[a]The step count was log transformed. Goal, Social=dummies representing the goal setting or social comparison conditions vs self-monitoring. A total of 1934 and 1960 observations were used for the motivation outcomes and step count, respectively.

[b]IV: independent variable.

[c]DV: dependent variable.

Discussion

Principal Findings

This study examined the effects of different BCTs implemented in Fitbit on subjective and objective levels of PA as well as motivations for PA. Three BCTs (ie, self-monitoring, goal setting, and social comparison) were offered via the smartwatch for 4 weeks, during which participants lived in their daily lives. Overall, participants showed excellent adherence to the interventions (older participants and those with a child or job showed even better adherence), and there were no dropouts at the end of the interventions. Although we found no significant increase in total PA (as assessed by the IPAQ-SF) or Fitbit-assessed step count, participants reported that the stage progressed typically from precontemplation to contemplation across the 3 BCT conditions. In addition, significant increases were detected in several aspects of motivation (ie, integrated and external regulation), and the day-to-day level of external regulation showed a larger increase in self-monitoring than in goal-setting conditions.

Overall, these results suggest that the effects of Fitbit-delivered BCTs on PA are marginal. There are several possible reasons for the detection of smaller-than-expected effects. First, we used an active control condition (ie, self-monitoring offered by a wearable device), unlike previous trials that compared the presence and absence of an activity tracker [10], which may have mitigated the detectable between-condition effects. Second, changes from the pre- to the postintervention assessment showed extremely large heterogeneity. This heterogeneity can be partly attributed to large individual differences (or SD) in baseline PA levels. Notably, the social comparison group showed an average increase of 22.1 (SD 80.9) METs-h/w, which is regarded as a sufficient increase in PA according to the national health recommendation (23 METs-h/w) [32]. However, a large SD prevented the effect from reaching statistical significance, which is in line with a recent meta-analysis of the heterogeneous effects

of social factors in behavior change interventions [26]. This may indicate that personalization (delivering social comparisons to people who appreciate social factors) is important for maximizing the intervention effect [48]. Third, we did not have a baseline period for the Fitbit assessment; on receipt of the Fitbit, the participants started each intervention immediately. Interestingly, the step count was slightly higher in the goal setting and social comparison groups than in the self-monitoring group over the course of the intervention (P=.051 and P=.06). These effects suggest that participants had already adapted their behavior on the first day of the interventions, which resulted in an overall elevation in step count, albeit with nonsignificant time-group interactions. These minor effects should be interpreted carefully, but it is possible that self-regulatory and social factors contribute a meaning addition to self-monitoring in PA promotion [24].

Our aim was to experimentally investigate the effects of mobile implementations of BCTs, and therefore, we decided to keep each BCT manipulation as simple as possible. However, our implementations might feel too simple compared with the features and functions equipped in commercial PA apps. For example, we set rigid goals for each participant (ie, 8000 or 9500 steps each day), but goal setting theory suggests that goals should be adequate and tailored to the individual skills (ie, doable but challenging) [25,49]. Also, other components could be considered as effective additions in real-life implementation, such as action planning, goal evaluation, and goal reevaluation. Similarly, social comparison could be provided in another form—for example, some participants commented in the postintervention interview that they would be more motivated if the leaderboard displayed the steps of close others (eg, real friends and family members). Several trials have tested the efficacy of collaboration and competition within a gamification intervention for PA, which gives a meaningful context of social comparison and may help enhance motivation to engage in the intervention [50,51].

We detected significant increases in the levels of integrated and external regulations in the postintervention assessment. These increases were not moderated by the BCT conditions, indicating that each group experienced almost equal increases in the 2 types of regulation. Similarly, day-level external regulation increased over the 4-week interventions, which was qualified by the significant time-group interaction. This interaction suggests that participants in the self-monitoring group experienced a larger increase in external regulation than those in the goal setting group. A cross-sectional survey of the Mexican general population [52] found that external regulation was predominant in the precontemplation stage, whereas intrinsic, integrated, and identified regulations increased as the stage progressed (the action and maintenance stage). The detected increase in integrated regulation may be a good sign, but the increase in external regulation may have both positive (eg, people may have found external rewards to start PA and to progress from the precontemplation stage) and negative aspects (eg, this may not directly lead to habit formation). Furthermore, the day-to-day increase in external regulation may suggest that participants in the self-monitoring group felt some pressure and tension regarding PA, as the questionnaire item stated that they felt that they have to exercise [30]. Thus, the significant interaction effect can be interpreted as the goal setting technique preventing participants from feeling obliged to engage in PA.

Limitations

These findings should be interpreted with consideration of several important limitations. First, we based the eligibility assessment on a 1-item SoC questionnaire, which is not an optimal screening tool. Approximately one-third of eligible participants were sufficiently active to exceed the national health recommendation (23 METs-h/w) at baseline. In the postintervention interview, some participants reported that they had not been aware of their activity level at eligibility screening but realized how active they were when responding to each item of the IPAQ-SF. Future research should consider a sufficiently detailed eligibility assessment for PA and preferably use an objective measure, such as a pedometer or accelerometer. Second, it was not possible to strictly control how the participants used each Fitbit feature during the intervention period. For example, we did not prevent participants from setting their own step goals, even in the self-monitoring or social comparison conditions. Although we did not detect any significant violations in the log of Fitbit usage, it might be appropriate to add a system to lock or unlock a particular function in the app and device to reduce potential contamination. Third, we did not conduct a follow-up assessment to test whether the intervention effects were maintained even after the end of the intervention. This decision was made because we could not give away the Fitbit, but it would be valid to leave the Fitbit with participants even after the end of the intervention if we wanted to observe a long-lasting follow-up effect. Fourth, during the study period, motivation was rated or reported each night together with the step count of the day. This assessment timing may have influenced how participants responded to the questionnaires—it is possible that people are more motivated for PA during the daytime. However, we decided not to administer multiple questionnaires (eg, in the morning; at random moments) within a day to reduce the burden on participants and to achieve high compliance.

Conclusions

Nevertheless, our results suggest that activity trackers are useful for increasing readiness and motivation for PA, although significant heterogeneity was identified. The addition of goal setting and social comparison potentially enhances step count, and goal setting may prevent feelings of pressure or tension from engaging in PA. However, to fully detect BCT-specific effects, a proper trial (eg, with a larger sample size, longer intervention and assessment periods, and different populations) is warranted. It is difficult to evaluate the effects of each BCT and their complex combinations (eg, [53]), but future research should expand to other BCTs often used in mHealth practices, such as messaging and rewards.

Abstract

Background: During adolescence, substance use and digital media exposure usually peak and can become major health risks. Prevention activities are mainly implemented in the regular school setting, and youth outside this system are not reached. A mobile app (“Meine Zeit ohne”) has been developed specifically for vocational students and encourages participants to voluntarily reduce or abstain from a self-chosen addictive behavior including the use of a substance, gambling, or a media-related habit such as gaming or social media use for 2 weeks. Results from a randomized study indicate a significant impact on health-promoting behavior change after using the app. This exploratory study focuses on the intervention arm of this study, focusing on acceptance and differential effectiveness.

Objective: The aims of this study were (1) to examine the characteristics of participants who used the app, (2) to explore the effectiveness of the mobile intervention depending on how the app was used and depending on participants’ characteristics, and (3) to study how variations in app use were related to participants’ baseline characteristics.

Methods: Log data from study participants in the intervention group were analyzed including the frequency of app use (in days), selection of a specific challenge, and personal relevance (ie, the user was above a predefined risk score for a certain addictive behavior) of challenge selection (“congruent use”: eg, a smoker selected a challenge related to reducing or quitting smoking). Dichotomous outcomes (change vs no change) referred to past-month substance use, gambling, and media-related behaviors. The relationship between these variables was analyzed using binary, multilevel, mixed-effects logistic regression models.

Results: The intervention group consisted of 2367 vocational students, and 1458 (61.6%; mean age 19.0, SD 3.5 years; 830/1458, 56.9% male) of them provided full data. Of these 1458 students, 894 (61.3%) started a challenge and could be included in the analysis (mean 18.7, SD 3.5 years; 363/894, 40.6% female). Of these 894 students, 466 (52.1%) were considered frequent app users with more than 4 days of active use over the 2-week period. The challenge area most often chosen in the analyzed sample was related to social media use (332/894, 37.1%). A total of 407 (45.5%) of the 894 students selected a challenge in a behavioral domain of personal relevance. The effects of app use on outcomes were higher when the area of individual challenge choice was equal to the area of behavior change, challenge choice was related to a behavior of personal relevance, and the individual risk of engaging in different addictive behaviors was high.

Conclusions: The domain-specific effectiveness of the program was confirmed with no spillover between behavioral domains. Effectiveness appeared to be dependent on app use and users' characteristics.

Introduction

Prevalence and Prevention of Substance Use in Vocational Schools

Substance use and other addictive behaviors such as gambling, screen-related gaming, and excessive use of digital media are widespread among adolescents and young adults across different cultures [1]. In Germany, the prevalence of substance-related and web-related addictive disorders peaks during adolescence [2-5]. Research suggests that vocational students are particularly vulnerable to substance use and addictive behaviors compared with age-matched peers in the general population [6].

Schools are an important setting for facilitating prevention programs because a large number of young people can be reached simultaneously [7]. However, vocational schools have been largely neglected concerning empirically evaluated prevention activities in Germany [8]. Approximately 50% of all graduates from conventional schools in Germany enter vocational training [9] and are thus not reached by available programs during the critical time of adolescence. This seems to be a serious limitation for national public health goals. Established prevention programs cannot be implemented in the vocational school setting without adaptation, as this setting differs from the normal school setting due to the combination of practical training in a company and vocational education at school. Obstacles to implementation might be limited class cohesion, time, and teacher involvement (see reference [9] for a detailed description of the vocational school setting in Germany).

Mobile Interventions

Digital interventions and mobile technologies have the potential to overcome these barriers, especially with a vast majority of young people owning smartphones [10]. Mobile prevention programs offer a location- and time-independent as well as cost-effective way to deliver health-promoting content efficiently and in doses that can be easily integrated into daily life [11-13]. However, the participation rates (ie, the reach) of such mobile prevention programs vary [14-17]. Furthermore, in a recent review, Diestelkamp et al [18] report that despite growing evidence for the effectiveness of mobile substance use interventions, it is largely unclear which specific elements can be effectively implemented using mobile technology and how the extent to which individuals use this content may be associated with different outcomes.

Studies across different outcomes and delivery modes imply that multiple factors can influence the use and outcomes of digital interventions and that usage metrics vary across different types of interventions [19]. Previous research has shown that intensity of use (eg, number of log-ins) and active user engagement (eg, module completion) can influence intervention outcomes [19-21]. For example, a recent feasibility study investigating user engagement with a mobile smoke-free app showed a positive association between increased app use and cigarette abstinence [22]. Furthermore, a study focusing on a mobile intervention for heavy drinking and smoking among college students found that receiving more modules of the intervention was significantly associated with a lower likelihood of any drinking during the 14-day assessment period and a significant reduction in smoking at 1-month follow-up [23]. Thus, on a general level, usage patterns of digital interventions appear to play an important role in their effectiveness. However, it is still very unclear which specific usage metrics have an impact and how large the potential impact is, depending on the design of the intervention, its objectives, and its target population. It is also not clear how users' background characteristics, such as sociodemographic factors, psychological characteristics, previous experiences with technologies, and the level of health symptoms, may influence intervention use and positive health outcomes.

Meine Zeit ohne Intervention

In a recent randomized study [24,25], we transferred the school-based prevention approach of a voluntary commitment into an app-based program for vocational students ("Meine Zeit ohne" [MZo]; IFT-Nord Institut fuer Therapie- und Gesundheitsforschung GmbH). The app (see Multimedia Appendix 1 for app screenshots) was developed for implementation in vocational schools. In the trial, students in the intervention group (IG) received access to the MZo app, which was available for download at the Google Play Store and the Apple App Store (described in detail by Pietsch et al [25]). It includes an introduction to the overall theme of habits and on potential risky health behaviors concerning substance and media use as well as gambling. The app features a short explanation video demonstrating the use and goals of the app. Participants were invited to select 1 behavioral goal for the next 2 weeks: complete abstinence or substantial reduction regarding their use of cannabis, smoking (cigarettes or e-products), alcohol, digital social media use, gaming, gambling, or "another habit." For the options of cannabis, alcohol, and gambling, only an abstinence goal could be selected. After choosing their behavioral goal and starting the challenge, participants received

daily push notifications at fixed times (in the morning and at noon) to remind them to rate their subjective confidence in reaching their selected behavioral goal for the next 24 hours and to enter whether they succeeded in achieving their goal on the previous day. Following the last rating after 2 weeks, students could download and share a certificate regardless of their challenge results. The results suggest that this app-based intervention is feasible and effective in a vocational school setting [25]. Vocational students in the intervention arm classes were significantly (odds ratio [OR] 1.24, 95% CI 1.05-1.46; *P*=.01) more likely to report health-promoting changes such as reductions in substance use behavior and gambling as well as daily screen time for gaming or social media 30 days after the end of the app challenge.

As the effects on health-promoting change for a specific area were larger when students had chosen that particular challenge area, it seems that variations in *how* the MZo app was used (eg, the frequency of use and choice of challenge) and personal characteristics of users may have an impact on the intervention effects. In addition, as suggested by 2 recent studies, it may be interesting to explore whether the effects of a specific behavior reduction or abstinence are limited to that specific behavior or have positive ("spillover") effects on other behaviors [26,27].

This paper presents an exploratory analysis, which focuses only on the IG and investigates who could be reached by the app and how the mobile intervention was used. The aims of this study were (1) to examine the characteristics of participants who used the app, (2) to explore the effectiveness of the mobile intervention depending on how the app was used and depending on individual participants' characteristics, and (3) to study how variations in app use were related to participants' baseline characteristics.

Methods

Ethical Considerations

Approval for the study was obtained from the ethics committee of the Center for Psychosocial Medicine at the University Medical Center Hamburg Eppendorf (approval number: LPEK-0121) and the responsible school authorities at each study site (Center for Education Monitoring and Quality Development at schools in Hamburg, Institut für Bildungsmonitoring und Qualitätsentwicklung; the Center for Prevention at the Institute for Quality Development at Schools in Schleswig-Holstein, Institut für Qualitätsentwicklung an Schulen Schleswig-Holstein; and the Bavarian State Ministry for Education and Cultural Affairs) prior to data collection. The study was conducted in accordance with the CONSORT (Consolidated Standards of Reporting Trials) guidelines and complied with the principles laid down in the Declaration of Helsinki [28]. It was registered in the German Clinical Trials Register public database (DRKS00023788), and a detailed study protocol was published [24]. Written informed consent was obtained from all participants prior to study enrollment. Participants did not receive any financial compensation for participating in the study. All substantial protocol deviations or modifications were communicated to the ethics committee and German Clinical Trials Register.

Study Design and Participants

The MZo evaluation study was a 2-arm multicenter, cluster-randomized, waitlist-controlled trial (randomized controlled trial [RCT]) to test the effectiveness of a low-threshold, mobile app–based intervention in a sample of vocational students in Germany. The MZo app consisted of a 2-week intervention period followed by a 30-day follow-up period. Data were collected through web-based questionnaires and app use logs, starting in March 2021 and ending in April 2022. The RCT was conducted in 3 study centers in Germany—Munich, Kiel, and Hamburg.

At these sites, schools were consecutively recruited with the support of local school authorities or directly using digital and printed information materials, school conferences, etc. After initial agreement from school principalities, research staff, social school workers, or principals contacted the teachers at the participating school and informed them about the study's aims and procedures. In the participating vocational schools, teachers and school principals selected classes to participate in the study. Participation in the challenge and the survey was voluntary. Since the study was conducted during the COVID-19 pandemic, enrollment, data assessment, and the introduction of the app could not take place in the classroom as initially planned but were done on the web if necessary. Randomization was done at the class level and performed before the baseline assessment. To achieve this aim, 2 classes were each paired into similar dyads based on the three class characteristics: (1) frequency of in-school education, (2) educational area (eg, technical or IT, services, and trade), and (3) year of training (eg, first, second, and third) [25]. Paired classes were then randomized into the IG or control group. Researchers had no access to the app data during the intervention.

Measures

Overview

This analysis used baseline measurements, follow-up measures (all self-reported), and mobile app use log data from study participants in the IG. Study variables are described in detail below. Sociodemographic data were collected at baseline via web-based questionnaires and included sex or gender, age, migration status, income, and highest level of education.

App usage metrics were collected through usage log files recorded by the mobile phone app on an external server. Usage log files included, for each participating user, the registration code to match the app data with the data collected in the questionnaires, information about the challenge (eg, challenge choice, decision to choose a reduction or abstinence goal, and reduction goal in units or time), confidence, as well as success ratings in meeting their challenge goal for each day. The log files were retrieved from the server at the end of the intervention period. Usage metrics could be divided into 3 categories, which are summarized in Textbox 1. The definitions of the variables frequent use and congruent use are described in detail below.

Textbox 1. Description of usage metrics.

- Selected challenge: Users selecting a specific challenge (cannabis, smoking or vaping, alcohol, gaming, social media, gambling, and "other").
- Frequent use: Users using the app frequently.
- Congruent use: Users selecting a challenge congruent to his or her personal relevance.

Frequent Use

The number of days of use was determined by the total number of days on which participants made a confidence rating entry in the app. The confidence rating variable was chosen because it had to be rated on the respective day. Thus, this variable determined whether or not participants were actively using the app on a certain day during the challenge. As the number of days of active use showed a left-skewed distribution, further analysis was done using the binary variable frequent use based on a median split (eg, above or below 4 days of active use). Thus, nonfrequent use was defined when users actively used the app for up to 4 days, and frequent use was defined when users actively used the app for more than 4 days.

Congruent Use

The congruent use variable identified users who selected a challenge that met their personal relevance. Personal relevance was defined for each behavioral area (tobacco, e-cigarettes, alcohol, cannabis, gambling, gaming, and digital media) when a predefined threshold for the frequency of that behavior was exceeded at baseline assessment. For cannabis use, personal relevance was defined as a positive 30-day prevalence. For alcohol, cigarettes, and e-products, personal relevance was defined as consumption at least once a week (ie, on more than 4 days) in the past 30 days. For social media, gaming, and gambling, personal relevance was defined using the median split. Thus, for social media, personal relevance was determined if social media use exceeded 4 hours per day, and for gaming, if gaming days per month exceeded 3 days. For gambling, personal relevance was defined as at least 1 gambling day per month. Congruent use was determined when personal relevance for a particular substance-related behavior or behavioral addictive–related behavior was met and a participant actually chose a challenge for the same behavior. For students without a personally relevant behavior (ie, no behavior exceeding these thresholds), congruent use was set when the challenge "other" was selected. For example, congruent use was set when someone who smoked more than 4 days a month selected the smoking challenge.

Personal Relevance Score

To further explore how the level of personal risk regarding substance-related and addictive behavior influenced health-promoting change, a continuous variable named personal relevance score was created based on the personal relevance variables for tobacco, e-cigarettes, alcohol, cannabis, gambling, and gaming as well as digital media (for definitions of thresholds, see the *Congruent Use* section). The intention was to quantify the number of personal relevant habits. The personal relevance score was the sum of personal relevant behaviors for each participant; for example, when a participant smoked cigarettes at least once a week and drank alcohol at least once a week, his or her personal relevance score was set to 2. The values of the personal relevance score ranged between 0 (no area of personal relevance) and 7 (7 areas of personal relevance).

Outcome Variables: Health-Promoting Change Variables

For this analysis, the dichotomous health-promoting change variables and a variable called general adverse health behavior improvement (GAHBI) were created according to Pietsch et al [25]. For alcohol, gambling, and cannabis use, a health-promoting change was defined as a positive 30-day prevalence at baseline compared with a zero 30-day prevalence at follow-up. For cigarettes and e-products, change was defined as a reduction of at least 50% in the monthly number of cigarettes or e-product units from baseline to follow-up. For social media and gaming, change was defined as a reduction of at least 20 minutes in daily screen time. The GAHBI was coded as health-promoting change if there was at least 1 change in the abovementioned areas.

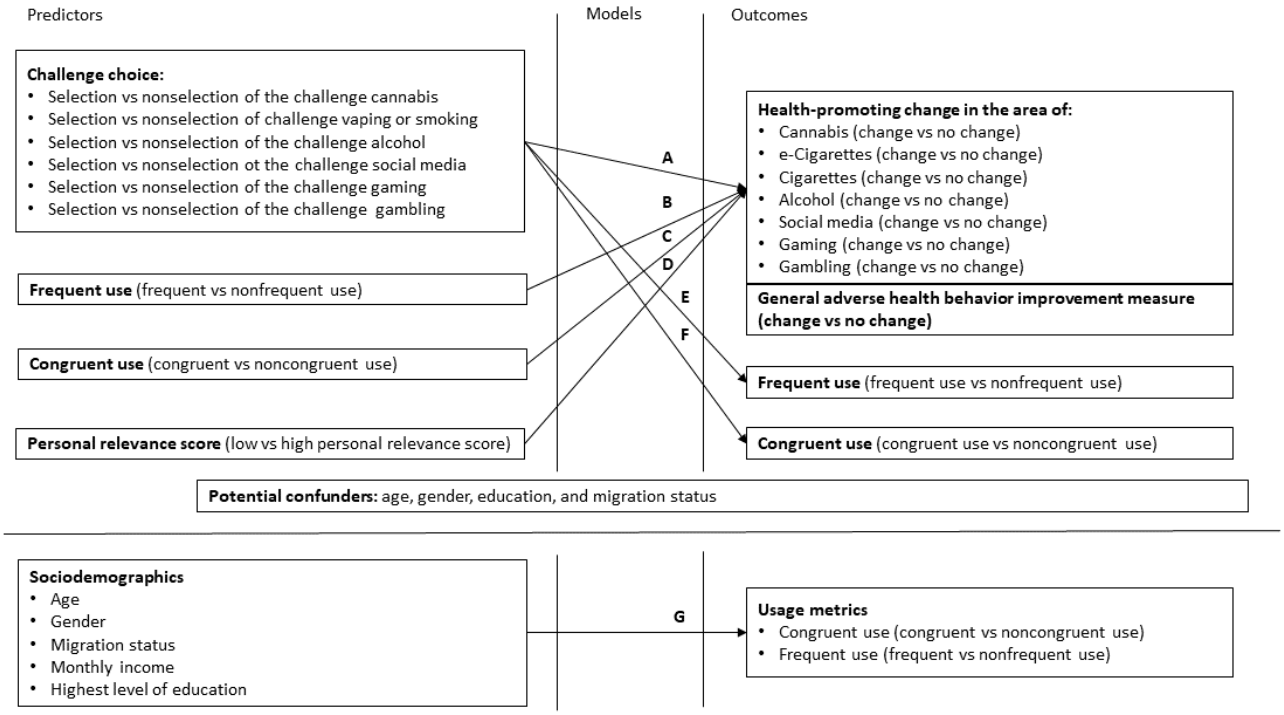
Statistical Analysis

Statistical analysis was performed using SAS for Windows (version 9.4 TS Level 1M7; SAS Institute Inc). Statistical significance was set at $P \leq .05$ (but exact P values are reported). Descriptive statistics were calculated using SPSS Statistics Release (version 26; IBM Corp). Differences in baseline characteristics between app users and nonapp users were assessed using Bonferroni-corrected 2-tailed t tests and chi-square tests. The relationship between the predictors (challenge choice, frequent use, congruent use, and personal relevance score) and the outcome variables (change in all dichotomous health-promoting change variables as well as the GAHBI [change vs no change]) was analyzed using binary multilevel mixed-effects logistic regression models (SAS Glimmix), accounting for the clustered structure of the data with clustering occurring within federal states, schools, and classes (see models A-D in Figure 1). For these results, ORs with corresponding 95% CIs are reported. Age, sex or gender, education, and migration status as potential confounders were included as fixed effects to the models. For the models for alcohol, cannabis, and gambling, the number of included confounders had to be reduced in order to achieve convergence. For the models for alcohol and cannabis, age and migration status were added, and for the model for gambling, migration status only.

The relationship between the usage metric of congruent use (yes vs no) and the selected challenge as well as frequent use was analyzed using binary multilevel mixed-effects logistic regression models (see models E and F in Figure 1). This was also done to analyze the relationship between the usage metric of frequent use and the selected challenge as well as congruent use. ORs, 95% CI, and P values were calculated and reported for all outcomes. As the usage metrics were important variables

in this study, they were further tested for associations with the sociodemographic baseline variables age, gender, migration status, monthly income, and highest level of education using multilevel mixed-effects logistic regression models (see model G in Figure 1).

Figure 1. Main analyses.

