, of which 50 (0.6%) were included in this review. A PRISMA flowchart of the article selection process is shown in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart—article selection process. *No registers were searched; **No automation tools were used; MSK: musculoskeletal.



We identified 3 previous systematic reviews, 2 (67%) of which we had already found while developing the protocol for this review [22,23] and 1 (33%) that was new [46]. One review focused specifically on the effects of text messaging for managing musculoskeletal pain conditions [22], while the remainder focused more broadly on digital health or mHealth for musculoskeletal conditions but covering some aspects of messaging [23,46]. The previous reviews were conducted in Australia, the United Kingdom, and the Netherlands, all countries classed as *very highly developed* according to their HDI. The characteristics of the reviews are shown in Table 1, and the findings are shown in Table 2. We did not identify any previous reviews related to design aspects of messaging for musculoskeletal pain conditions.

We included 47 papers describing 40 primary studies (22/40, 55% experimental; 16/40, 40% observational; and 2/40, 5% mixed methods). In total, 10% (4/40) of the experimental and observational studies had associated or embedded qualitative or mixed methods studies. The results of 5% (2/40) of the studies were multiply reported, and 8% (3/40) of the studies had either an associated design paper or a protocol paper containing design information. A total of 18 countries were represented, with the United States publishing the largest number of studies (9/40, 23%) followed by Australia (6/40, 15%) and Denmark (4/40, 10%). By HDI, most primary studies were conducted in *very highly developed* countries (36/40, 90%), 8% (3/40) were conducted in *highly developed* countries, and 3% (1/40) were conducted in a country of *medium development*. No studies were reported from countries of *low development*.

At the time of our search, 70% (35/50) of the previous reviews and primary studies had been published in the 3 years before our search. The characteristics of the primary studies are shown in Table 3 and Figure 2 [24,26,27,30-32,35-38,47-83].

Table 2. Findings of review papers related to messaging for people with musculoskeletal (MSK) pain conditions.

Study, year	Individuals, problems, and purpose	Design-related information	Outcomes assessed and review findings

Fritsch et al [22], 2020—effects of text messaging for managing MSK pain	• Review included 7 RCTs[a] on patients with MSK pain conditions (3 with RA[b], 1 with chronic widespread pain, 1 with upper- or lower-limb MSK injuries, 1 with frozen shoulder, and 1 with knee pain) [30-32,35-38,47]
	• Messaging used to support behavior change. Most studies targeted physical activity or medication compliance.
		• Messaging features varied across studies. Examples include individualization to patient goals, timing, frequency, duration, directionality, and other intervention characteristics.
		• The included studies provided little or limited description of the theoretical frameworks underpinning the interventions.
		• Patient preferences were not described.
			• Clinical outcomes such as pain, function, disability, exercise adherence, QoL[c], satisfaction with health care services, confidence in treatment, self-efficacy, and anthropometric measures
			• Findings:
			  • Text messaging+UC[d] vs UC
			  • No difference on pain [30]
			  • Equivocal or no difference on function [30,32]
			  • Equivocal or no difference on unscheduled appointments [31]
			  • Increase in calls to nurses [31]
			• Messaging as part of the intervention vs any treatment:
			  • Pain: decrease [37,38]; equivocal or no difference [35,47]
			  • Function: equivocal or no difference [35,47]; increase [36,37]
			  • Exercise adherence: increase in self-reported adherence; equivocal or no difference on assessor-reported adherence [36]
			  • QoL: equivocal or no difference [31]
			  • SF-36[e] MCS[f]: increase [35,37,47]
			  • SF-36 PCS[g]: increase [37]; equivocal or no difference [35,47]
			• Comparison of messaging vs phone counseling
			  • Patient feedback and AEs[h]: assessed in 7 studies; AEs reported in 3 studies unrelated to messages

Hewitt et al [23], 2020—digital health for managing MSK conditions	• Aspects of messaging were described in each of the following: 3 studies on self-management of back pain [24,25,27], 1 digitally delivered multidisciplinary pain program for back pain [28], and 1 conservative digital care program for knee pain [26].	• Not described	• Pain or function assessed via RCTs. • Messaging (along with phone calls or email reminders) was described in the context of "additional efforts to encourage engagement" or "additional forms of support." • Review concluded that "additional forms of support" may be linked to positive outcomes (including improvement in pain and function); however, variability in messaging intervention characteristics hinders conclusions regarding effectiveness specific to messaging.

Seppen et al [46], 2020—asynchronous mHealth[i] interventions for RA	• Included 3 RCTs assessing the effectiveness of SMS text message reminders for medication adherence [32] and reducing sitting time [37,48].	• Not described
		• Some studies incorporated patients' preferences; participants could select reminder frequency (1-5 per week) [37,48].
			• Messaging not evaluated directly; rather, patient outcomes relevant to the primary objective were assessed, such as medication compliance [32] and sedentary time [37,48].
			• Findings included the following:
			  • Increase in medication compliance[j] [32]
			  • Reduced sitting time [37]

RQ 1: Individuals, Problems, and Purpose

Previous Reviews

In the previous reviews [22,23,46] (Tables 1 and 2), the most commonly reported messaging interventions were for people with rheumatoid arthritis (RA) and back pain. For RA, messaging was used to monitor medication and disease activity [31] and improve medication adherence [32,46] and for reminders to reduce daily sitting time [37,46]. For people with back pain, messaging was used mostly as a component of self-management, with approaches focused on education and behavior change strategies [24,25], supportive messages provided by a health coach during periods of low engagement with a digital self-management program [27], and motivating messages sent as part of a multidisciplinary pain program [28].

Other studies described uses of messaging for people with knee pain, systemic lupus erythematosus, frozen shoulder, chronic widespread pain, and limb injuries or conditions. For knee pain, one study reported a lifestyle intervention focused on behavior change [22,38], and another reported participation reminders and app-based messaging with a personal coach as part of an exercise, education, or cognitive behavioral therapy (CBT) or weight loss or psychosocial support program [23,26]. For frozen shoulder, reminder, encouragement, and education messages were used to promote exercise compliance and improve shoulder function [30]. For chronic widespread pain, a CBT intervention used SMS text message diary completion prompts, with those diary entries then informing the treatment used by a therapist [35]. For limb injuries and conditions, messaging was used to promote adherence to a home exercise program in one study [36].

Primary Studies

Rheumatic diseases accounted for the largest proportion of the included primary studies (19/40, 48%), followed by studies on

multiple musculoskeletal conditions or pain sites (10/40, 25%), back pain (9/40, 23%), neck pain (1/40, 3%), and "other" (1/40, 3%; Table 3).

Rheumatic Diseases

Of the 19 rheumatic disease–related studies, 8 (42%) focused on osteoarthritis [26,38,52,53,55,57-59,78-80], 5 (26%) focused on RA [31,32,37,48,51,56,75], 2 (11%) focused on fibromyalgia [35,47,50], 2 (11%) focused on osteoporosis [49,76], and 1 (5%) each focused on ankylosing spondylitis [54] and chronic arthritis [77].

Of these 19 studies, 14 (74%) described the use of messaging to promote behavior change with the intention of improving levels of physical activity, assisting weight loss, improving sleep, or reducing stress [26,32,35,37,38,47,48,50,51,53-59,75,78-80]. A total of 11% (2/19) of the studies described messaging for providing information [49,52], and 5% (1/19) described the use of messaging to collect data for disease monitoring and guide clinical care [31]. In total, 26% (5/19) of the studies described aspects of design and development of messaging systems for people with knee osteoarthritis [79,80], osteoporosis [76], and chronic arthritis [77]. The design and development aspects are described in later sections.

Osteoarthritis Studies

Of the 8 studies on osteoarthritis, 2 (25%) focused on behavior change based on personalized goals. In the first study, which proposed personalized goals based on machine learning, participants were sent daily push notifications to remind them of their goals together with an interesting fact or answer to a frequently asked question [59,80]. Similarly, the second study used messaging to provide reminders to complete individualized physician-assigned goals and tasks, for which participants also used messaging to provide confirmation, or otherwise, that they had completed their personalized goals [55].