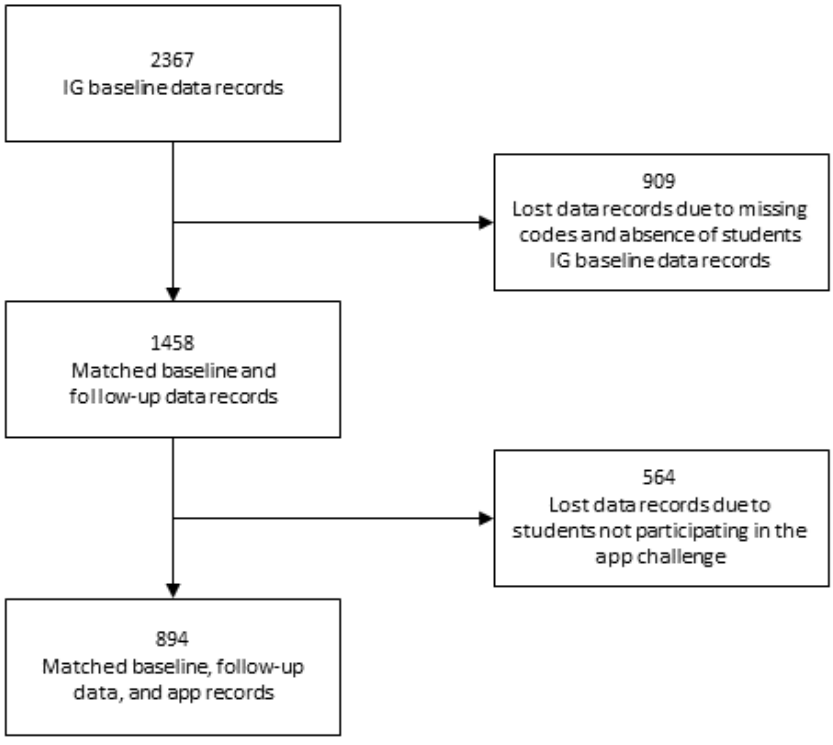


Results

Overview

Altogether, 2367 (51.6%) of 4591 students were randomized to the IG. The baseline and follow-up data of 1458 (61.6%) of the 2367 students in the IG could be matched by the corresponding codes of participants in the baseline and follow-up assessments. A total of 909 students were lost to follow-up due to absence or missing survey codes. Of these 1458 students, 894 (61.3%) started a challenge. Thus, 894 data records with baseline, follow-up, and app data could be included in the analysis (Figure 2).

Figure 2. Participant flowchart. IG: intervention group.



Sample Characteristics

The included sample (n=2367) consisted of 1308 (55.3%) male participants, 1040 (43.9%) female participants, and 19 (0.8%) participants who did not identify as binary. Their mean age at baseline was 19.2 (SD 4.2) years, and 786 (33.2%) reported a migrant background. Reported 30-day prevalence rates were 817 (34.5%) for smoking, 1536 (64.9%) for alcohol use, 294 (12.4%) for gambling, and 379 (16%) for cannabis use. In addition, IG students used social media for an average of 222.2 (SD 185.5) minutes per day and reported playing video games for an average of 99.6 (SD 140.1) minutes per day. The analysis revealed several differences between app users (students who used the app at least 1 time) and nonapp users (students who did not use the app at all) at the sociodemographic level. Students who used the app on average had a younger age and were more likely to have no migrant background, to have a medium monthly income, to have a middle school diploma, and to have vocational training in commerce, industry, and technology (Table 1).

Table 1. Description of the overall IG[a] sample, the IG sample with matched baseline and follow-up data records, and differences between app users and nonapp users in the matched IG sample assessed with Bonferroni-corrected 2-tailed t tests and chi-square tests.

Sociodemographics	Overall IG (n=2367)	Matched IG (n=1458)	App users (n=894)	Nonapp users (n=564)	*P* value
Age (years), mean (SD)	19.2 (4.2)	19.0 (3.5)	18.7 (3.5)	19.4 (3.6)	<.001
Sex, n (%)					
Male	1308 (55.3)	830 (56.9)	525 (58.7)	305 (54.9)	—[b]
Female	1040 (43.9)	618 (42.4)	363 (40.6)	255 (45.2)	.22

[c]As of June 12, 2024, a currency exchange rate of €1=US $1.075 is applicable.

Usage Metrics and Personal Relevance Score

A total of 894 (61.3%) of the 1458 students in the IG sample with matched data started the challenge (Figure 2). The mean number of days of active use was 5.62 (SD 4.76). With up to 4 days of active use, 417 (46.6%) of the 894 students using the app were nonfrequent users, 466 (52.1%) were frequent users with more than 4 days of active use, and 11 (1.2%) selected a challenge but had no days of active use. A total of 85 (9.5%) actively used the app throughout the entire intervention period of 14 days.

The challenge area most often chosen in the matched sample (n=894) was social media (n=332, 37.1%), followed by “other challenge” (n=159, 17.8%), alcohol (n=128, 14.3%), smoking or vaping (n=127, 14.2%), gaming (n=79, 8.8%), and cannabis (n=38, 4.3%). The least chosen challenge was gambling with 31 (4.2%) students. A total of 407 (45.5%) students chose a challenge congruent with their personal relevance. Of these 407

students, 126 (31%) selected a challenge in the category social media, 84 (20.6%) in the category smoking or vaping, 79 (19.4%) in the category alcohol, 61 (15%) in the category gaming, 23 (5.7%) in the category cannabis, 19 (4.7%) in the category "other challenge," and 15 (3.7%) in the category gambling.

The mean number of personal relevant behaviors was 1.88 (SD 1.32). Of all 894 students, 296 (33.1%) had a personal relevance score of 1, followed by 245 (27.4%) with a personal relevance score of 2, 245 (27.4%) with a personal relevance score above 2, and 108 (12.1%) with a personal relevance score of 0.

Association Between Challenge Choice and Health-Promoting Change or Congruent Use

ORs for health-promoting change in some areas were associated with the choice of challenge, particularly when the area of the challenge and health-promoting change were the same (eg, smoking or vaping challenge and health-promoting change in smoking; see model A in Figure 1). The results are displayed in Table 2. The ORs for health-promoting change increased for cigarettes (OR 3.51, 95% CI 2.14-5.76; *P*<.001) and e-cigarettes (OR 2.87, 95% CI 1.69-4.85; *P*<.001) for users who chose the smoking or vaping challenge. For users choosing the social media challenge, the ORs for a health-promoting change for social media increased (OR 1.66, 95% CI 1.25-2.20; *P*=.001) but decreased for a health-promoting change for smoking (cigarettes: OR 0.55, 95% CI 0.34-0.89; *P*=.001 and e-cigarettes: OR 0.56, 95% CI 0.33-0.92; *P*=.02). ORs for health-promoting change also increased for gaming (OR 1.77, 95% CI 1.09-2.89; *P*=.02) for users who chose the respective challenge. For users who chose the challenge "other challenge," ORs for health-promoting change increased for alcohol (OR 2.15, 95% CI 1.13-4.09; *P*=.02) but decreased for GAHBI (OR 0.63, 95% CI 0.42-0.96; *P*=.03) and social media (OR 0.66, 95% CI 0.45-0.97; *P*=.03). ORs were not reported when the number of participants with a health-promoting change for a particular model was less than 5.

Furthermore, the likelihood for the choice of a congruent challenge (see model F in Figure 1) was higher for users who chose the challenges smoking or vaping (OR 2.74, 95% CI 1.80-4.16; *P*<.001), alcohol (OR 2.17, 95% CI 1.45-3.26; *P*<.001), and gaming (OR 4.57, 95% CI 2.58-8.10; *P*<.001) and lower for users who chose the challenges social media (OR 0.57, 95% CI 0.34-0.77; *P*=.001) and "other challenge" (OR 0.10, 95% CI 0.06-0.17; *P*<.001).

Table 2. ORs[a] with a 95% CI for health-promoting change for students who chose a challenge corresponding to the health-promoting change area (see model A in Figure 1).

Health-promoting change	Participants, n	Events, n	OR (95% CI)	*P* value
Cigarettes	894	32	3.51 (2.14-5.76)	<.001
e-Cigarettes	894	26	2.87 (1.69-4.85)	<.001
Social media	894	185	1.66 (1.25-2.20)	<.001
Gaming	894	34	1.77 (1.09-2.89)	.02

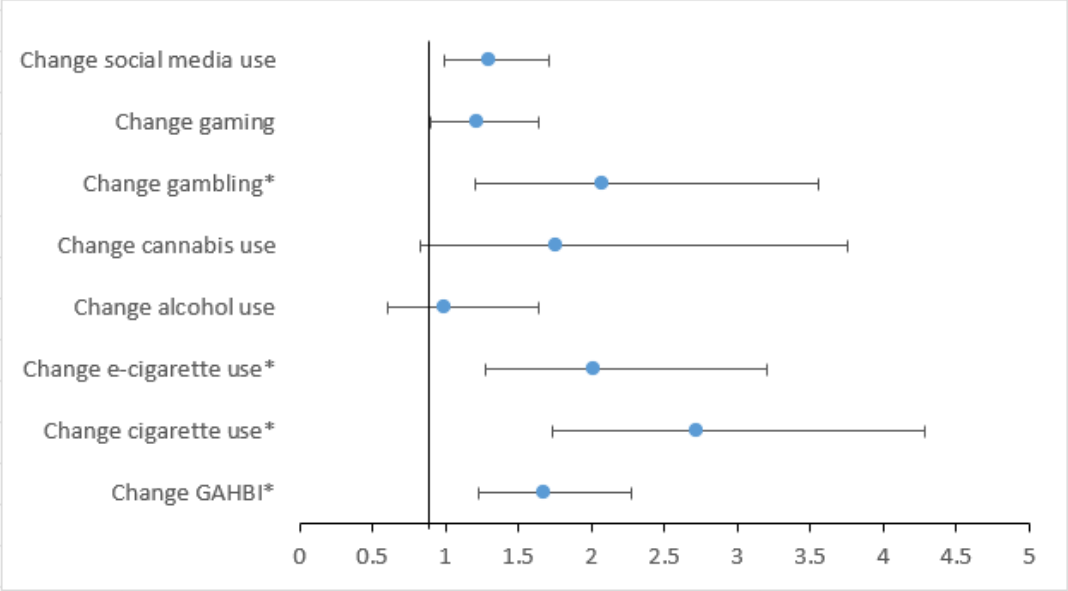
[b]Not available.

Association Between Congruent Use or Frequent Use and Health-Promoting Change Variables

Congruent use was associated with increased odds of health-promoting change (see model C in Figure 1) for cigarettes (OR 2.72, 95% CI 1.73-4.29; *P*<.001), e-cigarettes (OR 2.02, 95% CI 1.28-3.20; *P*=.003), gambling (OR 2.07, 95% CI 1.21-3.55; *P*=.008), and GAHBI (OR 1.67, 95% CI 1.23-2.27; *P*=.001). Thus, students with a personal relevance score for cigarettes who chose cigarettes as their challenge (congruent use) were 2.72 times more likely to report a health-promoting change in cigarettes than students with a personal relevance score for cigarettes who did not choose smoking but another challenge (incongruent use). The results are displayed in Figure 3. Frequent use showed lower odds for health-promoting change (see model B in Figure 1) for gambling (OR 0.47, 95% CI 0.26-0.86; *P*=.009; Multimedia Appendix 2).

Figure 3. Health-promoting change for students choosing a congruent challenge compared to students choosing an incongruent challenge (adjusted odds ratios with 95% CI). GAHBI: general adverse health behavior improvement. *P<.05.



Association Between the Personal Relevance Score and Health-Promoting Change

The odds for health-promoting change increased with each additional unit of the personal relevance score (see model D in Figure 1) except for alcohol (Table 3). Thus, there was an increase in the odds for health-promoting change between personal relevance scores of 0 and 1 and a further increase in odds between personal relevance scores of 1 and 2, meaning that those with a personal relevance score of 7 (personal relevance score for alcohol, cigarettes, e-cigarettes, cannabis, social media, gaming, and gambling) were most likely to show a health-promoting change. To sum it up, the more problematic consumption habits a student had, the more likely he or she was to have a health-promoting change, except for a health-promoting change for alcohol.

Table 3. ORs[a] with a 95% CI for health-promoting change increasing with each additional unit of the personal relevance score, except for alcohol.

Health-promoting change	Participants, n	Events, n	OR (95% CI)	*P* value
Cigarettes	894	99	1.63 (1.40-1.92)	<.001
e-Cigarettes	894	90	1.73 (1.47-2.04)	<.001
Social media	894	429	1.27 (1.14-1.41)	<.001
Gaming	894	248	1.25 (1.12-1.41)	<.001
Alcohol	894	71	0.97 (0.80-1.17)	.72
Cannabis	894	30	1.93 (1.49-2.50)	<.001
Gambling	894	63	2.43 (1.99-2.98)	<.001
GAHBI[b]	894	649	1.69 (1.46-1.95)	<.001

[a]OR: odds ratio.

[b]GAHBI: general adverse health behavior improvement.

Associations Between Congruent Use and Sociodemographic Variables

Congruent use was found to be a relevant predictor of health-promoting changes and was therefore analyzed for associations with participants' sociodemographic characteristics such as age, gender, income, migration, and highest level of education. With the exception of migrant background, none of the included socioeconomic variables were found to be associated with congruent use. The odds for congruent use were lower for students with a migrant background compared to students with no migrant background (OR 0.67, 95% CI 0.49-0.94; *P*=.02).

Discussion

Principal Findings

The aim of this study was to examine the reach of a low-threshold mobile prevention program and its effectiveness depending on participant characteristics and actual app use. To achieve this aim, metrics describing the use of the mobile intervention and a relevance score related to substance- and

addiction-related personal risk and their associations with health-promoting change were analyzed.

The exploratory study revealed three main findings: (1) approximately 6 out of 10 students (894/1458, 61.3%) used the app and were thus reached by the prevention intervention; (2) almost half (407/894, 45.5%) of the app users used the app in congruence with personal relevance, suggesting a relatively high awareness of their personal habitual behaviors; and (3) as health-promoting changes were influenced by congruent use, choice of challenge, and personal relevance score, it can be argued that these associations provide empirical support for differential effectiveness of the app.

The proactive invitation to participate in the program and in the study in vocational school classes, combined with the offer of a low-threshold mobile intervention, reached almost 2 out of 3 students (894/1458, 61.3%) in the matched IG sample who downloaded the MZo app and started a challenge. This participation rate appears to be substantial, given the fact that the MZo program was not integrated into regular school lessons, but students were encouraged to download the app to their personal smartphones. Moreover, the introduction of the program was rather brief, and about one-quarter of the students were introduced to the program on the web. Nevertheless, the participation rate matches other mobile phone intervention programs with similar target groups in Switzerland and Germany, focusing on reducing problematic drinking or supporting smoking cessation, which attracted between 50% and 70% of the students [14-17,29]. However, a recent review suggests that local and personal recruitment of users leads to higher adherence or program participation [30]. Due to limited access to schools during the COVID-19 pandemic, 24.1% (1106/4591) of the students were recruited on the web. A higher rate of students might have been reached if recruitment had entirely been done during face-to-face school visits. In terms of who used the app, the results showed that app users were on average younger and more likely to have no migrant background; to have a medium monthly income; and to have a vocational training in commerce, industry, and technology. Furthermore, there was an association between congruent use of the app and no migrant background.

Results indicate that frequent use had no influence on health-promoting change. It could be argued that for this low-threshold mobile app, active use was not a necessary requirement for health-promoting change, as users received reminders to continue the challenge twice a day, and no further content about the challenge or the goal achievement was provided by the app once the challenge was started. This distinguishes the app from other mobile prevention apps [22,31].

Results also indicate that the odds for health-promoting behavior change were higher when the area of individual challenge choice was equal to the area of behavior change, challenge choice was congruent with a behavior of personal relevance (eg, a regular smoker chose the smoking challenge), and the individual risk of engaging in addictive behaviors was high. Congruent use almost tripled the odds for a health-promoting change for cigarettes and doubled the odds for a health-promoting change for e-cigarettes and gambling. Moreover, congruent use was the only variable in the analysis that provided an increase in the odds for general adverse health behavior improvement. This effect was based on the health-promoting changes in cigarettes and e-cigarettes.

As students' challenge choices were self-selected, these results indicate that a certain awareness of problematic habitual behaviors in combination with a motivation to change these behaviors may lead to health-promoting changes. Recent studies confirm that awareness and intrinsic motivation are important factors for behavioral change [32,33]. However, in contrast to Brailovskaia et al [26,27], the effects of a specific behavior reduction or abstinence were limited to the corresponding health-promoting change area. Thus, a "spillover effect" from a challenge in one behavioral domain did not generalize to other outcomes in this study. The results also suggest that it is more difficult to achieve the goal of a health-promoting change when it is defined as complete abstinence from a substance (eg, alcohol and cannabis). One reason for this may be that the app was designed as a low-threshold intervention targeting habitual behaviors rather than an intervention providing therapeutic support to change behavior. In this study, 1 in 3 adolescents reported to drink alcohol regularly [4]. Therefore, total alcohol abstinence might be an unrealistic goal for this group. The same may be true for cannabis, especially for the 8.6% of the 18- to 25-year-old adults who reported to consume it regularly [4].

Furthermore, health-promoting change for social media and gaming, although defined as reduction goals, seems to be more difficult to achieve than the reduction of cigarettes or e-cigarettes. One reason for this may be that the data collection for this study took place during the COVID-19 pandemic. Limited real-life contact with peers due to COVID-19 restrictions led to an increased frequency and duration of digital media use [34]. Thus, it could be argued that reducing gaming and social media time may have been more challenging during the COVID-19 pandemic because there were fewer social contact alternatives.

The results also show that a challenge choice increased the odds for the respective health-promoting change areas for cigarettes, e-cigarettes, social media, and gaming, except for alcohol. This can be seen as an indicator that the app effectively supported users who were willing to change a particular behavior. These results also confirm that reducing consumption is easier to achieve than total abstinence (eg, alcohol). The effectiveness of the app is further demonstrated by the fact that the personal relevance score was associated with increased odds for health-promoting change for cigarettes, e-cigarettes, cannabis, gambling, gaming, and social media. It is likely that students with a higher degree of problematic health behavior as indicated by a high relevance score were more aware of their behavior and thus more motivated to change. On the other hand, it could also be expected that these users would be less likely to achieve a health-promoting change with such a minimalistic support program, as these users are likely to have greater problems with controlling addictive behaviors. It would be informative to know more about the motivational background of the users in more detail. However, this requires qualitative data, for example, in the context of mixed method studies, which appears useful when testing new complex interventions.

Limitations

This study has a number of limitations: (1) the attrition rate was high and biased (1473/2367, 62.2%), partly due to the anonymization procedure, which allowed linking of baseline, follow-up, and app data without collecting any personal information. (2) As all data were based on self-reported data, social desirability and a recall bias may have influenced the results of the study. (3) Data collection for the study took place during the COVID-19 pandemic in 2021-2022, with varying restrictions in schools concerning data collection and social contact. These restrictions also affected the lives, substance use, and other behaviors of the students and thus the results of the study and their generalizability. (4) The number of health-promoting change events for alcohol, cannabis, and gambling was low, so these results should be interpreted with caution. (5) The results concerning the personal relevance score should also be interpreted with caution. As the formal risk screeners for addictive behaviors did not show relevant results, the personal relevance score was pragmatically created with the aim of showing habitual behavior. (6) As a convenience sample was recruited from school classes and students participated voluntarily, the results cannot be generalized to vocational school students in Germany.

Comparisons With Prior Work

The main finding of this study, the influence of congruent use and challenge choice on the intervention outcomes, partially confirms previous findings of Brailovskaia et al [26,27]. On the one hand, health promotion can be achieved through behavioral abstinence or reduction, but on the other hand, in contrast to Brailovskaia et al [26,27], the results of this study indicate that the effects of a specific behavior reduction or abstinence are limited to that specific behavior. The odds of health-promoting change increased either when students chose a challenge corresponding to their personal relevance or when the challenge choice met the respective area of health-promoting change. However, it was not investigated whether there were other positive health effects, for example, on physical activity or on mental health. Future research should further deepen the knowledge of the effects of voluntary commitment on health-related outcomes. The finding that congruent use and individual choice can play an important role in the effectiveness of the MZo intervention supplements previous research discussing how the most appropriate metrics of use may differ between different types and aims of interventions and how the exploration of use can help to understand which metrics are most associated with effectiveness [19,22,31]. In addition, the results of the study point toward harm or risk reduction rather than abstinence-related prevention for adolescents. Furthermore, there was an influence of the personal relevance score on health-promoting change. Future research should therefore focus on an in-depth exploration of the most appropriate measures of use of different interventions, on how these mechanisms of use influence the effectiveness of different interventions, and on how these mechanisms are influenced by intervention design and personal characteristics. Looking at the role of habitual behavior in the effectiveness of the app could be another area for future research.

To improve future versions of the MZo program, the reach of the program could be extended by embedding it in regular school curricula. This may increase awareness of the MZo program but would also require higher teacher involvement. Given the current results, congruent use of the app should be more strongly encouraged to increase the effectiveness of the program. Moreover, individual suitability may be increased by providing additional individual options, such as reduction goals in the areas of gambling, alcohol, and cannabis.

Conclusions

The MZo program appears to be promising in supporting behavioral change across a spectrum of addictive behaviors. The prevention approach based on voluntary commitment can be introduced to vocational students with minimal effort and offers autonomous and mobile use with a low threshold for participating schools and students. It has the potential to reach and raise awareness among adolescents before habits become addictions.

Acknowledgments

The authors would like to thank Ludwig Kraus, Reiner Hanewinkel, Nele Fritsch, Simone Leuckfeld, Freia Biedenweg, Laura Borwieck, and Johanna Weymann for their contributions to the study. This work was supported by the Federal Ministry of Health Germany (ZMVI1-2519DSM216). Moreover, the authors thank the anonymous reviewer for their comments, which significantly improved the paper.

Authors' Contributions

KG and NA conceptualized the study’s aims and wrote the initial draft of the manuscript. KG, NA, and BP completed data preparation. KG completed the data analysis. AD supervised the analyses, advised on the choice of statistical methods, and supported the interpretation of the results. All authors contributed to interpretations of the results and to revisions and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Delivery of preventative interventions via mobile phone apps offers an effective and accessible way to address the global priority of improving the mental health of adolescents and young adults. A proven risk factor for anxiety and depression is elevated worry and rumination, also known as repetitive negative thinking (RNT).

Objective: This was a prevention mechanism trial that aimed to investigate whether an RNT-targeting self-help mobile phone app (MyMoodCoach) reduces worry and rumination in young adults residing in the United Kingdom. A secondary objective was to test whether the app reduces symptoms of anxiety and depression and improves well-being.

Methods: A web-based, single-blind, 2-arm parallel-group randomized controlled trial was conducted with 236 people aged between 16 and 24 years, who self-reported high levels of worry or rumination. Eligible participants were randomized to an active intervention group (usual practice, plus up to 6 weeks of using the RNT-targeting mobile app, n=119) or a waitlist control group (usual practice with no access to the app until after 6 weeks, n=117). The primary outcome was changes in worry and rumination 6 weeks after randomization. Secondary outcomes included changes in well-being and symptoms of anxiety and depression after 6 weeks and changes in all measures after 12 weeks.

Results: Participants randomly allocated to use the RNT-targeting self-help app showed significantly lower levels of rumination (mean difference –2.92, 95% CI –5.57 to –0.28; P=.03; η_p^2=0.02) and worry (mean difference –3.97, 95% CI –6.21 to –1.73; P<.001; η_p^2=0.06) at 6-week follow-up, relative to the waitlist control. Similar differences were observed for well-being (P<.001), anxiety (P=.03), and depression (P=.04). The waitlist control group also showed improvement when given access to the app after 6 weeks. Improvements observed in the intervention group after 6 weeks of using the app were maintained at the 12-week follow-up point.

Conclusions: The MyMoodCoach app had a significant positive effect on worry and rumination, well-being, anxiety, and depression in young adults, relative to waitlist controls, providing proof-of-principle that an unguided self-help app can effectively reduce RNT. This app, therefore, has potential for the prevention of anxiety and depression although longer-term effects on incidence need to be directly evaluated.

Introduction

There is growing concern about the early onset of mental health disorders in adolescents and young adults [1]. Poor mental health during adolescence can severely affect a young person's future life chances and can have a significant negative impact on health, education, and employment in later life [2,3]. Depression and anxiety are 2 of the most common mental health problems in adolescents and young adults, which significantly contribute toward global disability and produce a high economic burden [4]. In 2020, the prevalence of depression and anxiety disorders in adolescents globally was estimated at between 25% and 31% [5].

Although effective treatments for depression and anxiety have been developed and delivered in many countries, the evidence suggests that the overall prevalence of both disorders remains largely unchanged [6]. Because the prevalence of these common mental health disorders is so high, it is not possible for traditional delivery models of psychological intervention, such as a course of face-to-face sessions, to fully address the global need for treatment as it is unlikely there will ever be a sufficient number of trained mental health professionals [7]. Further, even if acute treatments were made widely available, as a consequence of the high levels of recurrence and relapse for depression and anxiety, it has been estimated that only a partial reduction of the overall prevalence could be achieved [6,8]. Effective prevention approaches are, therefore, considered essential in lowering overall prevalence rates as they have the potential to reduce both initial and recurrent episodes, thereby decreasing the demand for acute treatment [9]. Given the substantial increase in the incidence of depression and anxiety during mid-adolescence peaking in young adulthood [2], adolescents and young adults are considered an important group for which prevention of poor mental health is urgently needed [10-12].

While prevention interventions for anxiety and depression already exist for adolescents and young people, systematic reviews suggest that effect sizes are relatively small [13-15]. Further, most prevention interventions are delivered in person and require considerable input from trained professionals, such as teachers and therapists, which can increase costs and limit their availability [16]. While there is some evidence that supported interventions may have better adherence and efficacy than unguided interventions, their coverage and volume of delivery are constrained because each individual supporting the intervention has a finite capacity, such that these interventions cannot be made available to all who may benefit. As such, to ensure the large-scale coverage needed for effective mental health prevention approaches, there is potential value in supplementing supported interventions with ones that can be delivered to multiple users simultaneously and do not require additional input from practitioners (ie, nonconsumable self-help interventions [17]). The use of such nonconsumable self-help interventions would substantively increase the scalability and availability of preventative interventions making them more suitable for use as a public health approach at a population level.

The use of the internet and mobile phones has been increasingly explored as an avenue that may be able to increase the accessibility of prevention approaches and reduce the cost of intervention [18]. While internet and mobile-based interventions have many similarities, their method of delivery can vary. Mobile-based interventions, for example, are typically delivered through dedicated mobile apps and accessed on mobile phones, whereas internet-based interventions use web-based (or compatible) platforms designed to be accessed via laptops or personal computers. Internet-based interventions tend to deliver therapeutic content made up of pages working through a specific topic and more closely resemble a structured therapeutic session, for example, taking a set amount of time to complete and working through set content. Mobile apps, however, are based on more flexible use of "bite-sized" information and exercises, with less information on the screen, and allowing the user to "swipe" through available material to access the content they desire. The use of mobile phones is near ubiquitous in young people in the United Kingdom with an estimated 99% of those aged between 16 and 24 years using a smartphone on a regular basis in 2023 [19]. Further, mobile apps can help integrate behavioral changes into daily life—the app is always available to the user, making it well-suited for changing unhelpful habits. Mobile apps, therefore, provide a unique avenue in which to engage young adults in health-related activities, as well as promote good mental health and prevention strategies [20,21]. Despite a huge increase in the number of mobile-based mental health apps over the last 10 years [22], only a small number have been developed with scientific rigor. Further, many do not use established treatment principles nor have they been rigorously tested in robust well-powered randomized controlled trials (RCTs) [23]. While emerging evidence suggests that mobile-based apps can deliver efficacious treatment interventions for anxiety and depression [24,25], there have not been many trials examining their use for well-being promotion and prevention of poor mental health in young people specifically [26,27].

A psychological process thought to be key when promoting good well-being and preventing mental health problems is repetitive negative thinking (RNT) [28]. RNT is defined as a pattern of thinking that is repetitive, difficult to manage, and focused on negative content, which can significantly impact an individual's well-being and emotional functioning [28-30]. RNT encompasses various thought patterns, but the exemplars of RNT are worry and rumination which have been identified as robust risk factors for several mental health disorders [31]. Worry is described as a relatively uncontrollable chain of negative thinking about the future in the form of "What if" type

questions. Such thoughts can focus on typical everyday activities (such as work and relationships), as well as more catastrophic concerns (such as worrying that you may get hit by a falling tree) [32]. Rumination is a form of dysfunctional, negative thinking, which focuses on analyzing the causes and consequences of negative events. This can involve dwelling on past events and continually going over and over why things went wrong [32]. The degree of rumination experienced by an individual has been shown to predict the onset and duration of major depressive episodes [33,34], as well as the severity of depressive symptoms [35,36]. Rumination has also been shown to mediate the effects of other identified risk factors, such as neuroticism and stressful life events, on the onset of depressive episodes [37]. Worry has been identified as having strong associations with symptoms of depression and anxiety [38]. There is also evidence that increased levels of worry are predictive of greater symptom severity for both anxiety and depression [39] and that daily worrying predicts subsequent increases in anxiety [40]. There is extensive evidence that worry and rumination share a common process including evidence that they are highly correlated with each other and that this common factor accounts for their relationship with anxiety and depression, which underpins the conceptualization of the wider process of RNT [28,29]. There is robust evidence for RNT as a transdiagnostic risk factor, which is common across many psychological mood disorders including depression and anxiety [32,41]. The induction of RNT has been found to exacerbate symptoms of anxiety and depression such as negative thinking, delayed decision-making speed, poor problem-solving, and negative affect [42-45]. There is extensive evidence that RNT predicts future levels of depressive and anxiety-related symptoms, as well as the onset of depression [28,46]. As rumination and worry have been shown to be proximal risk factors that affect onset, maintenance, and relapse, RNT is considered an underlying mechanism for both anxiety and depression and is identified as an important target for preventative interventions [41,47].

There are several interventions that have been designed specifically to reduce RNT and improve general mental well-being, including those which have been trialed as digital interventions delivered via the internet. An RCT of a preventative intervention designed to target excessive levels of RNT found that both a group-based and internet version of a rumination-focused Cognitive Behavioral Therapy program significantly reduced RNT (d=0.53-0.89) and symptom levels of anxiety and depression (d=0.36-0.72) compared to a waitlist group [48]. Another trial involving 235 high-risk participants found that an internet-based version of the program reduced the risk of depression by 34% relative to controls and that participants showed a significant improvement in RNT and depressive symptoms in the short to medium term [49]. While there is promising evidence, therefore, that preventative interventions focused on reducing RNT are effective when delivered via the internet, there is limited research exploring the efficacy of RNT-targeting interventions delivered via a mobile phone app.

The Assessing and Enhancing Emotional Competence for Well-being in the Young project (ECoWeB) aimed to address the gap in large-scale trial evidence for preventative apps by developing and evaluating a self-guided mobile phone app (MyMoodCoach). The app for this large-scale trial was designed to promote emotional well-being and prevent mental health problems in adolescents and young adults through engaging and personalized tools that train psychological skills [50]. Specifically, this app was personalized by targeting the 2 most problematic components of emotional competence skills (from a set of 4: emotional regulation, emotional appraisal achievement context, emotional appraisal social context, and emotional perception and knowledge) for the user, which were identified in their baseline assessments [50]. One of these components was addressed via a module focused on targeting RNT for individuals identified as having elevated levels of RNT at baseline (reflecting poor emotional regulation and emotional competence skills). The trial described in the current paper is an off-shoot study of this larger project, specifically focused on testing the value of an app that targets RNT. In this study, we tested a standalone variant of the app used in the large-scale trial that included only the module focused on targeting RNT, aiming to shift users toward more adaptive emotional regulation skills.

Developing trials to evaluate preventative interventions can take considerable time and resources. However, while outcomes for prevention interventions typically focus on reducing the incidence (ie, new cases) of a specific mental health problem, prevention mechanism trials concentrate on the underlying etiological processes. This allows for a more detailed examination of proximal mechanisms. Prevention mechanism trials, therefore, offer an efficient way of establishing whether interventions can reduce risk factors associated with pathology, thereby evaluating their potential for prevention [51]. Since worry and rumination are established risk factors for anxiety and depression, this trial was a prevention mechanism trial to test whether the use of an app targeting RNT can reduce worry and rumination in young people, thus evaluating its potential as a prevention intervention. Our primary hypothesis was that people allocated to the RNT-targeting mobile app would show significantly lower levels of rumination and worry relative to those allocated to the waitlist control arm. A second hypothesis was that those allocated to the mobile app would also report significantly lower symptoms of anxiety and depression and higher well-being relative to waitlist control.

Methods

Study Design

A superiority 2-arm parallel-group RCT was conducted comparing an active intervention arm (usual practice plus up to 6 weeks of using the RNT-targeting mobile app) with a waitlist control arm (usual practice with access to the app only after a 6-week wait). As it was not possible to blind participants to their allocated groups, this was a single-blind RCT with only the researcher blind to participant group allocation. Further details can be found in the trial protocol [52]. This study was conducted according to the CONSORT (Consolidated Standards of Reporting Trials) guidelines [53,54] and extensions for nonpharmacological treatment interventions, as well as

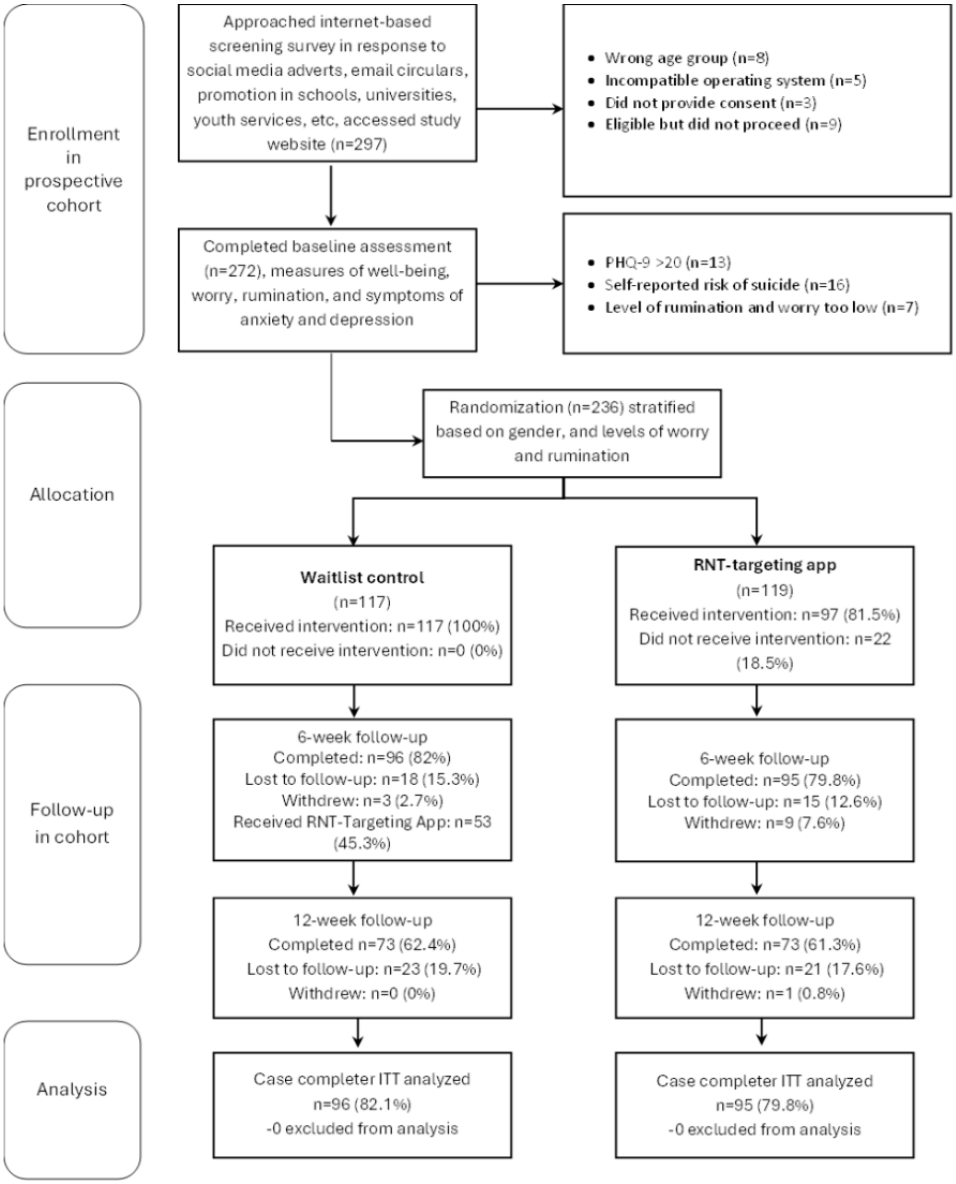
CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile HEalth Applications and on Line Tele Health) guidelines for improving and standardizing evaluation reports of web-based and mobile health interventions (Multimedia Appendix 1) [55].

Recruitment

We recruited young adults aged between 16 and 24 residing in the United Kingdom. The study was advertised on social media platforms, including Facebook (Meta Platforms) and Instagram (Meta Platforms), as well as an internal research recruitment system (Sona) used by the University of Exeter. Only participants who reported elevated levels of RNT at baseline were eligible for this trial. This was defined as scoring above the 50th percentile (ie, top half of scale) on either the Ruminative Response Scale (RRS; >34) or the Penn State Worry Questionnaire (PSWQ; >41). Participants also had to be aged between 16 and 24 years, currently residing in the United Kingdom, possess basic literacy in English and have access to a smartphone (either Android or iOS). Recruitment commenced on May 14, 2021, and ceased on October 11, 2021.

Participants were excluded at baseline if they reported elevated symptoms of depression indicating they required more specialist treatment, defined as having a score of 20 or higher on the Patient Health Questionnaire-9 (PHQ-9) [56] because this suggests a severe level of symptoms where a more intensive treatment from a mental health professional would be indicated. Participants who reported elevated symptoms of anxiety were included and automatically provided with additional information for accessing support if required. Other exclusion criteria included active suicidality or self-reported to be currently receiving treatment for a mental health problem (ie, psychological therapy, counseling, or psychiatric medication) at baseline. Those who self-reported having a current diagnosis of clinical depression, bipolar disorder, or psychosis were also excluded. A summary is given in the CONSORT flow diagram (Figure 1).

Figure 1. CONSORT flow diagram for the trial. CONSORT: Consolidated Standards of Reporting Trials; ITT: intention-to-treat; PHQ-9: Patient Health Questionnaire-9; RNT: repetitive negative thinking.



Screening and Consent Procedure

Potential participants were directed to a website providing further information about the study and were prompted to answer some prescreening questions, regarding their age and current experiences of mental health. Individuals who were not suitable at this stage (eg, outside of the specified age range) were automatically directed to a web page explaining why they were not suitable for the trial. Participants who passed this prescreening stage were then provided with an information sheet and asked to consent to provide contact details and complete a baseline assessment where suitability for the trial (ie, level of RNT and symptoms for anxiety and depression) was assessed more thoroughly. Following the baseline assessment, participants who met all eligibility criteria were then asked to consent to take part in the trial before being randomized into one of the 2 arms. Everyone accessing the trial website was provided with contact details for the research team.

Randomization

Randomization was conducted independently using a pregenerated computerized allocation algorithm. Randomization was in a 1:1 ratio and stratified across each arm according to the sex (male, female, and nonbinary) and level of RNT (50th-75th percentile vs 75th percentile or higher). Participants scoring in the highest quartile (at or above the 75th percentile) on either the RRS or PSWQ and in the top tercile on the other measure were identified as having high RNT, based on criteria used by Topper et al [48], which have previously been found to predict increased risk for subsequent depression [10].

Participant Flow

Overall, 297 people completed the prescreening process of whom 272 went on to complete baseline questionnaires and have their suitability for the trial assessed more thoroughly. In total, 236 participants met the eligibility criteria and were randomized to either receive access to the digital RNT-targeting self-help app straight away (n=119) or after a period of 6 weeks (n=117). The rate of follow-up attrition was 19.07% (n=45; intervention arm, n=24; and waitlist control, n=21) at 6 weeks and 38.14% (n=90; intervention arm, n=46; and waitlist control, n=44) at 12 weeks. These calculations included 11 (4.6%) participants who contacted the research team requesting to withdraw from the study, 1 of who did so after completing their 6-week follow-up. There were no missing data from any of the participants who completed their surveys. Further details are given in the CONSORT flow diagram (Figure 1).

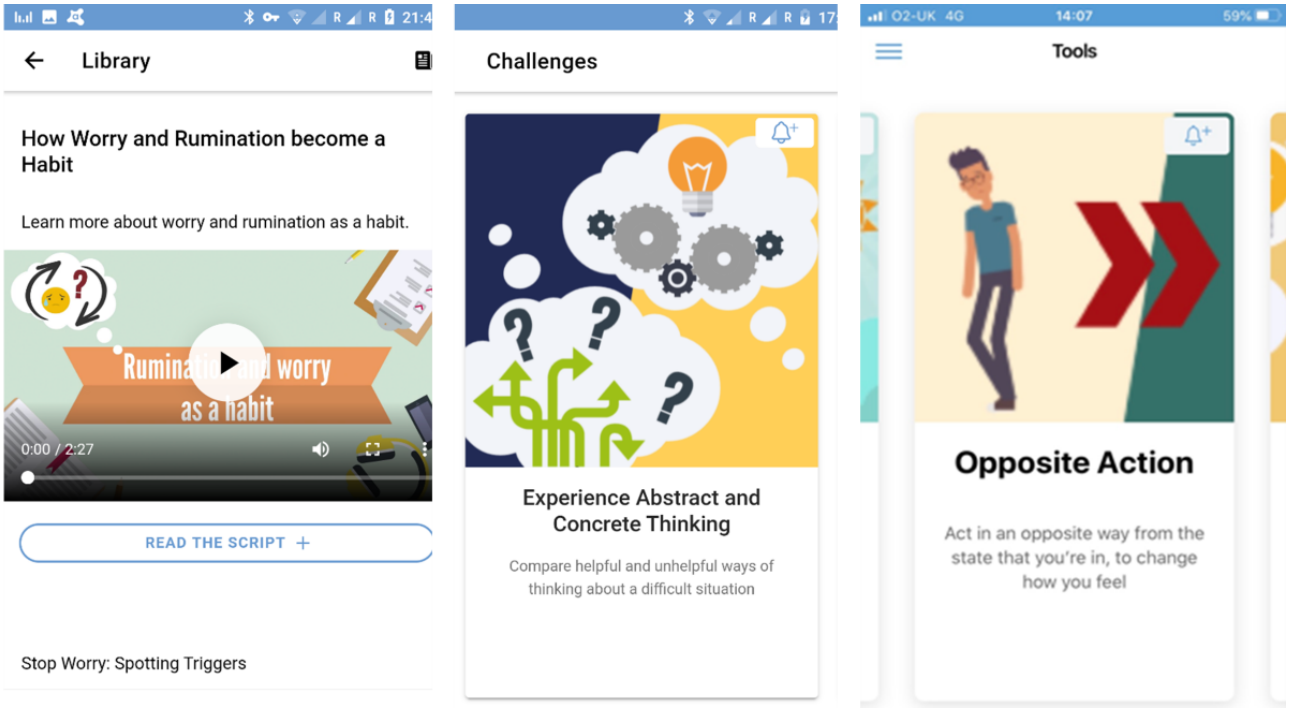
Interventions

Digital RNT-Targeting Self-Help App (Intervention Arm)

The self-help app used in this trial (called MyMoodCoach) was a focused version of the app evaluated in the main ECoWeB trial [50]. This standalone version was not personalized to each user and was specifically focused on reducing RNT to help improve emotion regulation, that is, it only included the emotional regulation rumination-focused module. The app included self-monitoring, psychoeducation, and active self-help exercises based on RNT-specific strategies from an evidence-based, rumination-focused cognitive behavioral therapy program intervention [48,49,57-59], adapting these evidence-based interventions from an internet-delivery context to an app format. Core elements of the intervention were designed to break the ruminative habit and enable users to shift toward a more helpful processing style. This involved coaching participants to spot warning signs for rumination and worry, and then plan alternative strategies. These included being more active, slowing things down, breaking tasks down, opposite action, relaxation, concrete thinking, becoming absorbed, self-compassion, and assertiveness. Participants were prompted to practice alternative strategies in response to their warning signs. The user interface includes text, pictures, audio recordings, animations, audio exercises, and questionnaires with tailored automated feedback. There was also a self-monitoring component which prompted users 5 times a day to rate their mood and level of rumination. The app featured a menu structure including a dashboard to monitor notifications and progress, a library function that had psychoeducation and explanatory animated videos, and an explore function to graph the self-monitoring responses made by the participant. The app also included challenges that provide learning exercises (eg, behavioral exercises) and tools that are brief strategies that young people can use at the moment when they need them (for example, compassion and relaxation exercises). The app was entirely automated (ie, self-guided) and designed for use on both iOS and Android phones. The app was accessed for free via each participant's smartphone app store.

Changes from the proven internet versions of the intervention [9,11] included information condensed so that "bite-sized" content reflecting 1 point of information was presented per swipe of the mobile phone screen and could be consumed in brief moments of time (rather than by scrolling down web pages each with multiple points of information); greater flexibility of use such that users could select any element of the app in any order from the menu (eg, use of tools or challenges) unlike the internet-delivered interventions, which tended to be more modular and arranged in a fixed structure and order, as a "lesson" or "session" that might take an hour to work through in its entirety. Some screenshots for the app are provided in Figure 2 and further details can be accessed via Multimedia Appendix 2.

Figure 2. Screenshots from the MyMoodCoach app from left to right: screen from the library of visual resources, screen within the challenges menu to enter the abstract and concrete thinking challenge, screen within the tools menu to enter the opposite action tool.



Waitlist Control Group

The waitlist control group received access to the RNT-targeting digital self-help app after a 6-week wait.

Baseline and Follow-Up Assessments

All outcome measures were completed by participants independently via a website at baseline, with follow-up assessments at 6-weeks and 12-weeks post randomization. Demographic information including, age, gender, employment status, and ethnicity, was collected only at baseline. Additional feedback about experiences of using the mobile app was only collected at the 12-week follow-up point. Automated emails were sent to participants at each follow-up point with a link to complete their survey. Further reminders were sent manually via email and text message if there was no response to the automated reminders.

As an incentive, all participants who completed their follow-up surveys were entered into a prize draw. Participants recruited via the University of Exeter Sona system could choose whether to be entered into the prize draw or receive course credits. Out of those eligible to participate in the trial, 82 (32.7%) chose to receive course credit. The researcher who was blind to treatment allocation was the only team member involved in sending out reminders to complete follow-up surveys. Other members of the team were available to follow up on issues of risk and answer technical queries from participants. Throughout the trial process, there were no deviations from the planned procedure with no incidents of unblinding being reported.

Outcomes

The primary outcome for this trial was changes in the levels of rumination and worry at the primary end point (6 weeks after randomization). Rumination was measured using the RRS [36]. The measure consists of 22 items that assess the tendency for an individual to respond to depressed moods with a focus on either the self, depressive symptoms, or negative consequences. Items are scored from 1 (almost never) to 4 (almost always) and total scores can range from 22 to 88 with higher scores indicating a higher level of rumination. The RRS has good internal consistency in an adolescent population (α=.88) [60] and test-retest reliability ranges from moderate to high (r=0.47 for over 1 year and r=0.80 for over 5 months) [33,61].

Worry was measured using the PSWQ [62], a 16-item self-assessment that assesses the intensity, tendency, and uncontrollability of worrying thoughts using a 5-point Likert scale for each item. Items are scored from 1 (not at all typical of me) to 5 (very typical of me) and total scores can range from 16 to 80 with higher scores indicating greater levels of worry. The measure has high internal consistency in both clinical and nonclinical samples (α=.88-.95), as well as good test-retest reliability (r=0.72-0.93 for 2 weeks and 1 month, respectively) [62].

Secondary outcomes for this study included changes in mental well-being and symptoms of anxiety and depression at the primary end point, as well as changes in all measures between 6-week and 12-week follow-up. Mental well-being was measured using the Warwick-Edinburgh Mental Well-being Scale (WEMWBS) [63]. The WEMWBS has demonstrated high internal consistency in both student and general populations (α=.89-.91), with good test-retest reliability (intraclass correlation coefficient=0.83; P<.01) [63]. The Generalized Anxiety Disorder questionnaire (GAD-7) [64] was used to assess symptoms of anxiety. Symptoms of depression were assessed using the PHQ-9 [65]. Both measures have demonstrated good internal consistency (α=.86-.92), as well as good test-retest reliability (0.83-0.84) [66].

To assess user's perspective on the app, participants were asked to rate the app on its ease of use, look and feel, features, and content on a 5-point Likert scale of 1 (terrible) to 5 (brilliant), as well as provide qualitative feedback about the positives and negatives of using the app. These questions were devised by the lead researcher and adapted from components of the technology acceptance model (TAM) and user experience (UX) design approaches [67,68].

Statistical Analysis

Power

An estimated minimum clinically important difference (MCID) for the primary outcome of the RRS was used to calculate the sample size for this study. One recommended approach for identifying the MCID is half of the SD for the respective index [69]. A conservative estimate of the normative SD for the RRS was identified based on previous research (mean 47.19, SD 7.58 to mean 48.89, SD 8.51) [48]. A reduction of 4 points on the RRS, therefore, was identified as an appropriate MCID. Using an α of .05 with 90% power, for an MCID of 4 required 85 participants per group (170 in total). Allowing for a 20% follow-up attrition rate, we aimed to recruit a minimum of 204 participants (102 per arm).