A total of 4 (50%) of studies focused on physical activity and exercise behavior change for people with knee osteoarthritis: of those, 1 (25%) used messages to decrease inactive behavior in people with knee osteoarthritis [53] and another (25%) used targeted personalized motivational reinforcement messages based on previous and current physical activity for people with osteoarthritis and sleep disturbance [57]. In the third study, which had an experimental design, the authors also explored patient attitudes and experiences of a self-directed digital health intervention incorporating automated messages to support strengthening exercises [78,79]. The fourth study, in which 77% of participants had knee osteoarthritis, described a digital care program that sent participants reminder messages if they did not engage with the program at the required intensity and also allowed participants to communicate with their health coach using messaging [26].

A single study focused on providing information for people with knee osteoarthritis, where messages were used to improve patients' knowledge about their condition and treatment options before consultation with their specialist as part of shared decision-making [52].

A further study focused on knee osteoarthritis prevention, describing a self-management lifestyle intervention for young to middle-aged rural-dwelling women that incorporated messaging to provide key behavior reminders [38].

RA Studies

Of the 5 studies on RA, 2 (40%) used message reminders as part of a motivational counseling intervention to reduce sitting time [37,48,56], and 1 (20%) focused on physical activity behavior change with messaging used for coaching, prompts, reminders, and monitoring of physical activity program adherence [51,75]. A further study assessed the effects of text messages on medication adherence [32]. One study collected data using text or app-based messaging for symptom or disease monitoring and patient-reported outcome measures [31].

In a study that recruited women with chronic widespread pain (80% met the American College of Rheumatology criteria for fibromyalgia), text messaging was used to prompt diary completion and allow participants to exchange short messages with their therapist. The diary information was used by therapists to inform patient care [35,47]. A second guided imagery study also focused on people with fibromyalgia used text messaging to remind participants to practice their imaging exercises together with randomly selected reinforcement messages [50].

A study on patients with osteoporosis and nontraumatic fractures used text messaging to provide patients with treatment advice based on a validated fracture assessment tool and assessed whether the advice provided subsequently changed primary care physician management of their fracture [49].

Finally, one study described the use of social media messaging (WeChat) for people with ankylosing spondylitis, with messaging used for appointment reminders, for communication between physicians and patients, to record follow-up information, and for patients to provide feedback [54].

Multiple Musculoskeletal Conditions or Pain Sites

A total of 10 studies focused on multiple musculoskeletal conditions or pain sites (n=1, 10% each on the neck or back [64], neck, shoulder, or back [66], and chronic knee or low back pain [LBP] [67]). A total of 50% (5/10) of the studies recruited participants with a range of musculoskeletal problems typically seen in the general population [36,60,61,65], and 20% (2/10) of the studies recruited adults with chronic pain but not pain exclusively of musculoskeletal origin [62,63]. A further study focused on chronic musculoskeletal pain in veterans [81].

Of these 10 studies, 9 (90%) described behavior change interventions [36,60-63,65-67,81], and 1 (10%) was focused on providing information [66].

For neck and back pain, one study described the use of an artificial intelligence–enabled app that implemented evidence-based guidelines for self-management, with messaging provided within the app to remind participants to exercise and provide contact with the treating team [64]. A second study on workers with neck, shoulder, or back pain also described the use of artificial intelligence, wherein a chatbot provided messages with exercise instructions and suggestions for symptom improvement [66]. One study focused on chronic knee

or LBP described a digital care program incorporating sensors and an app that allowed participants to communicate with a personal coach via SMS text messaging and app-based messaging [67].

Another 20% (2/10) of the studies included adults with chronic pain but not exclusively pain of musculoskeletal origin [62,63]. The first included patients being treated by a hospital-based pain management service for a range of conditions (LBP; cervical or upper-extremity, lower-extremity, abdominal or pelvic, and head or face pain; and multiple pain sites, with pain of ≥4 on a 0-10 scale). Participants used an app that incorporated reminders to complete daily assessments and also provided 2-way messaging [63]. The second study, with similar wide-ranging pain sites, used automated text messaging to prompt skill practice as part of an internet-delivered CBT program for chronic pain [62].

Regarding patients attending hospital physiotherapy services for a range of musculoskeletal problems, 10% (1/10) of the studies examined whether SMS text messaging could increase home exercise compliance [36]. In this study, compliance with exercises was encouraged via motivational SMS text messages sent by the physiotherapist. Similarly, the use of messaging to encourage home exercise compliance was described in a study on patients with musculoskeletal problems attending a chiropractic clinic [60].

In the physiotherapy outpatient setting, the use of SMS text message reminders to reduce clinic nonattendance was described in 10% (1/10) of the studies [61].

A total of 20% (2/10) of the studies focused on specific populations. The first, a community-based study, aimed to improve the physical activity of older adults (aged ≥60 years, most of whom had musculoskeletal problems) and used social media messaging (WhatsApp) to inform participants of scheduled walks and promote social interaction between participants [65]. The second study focused on a chronic musculoskeletal pain program in veterans and used behavior change messaging for stress management and adoption of healthy sleep practices and to increase engagement and retention in the program [81].

Back Pain

A total of 20% (8/40) of the studies described behavior change interventions [24,27,68-73,82], and 5% (2/40) described the design and development (described in a later section) [82,83]. Of the 8 behavior change studies, of these 4 (50%) described the use of individual or personalized messaging for physical activity goal reminders and reinforcement [24], encouragement messages and physical activity suggestions [69], motivational notifications for self-management [73,82], and individual activity level–based feedback messages provided on a PDA to encourage behavior change [68]. A total of 13% (1/8) of the studies described a self-management app with notifications to encourage walk breaks and posture exercises [72].

A total of 38% (3/8) of the studies described the use of 1- or 2-way messaging with a health coach, physiotherapist, or sports scientist for support, encouragement, and participation reminders as part of self-management programs [27,70,71].

Neck Pain

Only 3% (1/40) of the studies focused specifically on neck pain. This study described a behavior change intervention for office workers with chronic neck pain incorporating weekly messages about caring for their pain with information about the importance of exercise and to provide encouragement to complete prescribed exercises [74].

Other Conditions

A total of 3% (1/40) of the studies, on patients with frozen shoulder recruited from an orthopedic outpatient clinic, used messaging to provide reminders, encouragement, and education to promote shoulder exercise compliance [30].

RQs 2 and 3: Design and Development and Patient Preferences

Overview

In this section, we report findings related to the design and development of messaging interventions. Because patient preferences, where accommodated, were generally addressed through participatory or co-design, we have reported the results of review questions 2 and 3 together. The findings are presented in three groups: (1) information found in papers specifically focused on the design and development of messaging interventions, (2) information found in mHealth design papers where some aspect of messaging was described alongside other mHealth functions, and (3) incidental design and development information found in papers that reported the results of messaging or mHealth interventions. The design-specific papers are shown in Table 4 and Figure 3 [76-83].

Table 4. Papers focused on messaging design and development and patient preferences.

Study, year	Role of messaging	Design process (theory, method, and outcomes)
Johnson et al [81], 2017—describes the participatory design and pilot study of an mHealth[a] self-management program for veterans with chronic MSK[b] pain	• Tailored messages were an optional component intended to increase engagement and retention.	• Participatory design involving a panel of veteran advisors, experts, and end users (number not specified). Input sought through interviews, focus groups, and usability testing but not described in detail. • Messages were described as targeting behaviors, with message content and schedules matched to the participant's stage of change based on the transtheoretical model of health behavior change [84]. The process through which the message content and schedules were derived was not described. Example messages included the following: "As a Veteran, you likely know many people who have or had pain. Think about one of them who could inspire you to manage your pain. Stress can make people more prone to pain. If you lower your stress, you can help lower your pain. See PAC activity Get the Facts [short-url]."
Mork and Bach [82], 2018 (protocol)—describes the components and architecture of an app-based self-management decision support system for LBP[c] (self-BACK)	• Messaging (via push notifications) used within the app to encourage physical activity	• Authors stated that focus groups and iterative testing and development with patients, health professionals, and researchers were part of the development process without further detail. • Structured intervention mapping [85], behavior change theories [86], and normalization process theory [87] • During the development process, patients and health professionals (eg, physiotherapists and psychologists) were interviewed on their experience managing LBP. Educational content was reviewed by clinicians and researchers. • Patient case data (baseline information, physical activity monitoring, and weekly patient-reported health and adherence outcomes) were used to generate motivational notifications to encourage physical activity. Little messaging-specific design information was provided.
Ravn Jakobsen et al [76], 2018—describes the participatory design and development of an mHealth app for women with newly diagnosed osteoporosis	• Messaging used to communicate the results of a bone density scan (DXA[d]) to women and coordinate their follow-up appointment with their general practitioner.	• A participatory design [88] was used. The team consisted of researchers, women, physicians, other health care professionals, and app designers. • The iterative participatory app design process was somewhat unclear and described as commencing with 3 workshops (first, to generate ideas; second, to review wireframe designs; and third, to discuss the overall design content), followed by the creation of the design, feedback from users, development of a prototype, laboratory tests and feedback, adjustment, and final development. Messaging-specific design and development considerations were not described.