Analysis Plan

Data were analyzed using SPSS (version 28; IBM Corp) and the statistical analytical plan was finalized prior to data being unblinded. The primary analysis was based on intention-to-treat and all participants, regardless of their level of engagement, were included [70]. Missing data were handled via multiple imputations (MI) using a linear regression model with a monotone imputation method. As multiple imputations had equivalent results to case-completer analyses, only the case-completer intention-to-treat analysis results have been reported. Analysis of covariance (ANCOVA) at 6 weeks was used for both primary and secondary outcomes, with baseline scores as the covariate. ANCOVA was also used for both primary and secondary outcomes at 12 weeks with 6-week follow-up scores as the covariate.

Feedback about user experience was collated and analyzed using NVivo software (Lumivero) which identified common words and phrases occurring within the data to generate preliminary codes. The same software was then used to automatically group the identified codes into suggested themes. These preliminary themes were then checked and refined by the primary researcher before being finalized.

Ethical Considerations

Ethical approval for this study was obtained from the Ethics Committee of the School of Psychology, University of Exeter (eCLESPsy001977v5.1). All participants provided written informed consent. Data were collected in a pseudonymized manner and stored securely.

Results

Overview

Baseline demographics across both arms for the study are shown in Table 1. All participants were aged between 16 and 24 years and were predominantly White female students.

Table 1. Baseline demographics for each condition.

Baseline characteristics	RNT[a]-targeting app (n=119)	Waitlist control (n=117)
Age, mean (SD)	18.44 (2.01)	18.56 (2.4)
Sex, n (%)		
Male	15 (12.6)	16 (13.7)
Female	109 (84)	98 (83.8)
Non-binary or third gender	4 (3.4)	3 (2.6)
Ethnicity, n (%)		
White	95 (79.8)	96 (82.1)
Black, African, Caribbean, or Black British	2 (1.7)	1 (0.9)
Asian or Asian British	14 (11.8)	15 (12.8)
Mixed or other ethnic group	8 (6.7)	5 (4.3)
Employment, n (%)		
Employed (full-time)	5 (4.2)	9 (7.7)
Employed (part-time)	11 (9.2)	14 (12.0)

Student	95 (79.8)	90 (76.9)
History of mental health problems, n (%)		
Yes	18 (15.1)	19 (16.2)

[a]RNT: repetitive negative thinking.

Outcome at Primary End Point (6 Weeks)

Means and SDs for each measure and arm at each time point are shown in Table 2. One-way condition (intervention vs control) ANCOVAs found a significant main effect of intervention condition on rumination (Figures 3 and 4; $F_{1,188}$=4.72; P=.03; η_p^2=0.02), worry ($F_{1,188}$=12.24; P<.001; η_p^2=0.06), depression ($F_{1,188}$=4.14; P=.04; η_p^2=0.02), and anxiety ($F_{1,188}$=5.43; P=.02; η_p^2=0.03). These significant effects reflect that after adjusting for the covariate of baseline scores, participants randomized to use the RNT-targeting app in the intervention arm reported significantly lower rumination, worry, depression, and anxiety at 6-week follow-up than those randomized to the waitlist control (mean difference [rumination]: –2.92, 95% CI –5.57 to –0.28; mean difference [worry]: –3.97, 95% CI –6.21 to –1.73; mean difference [depression]: –1.34, 95% CI –2.63 to –0.04; mean difference [anxiety]: –1.46, 95% CI –2.7 to –0.23). Participants randomized to the intervention arm reported significantly higher well-being at 6 weeks than the waitlist control group ($F_{1,188}$=12.38; P<.001; η_p^2=0.06; adjusted mean difference 3.78, 95% CI 1.66-5.9).

Table 2. Means and SDs for all measures at each follow-up point.

Outcome at Follow-Up (12 Weeks)

At 12 weeks, participants who were initially allocated to use the RNT-targeting app maintained the changes that were made on all measures during the first 6 weeks, with no significant changes observed between the 2 follow-up points (see Table 3). After being introduced to the app at 6 weeks, participants in the waitlist control showed significant reductions in rumination, worry, anxiety, and depression and an increase in well-being (see Table 3). One-way ANCOVAs found no statistically significant differences between the 2 groups for any of the measures at the 12-week follow-up point ($F_{1, 143}$≤1.17; P≥.28).

Table 3. Within-participants contrast between the 6- and 12-week follow-up point.

	RNT[a]-targeting app			Waitlist control		
	F test (*df*)	*P* value	Effect size (η_p^2)	*F* test (*df*)	*P* value	Effect size (η_p^2)
RRS[b]	2.63 (1, 144)	.11	0.02	22.09 (1, 144)	<.001	0.13
PSWQ[c]	1.47 (1, 144)	.23	0.01	12.2 (1, 144)	<.001	0.09
WEMWBS[d]	0.93 (1, 144)	.34	0.01	20 (1, 144)	<.001	0.12

[d]WEMWBS: Warwick-Edinburgh Mental Well-being Scale.

[e]GAD-7: Generalized Anxiety Disorder-7.

[f]PHQ-9: Patient Health Questionnaire-9.

Adherence

Overall, 97 out of 119 (81.5%) participants in the intervention arm and 53 out of 96 (55.2%) in the waitlist control signed into the app. To estimate app usage, we calculated the mean number of days participants completed a daily mood rating (including those who never signed into the app). For those randomly allocated to use the RNT-targeting app, this was 8 (SD 10.92; range 0-40) days during the first 6-week period, and for the waitlist control, this was 3 (SD 6.31; range 0-31) days once given access to the app.

UX Findings

When identifying positive attributes about the app, participants consistently highlighted the mood tracker and tool features as being beneficial. Participants also identified that the app

provided them with useful skills to help improve their emotional management such as identifying unhelpful patterns, reflection, and analyzing their emotions more critically. Several participants noted that the app helped them feel relaxed and that it was most useful when they were experiencing heightened levels of distress or going through "a dark time." When identifying areas to improve, several features appeared to affect participants' motivation to regularly engage with it. A total of 9 comments highlighted that the app sent too many notifications which became very annoying; 11 comments alluded to the app being difficult to navigate and quite tiring to engage with on a regular basis; 8 comments noted experiencing frequent bugs and crashes; and 26 comments noted some design issues such as the range of emotions in the app being too limited, the questions used to evaluate daily events being repetitive, and the user interface being "too clinical" and not aesthetically pleasing. Overall, the average satisfaction rating from all participants who provided ratings regarding their experience (n=137) was 3.74 out of 5 (SD 0.73; ease of use: mean 3.99, SD 0.9; look and feel: mean 3.45, SD 1.08; features and functionality: mean 3.72, SD 0.87; content: mean 3.8, SD 0.94).

Discussion

Principal Findings

This was a prevention-mechanism trial that aimed to test whether an RNT-targeting self-help mobile phone app (MyMoodCoach) was effective at reducing worry and rumination in young adults. A further objective was to pilot the efficacy of the app in reducing symptoms of anxiety and depression and improving well-being.

As hypothesized, participants randomized to the MyMoodCoach app showed a significant decrease in both worry and rumination, relative to participants in the waitlist control condition. As hypothesized, participants randomized to the app also showed significant increases in well-being and reduction in anxiety and depression relative to the waitlist control group. All these changes were sustained at the 12-week follow-up point suggesting that any benefit of using the app is likely to persist over several months. Moreover, once they were given access to the app, participants in the waitlist control showed similar changes in RNT, anxiety, depression, and well-being, paralleling the benefits observed in the initial active intervention arm.

Patterns of change across the trial indicate that symptoms of depression during the first 6 weeks stayed constant in the intervention arm while worsening in the waitlist control group. This suggests that engaging in an intervention designed to target RNT may have a preventive effect on depressive symptoms consistent with the wider literature on rumination and worry as vulnerability factors for depression [39,71,72]. Further, this is consistent with previous RCTs that found that targeting RNT can have a medium-term preventive effect reducing the onset of depression [48,49]. The reduction of both anxiety and depression from a self-help app that explicitly targeted worry and rumination is also consistent with theoretical models proposing that RNT is a transdiagnostic risk factor that can affect symptoms associated with both disorders [41]. This research thus provides proof-of-principle of the value of targeting RNT as a mechanism to prevent anxiety and depression, consistent with the prevention mechanism trial approach. However, because we did not explicitly assess new onsets of major depression or anxiety disorders, and the follow-up was only short-term, longer-term follow-ups with an assessment of incidence are needed to rigorously test the potential of the self-help app targeting RNT as a prevention intervention. Despite app usage only being modest, it still had an effect. Further, the percentage of those not using the app (14%) was below the mean percentage of "non-users" reported in a recent meta-analytic review of adherence in mobile interventions (41.2%) [73].

In addition to its potential as a prevention intervention, the observed benefits of the app suggest there may be several clinical applications that could help reduce the burden on mental health services. As the intervention is focused on worry and rumination, the app could be offered to people who do not meet the severity threshold to access treatment for anxiety or depression, but still show high levels of RNT. It could also be offered as an interim approach for people on a waitlist for treatment as using the app may either reduce their associated symptoms or prevent their symptoms from getting worse. Moreover, as the app targets associated risk factors rather than a specific mental health problem, it may also help reduce the impact of stigma, which can prevent people from seeking support when distressed, and potentially increase engagement [74].

The study had several limitations. First, as all screening questionnaires were based on self-report, completed remotely, and no diagnostic interview was conducted, we cannot be sure that participants did not have a disorder at baseline. This also meant that we could not directly ascertain the effect of the app on the incidence of episodes of anxiety disorders and major depression. Second, participants were mainly White, female students, which may limit the generalizability of the findings, although we note a much greater proportion of females to males in the sample was expected given our inclusion criteria because elevated RNT tends to be much more common in females than males and has been found to partially account for the increased rates (nearly double) of depression and anxiety reported in females relative to males [75,76]. As such, this gender imbalance is not necessarily problematic for the purposes of developing an RNT-targeting preventative intervention for anxiety and depression but rather it accurately reflects the distribution of RNT in the target population. Future studies, however, will need to encourage more participation from other gender identities to confirm whether the app is effective for those who do not identify as female. Third, while the follow-up period in this study was appropriate for a prevention mechanism trial, a longer-term follow-up is needed to test the effect of the RNT-targeting app on preventing the incidence of episodes of major depression and generalized anxiety.

Conclusions

Despite some limitations, the MyMoodCoach app has the potential to offer a valuable contribution toward large-scale effective prevention for young people [77]. These results provide proof of principle that the intervention can effectively target

worry and rumination as possible prevention mechanisms for anxiety and depression in young people. As RNT is a well-established vulnerability factor, it is likely that this intervention will have a positive impact on the incidence of anxiety and depression in the medium-term.

Acknowledgments

Funding for this paper was provided by the Horizon 2020 Assessing and Enhancing Emotional Competence for Well-being in the Young (ECoWeB) project (grant 754657), which included this single-intervention study within the study protocol, which was peer-reviewed by the funding body. The study sponsor and funder have no influence on the conduct, delivery, or reporting of the research.

Authors' Contributions

EW and DE designed the trial. EW and AN coordinated the trial and randomization process. DE and EW prepared the statistical analysis plan and statistical analysis was conducted by DE. EW, TE, MF, and TR contributed toward the design and preparation of content for the repetitive negative thinking (RNT)–targeting app and helped coordinate the development of the app intervention. DE and EW contributed to the writing of the draft paper. AN, MF, TE, and TR reviewed and approved the final version.

Conflicts of Interest

MF is a cofounder and shareholder of Monsenso, whose solution delivered the app. EW is the developer of Rumination-focused cognitive-behavioural therapy, which is the intervention used in the app and receives payment for training workshops and royalties from the treatment manual published by Guilford Press. The other authors declare no conflicts of interests.

Abstract

Background: Physical exercise and exposure to air pollution have counteracting effects on individuals' health outcomes. Knowledge on individuals' real-time exercise behavior response to different pollution information sources remains inadequate.

Objective: This study aims to examine the extent to which individuals avoid polluted air during exercise activities in response to different air pollution information sources.

Methods: We used data on individuals' exercise behaviors captured by wearable and mobile devices in 83 Chinese cities over a 2-year time span. In our data set, 35.99% (5896/16,379) of individuals were female and 64% (10,483/16,379) were male, and their ages predominantly ranged from 18 to 50 years. We further augmented the exercise behavior data with air pollution information that included city-hourly level measures of the Air Quality Index and particulate matter 2.5 concentration (in μg/m^3), and weather data that include city-hourly level measures of air temperature (ºC), dew point (ºC), wind speed (m/s), and wind direction (degrees). We used a linear panel fixed effect model to estimate individuals' exercise-aversion behaviors (ie, running exercise distance at individual-hour, city-hour, or city-day levels) and conducted robustness checks using the endogenous treatment effect model and regression discontinuity method. We examined if alternative air pollution information sources could moderate (ie, substitute or complement) the role of mainstream air pollution indicators.

Results: Our results show that individuals exhibit a reduction of running exercise behaviors by about 0.50 km (or 7.5%; P<.001) during instances of moderate to severe air pollution, and there is no evidence of reduced distances in instances of light air pollution. Furthermore, individuals' exercise-aversion behaviors in response to mainstream air pollution information are heightened by different alternative information sources, such as social connections and social media user-generated content about air pollution.

Conclusions: Our results highlight the complementary role of different alternative information sources of air pollution in inducing individuals' aversion behaviors and the importance of using different information channels to increase public awareness beyond official air pollution alerts.

Introduction

Background

Air pollution remains an extremely serious environmental and health hazard [1]. Although exercising can improve one's health, doing so in polluted air can offset the health benefits and be detrimental to one's cardiovascular and respiratory health [2]. Providing air quality alert information has become an important initiative adopted by government authorities to protect the public from the risk of air pollution [3], with the anticipation that individuals will adjust their behaviors considering this information. Despite the availability of public health information, there is limited evidence to suggest whether individuals truly act upon this information and the extent to which they may adjust their outdoor exercise behaviors. Furthermore, with government agencies providing more detailed information, concerns have arisen over the danger of air pollution alerts losing their prominence, which can diminish the efficacy of information provision as a policy tool [4]. Thus, it is of immense interest to uncover individuals' actual reaction and to what extent individuals adjust their exercise behaviors in response to air pollution information.

Air quality alert information helps individuals to maximize the utility of their outdoor activities while accounting for the health risk from air pollution. Prior studies on the relationship between air pollution information and avoidance behavior primarily focus on the impact of mainstream or official air quality information sources [3,4]. Mainstream or official information on air pollution typically include particulate matter (PM) 2.5 concentration and Air Quality Index (AQI) which indicate the severity and potential health hazards of air pollution. In most countries, public agencies monitor and disseminate such information about a city's pollution parameters through AQI announcements on television, radio, newspaper, and website channels.

Beyond the mainstream sources, there are alternative information sources through which individuals can access air pollution information. Particularly, with the rise of social media, people can access alternative information on air pollution shared by the public on social media platforms and mobile chat apps [5]. Research has shown that social media messages are strongly correlated with AQI and are indicative of true particle pollution levels [6]. Despite the increasing impact of user-generated content on social media [7] and the availability of other information sources (eg, web–based social connections and mobile apps), there is a lack of knowledge in the literature on whether these alternative information sources may moderate (ie, substitute or complement) the effect of mainstream pollution information sources on individuals' exercise aversion behaviors.

Furthermore, current understanding of the impact of air pollution on individuals' exercise behavior is limited, and existing research evidence is mainly built on self-reported survey data [8]. These data can suffer from recall errors and social desirability bias [9], and is limited to provide detailed spatial and temporal attributes of exercise behaviors. However, air pollution levels can vary across different specific locations and fluctuate across time. Thus, it becomes critical to provide scientific evidence using real-time, disaggregate spatial and temporal data to understand the extent to which individuals avert exposure to polluted air in their physical activities in real time (ie, on an hourly basis), in response to different sources of air pollution information. According to recent reports on personal wellness and fitness, there is a rise in consumers' adoption of digital health services and technology-driven fitness programs. More consumers are also using wearable activity trackers, such as smart wristbands and fitness apps, which offer instant feedback on various exercise metrics [10]. Data from these wearable fitness devices and applications enable researchers to address the limitations previously mentioned.

Objective

We aimed to evaluate the extent to which individuals avoid polluted air during exercise activities, in response to different air pollution information sources. We also examined whether alternative air pollution information sources moderate the effect of mainstream information sources on individuals' exercise behaviors.

Methods

Data

In China, air pollution continues to persist at a concerning level and affects the economy and people's overall quality of life [11]. Research has shown that air pollution in northern regions of China led to a 5.5 year reduction in life expectancies of residents, compared with those in southern regions [12]. The alarming rate of air pollution makes China a valid and representative context to investigate the research questions.

We conducted empirical analyses using a novel data set of over 16,000 individuals' running exercise behaviors in 83 Chinese cities over a 2-year time span from January 2013 to November 2014, as captured by wearable devices and mobile fitness apps. This sample period is particularly appropriate because there was a confluence of multiple episodes of severe air pollution in China and the mass adoption of wearable and mobile devices from 2013 to 2014. The data on individuals' exercise activities were obtained from a China-based, web and mobile fitness platform that offers products (eg, smart wristband and mobile fitness apps) for tracking exercise activities which incorporate social network features. Users connect to the platform through a wearable device, web browser or mobile app, which enables them to track exercise activities, share their progress with peers, and leverage social networking features to foster support and encouragement among users. All data generated during physical exercise activities are synchronized to the platform's data servers and is viewable by users through the mobile app and website. This individual-level minute-by-minute exercise behavior data was further supplemented with hourly weather controls data and various air pollution information sources such as AQI and PM2.5 measures, social connections, Weibo tweets (a Chinese Twitter-like platform), and mobile apps.

Our exercise behavior data set includes information on individuals' user anonymous ID, sex, total cumulative distance (km) of exercise activity, reward points balance, exercise skill grade level, home and exercise city location, exercise distance

(km), exercise speed (km/h), exercise type (eg, running or walking), exercise tracking date and time (for both start and end of exercise session), tracking device type (eg, smart wristband or mobile fitness app), and calories expended. We removed, from our raw data set, exercise records or observations that had various issues such as duplicated records, missing exercise and home city locations, and outliers in terms of exercise distances (ie, top and bottom 0.5 percentiles, corresponding to likely errors in distances recorded that were >100 km or <0.01 km, for example). We focused only on running and excluded walking, as our data set cannot differentiate whether a physical activity was conducted indoor or outdoor, and walking can occur indoors from point to point. In contrast, running is a recreational physical activity that is mostly conducted outdoors in China [13], and thus is susceptible to the effects of air pollution. Our final data set consisted of 447,666 observations for 16,379 individuals with running exercise records across 83 cities in China over a roughly 2-year time span. In our final data set, 35.99% (5896/16,379) of users were female and 64% (10,483/16,379) were male. We do not have access to the users' age data; however, statistics from the focal fitness platform we analyzed suggest that their users' age ranged predominantly from 18 to 50 years [14]. Furthermore, in terms of the users' exercise behavior, the average exercise distance was around 6.61 km for the users in all the 83 cities, with an average exercise speed of around 8.74 km/h. At the weekly level, the average weekly exercise frequency was around 3.5 times, with an average distance of 7.13 km exercised each week.

We augmented the exercise behavior data with 2013 to 2014 air pollution information that includes city-hourly level measures of AQI and PM2.5 concentration (in $\mu g/m^3$) from both the Chinese Ministry of Environmental Protection (CN-MEP; provided data for 83 cities) and the US Department of State (US-DOS; it provided data for 5 cities with embassies located in Beijing, Chengdu, Guangzhou, Shanghai, and Shenyang). Finally, for control purposes in the empirical analysis, we acquired the 2013 to 2014 National Oceanic and Atmospheric Administration Integrated Surface Database's weather data for 83 cities that include city-hourly level measures of air temperature (ºC), dew point (ºC), wind speed (m/s), and wind direction (degrees). Table 1 shows the descriptive statistics for our data set at the individual user–level for both types of air quality indicator (ie, Air Quality Index-China [AQI-CN] and particulate matter 2.5-United States [PM2.5-US]) across the 5 cities of Beijing, Chengdu, Guangzhou, Shanghai and Shenyang, as well as across all 83 cities in our data set.

Table 1. Descriptive statistics (mean (SD)): individual-level data.

Variables	AQI-CN[a] (5 cities)	AQI-CN (83 cities)	PM2.5-US[b] (5 cities)
Exercise distance (km)	6.648 (4.423)	6.611 (4.413)	6.659 (4.438)
Air quality (PM2.5 or AQI)	89.983 (56.321)	88.339 (54.842)	63.515 (54.438)
50<air quality≤100	0.468 (0.499)	0.486 (0.500)	0.316 (0.465)
100<air quality≤150	0.177 (0.382)	0.182 (0.386)	0.105 (0.307)
150<air quality≤200	0.071 (0.257)	0.062 (0.242)	0.038 (0.190)
200<air quality≤300	0.046 (0.210)	0.037 (0.189)	0.021 (0.142)

[a]AQI-CN: Air Quality Index-China.

[b]PM2.5-US: particulate matter 2.5-United States.

[c]No recorded instance of air quality in this range.

Air Pollution Information Sources

In China, mainstream air quality and pollution information source is the official pollutant standards index such as the AQI (ie, CN-MEP) communicated by government agencies. Beyond the mainstream information source, there are multiple alternative sources or channels from which individuals can acquire air pollution information. First, social media Weibo tweets can serve as an alternative form of information on air pollution [6]. There is a strong correlation between the Air Discussion Index constructed based on Weibo tweets and the actual measured PM in the air [6,15]. Second, for the 5 cities of Beijing, Chengdu, Guangzhou, Shanghai, and Shenyang, AQI and PM2.5 information provided by US-DOS can serve as an alternative information source corresponding to the mainstream one provided by CN-MEP. Third, we consider the case of mobile apps as an alternative information channel for air quality information [16]. Specifically, we focus on the China AQI mobile app (renamed as Air Matters in 2016), which was the pioneer for this category of apps and released their version 4.0 with over 160 cities coverage on May 10, 2013 [17]. This version added monitoring stations data from >800 monitoring stations in over 160 cities, constituting a substantial 33% increase in city level coverage of air quality information for mobile phone users. Fourth, there can be anchoring effects where individuals possess alternative or self-referent local information such as the prevailing levels of air pollution in a city [18], which may not be known to new visitors exercising in a location that is not their home city. Finally, individuals can access air pollution information from their connected peers on the focal fitness platform. Prior studies suggest that there can be social contagion in exercise behaviors [19] and transmission of information through these social connections [7].

Statistical Analysis

Descriptive Analysis

Figures 1 and 2 show a spatial plot of the means and SDs of exercise distances by 5 different bins or ranges of AQI-CN (ie, AQI data from CN-MEP) measures in January 2013 across China's provincial-level administrative units. It is clear from Figure 1 that the mean running exercise distance is lower in the more heavily polluted provinces such as Hebei, Beijing, Tianjin, and Shandong (ie, the cluster of eastern provinces shaded in red), compared with the less polluted provinces along its southern coastline such as Guangdong, Fujian, Zhejiang, Shanghai, and Jiangsu. In terms of the SDs of exercise distance, Figure 2 shows that the variability of running exercise distance is higher in the less polluted provinces shaded in blue, light blue, and light green. Therefore, there is tentative descriptive evidence of individuals' exercise-aversion behaviors in response to air pollution in various Chinese provinces.

Figure 1. Mean of exercise distance. AQI: Air Quality Index.

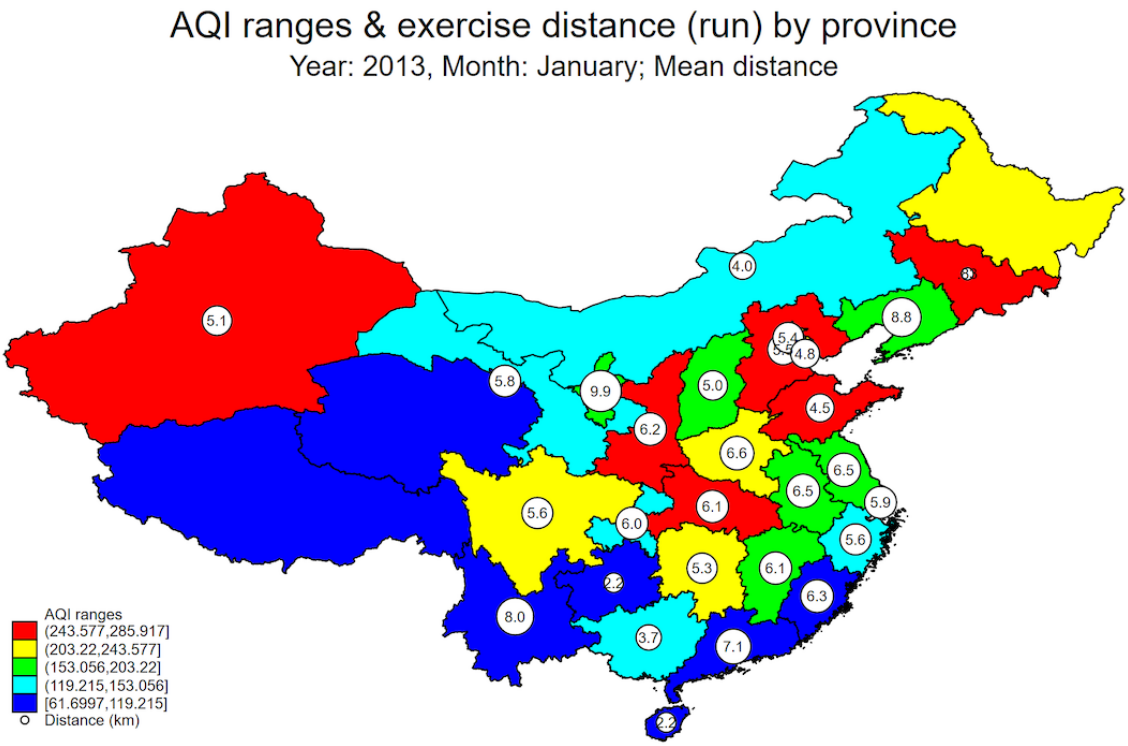

Figure 2. SD of exercise distance. AQI: Air Quality Index.

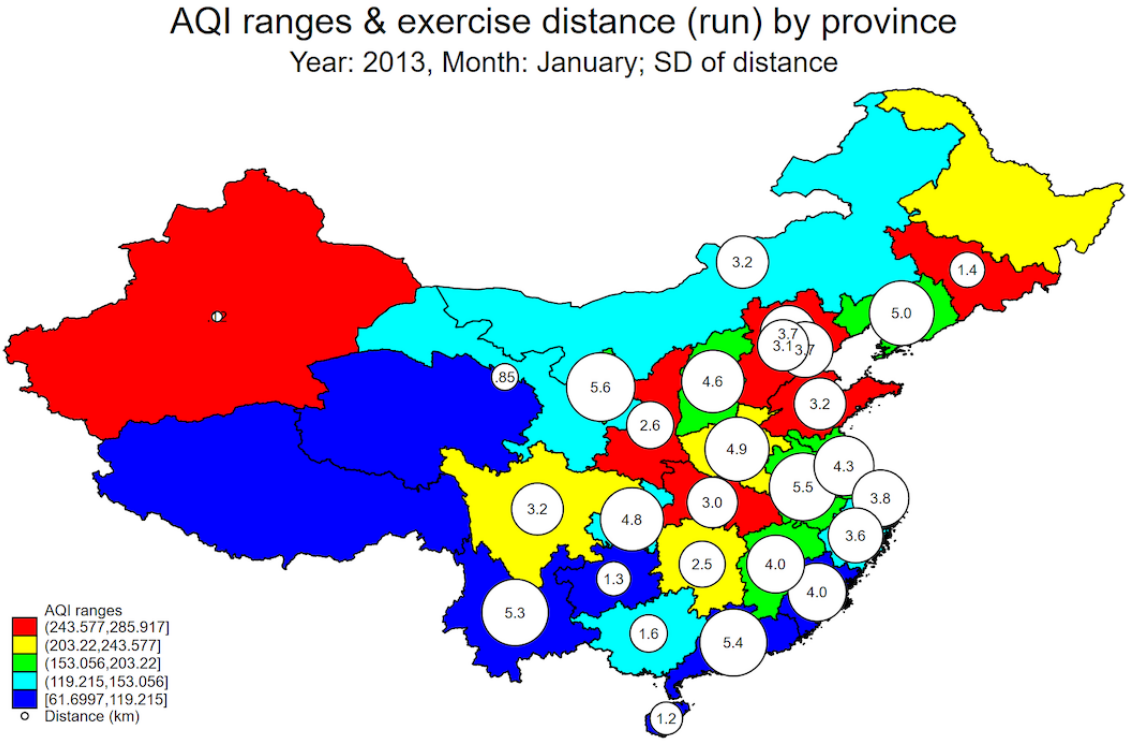

Linear Fixed Effect Model

We first specified a linear panel model specification for our focal variable of interest, that is, running exercise distance at different units of analysis (ie, individual-hour, city-hour, or city-day levels). Subscript *i* in equation (1) below refers to either an individual or a city (in a specific province shown in Figure 1), and *t* refers to the time unit of either hour or day.

$ExerDist_{it}$ captures the running exercise distance for an individual or a city at either the hourly or aggregated daily level. $AirQual_{it}$ is a vector of air quality indicators measuring the extent of air pollution at either the hourly or daily level, specific to the city where an individual conducts the running physical activities or exercises. We allowed for nonlinear effects of air pollution in our model specification by discretizing pollution levels through the use of dummy variables, which is a commonly used approach in the literature [20]. Specifically, we included dummy variables that correspond to the different pollution thresholds based on the CN-MEP standard of AQI (AQI 0-50: excellent, 51-100: good, 101-150: lightly polluted, 151-200: moderately polluted, 201-300: heavily polluted, and >300: severely polluted). In addition, in our model, we accounted for an individual's exercise speed ($ExerSpeed_{it}$), city-hour or day level temperature ($Temp_{it}$), dew point ($DewPt_{it}$), and wind speed ($WindSpeed_{it}$). Other controls include various dummy variables corresponding to the specific year, month, day of week, time of day, and city information during the incidence of an individual's running exercise activity. Furthermore, we performed various placebo tests to verify that it is indeed the air pollution levels in each specific city and specific date and hour that are driving the specific aversion responses of individuals' exercise behaviors (Table S1 in Multimedia Appendix 1).

Endogenous Treatment Effect Model

Daily and hourly variations (ie, the time unit of analysis for this study) of air pollutants can plausibly be considered as exogenous [21]. As air pollution is not randomly assigned to individuals, studies that attempt to compare aversion behaviors or health outcomes for populations exposed to varying pollution levels may not be adequately accounting for potential confounding factors. It is known that air quality is capitalized into real estate prices [22]. Thus, households with higher incomes or preferences for cleaner air are likely to sort into locations with better air quality. Failure to account for this sorting will lead to overestimates of the effects of pollution. Alternatively, pollution levels are typically higher in urban areas where there are often more educated individuals with better access to health care, leading to underestimates of the true effects of pollution.

To control for the potential endogeneity of mainstream air pollution indicators of PM2.5 and AQI measures, we used the endogenous treatment effect model [23] to model running exercise distance while accounting for the potential endogeneity (due to selection or sorting) of moderate to severe air pollution (ie, as indicated by the binary treatment dummy for AQI/PM2.5>150, ie, *AirPolluted*). The endogenous treatment effect model estimates an average treatment effect and the other parameters of a linear regression model for exercise distance, augmented with an endogenous binary-treatment variable for moderate to severe air pollution. The model specification is as follows:

where ε_{it} and u_{it} are bivariate normal with mean zero and covariance matrix Σ.

In our focal equation (2) of interest, $ExerDist_{it}$ captures the running exercise distance for an individual or a city at either the hourly or aggregated daily level. $AirPolluted_{it}$ is an individual or city-specific hourly or daily binary indicator for AQI-CN>150, that is, when air quality crosses into the moderate to severe air pollution range (ie, the same pollution threshold in literature [24], which have a substantial effect on individuals' decision to purchase health insurance). We also account for an individual's exercise speed ($ExerSpeed_{it}$) and weather conditions such as temperature ($Temp_{it}$), dew point ($DewPt_{it}$), and wind speed ($WindSpeed_{it}$). Appropriate control variables here include users' point balance and exercise skill grade on the focal fitness platform, and fixed effect dummies corresponding to the specific calendar year, month, day of week, and time of day information. In the treatment equation (3), the $AirPolluted_{it}$ indicator is a probit function of city-hour or day level wind speed ($WindSpeed_{it}$), wind direction ($WindDir_{it}$), air pressure ($AirPressure_{it}$), humidity ($Humidity_{it}$), and other controls such as calendar month and day of week fixed effects. Equations (2) and (3) above are estimated by maximum likelihood estimation.

Regression Discontinuity

To further bolster the confidence of our estimate for the causal effect of air pollution on exercise aversion behaviors, we used the regression discontinuity method [25,26] as a robustness check to estimate the effect of air pollution severity crossing specific AQI categorical thresholds on individuals' average running exercise distances at the city-hour level. We used the standard or continuity-based framework for regression discontinuity analysis, and specifically a sharp regression discontinuity design.

The regression discontinuity design can be used to isolate a treatment effect of interest from all other systematic differences between treated and control groups. Under appropriate assumptions [25,26], a comparison of individuals and cities for which the AQI indicators are barely below the moderate or severe pollution threshold and those for which the AQI indicators are barely above the same threshold will reveal the causal (local) effect of air pollution on exercise behaviors. If individuals and cities cannot systematically manipulate the air pollution indicators, observations just above and just below the cutoff will tend to be comparable in terms of all characteristics. Thus, right at the cutoff, the comparison is free of the complications introduced by systematic observed and unobserved differences between the treatment and control groups. Our regression discontinuity estimators are based on mean-squared error-optimal bandwidths. Further details of the regression discontinuity procedures and the related robustness checks are provided in Table S2 in Multimedia Appendix 2.

Moderation Effects Analysis: Alternative Information Sources

According to the Protection Motivation Theory, individuals' motivation to engage in protective behaviors is influenced by 2 cognitive appraisal processes, that is, threat appraisal and coping appraisal [27]. In the context of our study, the Protection Motivation Theory is helpful to understand how individuals assess the risk of air pollution to their health and their perceived ability to cope with these risks through personal actions, such as adjusting their outdoor exercise activities. The availability of alternative information sources or channels, such as social media platforms, play an important role in shaping these appraisals [28]. The alternative information sources can provide additional narratives or evidence about air pollution, which can affect the cognitive process of threat and coping appraisals. Specifically, the alternative information sources may amplify or attenuate individuals' perception of the threat (ie, the severity of the air pollution) and their belief in their capacity to take protective actions, such as modifying exercise routines. The interplay between alternative information sources and the cognitive appraisal processes emphasized by the Protection Motivation Theory underscores the necessity and significance of understanding the moderation effect of alternative information sources on the impact of mainstream air pollution information on individuals' exercise aversion behaviors. We further conduct empirical analyses using an individual-level linear fixed effect model in equation (1) to evaluate if alternative sources of air pollution information have interaction effects with mainstream air pollution information, such that they either mitigate or accentuate (ie, substitute or complement) the impact of mainstream air pollution indicators on individuals' exercise aversion behaviors.

First, we estimated if individuals' exercise averting response to the mainstream AQI-CN pollution measures will be accentuated with increasing volumes of social media Weibo tweets of Chinese language phrases associated with air pollution. Social media can serve as an alternative form of salient confirmatory or reinforcement information on air pollution. Social media Weibo tweets can amplify official messages and contribute to a sense of urgency or provide practical coping strategies for individuals [6], which may heighten perceived severity and vulnerability and likely lead to a stronger motivation to engage in protective behaviors.

Second, we evaluated whether individuals located in the 5 cities of Beijing, Chengdu, Guangzhou, Shanghai, and Shenyang with the alternative PM2.5-US information respond more dramatically in exercise aversion behaviors, compared with those in the other 78 cities with no such alternative pollution information. Information source and credibility significantly influence how individuals interpret and act on information about air pollution [29], with the US-DOS being regarded as a reliable source, potentially strengthening individuals' evaluation of the risk, and thus, promoting protective behaviors. We further estimated the effects using a neighboring matched-city approach (ie, matching Beijing to neighboring Tianjin, Chengdu to Chongqing, Guangzhou to Shenzhen, Shanghai to Hangzhou, and Shenyang to Dalian where there are no alternative PM2.5-US information).

Third, we evaluated if individuals' exercise aversion responses to the mainstream AQI-CN pollution indicator are affected by the increased 160 cities coverage of air quality information in the China AQI mobile app. The AQI mobile app can provide real-time data on pollution levels and health-related alerts about the specific risks of current air quality levels, which can heighten individuals' perception of the immediate risk and motivation to take protective action.

Fourth, we estimated whether individuals exercising in a location or city which is their home city alter their exercise behaviors to a larger extent during episodes of air pollution. Locals with anchoring knowledge for a specific home city have a coping advantage as they can refer to their experience to make informed decisions [30]. However, new visitors to a city may not possess local or home knowledge about the typical air pollution levels in a city and are likely to underestimate or overestimate the threat, affecting their coping appraisal and potential protective behaviors. This anchoring effect can therefore affect their perceived severity and coping appraisal.

Finally, we examined if individuals' exercise aversion behaviors are moderated by the numbers and types of social connections on the focal fitness platform. Information from connected peers often carries important weight because it comes from a trusted and relatable source [31], so the air pollution information shared by connected peers may increase individuals' awareness and perceived severity. We considered different types of social connections, that is, followers (incoming connections for the focal individual), followees (outgoing connections initiated by the focal individual), and mutual followers (individuals who are both the followers and followees for the focal individual).

Ethical Considerations

All the data in this study were collected in a manner that ensures the anonymity and privacy of individuals in our sample. Each user in our sample has a unique anonymous user ID, which is randomly generated by the focal fitness platform and has no connection to the participant's actual identity. This study was reviewed and approved by the Departmental Ethics Review Committee of School of Computing at the National University of Singapore. The DERC Case No. is SOC-22-03.

Results

Table 2 presents the model estimation results using the AQI-CN air quality indicators. Using a fixed effect model estimation approach at the individual-hour, city-hour, and city-day levels (ie, columns 1 to 3), we find significant evidence of individuals' pollution aversion behavior in terms of decreasing their running exercise distances when air pollution worsened. Such aversion behaviors in terms of decreasing their running exercise distances were more sensitive or in larger magnitudes during incidences of moderate to severe air pollution. At the individual and city-hourly level, when the air was moderately polluted (ie, 150<AQI-CN≤200), running exercise distances decreased by about 0.24 km (P<.001) to 0.32 km (P<.001) relative to when air quality was excellent (ie, 0<AQI-CN≤50). When the air was severely polluted (ie, 300<AQI-CN≤500), running distances dropped by about 0.72 km (P=.03) at the city-hour level and 0.73 km (P=.002) at the city-day level. The results from the endogenous treatment effect models show general consistency with those from the linear fixed effect models (Table 2). At the individual and city-hourly level, running distances decreased by 0.48 km (P<.001) to 0.87 km (P=.07) in episodes of moderate to severe air pollution. Furthermore, the results of regression discontinuity estimations confirm that there was a decrease in running exercise distance of 0.29 km (P=.07, without covariates) at the AQI-CN cutoff value of 150 for moderately polluted air conditions (Table S3 in Multimedia Appendix 2). Generally, these results on the extent of exercise aversion in terms of decreased running distances also corroborate those from the linear fixed effect and endogenous treatment effect models.

For the moderation effects of alternative information sources, first, we find that as the volumes of tweets (in millions) about the Chinese-language words for "haze" and "face mask" (which reflect health concerns and self-protection measures [12,32]) increase, there was a larger extent of decrease in running exercise distances during episodes of moderate to heavy air pollution. In particular, a 1 SD increase in the volume of tweets about "haze" and "face mask" (ie, 0.21 and 0.026 million tweets respectively) was associated with a drop of about 0.09 km (P=.02) to 0.12 km (P<.001) in running distances during heavily polluted episodes (ie, 200<AQI-CN≤300; Table 3).

Second, we find that relative to those in the other 78 cities, individuals exercising in the 5 cities of Beijing, Chengdu, Guangzhou, Shanghai, and Shenyang with alternative PM2.5-US information did tend to decrease running distances to a larger extent by about 0.25 km (P<.001) during light to moderate air pollution episodes (Table 3). Similarly, using a neighboring matched-city approach (ie, matching Beijing to neighboring Tianjin, Chengdu to Chongqing, Guangzhou to Shenzhen, Shanghai to Hangzhou, and Shenyang to Dalian where there are no alternative PM2.5-US information), the results further confirm that individuals in the 5 cities with alternative PM2.5-US information reduced running distances by 0.19 km (P=.002) to 0.22 km (P<.001) even in instances of low to light air pollution (Table 3).

Third, considering the case of mobile apps as an alternative channel for air quality information, we find that individuals exercising after the increased 160 cities coverage of air quality information in the China AQI mobile app, did significantly decrease their running exercise distances by about 0.30 km (P=.02) and 0.60 km (P=.004) during heavy and severe air pollution episodes respectively (Table 3).

[m]Controls: temperature, dew point, wind speed; year, month, day of week, time of day, city dummies; individual's exercise speed, reward points, and exercise skill grade.

Fourth, in all 83 cities, individuals exercising in a city which is their home tend to be more responsive in decreasing the extent of running distances during polluted air. Such a moderation effect increased in magnitude across light to heavy and severe pollution episodes, with the drop in running distances ranging from 0.14 km (*P*=.003) to 0.40 km (*P*=.01) for individuals exercising in their home locations (Table 4). Similarly, individuals exercising in the 5 cities of Beijing, Chengdu, Guangzhou, Shanghai, and Shenyang exhibited this similar home-location moderation effect of 0.16 km (*P*=.01) to 0.60 km (*P*=.07) across light to heavy and severe pollution (Table 4).

Finally, we observe a negative moderation effect of social connections on the physical exercise aversion response to mainstream pollution information sources. Specifically, the numbers of followers, followees, and mutual connections for a focal individual accentuate the decrease in exercise behaviors during polluted air, even in good or lightly polluted conditions (Table 4). We note that the extent of this negative moderation effect of 1 additional social connection on individuals' exercise behaviors during lightly polluted conditions (ie, a roughly 0.15 km drop; *P*=.001) is almost double that during good air conditions (ie, 0.08 km decrease; *P*=.02).

Discussion

Principal Findings

We examine the extent to which individuals avoid exposure to polluted air during exercise activities, in response to different sources of air pollution information, and whether alternative information sources moderate the effect of mainstream air pollution information sources on such exercise behaviors. Our findings show that (1) individuals exhibited a decrease in running exercise behaviors by about 0.50 km in instances of moderate to severe air pollution and (2) the alternative sources of air pollution information, such as social media user–generated content about air pollution and social connections, complement the role of mainstream air pollution information in inducing individuals' exercise-aversion behaviors.

Contrary to popular belief that people know how to cope with air pollution, such as reducing their outdoor physical exercising, our results show that individuals only reduce their running distances by about 0.50 km (or 7.5% on average across individuals in our sample) in instances of moderate to severe air pollution, and there is no causal evidence of reduced distances in instances of light air pollution. This averting response is less pronounced compared with that in previous studies based on different outcome metrics (eg, 8%-15% drop in outdoor facility attendances [21]; 14%-35% reduction in amount of cycling [33]). Individuals do seem to weigh the tradeoff of outdoor physical activities in the face of air pollution, but they did not exhibit a large extent of avoidance behaviors as expected. Drawing on the Protection Motivation Theory and related literature, there could be several potential explanations. First, individuals may not perceive air pollution as a severe health threat, or they have optimism bias about susceptibility to harm, which individuals consider themselves as less at risk than their peers regardless of their age and sex [34], and thus tend to view themselves as different from the susceptible group when assessing the risk of air pollution. If the perceived threat of air pollution is low, their motivation to change behavior such as reducing outdoor exercise will be low as well. Second, prior findings revealed that people who are healthy without asthma or cardiovascular disease are less likely to modify their behavior in the face of air pollution [35,36]. The participants in our sample, who are generally younger and in relatively good physical fitness [14,37], tend to underestimate the harmful impacts of air pollution during exercising, especially in the instances of light air pollution. Third, even if individuals recognize the risk of air pollution, they might feel incapable of changing their exercise routines due to personal constraints, such as lack of access to indoor exercise facilities or a strong preference for outdoor activities. Individuals might perform a cost-benefit analysis, either consciously or subconsciously, weighing the benefits of exercising outdoors against the potential health hazards of air pollution [38]. Individuals who perceive the benefits of outdoor exercise, such as enjoyment, social interactions, outweigh the potential negative impacts of exercising in polluted air, are less inclined to adjust their exercise behaviors.

Prior studies mainly focus on the air pollution information provided by official mainstream channels [3,4]. Our findings highlight the importance of alternative air pollution information sources beyond official channels in affecting individuals' perception of air pollution risk and helping them make informed decisions on reducing air pollution exposure during physical activities. Furthermore, our findings reveal the differential moderation impacts of alternative information sources on individuals' exercise behavioral responses during different air pollution conditions. In good to lightly polluted air conditions, the availability of alternative PM2.5-US information generally had the largest negative moderation impact. The PM2.5-US information offers an alternative perspective on air quality, potentially differing in methodology or perceived accuracy compared with local official sources based on AQI-CN. The existence of this alternative source allows individuals to cross-reference and assess the risks associated with air pollution more critically, which may amplify individuals' perceived severity of and vulnerability to air pollution episodes. The enhanced perception can potentially increase their motivation to engage in protective behaviors. In moderately to heavily polluted conditions, social media Weibo tweets of "face mask" and "haze" had the most significant and largest negative-moderation impact on the effect of mainstream pollution information on exercise aversion. Social media posts can amplify the perceived severity of and personal vulnerability to air pollution because information and personal experiences shared within one's social network can contribute to a heightened sense of risk. The visibility of collective attitudes and actions on social media strengthens the risk perception through social contagion [19], encouraging individuals to take protective behaviors. In the most severely polluted conditions, the availability of mobile app access to location-specific real-time air quality information had the most considerable negative moderation effect on exercise aversion behaviors. Given that many individuals use mobile phones to track their exercise activities, they are more likely to seek out air quality information using mobile apps before or during the exercises. Individuals use air quality mobile apps that provide real-time, localized air quality data, which can render the official air pollution information more personally relevant and actionable [39]. Such real-time and personalized data may lead to individuals to perceive the air pollution risk as more urgent and serious, prompting a stronger avoidance behavior in terms of reducing outdoor exercise.

Although prior literature has documented that exercise behaviors can be socially contagious [19], prior findings did not differentiate between the information transmission mechanism between different types of social connections. Our findings show that the efficacy of social connections as alternative sources of pollution information in affecting exercise aversion behaviors can rely on the type of social connection (ie, followers, followees, and mutual followers). Individuals tend to rely more on information about polluted air conditions from their followers and mutual followers and adjust the exercise aversion responses based on observational learning of peer behaviors [40]. Mutual followers, representing a stronger social bond, often share information perceived as more personalized or relevant. When individuals follow each other, the reciprocal

ties imply a higher level of engagement and trust, which makes information shared by mutual followers seem more relevant and credible [31]. Individuals tend to view their followers as peers who are similar to themselves or part of their in-group. This perception can increase the trust in the information shared by these followers, as it may be more personalized, relevant to the user's local context or specific interests, or validated by social proof from peers [41].

Limitations and Future Work

While our study represents an initial endeavor to examine the extent to which individuals adjust their exposure to polluted air during physical exercise, and respond in real time to diverse information sources, we contend that this study has several limitations. First, the data set was collected from individuals using wearable devices or mobile fitness apps linked to a web and mobile fitness platform. We acknowledge that these individuals in our research sample are likely to have come from a selected sample who may be more predisposed to physical exercise activities compared with the general population. In this sense, the degree of air pollution aversion identified in our study is likely to be a conservative estimate. This is because enthusiasts of sports or fitness might not alter their physical activity routines, even during periods of air pollution. To mitigate this issue, researchers in future work could aim for a more representative sample of the general population or leverage field experiments. Second, regarding the phenomenon of web and mobile fitness platform and their gamification features, we acknowledge that individuals' decisions in our data sample to engage in exercise activities could have been driven somewhat by the gamification elements on the platform. Nevertheless, in our empirical analysis at the individual user level, we control for these effects in our empirical models by including the user's reward points and exercise skill grade as certified by the platform. Investigating the role of gamification elements on the platform in driving and sustaining behaviors aimed at health and fitness enhancement presents an intriguing research opportunity [42]. Third, future research could beneficially identify the threshold where the health benefits of physical activity in polluted conditions become outweighed by its adverse effects, taking into account various pollution levels and population demographics (eg, healthy individuals vs those with specific susceptibilities).

Conclusions

In conclusion, this study is one of the firsts to uncover to what extent individuals weigh the exercise benefit-harm tradeoff to adapt their exercise activities in response to different air pollution information sources. The main strengths of this study include using comprehensive, disaggregate spatiotemporal data of both mainstream air pollution information sources and individuals' detailed exercise behavioral records from wearable and mobile devices, examining individuals' exercise-aversion behaviors in near real time on an hourly basis, and identifying and evaluating the impact of multiple alternative air pollution information sources. Furthermore, this study reveals the important role of different alternative sources of pollution information in inducing individuals' exercise aversion responses.