Nelligan et al [79], 2019—comprehensive description of the identification of behavior change targets; design of SMS text message library to support adherence to home exercise for people with knee OA[e]	• SMS text message–based intervention
	• Automated behavior change messages to promote exercise, with adaptive messages triggered by participant responses
		• Phase 1: theoretical rationale and application to inform the intervention
		  • SMS text messaging was selected as the mode of delivery based on literature describing it as a scalable, effective, efficient, and affordable way to promote adherence to health behaviors [19,89-94]. The authors used a previous scoping review [95] that mapped barriers and facilitators against the Theoretical Domains Framework [96]. Furthermore, the COM-B[f] framework for understanding health behavior [97] and the BCW[g] [97,98] were used throughout this phase. Previous work was used to identify messaging intervention functions appropriate for the SMS text messaging format [99].
		• Phase 2: development of SMS text messaging functions and a message library
		  • The SMS text messaging functionality was guided by the literature [100]. SMS text messages were automated and adaptive. Participants' self-reported exercise adherence triggered a BCT[h].
		  • The content of the messages was codeveloped by 7 academics, 4 physiotherapists, and 1 person with knee OA. The authors based their messaging frequency on previous literature, which, while inconsistent, suggests that 3 messages per week tapered over time was appropriate [92,100]. Examples are provided in appendixes accompanying the authors' article [79] and in Table 5.

Study, year	Role of messaging	Design process (theory, method, and outcomes)
Geuens et al [77], 2019—identified feature preferences and motivations for a hypothetical self-management app for chronic arthritis	• Messaging as a component in an app • To provide medication or postural reminders	• Authors referred to the PSD[i] model [101]. • Structured interviews to identify patient preferences for features in a hypothetical app and their motivations for selecting those features • Limited messaging-specific information provided; however, reminders were rated highest in terms of desired features (medication and also posture). Praise and reward messages were considered less important, and social interaction features were rated the lowest.
Pelle et al [80], 2019—describes the theoretical framework and iterative design of an app for OA self-management	• App was developed through an iterative design process that comprised medical researchers, physicians, physical therapists, patient representatives, and app developers.	• Iterative development process involving researchers, health professionals, app designers, and patient representatives over 3-week "sprints" of development; user testing; reiteration; and, finally, pilot-testing • After a review of the literature and consensus meetings, it was determined that motivation enhancement techniques such as reminders could increase the intervention effect. • The Fogg Behavior Model [102], persuasive design [103], and daily push notifications to remind users of their goal and provide education on OA
Fritsch et al [83], 2021—described the co-design process for a bank of evidence-based messages for an LBP self-management text messaging intervention	• Iterative codevelopment to identify relevant domains, content sources, frequency, appropriate timing, and a series of evidence-based messages for self-management of LBP	• Behavior change methodology [104] previously used by Redfern et al [105,106] that links BCTs to frameworks such as information-motivation-behavior, theory of reasoned action, theory of planned behavior, social cognitive theory, control theory, and operant conditioning. • 2-phase process previously used to develop messages in cardiology [106] conducted with consumers, researchers, and clinicians (n=39) to generate 82 messages • Phase 1: development of concept and content with 15 consumers, clinicians, and researchers over 2 workshops to determine messaging features. In the workshop, it was decided that 4 weekly messages would be sent across the domains to provide education, motivation, or behavior change. Timing of appropriate messages for LBP self-management (9 AM, 12:30 PM, 4 PM, and 6 PM) was drawn from the literature [90,105]. • Messages were subsequently drafted by 2 researchers and 2 consumer representatives and were then reviewed by 2 researchers with expertise in behavior change. • Phase 2: iterative web-based review phase beginning with experts, then followed by consumers. Each message was reviewed by at least 2 participants in each round. Experts provided a score (mean 8.3/10) for appropriateness of content with consideration to current evidence and the likelihood of clinical effectiveness. Messages with a score of <8/10 (34%) were revised and then assessed by people with lived experience with LBP. These consumers scored each text messages on utility of content, understanding, and language acceptability. Messages with a score of <12/15 (31%) were revised according to feedback. Most frequently, consumer feedback focused on making the content more specific and less technical and including more examples.

Papers Focused Specifically on Messaging Design and Development

A total of 4% (2/47) of the papers comprehensively described the design and development of SMS text messaging interventions for knee osteoarthritis [79] and back pain [83].

An SMS Text Messaging Intervention to Support Home Exercise Adherence for People With Knee Osteoarthritis

In 2019, Nelligan et al [79] comprehensively described a formal two-phase process to (1) identify behavior change targets and (2) design a library of SMS text messages to support adherence to home exercises for people with knee osteoarthritis. The development was guided by the recommended steps for developing text messaging–based programs for health behavior change published by Abroms et al [100] in 2015.

The first phase of development, comprising 3 stages, focused on target behavior, barriers, facilitators, and behavior change techniques using the Behavior Change Wheel framework [97,98]. Stage 1 drew on the literature to define the problem in behavioral terms, explaining the behavioral target and context and the barriers and facilitators for people with knee osteoarthritis in terms of participating in exercise mapped to domains in the Theoretical Domains Framework [96]. Barriers and facilitators relevant to the target behaviors were organized using the Capability, Opportunity, and Motivation–Behavior model for behavior change [97]. Stage 2 mapped barriers and facilitators to select intervention functions and behavior change techniques appropriate for implementation using SMS text messaging [93]. In stage 3, behavior change techniques for each function were identified from the Behavior Change Technique Taxonomy (version 1) [99].

The second phase involved the development of SMS text messaging functionality, specifically, a message library of content and determination of message frequency and level of interaction. Messaging content was derived by taking each barrier- or facilitator-linked behavior change technique identified in the first phase and constructing a relevant SMS text message. Message content was derived with input from 12 participants (1 person with knee osteoarthritis, 7 researchers, and 4 physiotherapists). In total, 3 authors derived the final message bank. A fourth author reviewed the final SMS text message wording to ensure that it was consistent with the Behavior Change Wheel mapping process and the identified behavior change techniques. The final message bank was organized into a 24-week schedule, assessed using literacy tools for readability, and tested by the authors for functionality and errors.

Author-provided examples of the mapping process and resulting SMS text message content for example barriers and facilitators are shown in Table 5.

Table 5. Example barrier and facilitator mapping process, abridged from Nelligan et al [79].

	COM-B[a] category [97]	TDF[b] domain [96]	Intervention function [99]	BCT[c] [99]	Resulting SMS text message content
Barrier mapping					
Forgetfulness	Psychological capability	10—memory, attention, and decision processes	Training	8.3—habit formation	"[Name], it can be hard to remember. We suggest making the exercises a habit. Set aside the same time each day to do them. It's much harder to forget when something is a daily routine."
Facilitator mapping					
Prioritizing exercise	Psychological capability	14—behavioral regulation	Enablement	10.9—self-reward	"Did you prioritize your exercises this week and get them done? Then reward yourself, [name]! Sticking to an exercise program for this long is a real accomplishment that deserves celebration."

[a]COM-B: Capability, Opportunity, and Motivation–Behavior.

[b]TDF: Theoretical Domains Framework.

[c]BCT: behavior change technique.

A Messaging Self-Management Intervention for LBP

In 2019, Fritsch et al [83] described the co-design process used to derive a bank of evidence-based lifestyle-focused messages for an LBP self-management text messaging intervention.

The authors used an iterative 2-phase co-design approach based on a framework used to design prevention messages for patients with cardiovascular disease previously published by Redfern et al [106] in 2014.