Our findings offer insights for public health management and personal health decision-making from several aspects. First, policy makers may need to reassess the messaging and strategies used to communicate the risks associated with outdoor activities during episodes of high air pollution. Health authorities can use more personalized communication strategies, such as targeted messages for at-risk populations such as children, older adults, or those with respiratory conditions. To increase public awareness, reliance on traditional media and official air pollution alerts are not sufficient, public health authorities should leverage multitiered communication strategies that account for various demographics, including varying access to technology, as well as diversified information channels to keep the public engaged and informed about the dangers of high air pollution levels, especially in relation to outdoor activities. For instance, public health authorities may establish partnerships with tech companies and app developers to ensure the dissemination of air quality data is prompt, precise, and user-friendly. This can help create more tailored and engaging content that effectively promotes protective behaviors. Furthermore, the public awareness campaigns can be designed to capitalize on the virality and user engagement aspects of social media and mobile fitness platforms, utilizing these platforms to generate interactive and shareable content that facilitates the message dissemination. The dynamic nature of social media and mobile apps allow for real-time updates, which can keep the public informed during rapidly changing air quality situations, enhancing the public's awareness and engagement in protective behaviors.

Second, our findings underscore the importance of disseminating location- and time-referent air quality information (eg, green space vs industrial area and 1-hour vs 24-hour AQI measurements) to better enable the public in evaluating the benefits and risks of health maintenance behaviors during air pollution episodes. Air quality can vary significantly within short distances and fluctuate throughout the day due to various factors such as traffic patterns, weather conditions, and industrial activities. By disseminating air quality information that is both location and time-referent, public health authorities can provide the public with a more comprehensive understanding of air pollution risks, which enables individuals to make better decisions about when and where to engage in outdoor activities. Specifically, by using mobile apps and related notifications, public health authorities can use location and time-specific air quality data and push real-time air quality updates to populations in high-risk areas. For instance, during a pollution spike in an industrial zone, authorities can advise residents on precautionary measures. Social media and mobile fitness platforms can serve as channels for sharing broader air quality trends and advisories. Such information can also be directly disseminated to individuals, citizens, and employees participating in increasingly popular wellness programs initiated and run by government agencies and commercial organizations (eg, insurance companies), and enabled by dedicated mobile apps or wearable devices for such programs.

Third, for the design of wearable devices and mobile apps, manufacturers of wearable devices and activity trackers can combine air pollution and health advisories with device features that monitor ambient air quality and users' bio-physical

indicators such as blood pressure that has been shown to be related to the extent of airborne pollutants. Mobile fitness app developers can also provide comprehensive real-time updates of mainstream and alternative information of air quality conditions through AQI measures, social connections, social media content, and geo-location advisories. For instance, with GPS information from mobile devices, app developers can issue time- and location-specific advisories based on real-time geo-locations of individuals and social connections engaged in physical activities or exercises, such as encouraging exercises in green spaces or parks, rather than alongside major roads with heavy vehicular traffic. With such real-time air quality data of different locations delivered through mobile apps or wearable devices, individuals can better assess the risks and make informed decisions about when and where to exercise outdoors. Future research should explore the long-term impact of repeated exposure to air pollution information and its impact on behavior over time, and explore whether individuals habituate to the alerts or if there are cumulative effects.

Abstract

Background: Chronic noncommunicable diseases (NCDs) account for major disability and premature mortality worldwide, with low- and middle-income countries being disproportionately burdened. Given the negative impact of NCDs on employee performance and work productivity, there is a rising need for stakeholders to identify effective workplace solutions that can improve employee health outcomes. As the workplace becomes more dispersed post pandemic, digital behavioral coaching offers a scalable, personalized, and cost-effective method of managing chronic disease risk factors among employees.

Objective: This study aimed to retrospectively evaluate the impact of a digital behavioral coaching program on year-to-year changes in employee health status in a cohort of Indonesian employees.

Methods: This retrospective real-world exploratory analysis of secondary health data followed 774 employees of an Indonesian company who completed company-sponsored health screenings between 2021 and 2022 and were given access to Naluri (Naluri Hidup Sdn Bhd), a holistic digital therapeutics platform offering digital behavioral health coaching and self-help tools. Participants were retrospectively classified as those who received active coaching (n=177), passive coaching (n=108), and no coaching (n=489). Linear mixed-effects models were used to evaluate the year-to-year changes in health outcomes across the 3 employee groups, with post hoc analyses evaluating within-group differences between the 2 time points and between-group differences at follow-up.

Results: Significant time×group interaction effects were detected for body weight, BMI, hemoglobin A_{1c}, low-density lipoprotein, total cholesterol, and systolic and diastolic blood pressure. Post hoc pairwise comparisons revealed significant improvements in hemoglobin A_{1c} (mean difference [M_{diff}]=–0.14, P=.008), high-density lipoprotein (M_{diff}=+2.14, P<.001), and total cholesterol (M_{diff}=–11.45, P<.001) for employees in the Active Coaching group between 2021 and 2022, with the other 2 groups reporting deteriorations in multiple health outcomes throughout the 2 time points. At follow-up, those who received active coaching between 2021 and 2022 reported significantly lower body weight (P<.001), BMI (P=.001), low-density lipoprotein (P=.045), and total cholesterol (P<.001) than the No Coaching group.

Conclusions: This study demonstrates real-world outcomes and implications supporting the use of workplace digital behavioral coaching in improving employee health status. Given the rising burden of NCDs in the Southeast Asian region, our findings underscore the role that workplace digital health interventions can play in preventing and managing chronic disease risk factors.

Introduction

Chronic noncommunicable diseases (NCDs) are responsible for 74% of deaths worldwide [1], and approximately 38% (15.2 million) of these deaths occur prematurely, affecting people aged 30 to 70 years [2]. The World Health Organization (WHO) estimates that 69% of all deaths in the Southeast Asian region are due to NCDs [3], which roughly translates to 9 million of the regional population dying each year from NCDs, with 52% of deaths occurring prematurely in those younger than 70 years of age [3]. In Indonesia, NCDs are estimated to account for 76% of all deaths in the country [1], with cardiovascular diseases and diabetes accounting for an estimated 35% and 6% of proportional mortality, respectively [4]. Indonesia's rapid urbanization over the past decade has not only led to higher individual life expectancy but also higher rates of modifiable NCD risk factors such as unhealthy diet choices and sedentary lifestyles, ultimately contributing to the rise of an aging population at risk of developing NCDs [5].

Largely due to stretched and overburdened health care systems, low- and middle-income countries are disproportionately affected by the burden of NCDs [6]. The COVID-19 pandemic has also disrupted essential health service provision for NCDs in the region, further burdening health care systems and creating long-term impacts on health and mortality in the region [7]. Similarly, although Indonesia has been shifting its health care disease burden from communicable diseases to NCDs [5], the COVID-19 pandemic has largely disrupted the nation's NCDs services in primary health care [8], highlighting the need for a multi-stakeholder, multi-component, and preventative approach to managing NCDs in the nation. As health care systems worldwide continue to tackle the downstream impact of the COVID-19 pandemic, a growing body of evidence sheds light on the potential of digital health as a resource-efficient solution for health care systems and health care payers [9,10], making their real-world uptake more relevant for NCD prevention as traditional health care systems in the region continue to be overburdened.

Beyond health care, workplace-level interventions have a high magnitude of impact in addressing and managing chronic disease risk factors [11]. Working adults spend more than a third of their lives in the workplace [12], which makes them increasingly vulnerable to work-related risk factors such as sedentary work, work stress, and easy access to unhealthy food [13]. For this reason, the WHO recommends workplace health promotion programs as an effective avenue to target physical inactivity and unhealthy dietary habits—two important modifiable risk factors for obesity, hypertension, diabetes, and hypercholesterolemia [14]. Although workplace health improvement initiatives have traditionally been physical and face-to-face in nature, the COVID-19 pandemic has highlighted the need for digital offerings that provide more accessible, personalized, and diverse offerings, that are becoming increasingly more relevant as offices become more dispersed in a post–COVID-19 world. Given that unmanaged NCDs adversely affect employers through increased health care costs, rising premiums, and increased work absenteeism and presenteeism [15,16], there is a rising need for employers to effectively use the workplace as an avenue for health promotion and NCD prevention.

Major modifiable risk factors for NCDs are often behavioral in nature, such as tobacco use, excessive alcohol use, unhealthy diets, and physical inactivity [17]. For this reason, interventions that aim to prevent or self-manage chronic disease risk factors often rely on behavioral change frameworks to create long-term and sustainable behavioral changes [18-20]. Digital behavioral health coaching is a scalable and accessible method of delivering patient-centered health coaching, which is defined by an individual's interpersonal relationship with a certified coach that allows individuals to develop intrinsic motivation, create sustainable change, and increase accountability through the use of behavioral change theory, motivational strategies, and communication techniques [21]. Concurrently, there is growing evidence to support the effectiveness of digital workplace behavioral coaching interventions in improving various chronic disease risk factors [22], such as weight and BMI [23-27], waistline circumference [26,28], blood pressure (BP) [23,26,28], cholesterol levels [26,28], and blood glucose levels [28].

A majority of studies evaluating digital workplace interventions are based in Western or high-income countries. Different health system capacities, income levels, health literacy levels, and health-seeking cultures necessitate more studies that are localized within the region to more accurately evaluate the impact of digital workplace interventions in the Southeast Asian population [29]. This study leverages a retrospective analysis of secondary employee health data to fill in the current gap in digital workplace health interventions in the region, by exploring year-to-year changes in employee physical health status associated with different levels of coaching delivered by Naluri, a Southeast Asian digital therapeutics platform, as part of a workplace health improvement program implemented in an Indonesian mining company. We focus on changes in BMI, waistline circumference, lipoprotein and total cholesterol levels, hemoglobin A_{1c} (HbA_{1c}), BP—all of which are primary indicators of obesity, hypercholesterolemia, diabetes, and hypertension, respectively.

Methods

Study Design

This was a retrospective, observational, and exploratory study using secondary, longitudinal data from a cohort of employees at a prominent mining company in Indonesia.

Settings and Participants

Indonesian labor regulations stipulate that employers conduct regular mandatory health examinations to assess the physical health and ability of employees [30]. In 2021 and 2022, employees of a mining company were invited to complete a company-sponsored health screening that measured current employee health profiles such as weight, BP, blood glucose, and cholesterol levels. Participants of this study were those who had completed the annual company-sponsored health screening in 2021 and 2022, with the inclusion criteria set to employees with valid and matching health data across the 2 health screenings. Exclusion criteria were set to (1) employees with

missing health data, who did not complete either one or both health screenings in 2021 and 2022, (2) employees reporting an active pregnancy status during either or both health screenings in 2021 and 2022, and (3) employees whose health data were considered as unreasonable or improbable due to extreme outliers beyond clinically realistic levels.

After completing their health screening in 2021, employees were given access to receive digital health services provided by Naluri as part of their employer-provided employee wellness benefits. Employees were given the autonomy and freedom to voluntarily receive Naluri's digital health services, with no external coercion or pressure to join from their employers or from Naluri personnel. Based on the employee health profile from the 2021 health screening, 300 employees with the highest risk factor indicators for obesity, hypercholesterolemia, diabetes, and hypertension were then identified and invited to join a 16-week structured, intensive digital chronic disease management program (CDMP) delivered on the Naluri mobile app (Naluri Hidup Sdn Bhd) at 2 points throughout the year, that is, in April 2022, and later in June 2022. Employees were invited to join Naluri's CDMP if their 2021 health screening outcomes met 2 or more of the following criteria: (1) HbA_{1c}≥5.7%; (2) total cholesterol level≥201.08 mg/dL; (3) BMI≥23 kg/m^2; or (4) systolic BP≥120 mm Hg and diastolic BP≥80 mm Hg. At the end of 2022, all employees, regardless of use or engagement with Naluri services, were again invited by their employers to participate in an annual company-sponsored health screening.

Employees who fulfilled this study's inclusion criteria were retrospectively categorized into three groups, which were (1) Active Coaching group, comprising employees who were invited and voluntarily enrolled into a 16-week, active, coach-led structured intensive digital CDMP during the interval between the 2021 and 2022 health screening; (2) Passive Coaching group, comprising of employees who voluntarily accessed self-led, unstructured, and passive digital behavioral coaching on the Naluri app through their employee assistance program (EAP) during the interval between the 2021 and 2022 health screening; and (3) No Coaching group, which are employees who reported no use of Naluri digital health services during the interval between the 2021 and 2022 health screening.

Intervention

Active Coaching: Naluri CDMP

The Naluri CDMP is a 16-week intensive disease prevention program that uses a multidisciplinary team–based approach to improve physical health outcomes and chronic disease risk factors, primarily targeting indicators for obesity, hypercholesterolemia, diabetes, and hypertension. Naluri adopts the transtheoretical model of behavioral change [31] to help individuals adopt and maintain lifestyle habits that can sustainably improve health outcomes. The 16-week CDMP comprises 5 stages. First, Getting Started, where individuals get onboarded onto the program, build rapport with their assigned coaches, and set baselines and expectations. Second, Preparation, where individuals discover their current needs and motivation, discuss habit formation and planning, and set behavioral goals. Third, Action, which involves skill building across 3 domains—behavior, cognitive, and emotion regulation—to help individuals build healthy habits, adjust mindsets, and manage emotions. Fourth, Resilience, which focuses on empowering individuals to overcome challenges, with emphasis on resilience boosting modules such as dealing with relapses, setbacks, and weight plateaus. Finally, Maintaining Success, which focuses on maintenance and inspiring accountability to prepare individuals for long-term, sustainable, and independent healthy living. Throughout each stage of the program, participants had access to a multidisciplinary team of health coaches, such as dietitian, fitness coach, medical advisors, and more, led by a mental health coach (master's-level health or clinical psychologist or a certified counsellor), who follow a comprehensive curriculum rooted in cognitive behavioral therapy and motivational interviewing to provide dedicated and continuous holistic support to help goal setting and habit formation.

Each week of the CDMP starts with a weekly check-in with a respective coach (eg, psychologist, dietitian, fitness coach, or medical advisor), where each coach engages in individual text-based coaching over the Naluri mobile app. Coaches were provided a coaching framework to follow throughout the program, with coaching objectives set for each week of the CDMP. For example, in week 2, which falls under the "Preparation" stage, mental health coaches were tasked to assess for participants' current mindsets, behaviors, barriers, and health goals, dietitians were tasked to assess for past dietary attempts for weight management and current eating patterns, while fitness coaches were tasked to assess for participants' current and past exercise history. In addition, coaches were also tasked to assign participants to complete educational modules to supplement the objectives and goals for each week of the program. Throughout the 16 weeks, participants were also assigned to complete and update their thought, food, weight, and exercise journals, at a minimum of once per week. Although the CDMP involved a structured curriculum and framework, the coaching received by the participants were also personalized to tailor to their current health needs and goals.

Passive Coaching: Naluri EAP

Naluri's EAP is a passive, self-led, and digitally-delivered service for employees seeking mental or physical health support. Although the Naluri EAP provides individuals with access to holistic digital health coaching from a multidisciplinary team of health care professionals, unlike the CDMP, the Naluri EAP is an unstructured and low-intensive service that allows individuals to personalize their own health improvement journey in a nonlinear fashion. The Active Coaching group received structured and proactive coaching by the CDMP whereas those in the Passive Coaching group were free to use any of Naluri's digital services as they saw fit, following no particular guidance or structure.

Naluri Mobile App

Both the Naluri CDMP and EAP are delivered digitally through the Naluri mobile app, a human-driven, artificial intelligence–augmented digital therapeutics platform that provides holistic digital care solutions aimed at predicting,

preventing, and managing cardiometabolic and mental health conditions (Figure 1). In addition to a team of on-demand multidisciplinary coaches to provide accessible and on-demand coaching, the Naluri app is also optimized with evidence-based digital tools that facilitate behavioral change through features that promote goal setting and self-monitoring. These include habit trackers and artificial intelligence–augmented health journals that allow users to log and monitor their food intake, thoughts and emotions, weight, and BP; educational modules on topics such as resilience, diet and nutrition, managing chronic care, and exercise libraries; and the ability to set personalized challenges, as well as join support groups.

Physical Outcomes

The physical health outcomes used in this study are sourced from secondary health data collected as part of an annual company-sponsored health screening for employees, which serves as the basis for this study's outcome measures. In addition to physical health outcomes, participants' self-reported ages and genders were also sourced from the data collected during the health screening.

We identify primary physical outcomes as changes in employee health profile, namely BMI, low-density lipoprotein (LDL) level, high-density lipoprotein (HDL) level, total cholesterol level, blood glucose level measured as HbA_{1c}, systolic and diastolic BPs, body weight, and waistline circumference from 2021 to 2022. All physical health outcomes were measured by health practitioners specially contracted to conduct employee physical health screenings, which were then shared with Naluri for further evaluation.

Statistical Analysis

All analyses were performed on RStudio version 2022.07.0+548, using R (version 4.2.1; R Core Team). Statistical tests were 2-sided and evaluated at a $P<.05$ significance threshold. We identify physical health outcomes at 2021 as "baseline" and physical health outcomes at 2022 as "follow-up." Descriptive statistics were calculated for sociodemographic variables, such as age and gender, and for all outcome variables, reporting means and SDs for continuous data, and frequencies and percentages for categorical data. We report standardized mean differences to evaluate for incomparability across the 3 groups on age, gender, and all outcome variables at baseline, where standardized mean differences >0.1 would indicate evidence of imbalance across the 3 groups [32].

Linear mixed-effects models (LMMs) were used to assess the year-to-year changes in individual health outcomes, with time, group, and time by group interaction as fixed effects, and participants as random effects. LMMs, which allow for comparisons between- and within-groups at multiple time points, are considered to have more statistical power than traditional methods of evaluating interventions such as mixed ANOVAs or ordinary least squares regressions [33]. As group randomization was not possible for this study, participants were modelled as a random intercept to account for individual differences across all group conditions [34]. In addition, all models included gender, age, and baseline outcomes as covariates. Baseline covariate adjustments are a reliable and statistically efficient method of accounting for selection bias in nonrandomized observational studies [35], more so since any baseline differences across the 3 groups in this study are likely an inherent property of group membership [36]. All models were implemented through the *lme4* package [37] using restricted maximum likelihood estimation, and the significance of fixed effects was evaluated through *P* values derived using Satterthwaite approximations from omnibus ANOVA tests on the *lmerTest* package [38], which has been shown to produce lower type I error rates [39]. Post hoc pairwise comparisons were conducted to explore the direction of significant interactions between group and time using the *emmeans* package

using the Tukey method to adjust for multiple comparisons [40]. Effect sizes were assessed using Cohen *d* statistics, which describes an effect size of 0.2 as small, 0.5 as medium, and 0.8 as large [41].

Ethical Considerations

This study was not preregistered. This study was approved by the Medical and Research Ethics Committee, Ministry of Health Malaysia (NMRR ID-23-01212-PQH). Implied consent was obtained from participants when they accepted the Naluri mobile app privacy policy during the creation of their user accounts, which includes a clause stating that anonymized user data may be used for research purposes. The data used in this study was transferred and stored in compliance with HIPAA (Health Insurance Portability and Accountability Act) requirements. All raw data were anonymized and deidentified by independent parties before extraction for this study. No compensation was offered to participants as part of this study.

Results

Participant Characteristics

A total of 774 employees fulfilled the inclusion criteria and were included as participants in this study. Of the 300 invited to receive active coaching, 177 employees voluntarily participated in the CDMP. Of the remaining employees, 108 reported the use of the Naluri mobile app and received passive coaching, whereas 489 employees reported no use of Naluri's digital services and thus received no coaching. The unequal sample sizes seen among the 3 groups reflect the real-world nature and voluntary enrollment of the employees into the offered digital health interventions.

The mean age of the overall sample was 38.51 (SD 8.32, range 21-81) years, and the majority of the participants identified as men (583/770, 75.71%). Table 1 presents the sample characteristics and baseline variables by group. Due to the nonrandomized nature of the study's design, significant imbalances were evident for all baseline demographic and outcome variables between the 3 participant groups.

Table 1. Participant characteristics and baseline variable (N=774).

Variable	Active coaching (n=177)	Passive coaching (n=108)	No coaching (n=489)	Active vs passive coaching, SMD[a]	Active vs no coaching, SMD	Passive vs no coaching, SMD
Age[b] (years), mean (SD, range)	41.14 (7.78, 25-58)	35.80 (8.01, 22-52)	38.16 (8.33, 21-68)	0.68	0.37	–0.29
Gender[b], n (%)				0.75	0.13	0.61

Total cholesterol (mg/dL), mean (SD)	230.05 (38.53)	190.69 (34.05)	199.66 (36.56)	1.09	0.81	–0.25
Systolic BP[f], mean (SD)	123.22 (12.67)	112.32 (13.72)	115.41 (11.49)	0.83	0.65	–0.25
Diastolic BP, mean (SD)	80.43 (6.60)	74.69 (6.87)	75.90 (6.93)	0.86	0.67	–0.18
Waist circumference (cm), mean (SD)	96.32 (8.91)	89.59 (11.06)	87.57 (10.13)	0.67	0.92	0.19

[a]SMD: standardized mean difference.

[b]For gender and age, total n=770 due to missing demographic values at baseline.

[c]HbA_{1c}: hemoglobin A_{1c} or glycated hemoglobin.

[d]LDL: low-density lipoprotein.

[e]HDL: high-density lipoprotein.

[f]BP: blood pressure.

Primary Health Outcomes

Table 2 presents descriptive statistics for all measured health outcomes at baseline and follow-up and omnibus results for fixed effects from the LMM analyses. As expected, the participants who were invited to receive active coaching reported poorer health outcomes in comparison to the other groups at

baseline. Participants who received active coaching within the year reported improvements in their health outcomes at follow-up, with the most noticeable improvements being total cholesterol levels (mean difference [M_{diff}]=–11.34 mg/dL). Those who engaged in passive coaching reported unchanging or slight deterioration in their health outcomes at follow-up, where slight improvements were only seen in HDL (M_{diff}=+1.89 mg/dL) and total cholesterol (M_{diff}=–0.78 mg/dL) levels. In comparison, participants who engaged in no coaching throughout the year recorded deteriorations in a majority of their health outcomes at follow-up, with the exception of improvements in HbA_{1c} (M_{diff}=–0.03%) and HDL levels (M_{diff}=+3.15 mg/dL). Results from LMMs showed a significant interaction effect of group×time for almost all health outcomes (P<.05) except for HDL (P=.09) and waist circumference (P=.06), indicating the presence of significant differences in the year-to-year change of health outcomes across the 3 groups.

Table 2. Means and SDs of health outcomes at baseline and follow-up by group with corresponding results of fixed effects from linear mixed models.

[a]Indicate statistical significance.

[b]HbA$_{1c}$: hemoglobin A$_{1c}$ or glycated hemoglobin.

[c]LDL: low-density lipoprotein.

[d]HDL: high-density lipoprotein.

[e]BP: blood pressure.

Tables 3 and 4 present results from post hoc pairwise comparison of estimated marginal means from the LMMs, reporting contrasts for within-group differences in health outcomes over time, and contrasts for between-group differences at follow-up measurement. Those who received active coaching reported significant improvements in HbA_{1c}% (M_{diff}=–0.14, *P*=.008), HDL (M_{diff}=+2.14, *P*<.001), and total cholesterol levels (M_{diff}=–11.45, *P*<.001) between the years of 2021 and 2022. While the Active Coaching group did record improving trends in body weight, BMI, systolic and diastolic BPs, and waist circumference, these improvements were not substantial enough to be considered statistically significant. In comparison, participants who engaged in passive coaching only reported a significant improvement in HDL levels (M_{diff}=+1.95, *P*=.04) between the 2 time points, with the group recording deteriorations in a majority of their remaining outcomes, specifically in LDL levels (M_{diff}=+9.10, *P*=.001) and systolic BP (M_{diff}=+3.71, *P*=.005). Separately, employees who received no coaching at all between 2021 and 2022 also recorded larger deteriorations in year-to-year changes of health outcomes, with the No Coaching group recording significant deterioration in body weight (M_{diff}=+0.56), *P*<.001), LDL levels (M_{diff}=+8.47, *P*<.001), systolic BP (M_{diff}=+1.93, *P*=.001), and waist circumference (M_{diff}=+3.41, *P*=.009).

Pairwise contrasts of health outcomes at follow-up revealed significant between-group differences for body weight, BMI, LDL, and total cholesterol levels that are in favor of the Active Coaching group. Compared with the No Coaching group, those who received active coaching between 2021 and 2022 reported significantly lower body weight (*P*<.001), BMI (*P*=.001), LDL (*P*=.045), and total cholesterol (*P*<.001) at the follow-up screening. Similarly, the Active Coaching group also reported lower body weight than the Passive Coaching group (*P*<.001) at follow-up.