Phase 1 consisted of two 2-hour workshops intended to develop the concept, initial content, and messages. Workshop participants were researchers, clinicians with specific knowledge related to LBP, and consumer representatives from the support group Musculoskeletal Australia. At the first workshop, participants identified important domains relevant to LBP (exercise, education, mood, use of care, sleep, and medication) through reference to an evidence-based consumer resource (*Managing your pain: An A-Z guide*; Musculoskeletal Australia). The second workshop was focused on identifying sources of content for messages and duration, frequency, and timing of messages. Identified sources of content were relevant peer-reviewed literature, Australian and international clinical practice guidelines for LBP, and consumer group patient educational resources. Message frequency (4 messages per week) and timing (9 AM, 12:30 PM, 4 PM, and 6 PM) were based on previous work in coronary heart disease [107]. The development team considered that an intervention program duration of 12 weeks would be appropriate, with *exercise* domain messages being sent twice per week (emphasizing the importance of remaining active) and 1 message sent per week for each of the other domains.

This phase of the development process was also informed by previous work on factors related to engagement, perceived usefulness, behavior change, and delivery preferences for patients with coronary heart disease [105].

Following the workshops, a team comprising 2 researchers and 2 consumer representatives drafted evidence-based behavior change messages following the same theoretical approach by Redfern et al [106]. Messages were focused on education, motivation, or behavior change in the domains of *providing information or encouragement*; *prompting about consequences, intention formation, monitoring self-behavior, and barrier identification*; *advice about setting graded tasks*; and *strategies aimed at relapse prevention* and *the use of prompting and cues*. The team drafted an initial set of 82 positively phrased messages (by domain: 40 *exercise* messages, 10 *education* messages, 10 *mood* messages, 8 *use of care* messages, 7 *sleep* messages, and 7 *medication* messages) to take forward to the second phase of development.

In the second phase, the authors used a web-based survey of leaders in the field of LBP management to assess the appropriateness of the message content, gather opinions on the likelihood that the messages would be clinically effective, and make recommendations for message content improvement. The mean score for the messages from the expert review was 8.30/10. Messages with a score of <8/10 (34%) were modified in response to accompanying feedback. Subsequently, consumers scored each text message on utility of content, understanding, and language acceptability. Text messages with a consumer review score of <12/15 (31%) were revised according to feedback (mean score 12.5/15 points). Most frequently, consumer feedback focused on making the content more specific and less technical and including more examples.

Papers Describing the Design and Development of Messaging Within mHealth Apps

A total of 9% (4/47) of the papers described the design and development of more general mHealth interventions, where those interventions contained some use of messaging (alongside other mHealth features) for people with knee or hip osteoarthritis [80] and back pain [82], pain self-management for veterans [81], and women newly diagnosed with osteoporosis [76]. In total, 2% (1/47) of the papers focused on feature preferences for an app to support the self-management of chronic arthritis [77].

In each case, the design of the overall intervention was typically well described; however, the design of the content, timing, and frequency of the messaging components was not described in detail (Table 4). Because these papers provided little useful

messaging-specific design and development information, we do not discuss them any further.

Incidental Design and Development Information Contained in Papers Reporting the Results of mHealth Interventions

We found little useful design-related information contained within the papers describing results of interventions. Typically, the papers described the purpose and behavior of the messaging component within their intervention, but the design processes used to determine message content, timing, and frequency were described incidentally or not at all (studies shown in Tables 6 and 7) [30,35,36,38,47,50,60,62,63,65,66,72,74]. For example, one paper provided examples of messages intended to provide encouragement, education, or motivation but provided no explanation of how these were derived [30]. Similarly, some papers (4/47, 9%) made a passing reference to co-design processes involving patients and clinicians but provided limited detail [37,48,55,56].

Some papers (17/47, 36%) described the use of messaging *adaptivity* (ie, dynamic system-initiated changes to the delivery of messaging to personalize content, frequency, or timing of messages based on automated or manual triggers) or *individualization*. Triggers for adaptivity included self-reported exercise adherence [79], automated physical activity data derived from wearables [57,68,73], self-reported data [54,66,71], personalized goals [37,48,55,56], and manual adaptivity triggers initiated by study personnel [31,63] and health coaches [26,27,67,70]. However, in these papers, no substantial detail was provided on the design considerations or processes related to the development of the intervention's adaptive behavior.

Table 6. Messaging-specific intervention studies—efficacy and effectiveness.

Study, year	Objective	Duration and sample size (n)	Outcomes favoring messaging	Equivocal outcomes
Newell [60], 2012	Experimental study; for patients receiving chiropractic exercise advice, does text messaging with their practitioner, compared with no text messaging, improve exercise compliance?	4 weeks (32)	• Self-reported exercise compliance (NRS[a])	• Patient-perceived practitioner care (NRS)
Taylor et al [61], 2012	Experimental study; for patients attending outpatient physical therapy clinics, do SMS text message reminders, compared with no reminders, reduce clinic nonattendance?	1 day (679)	• Nonattendance at outpatient physiotherapy appointments (proportion)	• Appointment attendance (proportion) • Appointment cancellation (proportion)
Gandy et al [62], 2016	Observational study; for patients receiving an internet-delivered CBT[b] program for pain, is the addition of message skill practice prompts, compared with no prompts, feasible and effective?	8 weeks (195)	• Acceptability of SMS text messages (Likert scale)	• Treatment satisfaction (Likert scale) • Pain-related disability (RMDQ[c]) • Depression (PHQ-9[d]) • Anxiety symptoms (GAD-7[e]) • Pain intensity (WBPQ[f])
Theiler et al [49], 2016	Observational study; for patients with osteoporosis, do SMS text message reminders, compared with no reminders, improve adherence to drug therapy?	2 months (399)	• Engagement with health care providers (proportion)	• None
Chen et al [30], 2017	Experimental study; for patients with frozen shoulder, are reminder, encouragement, and educational messages delivered via mobile phone, compared with no messages, effective to increase exercise adherence and physical functioning?	2 weeks (66)	• Patient-reported compliance with shoulder exercises[g] • Range of motion in forward flexion and internal and external rotation (goniometry) • Patient satisfaction with SMS text messaging intervention (Likert scale)	• Shoulder function (Simple Shoulder Test) • Shoulder abduction (goniometry) • Shoulder pain (VAS[h])
Jamison et al [63], 2017	Experimental study; for patients with chronic pain using an app to record their progress, does 2-way supportive messaging, compared with no messaging, increase use or improve measures of pain or mood?	3 months (105)	• Patient perceptions (more appealing, easier to use, easier to navigate, and less bothersome) • Favored controls: participant perceptions of the responsiveness of providers to their reports	• Frequency of use • Pain (BPI[i]) • Activity interference (PDI[j]) • Mood (HADS[k])
Timmers et al [52], 2018	Experimental study; for patients with knee osteoarthritis, does delivering education via an interactive mobile app, compared with standard education, increase patients' knowledge of their illness and treatment options?	7 days (213)	• Actual knowledge[l] • Perceived knowledge[l] • Patient satisfaction (NRS)	• None
Bartholdy et al [53], 2019	Experimental study; for patients with knee osteoarthritis, do messages containing information and advice about the importance of performing daily activity, compared with no messages, lead to improved levels of activity?	6 weeks (38)	• None	• Time spent physically inactive, standing, and moving (accelerometry) • Self-reported change in physical activity[m] • Pain severity, quality of life, and disability[n]
Mary et al [32], 2019	Experimental study; for patients with rheumatoid arthritis, compared with standard pharmacist consultation, does a 15-min pharmacist-led counseling session or message reminders improve methotrexate adherence?	6 months (96)	• Medication adherence (CQR-19[o]) • Patient satisfaction (Likert scale)	• Medication adherence (GS[p] and MPR[q]) • Disease activityr

Study, year	Objective	Duration and sample size (n)	Outcomes favoring messaging	Equivocal outcomes
Kuusalo et al [31], 2020	Experimental study; for patients with rheumatoid arthritis, does using automated messages for enhanced monitoring, compared with routine care, improve disease activity and remission and quality of life?	6 months (166)	• Physical functioning at 6 months after randomization (SF-36[r]) • Health care resource use (nurse telephone contact)	• Patients' confidence in treatment (VAS) • Physical and mental health–related quality of life (SF-36) • Physical functioning at 12 months after randomization (SF-36) • Disease activity[s] • Group rates of remission (proportion) • Health care resource use[t]
Anan et al [66], 2021	Experimental study; for workers with neck and shoulder stiffness and pain or LBP[u], does an AI[v]-assisted interactive health promotion system that operates through a mobile messaging app, compared with usual workplace exercise routine, lead to an improvement in musculoskeletal symptoms?	12 weeks (94)	• Pain intensity (Likert scale) • Perceived symptom improvement (Likert scale)	• None

[a]NRS: numeric rating scale.

[b]CBT: cognitive behavioral therapy.

[c]RMDQ: Roland-Morris Disability Questionnaire.

[d]PHQ-9: 9-item Patient Health Questionnaire.

[e]GAD-7: 7-item Generalized Anxiety Disorder Scale.

[f]WBPQ: Wisconsin Brief Pain Questionnaire.

[g]Calculated as days answered "yes" to exercise/total days in the intervention.

[h]VAS: visual analog scale.

[i]BPI: Brief Pain Inventory.

[j]PDI: Pain Disability Inventory.

[k]HADS: Hospital Anxiety and Depression Scale.

[l]Customized scale (actual perceived level was measured on a 0-36 scale, or perceived level was measured on a 0-25 scale).

[m]Customized scale for change in self-reported physical activity (included no change, less time, or 0-3.5 more times compared to baseline).

[n]Knee Injury and Osteoarthritis Outcome Score.

[o]CQR-19: Compliance Questionnaire on Rheumatology.

[p]GS: Girerd score.

[q]MPR: medication possession ratio.

[r]SF-36: 36-item Short-Form Health Survey.

[s]Disease Activity Score–28 for Rheumatoid Arthritis, Health Assessment Questionnaire, erythrocyte sedimentation rate, and C-reactive protein.

[t]Except nurse telephone contact.

[u]LBP: low back pain.

[v]AI: artificial intelligence.

Table 7. Mobile health (mHealth) studies with an embedded messaging component.

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
Kristjánsdóttir et al [35,47], 2013—short- and long-terms effects of a smartphone-based intervention with diaries and therapist feedback to reduce catastrophizing and increase functioning in women with chronic widespread pain	4 weeks (140)	Experimental study: • Following a 4-week inpatient rehabilitation program, the study randomized participants to either a smartphone intervention or no smartphone intervention (controls). Follow-up occurred immediately after the intervention at 5 and 11 months. Smartphone intervention: • Initial in-person session with a nurse to discuss functioning, health-related behavior goals, support needs, values, and value-based activities. • Online web-based diaries completed 3 times a day on a smartphone covering pain interference, feelings and thoughts related to avoidance, catastrophizing and acceptance, planned and previous practice of self-management activities, and daily value-based and practical activities. • Daily written situational feedback from a therapist based on the information entered in the diaries • Audio files with guided mindfulness exercises SMS text messaging was used to prompt participants to complete their diaries and notify them when therapist feedback had been provided.	Reported between-group effects: • Small effects on catastrophizing (PCS[a]) and value-based living (CPVI[b]) immediately after the intervention. Effect was nonsignificant at the 5-month follow-up. • Moderate effect on acceptance (CPAQ[c]) immediately after the intervention and at the 5-month follow-up. • Moderate effect on sleep disturbance (VAS[d]) and functioning and symptom severity [69] at the 5-month follow-up • No effect on pain • No significant between-group differences at the 11-month follow-up
Dekker-van Weering et al [68], 2015—pilot study of an activity-based feedback system for people with LBP[e]	15 days (17)	• Observational study; participants' daily activity was measured using a body-worn sensor. • Real-time, hourly, personalized feedback was tailored to the individuals' objectively measured activity level (eg, to discourage movement, to encourage movement, or a neutral message).	• Encouraging feedback led to an increase in PA[f]. • Discouraging feedback led to a decrease in PA. • Greater participant response to feedback messages was associated with decreased pain scores.
Demmelmaier et al [75], 2015, and Nordgren et al [51], 2018—short- and longer-term (2-year) evaluation of an outsourced program to encourage PA in people with RA[g]	12 months (191)	• Observational study • Intervention: community-based exercise, support groups to facilitate behavior changes and feedback from physical therapists • 2 messages each week were sent to collect data on how often the participant engaged in circuit training and moderately intense exercise.	• Patients perceived the use of professional coaches and text messages to support the adoption of physical exercise as helpful. • While improvements in self-reported physical activity, the proportion of participants who maintained increased physical activity, decreased significantly during year 2 of the study. Grip strength and quality of life reduced significantly during year 1 and 2 of the intervention. Reductions in activity limitation, systolic blood pressure and waist circumference were observed during second year. With most other health improvements sustained during year 1 and 2 of the study • Participants reported that the text messages were a good reminder to engage in exercise (rated 4/5 on perceived value).

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
Thomsen et al [37], 2016; Thomsen et al [48], 2017; and Thomsen et al [56], 2020—evaluating the effect of motivational interviewing and messages on sitting time in patients with RA	4 months; follow-up: 10 and 22 months (150)	• Experimental study; patients randomized to 3 individual motivational counseling sessions and messages aimed to reduce sedentary behavior (intervention) versus no contact and instructions to maintain usual lifestyle (controls). • Manually created individual tailored messaging was used to remind participants of goals that they had set in their individual counseling sessions. Participants selected the frequency and timing of messages.	Reported between-group effects: • Reduction in sitting time of –2.2 hours per day (95% CI –2.72 to –1.69) favoring the intervention • Secondary measures, including fatigue, pain, self-efficacy, and HRQoL[h], also favored the intervention.
Lambert et al [36], 2017—evaluating whether patients with MSK[i] conditions have better adherence to home exercises when content is delivered via an app-based intervention compared to paper handouts	4 weeks (77)	• Experimental study; participants randomized to receive home exercise program information via an app together with phone calls and motivational messages (intervention) versus paper handouts (controls) • All participants were prescribed a 4-week exercise program.	Reported between-group effects: • Small significant differences in adherence to the exercise program (NRS[j]; 1.3/11 points, 95% CI 0.2-2.3) and function (PSFS[k]; NRS 0.9/11 points, 95% CI 0.1-1.7) • There were no significant differences in disability, patient satisfaction, perceived global impression of change, or assessor-reported adherence.
Lee et al [74], 2017—assessed the effectiveness of app-based exercises supported by weekly messages in office workers with chronic neck pain	8 weeks (20)	• Small experimental pilot study in the workplace; participants randomized to receive prescribed exercises via a smartphone app (intervention) versus receiving a brochure and pain education (controls) • Both groups received weekly education and encouragement messages.	Reported between-group effects: • Statistically significant difference in pain intensity (VAS; 0-10) and functional disability (NDI[l]; expressed as a percentage); note: despite randomization, compared with controls, the intervention group had higher pain intensity at baseline (mean VAS score 5.20, SD 2.19 vs 4.02, SD 1.75) and a much higher NDI (mean 26.8, SD 9.68 vs 17.70, SD 9.20). • No between-group differences in the secondary outcomes of strength, fear avoidance, and quality of life (SF-36[m])
Chhabra et al [24], 2018—assessed the effect of a smartphone app on pain and function in patients with chronic LBP	12 weeks (93)	• Experimental study; participants randomized to receive daily activity goals (back and aerobic exercise) in addition to written prescriptions (medication and recommended level of PA) provided through an app (intervention) versus written prescriptions only (controls) • Activity goals were personalized based on participants' health status, activities of daily living, and daily activity progress. Automated reinforcement messages were delivered via app push notifications.	• Reported between-group effects: no significant difference in pain (NRS) and significant difference in disability (MODI[n]) favoring the intervention
Lo et al [64], 2018—assessed the feasibility of an AI[o]-embedded mHealth app for chronic neck and back pain in promoting self-management	Unclear (161)	• Observational study • Intervention: educational content including information on the pathophysiology of neck and back pain and principles of exercise for management of pain and coping strategies. Information was pushed via messages to participants' social media accounts.	• Pretest-posttest increase in time spent on rehabilitation exercises (custom questionnaire) • Mean "self-reported improvement" of 65% (0-100 scale) • Pretest-posttest reduction in pain from a median of 6 (IQR 5-8) to 4 (IQR 3-6; NRS 0-10) • Perceived usability was 73/100 (cutoff for "acceptable" was 68/100; SUS[p])
Mecklenburg et al [26], 2018—assessed the efficacy of a remotely delivered digital care program for chronic knee pain	12 weeks (162)		