Discussion

Principal Findings

In this observational study analyzing retrospective data of 774 employees, receiving active coaching by the Naluri digital CDMP was associated with statistically significant improvement in year-to-year changes in health outcomes. We found significant group×time interaction effects for body weight, BMI, HbA_{1c}, LDL, total cholesterol, and systolic and diastolic BPs. Post hoc pairwise comparisons revealed that, of the 3 naturally occurring groups observed in this real-world study, those who engaged in passive coaching or no coaching at all recorded deteriorating trends in body weight, LDL, systolic BP, and waist circumference from 2021 to 202. Between-group contrasts also revealed that, at follow-up, employees who had received active coaching reported significant improvements in body weight, BMI, and total cholesterol compared with those who did not receive any form of coaching. Overall, our findings suggest that structured, intensive, and active digital health coaching was associated with an improvement in overall employee health status and minimizing chronic disease risk factors in an Indonesian workforce sample.

Our study adds to the growing evidence supporting the use of digital behavioral health coaching in improving health-related outcomes in the workplace. A systematic review of 22 randomized controlled trials found that digital health interventions in the workplace create a positive impact on health-related workplace outcomes such as diet, exercise, mental health, and job satisfaction [22]. Similarly, a systematic review of 22 studies found that digital health coaching was effective in managing and improving HbA_{1c}, weight loss, and BMI [42]. Although the effect sizes observed in this study were primarily small to medium in magnitude, our findings are similar to that of Nkhoma et al [43], which similarly found a small effect (Hedges g=0.29) in a meta-analysis of digital interventions on HbA_{1c}. Among studies looking into the Asian population, mobile-based digital workplace wellness interventions have been successful in reducing overall cardiovascular disease risk among hospital management workers in China [44], reducing the incidence of type 2 diabetes among male employees in India [45], and improving body weight, blood triglyceride, and systolic BP among university employees in Malaysia [46]. Although previous studies have demonstrated the effectiveness of workplace health promotion programs in improving employee metabolic health outcomes in Indonesia [47], to our knowledge, this study is the first to have looked into the real-world effects of workplace digital behavioral coaching among Indonesian employees.

Of the 3 groups of employees observed in our study, those who did not engage with or receive any form of digital coaching reported significantly poorer year-to-year health status compared with the other groups. Observational studies using propensity-matched controls have also demonstrated similar results, with Wilson et al [25] reporting year-to-year weight gain and an increase in fasting blood glucose in their propensity-matched control group. The trend in health outcomes among the participants in the No Coaching group offers a real-world glimpse of the year-to-year deterioration in health that can occur naturally and highlights the importance of preventative workplace health programs even for employees who are considered physically healthy. In a longitudinal study following a cohort of Singaporean employees, Sathish et al [48] observed a natural increase in physical inactivity, an increase in the prevalence of overweight or obesity, and significantly worsening dietary habits within 12 months. Similarly, large-scale studies have projected a 35.4% increase in diabetes prevalence by 2050 across the Southeast Asian region [49]. Given the intrinsic NCD health risks associated with traditional workplace environments [13], and the increasing stressors modern employees continue to face [50,51], our results reinforce the importance of workplace health interventions in reversing natural downward health trends and call attention to the health burdens that employers in the region will need to carry if no proactive action is taken.

Interestingly, despite having access to similar Naluri digital services as the Active Coaching group, we observed no change and even deterioration in a number of health outcomes among the group of employees who engaged in passive coaching. This may be attributed to the unstructured nature of the coaching received by this group of employees. Although limited evidence does suggest that unstructured and self-directed digital interventions can be effective in improving health outcomes [52,53], our findings are more aligned with the previous studies in this area that highlight the effectiveness of structured over unstructured digital interventions [54,55]. To this effect, our results highlight the strength of using Naluri's digital tools within the context of a structured and theory-driven intervention framework as compared with passive, unstructured, and self-driven use. Separately, participant-related characteristics such as motivation and self-determination have been shown to be important drivers of behavioral change in digital interventions [56]. The mere knowledge that employees in this group were not at high risk during the baseline screening may have precluded them from developing the motivation and self-determination needed to improve their health [57], similar to what is seen in individuals at the precontemplation stage [31].

Currently, there is limited evidence that supports the use of digital health programs for improving physical outcomes in a Southeast Asian population [58]. To our knowledge, our findings are the first in the region to use real-world data, thus building the body of evidence supporting the use of digital health for real-world NCD prevention. Despite the relative infancy of digital health in Southeast Asia, the region is also known as one

of the fastest adopters of mobile health technologies in the past decade [59], with Indonesians reporting one of the highest rates of smartphone health information-seeking behavior in the region [60]. To this effect, our findings highlight and reinforce the potential of digital health interventions as a cost-effective, resource-efficient, and scalable avenue for the prevention and management of NCDs in the region.

Limitations

The findings of this study should be interpreted within the context of several limitations. All employees included in the study were given access to their company's corporate-sponsored wellness initiatives within the period of 2021 to 2022, which were not limited to Naluri's digital health coaching. The potential use of additional health improvement initiatives outside of those described in this study may have inflated or concealed within- or between-group differences in health outcomes at follow-up. In addition, given that the sample groups were retrospectively determined based on health screening data, self-selection, and natural usage patterns, outcomes of the study are likely susceptible to selection bias, despite our best efforts to control for this statistically. Admittedly, the nonrandomized and noncontrolled design of this study limits proper inferences of causality as well as limits the representativeness of our findings.

Furthermore, the retrospective and observational nature of this study precludes us from controlling for measured or unmeasured confounding variables such as mental health status or the existence of comorbid physical health conditions [61]. The omission of these potential confounding variables, though unavoidable in retrospective, observational studies [61], can in fact lead to an overestimation or an underestimation of the observed associations we see between coaching status and employee health outcome at follow-up. However, the observational nature of our study does offer a reflection on the real-world outcomes and implications of offering digital coaching and health improvement initiatives in the workplace. Separately, we did not look into participant engagement and adherence to the interventions, and this hinders any inferences on the dose-response relationship between the intervention and our study outcomes [62]. Despite these limitations, the real-world setting of our study provides ecological validity to our findings, prompting the need for more real-world studies of digital health use in the region, more so given the low adoption of digital interventions outside of randomized controlled trials [63]. To further contextualize the effectiveness of digital health interventions in the workplace, there is a need for future studies to look into the long-term outcomes and real-world cost-effectiveness of these programs.

Conclusion

This study retrospectively investigated the year-to-year changes in employee health outcomes associated with a workplace digital behavioral coaching intervention. We found that an active coaching CDMP led to significant year-to-year improvements in multiple measures of employee health outcomes compared with those receiving passive coaching or no coaching at all. Despite methodological limitations, our study provides real-world evidence to support the use of digital workplace interventions in NCD prevention in the region.

Acknowledgments

The study authors wish to thank the cofounders of Naluri, Azran Osman-Rani, and Dr Jeremy Ting, for their support in driving this project. We further wish to thank the team at Naluri who were involved in the intervention delivery for this cohort of employees.

Data Availability

The data used and analyzed for this study are available from the corresponding author on reasonable request.

Authors' Contributions

AFAA and TO conceptualized the study. AFAA acquired and analyzed the data and wrote the original draft of the paper. TO reviewed and edited the manuscript. All authors approved the final version of the paper.

Conflicts of Interest

AFAA and TO are employed by Naluri Hidup Sdn Bhd, which created the mobile app and digital behavioral coaching intervention used in the study. The authors declare that this study received funding from Naluri Hidup Sdn Bhd.

Abstract

Background: Mobile health apps can facilitate access to effective treatment and therapeutic information services. However, the real-world effectiveness of mobile apps for smoking cessation and their potential impact in everyday settings remain unclear.

Objective: In an ecological context, this study aimed to estimate the engagement rate of a mobile app–based smoking cessation preparation program and its potential impact on users' willingness, ability, and readiness to quit smoking.

Methods: A total of 2331 "organic users" (ie, users who discover and install a mobile app on their own, without any prompts) chose 1 of 2 program versions of the mobile app (Kwit): the basic version or the premium version. Both versions were identical in design, with 4 more evidence-based content items and strategies in the premium version. Outcomes were analyzed based on automated data registered in the app (engagement rate, motivation to quit, motivation type, motivation levels, and satisfaction level). Mann-Whitney and χ^2 tests were used to compare the results of both groups.

Results: As expected, in the ecological context, a high dropout rate was observed at different moments. A significant difference was observed between the 2 versions (n=2331; χ^2_1=5.4; *P*=.02), with a proportionally higher engagement rate in the premium version (premium=4.7% vs basic=2%). Likewise, differences were also observed between the 2 groups in terms of reasons to quit (n=2331; χ^2_4=19; *P*≤.001; V=0.08), motivation type (n=2331; χ^2_7=14.7; *P*=.04), and motivation level. Users of the app's premium version more frequently reported "well-being" (23.3% vs 17.9%) and "planning a pregnancy" (7.4% vs 4.4%) as their primary reasons for quitting smoking compared to those with the basic version. Moreover, they reported being more likely to be driven in the smoking cessation process by intrinsic motivation (premium=28% vs basic=20.4%), as well as feeling significantly more willing (*z* score=156,055; *P*≤.001; Cohen *d*=0.15), able (*z* score=172,905; *P*=.04; Cohen *d*=0.09), and ready (*z* score=166,390; *P*=.005; Cohen *d*=0.12) to stop smoking than users who had the basic version before completion of the preparation program. Among participants who finished each version of the program (premium: 9/189, 4.8%; basic: 47/2142, 2.19%), significant improvements in motivation levels were observed in both groups, although in different areas for each group (willingness levels for the premium group and ability for the basic group).

Conclusions: These results suggest that even in ecological contexts where engagement rates are meager, the Kwit preparation program can address ambivalence by increasing willingness to change, self-confidence, and readiness to quit among its users, especially those who feel less able to do so. Further development and evaluations are needed to better understand determinants for regular mobile health apps.

Introduction

Tobacco Consumption

The World Health Organization (WHO) considers smoking an epidemic that affects >1 billion people worldwide. It is a public health issue for many countries because tobacco use is one of the leading risk factors for a significant number of deaths and disabilities worldwide, and although preventable, the economic and social costs of disease burden remain very high [1]. On the basis of WHO recommendations, France's national tobacco reduction program successfully addressed tobacco consumption, as the quit rate has been decreasing significantly since implementing several tobacco control policies in 2014 (ie, the reimbursement of approximately EUR €150 [US $166] per year for nicotine replacement products, monitoring of health warnings, media restrictions, and taxation of cigarette packs) [2].

Although all these policies have had some success in increasing smoking cessation, the long-term abstinence rate is still extremely low despite 60% of worldwide smokers expressing their willingness to quit. In France, at least 29.9% of daily smokers tried to stop for at least a week the previous year without long-term success [2]. In addition, results from double-masked clinical trials show that the willingness to quit and actual reductions in smoking behavior are limited by the content of nicotine present in cigarettes, even in participants who were not initially interested in quitting [3,4]. Complex factors must be considered for long-term abstinence, such as the social influence of marketing misinformation about tobacco consumption, nicotine pharmacokinetics, everyday cue conditioning, withdrawal symptoms, and a comprehensive discussion of treatment options and goals [5].

Treatment for Smoking Cessation

Multiple treatment approaches have been explored because of the complexity of tobacco dependence. To date, 2 major treatment categories have been used to treat tobacco use disorder: pharmacological treatments (eg, nicotine replacement therapy, bupropion, and varenicline) and nonpharmacological approaches (eg, motivational interviewing, cognitive and behavioral therapies, and acceptance and commitment therapy) [6]. In addition, new treatment goals have been proposed as alternatives to total and abrupt abstinence. These include gradually reducing cigarette consumption or using methods like snus and vaping to lower the risks associated with smoking, particularly for individuals with high nicotine dependence [4,5].

Both WHO and the French Ministry of Health recognize the impact of mobile health (mHealth) by promoting communication on social networks and using new technologies (eg, helplines, government mobile apps, and specific websites) to facilitate access to information and, thus, health care for smoking cessation [7,8].

mHealth Apps for Smoking Cessation

Overview

mHealth refers to emerging technologies for accessing health and medical services through mobile devices [9]. This includes mobile eHealth apps (known as mHealth apps), which are software that provide health and wellness services, designed exclusively for mobile devices (smartphones and tablets) [10]. With nearly 70% of the world's population having a smartphone and access to the internet, mHealth apps can promote access to smoking cessation treatments [11]. mHealth apps can facilitate access to effective treatments and therapeutic information services by (1) adapting and translating "active principles" (the term used to refer to the various strategies and practices of evidence-based behavioral and cognitive therapies) into a digital format; (2) facilitating communication with health professionals, allowing a more flexible and personalized relationship (chat and social groups); and (3) encouraging a sense of responsibility and commitment to one's health through "nudges," such as positive reinforcement through messages or notifications, habit tracking, regular feedback, and audiovisual support [12].

Despite the many benefits of using mobile apps for smoking cessation, research is still in its infancy. It faces specific challenges: the quality of content, the range of potential uses, and engagement with mHealth apps for smoking cessation.

Content Quality of Mobile Apps for Smoking Cessation

According to a systematic review and meta-analysis, there is a relationship between the number of cognitive and behavioral techniques used in smoking cessation programs and short- and long-term effectiveness [9]. However, according to a recent review of the content analysis of mobile apps for smoking cessation in France, in 2020, (1) the average quality of mobile apps was 3.5 out of 5 (median 3.1; range 1-3) based on the Mobile App Rating Scale, (2) most of the apps made little use of the "active ingredients" of evidence-based therapies (between 4 and 38 out of 93 indexed cognitive behavioral therapy [CBT] techniques), and (3) there was a lack of information that delivers proper advice regarding the use of approved pharmacotherapy or the implementation of behavioral techniques specific to helping people prepare for smoking cessation[10]. In contrast, only some apps have been extensively studied and made available in France [11]; however, they still need to be presented using a proper taxonomy of behavior change techniques to facilitate further research on their mobile app content quality.

The Range of Potential Uses of an mHealth App

Current studies primarily address smoking cessation mobile apps as self-help material used as a stand-alone treatment by their users [12-14], not focusing on other treatment goals of smoking cessation interventions such as facilitating risk reduction and relapse prevention [5,15,16]. Moreover, mobile apps can also be used as a complementary tool that enables continual accompaniment of the patient throughout their treatment by health professionals. The transtheoretical change

model framework developed by framework of Prochaska and Prochaska [17] will be used to illustrate this purpose.

This model states that a long-term change (ie, smoking cessation) results from different stages. Each stage has specific challenges; once addressed successfully, the person can continue their change journey by following the next stage. The first stages of change (precontemplation, contemplation, and preparation) are about raising awareness of the target behavior and creating an action plan by identifying the benefits of quitting, decreasing the perceived difficulties of change, and acknowledging the pharmacological and psychological therapy. Hence, mobile apps can highlight therapeutic information on dependency and how pharmaceutical aids work. Mobile apps can also be used as an ecological momentary assessment tool through which it is possible to monitor cravings in real time to collect information that helps to formulate hypotheses on the precipitating and maintaining factors that lead to tobacco consumption [18]. On the basis of the previous assessment, it is possible to individualize therapeutic interventions by understanding the individual experience of craving through repeated and ecological measures [15].

In the action phase, the person can change the target behavior [17]. Therefore, to manage cravings differently instead of smoking, a person can experiment with new methods that can be transitional and complementary, such as the use of pharmacological (ie, nicotine replacement therapy or medications) and psychological substitute strategies (ie, avoiding a specific place or person). In this phase, mobile apps can be a tool that prompts experimentation of new strategies by giving different types of feedback on behavior (ie, monitoring nicotine consumption, meditation exercises, distraction activities, etc) as well as being a motivational levier that highlights the benefits of smoking cessation or its reduction in different aspects of the user's life (health benefits and savings).

In the maintenance phase, "relapse" is perceived as the norm and not the exception, so it can be a learning opportunity in which the goal is to anticipate and prevent high-risk situations as well as navigate through the moment of the onset of craving by creating a relapse prevention plan [17]. Mobile apps can be a tool that helps monitor emotional changes and track withdrawal symptoms, both very common to relapse. On the basis of previous use, the mobile app can also provide feedback indicating treatment effectiveness and the risk of relapses.

As a result of these insights, Kwit app—a French mobile app initially conceived for maintaining smoking cessation—released the Kwit's 9-step preparation program for smoking cessation (9s-Kwit's program) in July 2021. A new feature specifically designed for users self-identifying as being in the preparation phase of smoking cessation according to the transtheoretical model of change developed by Prochaska and Prochaska [17], this program is based on cognitive and behavioral therapy for smoking cessation as well as dialectical and behavioral therapy, motivational interviewing, and self-determination theory.

Engagement With Digital Interventions Such as mHealth Apps for Smoking Cessation in Real Settings

As in any treatment protocol, "adherence to therapies is an important determinant of treatment success" [19]. The smoking cessation intervention attrition rate could be as high as 77% [20]. Conversely, mobile apps for chronic diseases face similar challenges as other mHealth apps, with attrition rates ranging from 43% (95% CI 16-63) in randomized controlled trials to 49% (95% CI 27-70) in observational studies [21]. To date, the dropout rate of some smoking cessation apps tested in a controlled scenario could vary from 19.3% after 28 days of use [22] to 39.5% after 87.3 days [23]. However, it remains to be seen what the attrition rate of smoking cessation mobile apps in ecological contexts would be [24-27], particularly with organic users. In this study, "organic users" or "organic installs"—terms primarily used in mobile app marketing—refers to individuals who discover and install a mobile app on their own, without any influence from paid marketing. Crucially, for the purposes of our research, these organic users are characterized by their autonomy to download the app and pursue smoking cessation. This autonomy distinguishes them significantly from users who participate in studies for compensation or who are mandated to use the app by health care institutions. Therefore, it is hypothesized that organic users will exhibit different behaviors and levels of engagement in smoking cessation compared to their nonorganic counterparts.

In conclusion, even if an app includes all the therapeutic guidelines, it can only be effective if used regularly [10,24,27]. Understanding how users engage periodically with their health treatment is challenging for mHealth apps [24,27,28]. Therefore, it is essential to identify and assess the main factors that favor using mobile apps for smoking cessation. To this end, the various research methods should ensure ecological validity in a design of evaluation setup that matches the user's real work context [29] and ensures that the behavioral responses obtained represent the natural behaviors of people who want to quit smoking with the help of a mobile app [30].

The aims of this study were, therefore, to (1) explore, in an ecological context, the engagement rate of a 9s-Kwit's program on a mobile app and (2) estimate the impact of the program on the motivation level among users who finished the program.

We hypothesized that (1) given the ecological context of this study, we will observe a remarkably high dropout rate between 80% and 95% of the users participating in the study. In addition, we sought to examine some key factors' role in the Kwit program's engagement rate. Specifically, (2) we hypothesized that the attrition rate within the intervention could be explained by the version of the program (basic and premium), the lack of relevance and understandability of the program content, the primary motivation to quitting smoking (ie, "money" or "family"), the lower levels of internalization to stop smoking (external motivation), and the lower level of motivation to quit before starting the program. Finally, we hypothesized that (3) users' perception of their willingness, ability, and readiness to stop smoking will significantly improve after finishing the 9s-Kwit's program.

Methods

Overview

This observational study was conducted from July 4, 2021, to July 28, 2021, in an ecological context. It represents the natural behaviors of people who downloaded and used the app to prepare for smoking cessation. In detail, this ecological context includes the following (1) the participants were organic users (users that installed the app because of their search results and without having encountered paid advertisements before onboarding); (2) only information essential for the everyday use of the mobile app was collected, and only data required for the study were exported to be analyzed (ie, no demographic data were collected before onboarding); (3) no compensation was offered to the users for their participation in the study; and (4) they checked a nonpreemptive box to give their consent to the collection and analysis of data related to their use of the app for research and improvement purposes. If an organic user chooses not to allow Kwit app to use their data for research, this preference is recorded in the server. This choice does not affect the quality of the services offered by the Kwit app. All users, regardless of their data use choice, have the option to access the premium version of the app. This ensures that there is no ethical compromise in the provision of services.

Ethical Considerations

The local French Ethical Committee (South-East) validated the protocol study on March 25, 2021. The research identification number is 2020-A02733-36, and the committee's reference is CPP 20.10.02.44945 [31]. This study adheres to the ethical principles outlined in the Declaration of Helsinki. This feasibility study is part of a prospective study registered on April 8, 2022 (ClinicalTrials.gov NCT05318651). It aims to identify critical determinants of smoking cessation mobile app use among smokers seeking to quit.

Participants

Participants were aged at least 18 years and had a compatible smartphone (iOS 13.3 and above) with regular internet service. In total, 2 groups of participants were followed according to the type of program version they had access to, basic or premium.

Before participating in the program, participants were required to create an account that pseudonymized their personal information, including billing information where applicable. The Kwit app offered 2 versions: premium and basic. The choice between them was influenced by whether the participant opted for a 7-day free trial.

The premium version was available to users who opted for the free trial and provided full access to all features of the program. In contrast, the basic version limited the user's access to only 4 levels of the program (steps 0, 1, 2, and 8). It is important to note that both versions visually presented the same program dashboard screen to ensure a consistent user experience. The user journey leading to the 9s-Kwit's program dashboard is detailed in Multimedia Appendix 1.

In terms of pricing structure, the premium version of the Kwit app was offered through a 7-day free trial during the study period from July 4, 2021, to July 28, 2021. This trial period gave users the flexibility to discontinue the service if they wished. After the trial period, if the subscription was continued, it was considered an agreement to a monthly membership fee of EUR €9 (US $9.96). This pricing was strategically set to approximate the cost of a pack of cigarettes in France at the time, aligning the cost of the app with a tangible smoking expense and making the value proposition relatable and practical for users.

Intervention

The 9-step Kwit's program was developed after 2 years of research and development, as part of a PhD thesis, in collaboration with the University of Paris Nanterre. The content of this program was defined and coordinated by the cognitive behavioral psychologist and PhD student to be then executed by a team composed of a user experience designer, 3 software developers with at least 10 years of experience, a researcher in public health and clinical research, and 4 interns with a psychology master's degree. The 9s-Kwit's program has been developed for commercialization and designed for direct delivery as a mobile app intervention on Apple and Google Stores. This program is based primarily on cognitive and behavioral therapy for smoking cessation but is also inspired by dialectical and behavioral therapy, motivational interviewing, and the self-determination theory.

The 9s-Kwit's program comprises 9 steps from step 0 (s0) to step 8 (s8). Through different activities, each step aims to explore a specific aspect of tobacco use that has already been identified as essential to consider in treating smoking cessation [9,32]. A presentation of the 9s-Kwit's program's home screen, a summary of its contents, and an example of the activity screen per step are presented in Multimedia Appendix 2.

The presentation of the activity starts as follows: each activity starts with an informative screen that introduces the activity's main goals, then the activity itself, and ends with a feedback screen (Multimedia Appendix 3). When the user finishes an activity, the next one is unblocked. Different types of feedback coexist to inform the user that an activity is completed: (1) the color of the activity title changes (ie, in s0 from gray to blue), (2) information about the date and hour is presented instead of the average duration of the activity, (3) the icon next to the title activity changes from a lock to an arrow to show that the next activity is then accessible, and (4) the activities that are already done have a summary card if you click on it. Once all activities of the same step are completed, the next step is unlocked.

The initial step (s0) consists of becoming aware of one's motivation to engage in a change process, but to change the target behavior, motivation alone is not enough; it is crucial to get out of "self-pilot" mode and adopt an "observer attitude" to understand the association between the target behavior, its antecedents, and its consequences. Therefore, in the first step (s1), users are encouraged to monitor their behavior and create a baseline of the contexts and intensity of cravings and the inner strategies that have helped them cope. The behavioral baseline provides users with an objective measure that assists them in

recognizing patterns of cravings and helpful strategies. The second step (s2) focuses on the different components of dependency, and by using the Horn scale, it is possible to explain how opposing stimuli can induce people to smoke (ie, relaxation vs stimulation). On the basis of the results, users receive advice on new behavioral strategies. The third step (s3) proposes that users categorize cravings according to their short-term benefits (pleasure or relief) and then some mindfulness exercises. The fourth step (s4) defines a goal and a road map adapted to the user's resources. Steps 5, 6, and 7 teach new coping strategies for the 3 dependence types (s5: environmental, s7: psychical, and s7: psychological). The final step (s8) invites users to define a quit date and acknowledge the cognitive barriers to quitting. The program encourages being kind to oneself when slips and relapses occur and celebrating each small step toward the desired change. None of the program versions used in this study have the gamification layer where users earn points at the end of each activity, have their avatar, or any educational reading content or community layout that now exists in the platform. Table 1 details all activities of each of the 9s-Kwit's program according to the taxonomy on behavior change techniques developed by Michie et al [33].

Table 1. Overview of the behavioral and cognitive techniques (BCTs) and goals presented by step (s) and activity (a) of the 9s-Kwit's program based on the taxonomy developed by Michie et al [33].