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
		• Experimental study; participants randomized to receive involved sensor-guided exercise therapy, psychoeducation, cognitive and behavioral therapy, and behavioral monitoring via the "Hinge Digital Care Program" (intervention) versus 3 digital education sessions and TAU[q] (controls) • The app included a coach and peer support discussion via messaging. Message or email reminders were sent if participants did not appear to engage at the recommended intensity of the program.	Reported between-group effects: • Significant difference in pain and physical functioning (KOOS[r]), pain (VAS), and stiffness (VAS) favoring the intervention • Interest in and the likelihood of needing surgery decreased, and patients' understanding of their condition improved. • Estimated surgery cost savings of US $4340 over 1 year and US $7900 over 5 years for participants who completed the digital care program compared to controls
Molinari et al [50], 2018—assessed the efficacy of using guided imagery to have patients with fibromyalgia picture their best possible selves	4 weeks (80)	• Experimental study; participants randomized to receive "Best Possible Self," a web-based app multimedia system to support patients through guided imagery (intervention) versus "Daily Activities" (active controls) • The active control condition was not well described. • Participants in both arms received 2 reminders each week via SMS text messaging prompting them to practice the guided imagery exercise.	Reported between-group effects: • Postintervention improvements in depression, positive affect, and self-efficacy favoring "Best Possible Self" • At the 30-month follow-up, there was improved optimism and negative affect favoring "Best Possible Self."
Rabbi et al [69], 2018—evaluate the feasibility and acceptability of a personalized app for PA recommendations for adults with chronic pain	5 weeks (10)	• Observational study • Intervention: MyBehaviourCBP app, which generated PA recommendations based on sensor-detected PA. Recommendations were contextualized to the environment (road names), and new suggestions were continuations of the users' repeated behaviors (eg, "Take walking break near Thompson St for 24minutes today"). • Study comprised a 1-week period with no recommendations, 2 weeks with generic recommendations provided by an expert, and 2 weeks with automated recommendations.	• Participants found the dynamic recommendations easier to adopt than the static generic recommendations. All participants found the recommendations "helpful." • Walking duration during the dynamic phase was greater than in the static phase (+4.9 min/d); no significant differences in pain ("Likert" scale; 0-10) and nonwalking exercise (min) were found. • Qualitative feedback included that participants wanted notifications in the moment and adaptivity in relation to the weather or weekend days in addition to information related to the relationship between pain and activity levels.
Selter et al [70], 2018—described patient engagement and perceived utility and assessed the validity of a smartphone app module to quantify the functional status for people with chronic LBP	12 weeks (93)	• Observational study • Intervention: physical therapy program using the Limbr app involving 3 daily self-reports of pain and activity level and chat-based health coaching • Health coaches monitored data and sent participants messages to provide support and remind them to interact with the program. • Participants with low engagement (eg, only 1-2 interactive components per week) were sent weekly emails containing visual feedback on their use.	• High level of attrition (38% completion rate); engagement was reported as "high amongst completers." • Depending on the type of self-report, 21%-32% interacted with the app. • 76% of patients found that daily notifications helped them remember to complete their exercises, and 71% found that they helped them complete the daily surveys.
Wang et al [38], 2018—evaluated the effectiveness of a community-based self-management lifestyle program for young to middle-aged women with knee pain living in rural Australia	12 months (649)	• Experimental study; participants randomized to receive 1 group session, monthly SMS text messages, 1 phone coaching session, and a program manual (intervention) versus 1 session of general women's health education (controls) • Program intended to improve lifestyle and prevent weight gain.	Reported between-group effects: • Overall, no difference in the risk of knee pain worsening over 12 months • For women who had knee pain at baseline (WOMAC[s]; 35% of participants), there was a lower risk of knee pain worsening over 12 months favoring the intervention, although this effect was only statistically significant for women with a BMI of ≥25 kg/m2 (OR[t] 0.28, 95% CI 0.09-0.87).

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
Frei et al [65], 2019—assessed the effectiveness and feasibility and participant perceptions of a community-based PA intervention	12 months (29)	• Observational study • Intervention: the intervention facilitates and encourages participants to arrange walking groups within their local area. • The messaging app, WhatsApp, was used to facilitate communication between the participants and study team.	• Increased the minutes that participants engaged in moderate- to vigorous-intensity activity; no significant changes in step count • 76% of participants reported that they attempted to recruit their peers to participate in the intervention. • 62.4% of participants sent messages. • Participants continued to organize walking groups via WhatsApp after the study team ceased their involvement.
Ji et al [54], 2019—described the design and preliminary evaluation of an interactive mHealth tool designed to help with the management and self-management of ankylosing spondylitis	13.3 months (1201)	• Observational study • Intervention: app designed to provide patient education on disease management and assist patients with medication adherence (SpAMS[u]) • The tool consisted of a patient and physician portal and was linked to the social media app WeChat to allow for communication between physicians and patients, collect follow-up data, and obtain patient feedback.	• Improvement in the proportion of patients with inactive disease or low disease activity from baseline to a mean follow-up time of 13.3 months (57.2%-79.2%) • Problems solved using SpAMS avoided 29.1% of clinic visits. • Average savings of 5.3 hours per patient in travel time and US $51 per person in personal expenses (15% of Chinese monthly disposable income) on physicians.
Shebib et al [27], 2019—evaluated the efficacy of a digital care program for patients with LBP	12 weeks (177)	• Experimental study; participants randomized to receive a remotely administered digital care program that involved cognitive behavioral therapy, sensor-guided exercise therapy, education, symptom tracking, and unlimited personal coaching (intervention) versus 3 digital education articles and TAU (controls)	Reported between-group effects: improvements favoring the intervention in pain (MvK[v]: mean –16.4, 95% CI –22 to –10.9; VAS: mean –16, 95% CI –22.5 to –9.4), disability (MvK: mean –13, 95% CI –19.3 to –6.7; ODI[w]: mean –4.1, 95% CI –6.5 to –1.8), impact on daily life (VAS: mean –11/8, 95% CI –19.3 to –4.3), and understanding of their condition and treatment options (0-4; mean 0.5, 95% CI 0.2-0.7) and decreased interest in back surgery (mean –0.4, 95% CI –0.7 to –0.1)
Støme et al [55], 2019—feasibility study Investigating the acceptability, usability, and utility of a mobile app supporting goal achievement in patients with OA[x]	12 weeks (12)	• Observational study • Intervention: Vett app sent participants personal reminders to complete tasks that aligned with their PA, weight loss, and stress reduction goals. • Participants were assigned 2 to 3 weekly physician-developed tasks and self-monitored their progress or received individualized feedback.	• Primary reported outcome was mean goal achievement, which had a pretest-posttest improvement of 48%. • Mean user satisfaction was 81/100, and technical usability was 80/100 to 84/100.
Zaslavsky et al [57], 2019—pilot study that assessed the feasibility and preliminary efficacy of a self-management mHealth intervention aimed at improving sleep among older adults with OA and disturbed sleep	19 weeks (24)	• Observational study • PA feedback based on wearable (Fitbit) data • Participants received weekly personalized messages with motivational feedback in relation to their step count data. • Participants who maintained or increased their step count received reinforcing messages. Those with declining step counts received encouraging messages. • Participants also received motivational interviewing geared toward discussing the participants' goals and strategies to facilitate behavior change.	• Small pretest-posttest improvements in mean insomnia (ISI[y]; 1.2 points, 95% CI 2.45-0.05) and ASD[z] (2.5 points, 95% CI 0.9-4.1) and self-reported overall sleep quality (derived from sleep diaries; 0.3 points, 95% CI 0.02-0.58) • Nonsignificant improvements in step count, pain intensity, pain-related disability, self-efficacy, and sleep diary data and variables
Almhdawi et al [72], 2020—assessed the efficacy of an mHealth smartphone app in patients with LBP	6 weeks (39)	• Experimental study; participants randomized to receive evidence-based instructions, therapeutic exercises, and reminders (intervention) versus instructions about nutrition (controls) • Both arms received the app; the intervention group received reminders for walk breaks, posture, and exercises.	

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
			Reported between-group effects: • Significant reductions (Cohen *d*) in pain intensity (VAS; 1.71, 0-11) and pain-related disability (ODI; 1.08) and improvements in physical quality of life (SF-12[aa] PCS[ab]; 1.18) • No significant differences in mental quality of life (SF-12 MCS[ac]); depression, anxiety, and stress symptoms (DASS-21[ad]); sleep quality (PSQI[ae]); and self-reported PA (IPAQ[af])
Bailey et al [67], 2020—evaluated the efficacy of a digital care program in patients with chronic knee and back pain	12 weeks (10,264)	• Observational study • Intervention: Hinge Health app, which delivered education, sensor-guided exercise therapy (using a Bluetooth wearable sensor), behavioral health support, and 1:1 health coaching • Patients were assigned a health coach, and communication occurred via SMS text messaging, email, or app-based messaging.	• 78% completed the program, with 69.6% achieving minimally important change in pain (20 points or 30% from baseline; VAS). • Greater reduction in pain scores was associated with increasing levels of engagement in exercise therapy and participant-to-coach interactions. • Significant reduction in the proportion of participants categorized as having depressive (PHQ-9≥5) or anxiety (GAD-7≥5) symptoms at 11 weeks compared with baseline (depression decreased by 57.9%, and anxiety decreased by 58.3%) • Mean 1-year surgery likelihood score (subjective self-report response to the following question: “What do you think are the chances you’ll have [back/knee] surgery in the next year, in %?”; 0%-100%) decreased by 67.4% with respect to baseline.
Hasenöhrl et al [71], 2020—evaluated the feasibility and acceptance of orthopedists prescribing therapeutic exercises via a smartphone app to patients with nonspecific back pain	4 weeks (prestest-posttest assessment: 27 and semistructured interview: 16)	• Small observational study with a qualitative component • Intervention: individual physician-selected exercises sent via in-app messaging (n=27 participants). The physician could provide encouragement and mental support or unlock new exercises. • Qualitative component: interviews and thematic analysis with a random sample of 16 of the 27 participants (research question not well described)	• Reduction in mean hip circumference (–1.54, SD 2.75 cm) • Reduction in back pain (ODI; mean –2.67, SD 4.99) • Quality of life (SF-36): improved physical functioning (+5, SD 11.9); improved bodily pain (+14.8, SD 7.8); vitality (+7.2, SD 14.8) • Participants reported that they would have preferred 2-way messaging
Nelligan et al [78], 2020 (qualitative), and Nelligan et al [58], 2021 (RCT[ag])—explored the experiences and attitudes of patients with knee OA who participated in an mHealth intervention to support exercise	24 weeks (16)	• Qualitative study (n=16 participants) embedded in an RCT with a targeted recruitment of n=206 • Participants were randomized to receive website+SMS text messaging adherence support+home exercises (intervention) versus website only (controls). • The website contained educational information (OA and exercise), PA recommendations, and prescription of knee-strengthening exercises. • If participants adhered to the exercise program, they received a positive reinforcement message. If participants did not adhere, they were asked to select a barrier. All participants received behavior change techniques to assist with exercise adherence.	

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
			• Five themes were reported: (1) technology was easy to use, (2) facilitators to exercise participation (credible information, website features, exercises that could be done unsupervised, and freedom to adapt exercises to suit needs), (3) sense of support and accountability (SMS text messaging served as a good reminder to engage in exercise, was easy to use, and held them accountable to weekly exercise; SMS text message tone and automation could trigger guilt or shame; and inability to contact someone when needed), (4) positive outcomes (symptom improvement, self-management confidence, and encouragement of active living), and (5) suggestions for real-world application (preference for provision by a health professional and should be subsidized or low cost). • Primary outcomes favored in the intervention group in the RCT: decrease in pain scores (NRS; mean difference=1.6, 95% CI 0.9-2.22); increase in function (WOMAC; mean difference=5.2, 95% CI 1.9-8.5) • Most secondary outcomes favored the intervention, which included KOOS pain, function in sport and recreation, ASES[ah] pain and function subscales, AQOL-6D[ai], and overall satisfaction (Likert scale). Changes in PASE[aj], ASES function, and SEE[ak] were similar between groups. • Average participant message response rate was 73% (SD 7.5%), and 8% opted out. Patient perceptions (7-item Likert scale): mean perceived usefulness was 5.3 (SD 1.8), and mean agreement with message frequency was 5.3 (SD 1.7). Adverse events: 15.3% (intervention) vs 6.3% (control); a greater portion of the intervention group had knee pain (9.6%) compared to those in the control group (1.3%); a similar proportion used cointerventions throughout the study period.
Nordstoga et al [73], 2020, and Mork and Bach [82], 2018 (protocol)—evaluated the usability and acceptability of an mHealth intervention, selfBACK, in patients with LBP	4 weeks (16)	• Observational study • Intervention: the smartphone app provided participants with weekly self-management plans with content related to PA, flexibility exercises, and patient education. • Behavior change techniques were incorporated into the app (eg, goal setting, feedback, monitoring, information about health consequences, and prompts). • Motivational notification messages were sent to the participants' smartphones.	• Participants received an average of 1.8 notifications per day. • Participants opened 42% of the notifications; of those opened, 90% were liked, and 8% were disliked; notifications of goal attainment were most frequently liked by participants. • There was a lack of consensus on the frequency and appropriateness of motivational notifications. • Motivational reminders served as facilitators of the intervention. • 50% of the participants found the motivational messages useful. • 30% of the participants found the notifications to be irrelevant and not functioning properly (eg, unsynchronized).
Pelle et al [59], 2020—investigated the effect of an mHealth intervention on secondary health care use in people with hip and knee OA	6 months (427)		

Study, year	Duration and sample size (n)	Intervention and messaging features	Summary of findings
		• Experimental study; participants assigned to receive a self-management app (Dr Bart mHealth app) intended to support goal setting and education and enhance motivation, with daily push notifications providing reminders on selected goals and educational information (intervention) versus TAU (controls) • TAU consisted of any treatments initiated by participants.	Reported between-group effects: • No difference in knee- or hip-related OA secondary health care use • Significant group differences favoring the intervention were found between baseline and the 6-month follow-up for symptoms (mean difference=2.6, 95% CI 0.4-4.9), pain (mean difference=3.5, 95% CI 0.9-6.0), and activities of daily living (mean difference=2.9, 95% CI 0.2-5.6; HOOS[al] and KOOS). • No differences were found in any other outcome measures.

RQs 4 and 5: Evaluation Methods, Efficacy, Effectiveness, and Economics

To avoid repetition, the findings of review questions 4 and 5 are reported together. A total of 28% (11/40) of the studies directly compared the use of messaging with an alternative; a further 60% (24/40) of the studies evaluated mHealth interventions with embedded use of messaging.

Studies Comparing the Use of Messaging With an Alternative

Of the 11 studies that directly compared messaging to an alternative, 9 (82%) had an experimental design and 2 (18%) were observational. In most cases, the comparator or control condition was no messaging or treatment as usual, with outcome measures varying by the intent of the intervention. Of these 11 studies, 3 (27%) [30-32] were described in the previous review on the effectiveness of text messaging interventions on the management of musculoskeletal pain [22], and the remainder were not, likely because they did not meet the inclusion criteria or were published later [49,52,53,60-63,66].

Overall, the outcomes either favored the messaging condition or were equivocal.

Examples of outcomes favoring messaging interventions included improved knowledge of the illness and the available treatment options and physical activity for knee osteoarthritis [52,53], improved medication adherence and physical functioning for RA [31,32], improved attendance to outpatient physiotherapy [61] and engagement with general practitioner [49], and improved exercise compliance for frozen shoulder [30] and mixed musculoskeletal conditions [60]. However, despite participants sometimes reporting messaging as *acceptable* [62] or *appealing* [63], and while improved pain intensity was found in participants with neck and shoulder pain and LBP [66], some studies (4/40, 10%) reported equivocal findings for important patient outcomes such as time spent physically active [53], pain [53,63], and quality of life [31,53].

In no studies did the primary outcome favor the control condition. In only one study, a secondary outcome (clinician responsiveness) favored the control condition. In this study, patients with chronic pain recorded their progress using an app, with intervention recipients also having access to messaging with their clinician (controls could report progress but had no messaging). Control participants perceived their clinicians to be more responsive to their progress reports [63].

No studies reported economic outcomes.

The studies are summarized in Table 6.

mHealth Studies With Embedded Messaging Components

A total of 24 studies evaluated mHealth interventions containing some form of embedded messaging component (n=11, 46% experimental; n=11, 46% observational; n=1, 4% observational with a qualitative component; and n=1, 4% qualitative embedded within an experimental study).

The results of efficacy and effectiveness were mixed, but because messaging was embedded within a larger mHealth intervention, it was not possible to isolate the messaging-specific effects from the overall intervention effects.

A total of 8% (2/24) of the studies reported economic outcomes—avoided surgery costs associated with a digital education program for chronic knee pain, in which messaging was used for coaching or peer support and program engagement reminders [26], and reduced travel time associated with a self-management mHealth tool for ankylosing spondylitis, in which social media messaging was used for communication between physicians and patients [54].

While it was not possible to isolate messaging-specific effects, these studies are included for completeness and summarized in Table 7.

Discussion

Principal Findings

To our knowledge, this is the first study to comprehensively map how mobile messaging has been used in the treatment and self-management of musculoskeletal conditions. We mapped the conditions and purposes for which messaging has been used and the approaches used to design and develop messaging interventions and summarized the evidence of efficacy, effectiveness, and economics from both experimental and observational studies. Our intent was to draw together all the available relevant information to help inform the future design of messaging interventions for people with musculoskeletal conditions and identify research gaps.

While previous reviews in this area are few, this work builds on 3 existing syntheses of the effectiveness of messaging interventions for people with musculoskeletal conditions. One review focused specifically on text messaging interventions for musculoskeletal pain [22]. The review included studies across a range of musculoskeletal problems and included both studies in which messaging was added to and compared with usual care (findings of positive effects only on exercise and medication adherence) and studies in which messaging was a component of a larger intervention (reporting some small effects on pain intensity, function, care-seeking behavior, exercise and medication adherence, and quality of life). Overall, the quality of the evidence was low. The 2 other reviews focused more generally on digital health for managing musculoskeletal conditions [23] and mHealth interventions for people with RA [46].

In this review, all the included studies that assessed intervention efficacy or effectiveness (on pain [30,53,63,66], function [30,31,63], disability [53], adherence to the intervention [30,60,63], physical activity levels [53], appointment attendance [49,61], health care contact [31], mood [63], quality of life [31,53], remission [31], and disease activity [31,32]) reported either equivocal findings or findings favoring messaging.

The notable absence of studies reporting negative outcomes may suggest publication bias. The lack of economic studies is also concerning; no messaging-specific studies reported economic outcomes. While, of the 40 studies, 2 (5%) digital or mHealth studies with messaging components did report

economic outcomes, including avoided surgery costs and reduced travel time [26,54], the embedded nature of messaging means that it is not possible to attribute the observed savings specifically to the messaging components. While a previous review has shown messaging to be cost-effective in some circumstances, there is no information on the economic effects on musculoskeletal pain conditions; in cases in which messaging interventions are shown to be effective, further studies should be conducted to assess their economic effects [22,108].

We identified studies describing the use of messaging across a range of musculoskeletal conditions, with rheumatic diseases representing almost half (19/40, 48%) of the included studies, of which two-thirds (13/19, 68%) focused on osteoarthritis and RA. Somewhat surprisingly given its high population prevalence, back pain was represented by less than a quarter of primary studies (9/40, 23%). A further quarter of the studies (10/40, 25%) addressed multiple musculoskeletal conditions, but most (30/40, 75%) targeted single musculoskeletal conditions and pain sites despite evidence that musculoskeletal conditions often do not occur in isolation (eg, in Australia, 64% of people with back pain and 74% of people with arthritis have at least one other chronic condition) [3].

More than 80% of the included primary studies (34/40, 85%) focused on the use of prompts and reminder messages to foster positive behavior change at the individual level, most commonly in combination to encourage movement (eg, to increase physical activity, reduce sitting time, and improve compliance with prescribed exercise); compliance with prescribed medication; the practice of coping skills; and the meeting of personal goals. While a small number of studies (10/40, 25%) described the use of unidirectional or 2-way messaging with a health coach or exercise or sports scientist for support and encouragement, more studies (11/40, 28%) described the use of automated and unidirectional messaging, which, while economical on resources, may limit effectiveness in fostering behavior change.

While most studies (34/40, 85%) focused on influencing individual behavior change, there appears to be limited research into the use of messaging to improve treatment or self-management at the broader system level (eg, to improve health care processes, handover communication, and continuity of care between providers). One study on RA used SMS text messaging–based monitoring of medication adherence and disease progression to inform follow-up nurse contact but found no difference in the primary outcome of remission [31]. A second study on a digital health platform for ankylosing spondylitis management consisting of a patient and physician portal and 2-way chat via social media reported improvements in the proportion of patients with inactive disease and an avoidance of 29.1% of in-person clinic visits [54]. Future studies could focus on addressing the gaps in knowledge on more process- or system-focused interventions.

Overall, we found limited information about messaging design. One study (1/40, 3%) used development processes previously described by Redfern et al [106], which, while originally focused on cardiovascular event prevention messaging, have since been more widely adopted and adapted in the co-design of text messaging interventions, including for diabetes prevention [109], endometriosis support [110], and support after breast cancer treatment [111]. Similarly, one study (1/40, 3%) used guidance for the development and testing of messaging in health behavior change developed by Abroms et al [100].

Only 4% (2/47) of the papers provided comprehensive information about message design and development [79,83] and highlighted the importance of taking a formal approach and having a theoretical underpinning and meaningful consumer involvement. Beyond these 2 papers, design was typically poorly described or not described at all, and many projects appeared to leapfrog from concept to implementation with a limited or absent design phase, perhaps not recognizing the importance of formal design for subsequent adoption.

While some papers (8/47, 17%) did describe elements of participatory design or co-design, some papers (4/47, 9%) provided limited detail or had limited consumer involvement, or in some cases, consumers were involved after the design had already been conceived by researchers and clinicians. In most cases, we found that papers described the theoretical basis underlying their intended behavior change well, but consistent with a previous review [22], we found few detailed descriptions of the process through which the content, timing, and frequency of the messages were derived. This remains an important weakness in the musculoskeletal literature specifically and has been identified more generally by others [100,106]. Further work should be conducted to elicit preferences regarding these processes from people across the spectrum of musculoskeletal conditions.

The strengths of this review include our comprehensive search strategy and the inclusion of a wide range of studies and designs, providing a rich map of the literature expanding the insights provided by previous effectiveness-focused reviews. A limitation is that we focused specifically on the use of messaging in patient care and self-management, and it is possible that there are other messaging applications relevant to people with musculoskeletal conditions. However, we made this review as broad as possible within available resources. Because a comprehensive synthesis was time-consuming and we last conducted the searches in 2022, there may be important, more recent studies that we missed in this review. Similarly, resources did not allow us to review the gray literature.

Conclusions

In conclusion, messaging has been used for the care and self-management of a range of musculoskeletal conditions with generally favorable outcomes reported. Nonetheless, there are areas that should be addressed by future research to improve the quality of intervention design, which will hopefully translate into uptake and sustainability. First, preferences related to messaging content, timing, and frequency should be further explored specifically among people with musculoskeletal conditions, eliminating the reliance on information from other disciplines. Second, teams should incorporate digital intervention design expertise, follow formal design processes, and clearly describe design considerations and processes used. Finally, in cases in which messaging interventions are shown to be effective, further studies should be conducted to assess

their economic effects and practical considerations related to implementation and sustainability.

Authors' Contributions

MS, NA, and RE conceptualized the study. SSR and NA developed, pilot-tested, and refined the search strategy. SSR conducted the final searches. SSR, JL, CEE, RE, CR, SR, and NA screened the articles. JL, CEE, and NA extracted and confirmed the data. All authors contributed to data synthesis, manuscript development, and critical review. All authors approved the final version of the manuscript.

Conflicts of Interest