ABS[a,b]	Type of activity	BCT number and label[a]
s0a1	Identify main reason to quit: health, well-being, economy, family, and planning a pregnancy	1.9 Commitment
s0a2	Identify the level of willingness, ability, and readiness to quit smoking using a visual analog scale	1.9 Commitment
s0a3	Define a landmark that recalls reason to quit when craving arises	1.9 Commitment
s0a4	Identify the degree of internalization of abstinence motivation using the French Smoking Cessation Motivation Scale	1.9 Commitment
s1a1	Introduction of the "plus bottom": craving arousal monitoring for 24 hours: context, intensity, and action (let it go or smoke)	2.1 Self-monitoring of the behavior
s1a2	Mindfulness exercises (3 minutes) focus on observing automatic responses when cravings arise, encouraging an observer's attitude	8.2 Behavior substitution
s2a1	Horn scale: physical, psychological, and behavioral dependency assessment	2.7 Feedback on outcome of behavior
s2a2	Identify the relationship with smoking through an open self-questionary about when the behavior installs and the reason it maintains in the time	4.2 Information about antecedents
s3a1	Identification of the most difficult craving to overcome in the journey and it impacts on the body and cognition	5.3 Monitoring of emotional consequences
s3a2	Classify cravings into anchored (routine) and reflex (contextual) types	4.1 Instruction on how to perform a behavior
s3a3	Mindfulness exercises (3 minutes)	8.2 Behavior substitution
s4a1	Assessment of current resources available to execute an action plan	1.4 Action planning
s4a2	Three types of experiences were proposed to be completed within 24 hours based on S4a1 for craving management: (1) "Act consciously" mindfulness exercises: for those not willing to stop smoking; (2) "Choosing your cravings": based on S3a1, users anticipated strategies to reduce "anchored" cravings; and (3) "Overcoming all cravings:" users anticipated craving management strategies for all cravings	1.1 Goal setting behavior and outcome
s4a2	Three types of experiences were proposed to be completed within 24 hours based on S4a1 for craving management: (1) "Act consciously" mindfulness exercises: for those not willing to stop smoking; (2) "Choosing your cravings": based on S3a1, users anticipated strategies to reduce "anchored" cravings; and (3) "Overcoming all cravings:" users anticipated craving management strategies for all cravings	11.1 Regulation by pharmacological support
s5a1	Assess nicotine dependency with the Fagerström Test for Nicotine and give proper feedback about dependency level and offer recommendations for pharmacological therapy options that could complement the app, if necessary	8.2 Behavioral substitution
s6a1	Introduction of new features of the "plus bottom": tracking nicotine substitutes or the vape consumption, mindfulness exercises, drinking water, and breathing exercises. Advise on how to avoid exposure to specific social and contextual cues	12.1 Restructuring the physical and social environment
s7a1	Identify barriers to quitting, such as learned helplessness, fear of withdrawal symptoms, and automatic behaviors related to craving management	13.3 Incompatible beliefs
s7a2	Recognize a behavior as it is and not as part of user's identity	13.4 Valued self-identity
s8a1	Identifying barriers to quit and propose some solutions to overcome it: the fear to stop smoking (eg, weight, stress, and concentration)	8. Behavior rehearsal
s8a2	Identify the level of willingness, ability, and readiness to quit smoking using a visual analog scale of s0a1 and give proper feedback	13.3 Incompatible beliefs

ABS[a,b]	Type of activity	BCT number and label[a]
s8a3	Recognize old behavior goals and consolidate experience through feedback. Define a future quit date	1.11 Review behavior goals

[a]This program content is created based primarily on cognitive and behavioral therapy for smoking cessation as well as dialectical and behavioral therapy, motivational interviewing, and self-determination theories.

[b]Activity by step=first activity of the step 0 (s0a1).

Outcome Variables and Measurements

In total, 4 different types of measurements were used: ecological momentary assessment to measure engagement rate and version of the program ("a method of data collection whereby a record is made each time a predefined event occurs" [18]); a visual analog scale (VAS) to measure user's perception of their willingness, ability, and readiness to quit smoking (the VAS slider ranged from 0 to 10); a Likert-type scale to measure the internalization degree to stop smoking, which can range from none (amotivation) to completely internalized (intrinsic motivation); and a multiple-choice question to measure user's relevance and understandability of the program content and the users' main reason to quit. Examples can be found in Multimedia Appendix 3.

Engagement Rate Toward the 9s-Kwit's program

The engagement rate is the ratio of users who completed the program from the first use (step 0) to the last activity proposed in 9s-Kwit's program (step 8).

Motives for Quitting Smoking

On the basis of previous studies on reasons for quitting smoking [34-36], users were asked to choose 1 of 5 reasons: health, wellness, money, family, and planning a pregnancy, using the following statement: "My main reason for quitting smoking is..." (Multimedia Appendix 3).

Motivation Level: The Willingness, Ability, and Readiness to Quit Scale

Using a VAS, users rated their perception of their willingness, ability, and readiness to quit smoking at the beginning (S0) and the end of the program (S0). For this purpose, each question was presented on a single screen and in the following order: (1) "To what extent this change is a priority for you right now?" (*willingness*), (2) "To what extent are you confident in your ability to change right now?" (*ability*), and (3) "To what extent do you feel ready to take action?" (*readiness*). This way, users could move a slider from 0 (lowest) to 10 (highest) on each screen (Multimedia Appendix 3). For statistical analysis purposes, scores <3 are defined as "low," scores between 4 and 7 are defined as "moderate," and scores >7 are defined as "high."

Nature of Motivation to Quit Smoking

The French Smoking Cessation Motivation Scale (F-SCMS) is a self-reported measure based on the self-determination theory, demonstrating good internal consistency (α=.86; ωh=0.7; ωt=0.89) and content validity (common-fit index=0.905, standardized root mean square residual=0.045, and root mean square error of approximation=0.087). The 18 items are divided into 6 subscales (each composed of 3 items) corresponding to the degree of internalization that participants have toward quitting smoking. The subscales are presented from no internalization to complete internalization of a behavioral change process: (1) amotivation, (2) external, (3) introjected, (4) mixed, (5) identified, (6) integrated, and (7) intrinsic motivation. We have previously validated the scale (F-SCMS) used in this study and explained the internalization process in a separate publication [37].

The scale was presented as follows within the app. Each screen was composed from top to bottom in the following order: (1) the statement "Right now," (2) the item appearing as a card, and (3) the list with 5 Likert-type response options ranging from 1 (does not match at all) to 5 (matches exactly). Once the user answered all the items, they could receive predefined feedback corresponding to their degree of internalization [37].

Perceived Content Relevance of s0

The last activity of s0 of the program was the evaluation by the users of the comprehensibility and relevance of the contents presented during this step. The question was presented as "You have completed Step X. How would you define it?" with the following 3 options: (a) *understandable and relevant*, (b) *understandable but irrelevant*, and (c) *not understandable and irrelevant.*

Statistical Analysis

We performed descriptive analyses to characterize the 2 groups' baseline samples and outcomes of interest. We conducted the Mann-Whitney test and a χ^2 test of association to compare differences between both groups at the beginning of the program in terms of the main reason to quit, the motivation level to quit smoking, the nature of the motivation, and the perceived content relevance at the beginning of the program. We conducted a Student *t* test (2-tailed) to estimate the program's impact on the motivation levels of the program completion for each group. For each test, a *P* value <.05 will indicate statistical significance. Analyses were conducted using Jamovi V2.3.8.

Results

Overview

A total of 2331 users started the preparation program. Overall, 91.89% (2142/2331) of the initial sample used the basic version of the program, and 8.1% (189/2331) used the premium version. As a reminder, the app's premium version allowed access to each program step's activities (from s0 to s8), whereas participants with the basic version had access only to s0, s1, s2, and s8 activities.

Table 2 presents the distribution of participants of both versions of the program in terms of (1) motives for quitting smoking, (2) motivation level to quit smoking, (3) motivation nature, and

(4) perceived content relevance of step 0. In general, participants' main reason for quitting smoking was health (1173/2331, 50.32%), followed by savings (450/2331, 19.31%), well-being (428/2331, 18.36%), family (172/2331, 7.38%), and planning a pregnancy (108/2331, 4.63%). At baseline, 80.65% (1880/2331) of the total sample was moderately motivated to quit smoking according to the Willingness, Ability, and Readiness to Quit (WAR) scale mean score, and 50.45% (1176/2331) fell into the 2 highest categories of internalization level for smoking cessation—integrated motivation (687/2331, 29.47%) and intrinsic motivation (489/2331, 20.98%)—according to the F-SCMS scale. Upon completion of step 0, the content of this step was considered by 71.55% (1668/2331) of the users as understandable and relevant (option A), by 10.98% (256/2331) as understandable but irrelevant (option B), by 0.82% (19/2331) as incomprehensible and irrelevant (option C), and 16.65% (388/2331) of the initial sample did not answer the question.

Table 2. The quantity and proportion of participants engaged in each activity of step 0[a] (motives for quitting smoking, level of motivation to quit smoking, nature of motivation, and perceived content relevance).

Motives for Quitting Smoking

According to the χ^2 test of association and Cramér value (n=2331; χ^2_4=19; *P*≤.001; V=0.08), users of each version of the program have reported proportionally different reasons for quitting smoking. Those who choose to get the premium version of the program were less likely to choose savings as their main reason to quit smoking (premium=8.5% vs basic=20.3%) but more likely to choose the well-being (premium=23.3% vs basic=17.9%) and planning a pregnancy (premium=7.4% vs basic=4.4%) options.

Level of Motivation to Quit Smoking

Concerning the total score of the WAR scale, 3 levels of motivation were calculated based on the average score of 3 subscales: low (0-3), medium (4-7), and high (8-10). Most users (1880/2331, 80.7%) reported a moderate motivation to quit smoking at the beginning of the preparation program (s0; 1880/2331, 80.65%; mean 5.85 out of 10, SD 1.68). There was no significant difference between basic (n=2076) and premium (n=183) users when comparing these 3 categories (n=2331; χ^2_3=6.48; *P*=.09) at s0a2. Nevertheless, when the ordinal data were compared using the Mann-Whitney test, the 2 groups differed significantly but with a very slight effect within the total score and every subscale. Users who had the premium version of the app reported feeling significantly more willing (*z* score=56,055; *P*≤.001; Cohen *d*=0.15), capable (*z* score=172,905; *P*=.04; Cohen *d*=0.09), and ready (*z* score=166,390; *P*=.005; Cohen *d*=0.12) to stop smoking than users who had the basic version before completion of the preparation program.

Nature of Motivation to Engage With a Smoking Cessation Process

The internalization degree of motivation to quit smoking differs significantly between basic and premium users according to the χ^2 test of association (n=2331; χ^2_7=14.7; *P*=.04). Premium users are less likely to score in the “amotivated” profile (premium=1.6% vs basic=3.6%) and more likely to be driven by intrinsic motivation (premium=28% vs basic=20.4%) to engage in a smoking cessation process. In addition, the proportion of participants for whom no answer was received is lower in the premium group than in the basic group (premium=17/183, 9% vs basic=340/2076, 15.9%).

Perceived Content Relevance of s0

The content assessment of s0 differs between premium and basic users according to the χ^2 test of association (n=2331; χ^2_3=9.7; *P*≤.02), and by contrast, there are fewer premium users for whom a response is missing (–7.2%).

Engagement Rate Toward the 9s-Kwit’s program for Smoking Cessation in an Ecological Context

Overview

As shown in Figure 1, the engagement rate with the program drops significantly at 3 different moments. The biggest dropout concerns both samples (basic and premium) in between activities s0a4 and s1a1 (basic=–90.3% and premium=–70.1%). The second dropout was observed in the basic user sample between s2a2 and S8a1 (–4.2%), and the third dropout was within the premium sample from S4a2 to S5a1 (–12.5%). The proportion of participants who started each program activity is detailed in Table 3.

Figure 1. Engagement rate of the basic and the premium sample by activity for each step of the 9s-Kwit's program. a: activity; s: step.

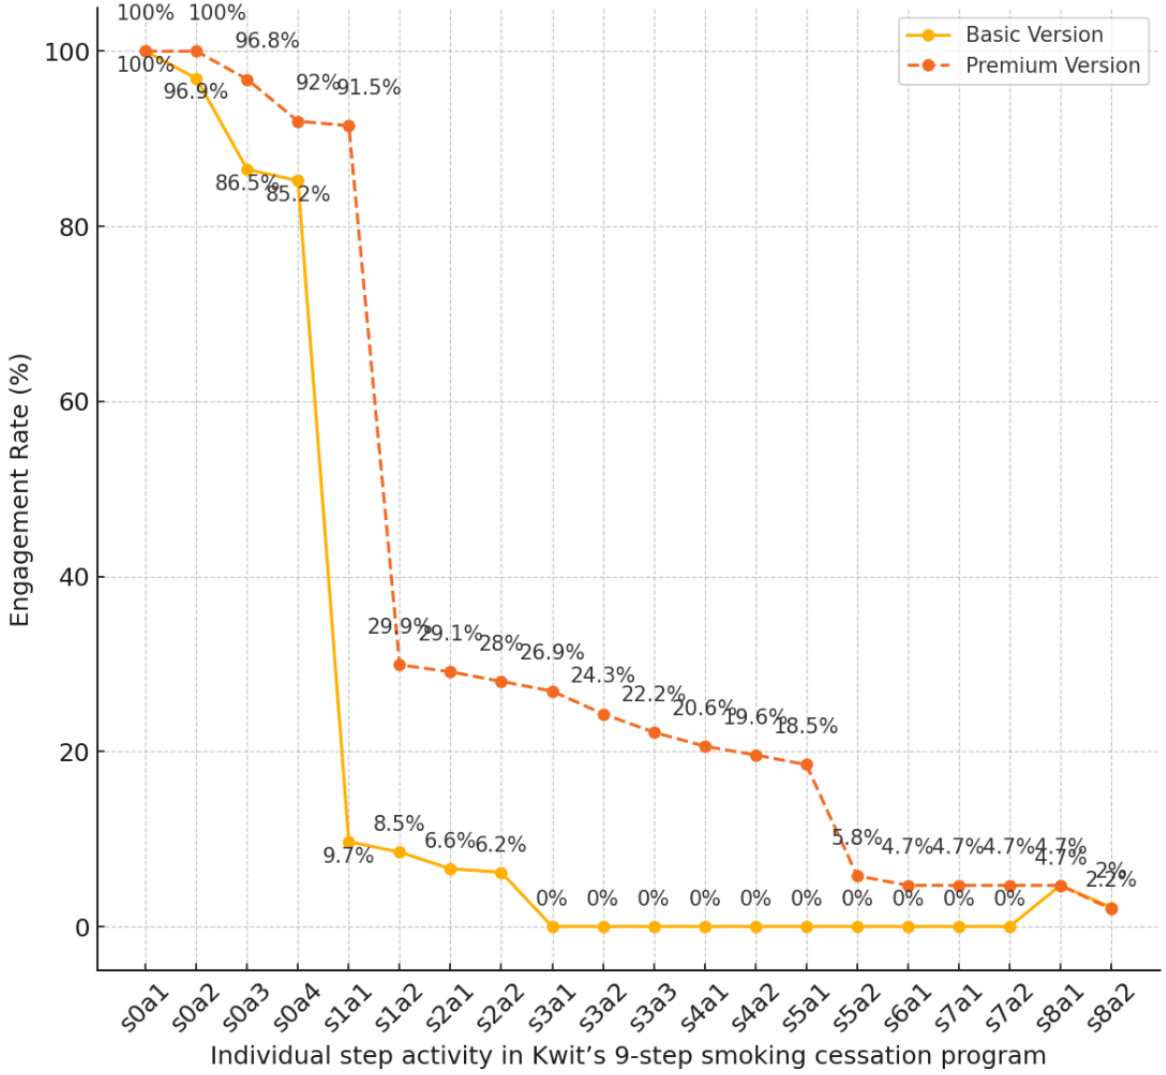

Table 3. Proportion of participants who completed each activity of the 9s-Kwit's program.

Activities by steps[a]	Total sample started, n (%)	Basic sample started, n (%)	Premium sample started, n (%)	Chi-square test of association and Cramér value (*df*)	*P* value
s0a1	2331 (100)	2142 (100)	189 (100)	—[b]	—
s0a2	2259 (96.9)	2076 (96.9)	183 (96.8)	—	—
s0a3	2238 (96)	1853 (86.5)	174 (92)	—	—
s0a4	1998 (85.7)	1825 (85.2)	173 (91.5)	7.8 (1)	.005
s1a1	265 (11.4)	209 (9.7)	56 (29.9)	68.1 (1)	≤.001
s1a2	236 (10.1)	181 (8.5)	55 (29.1)	—	—
s2a1	195 (8.4)	142 (6.6)	53 (28)	—	—
s2a2	184 (7.9)	133 (6.2)	51 (26.9)	—	—
s3a1	46 (1.9)	0	46 (24.3)	—	—
s3a2	42 (1.8)	0	42 (22.2)	—	—
s3a3	39 (1.6)	0	39 (20.6)	—	—
s4a1	37 (1.6)	0	37 (19.6)	—	—
s4a2	35 (1.5)	0	35 (18.5)	—	—
s5a1	11 (0.5)	0	11 (5.8)	—	—
s6a1	9 (0.4)	0	9 (4.7)	—	—
s7a1	9 (0.4)	0	9 (4.7)	—	—
s7a2	9 (0.4)	0	9 (4.7)	—	—
s8a1	59 (2.5)	50 (2.4)	9 (4.7)	—	—
s8a2	57 (2.4)	48 (2.2)	9 (4.7)	—	—
s8a3	54 (2.3)	44 (2)	9 (4.7)	5.43 (1)	.02

[a]The percentage in brackets is calculated in relation to the initial number of participants per group.

[b]Not applicable.

In addition, based on the χ^2 test of association and Cramér value, there is a significant difference between basic and premium users in terms of the engagement rate at the end of step 0 (s0a4; n=2331; χ^2_1=7.8; *P*=.005), the beginning of step 1 (s1a1; n=2331; χ^2_1=68.1; *P*≤.001), and the end of the preparation program (S8a3; n=2331; χ^2_1=5.43; *P*=.02). Premium users were more likely than basic users to finish the last activity of step 0 (s0a4; premium=91.5% vs basic=85.2%), start the new step (s1a1; premium=26.9% vs basic=9.7%), and complete all the program's activity until the definition of the quit date (S8a3; premium=4.7% vs basic=2%).

The Impact of the Program Completion on Users Who Finished the Program on Motivation Levels Toward Quitting

From an initial sample of 2331 ecological users, only 57 (2.4%) completed activity s8a2, which assesses the motivation levels regarding WAR scale. Table 4 presents the WAR scale and subscales scores from the beginning (s0a2) to the end of the program (s8a2) of the 2 users' groups who finished the program (57/2331, 2.4%) as well as the Mann-Whitney score.

Table 4. Description of the Total Willingness, Ability, and Readiness To Quit (WAR) scale scores and subscales at the start (s0a2) and end (s8a2) of the 9s-Kwit's program (n=57).

WAR scale	Total sample		Basic sample (n=48)		Premium sample (n=9)		Mann-Whitney test[a]		*P* value
	Values, mean (SD)	Values, median	Values, mean (SD)	Values, median	Values, mean (SD)	Values, median	U	Cohen *d*[b]	
Willingness									
s0a2	7.46 (1.89)	8.00	7.40 (1.87)	7.00	7.78 (2.11)	8.00	188	0.12	.54
s8a2	7.75 (1.91)	8.00	7.63 (1.94)	8.00	8.44 (1.67)	9.00	160	0.26	.21
Ability									
s0a2	5.33 (1.89)	5.00	5.02 (1.71)	5.00	7.00 (2.06)	7.00	94	0.56	.007
s8a2	6.25 (2.14)	6.00	5.98 (2.09)	6.00	7.67 (1.94)	7.00	118	0.45	.03
Readiness									
s0a2	6.30 (1.99)	6.00	6.23 (1.86)	6.00	6.67 (2.69)	6.00	201	0.06	.75
s8a2	6.86 (2.06)	7.00	6.77 (2.05)	6.50	7.33 (2.12)	7.00	184	0.15	.48
Total									
s0a2	6.36 (1.37)	6.33	6.22 (1.22)	6.00	7.15 (1.68)	6.33	190	0.12	.57
s8a2	6.95 (1.68)	6.67	6.79 (1.64)	6.67	7.81 (1.73)	7.60	144	0.32	.13

[a]*P* values for the Mann-Whitney test were statistically significant at $P<.05$.

[b]Cohen *d* effect size indicating the magnitude of the effect, where a small effect is approximately $d=0.2$, a medium effect is $d=0.5$, and a large effect is $d=0.8$.

To estimate the program's impact on the motivation levels of the program completion, Student *t* tests were conducted within each group.

At the beginning of the program, users who finished (57/2331, 2.4%) reported feeling, on average, highly willing to quit smoking (7.46/10), moderately confident in their abilities to do so (5.33/10), and moderately ready to start the quitting journey (6.30/10). A Mann-Whitney *U* test was performed to assess whether scores on the WAR scale and its subscales differed significantly between users of each group both at the beginning and at the end of the program. The results indicated that only subscale Ability differs significantly between both groups' samples (basic and premium), with a moderate effect size ($U=6.86$; *z* score=118; $P=.02$; $d=0.45$) before (s0a2) and after the program completion (s8a2). Users who had the app's premium version reported feeling significantly more capable of smoking cessation than users who had the basic version before (basic=5.02; premium=7) and after (basic=5.98; premium=7.33) the completion of the preparation program.

Premium users who finished 9s-Kwit's program reported, with a high effect size, significantly higher scores than at the beginning of the program on the Willingness subscale ($t_8=2.83$; $P=.02$; Cohen $d=0.9$) and the total score of the WAR scale ($t_8=3.16$; $P=.01$; Cohen $d=1.05$). Conversely, users who completed the basic version of the program (4 steps) reported, with moderate effect size, significantly higher end-of-program scores in the Ability subscale ($t_{47}=3.17$; $P=.003$; Cohen $d=0.46$) and a total score of the WAR scale ($t_{47}=2.92$; $P=.005$; Cohen $d=0.42$), and with low effect size, significantly higher end-of-program scores in the Readiness subscale ($t_{47}=1.857$; $P=.07$; Cohen $d=0.26$).

Discussion

Overview

This study aimed, in an ecological context, to explore the engagement rate of a 9s-Kwit's program on a mobile app (Kwit app); to examine some moderating agents that could contribute to the engagement rate we observed; and to estimate the impact of the program on the motivation level among users who finished the program. An ecological context refers to research conducted in natural, real-world settings as opposed to controlled laboratory environments. This approach is crucial for several reasons. First, it embeds our investigation in real-life scenarios where participants interact with the Kwit app as part of their daily routines. This allows us to gain authentic insights into user behaviors, app engagement levels, and the program's impact, mirroring genuine use patterns more accurately than laboratory conditions could. Such insights are invaluable for designing interventions that are not only effective in theory but also practical and beneficial for users in their real-world context.

Principal Findings

Overview

A total of 2331 users, all of whom were active smokers without a set quit date, started the 9s-Kwit's program. Most users (2142/2331, 91.89%) opted for the basic version of the program, whereas 8% (n=189) selected the premium one. Only 2.3% (54/189) of the initial sample reached the last step of the program (s8), which consisted of defining a quit date.

Notably, there was a marked difference in completion rates between the 2 versions: 4.7% (9/189) of premium users finished all program steps, which was higher than the 2.95% (44/2142)

completion rate observed in the basic version. This significant disparity in engagement rates (n=2331; χ^2_1=5.4; *P*=.02) highlights a greater commitment among premium users, despite them having more steps to complete.

To better understand the attrition phenomenon, we monitored user engagement at each program activity and observed 3 prominent dropouts. The first and most significant was observed between the last activity of step 0 (s0a4) and the beginning of step 1 (s1a1), with higher attrition rate among basic users compared to premium users (Table 2). The second dropout was observed in the basic user sample between s2a2 and s8a1 (–4.2%), and the third dropout was within the premium sample from activity s4a2 to s5a1 (–12.5%). These dropout patterns can be attributed to 3 main factors: (1) specific user characteristics (ie, areas of motivation and perceived content relevance), (2) the specific attributes of the app's user experience and the cognitive effort required to engage with different activities, and (3) typical attrition rates for smoking cessation interventions and the regular use of mHealth solutions.

Specific User Characteristics at the Beginning of the Program

In this study, data collection was confined to what was essential for the program's use, focusing on motivation areas and perceived content relevance, without collecting demographic information or insights into users' health and technology literacy. Following the rationale that user motivation to quit and user satisfaction with the app determines user engagement, higher engagement rates were anticipated. Only 26.9% (56/2142) of premium users and 9.7% (209/189) of basic users progressed beyond the initial stage of the program (from s0a4 to s1a2). Notably, while >70% (1668/2331) of both groups rated the content as "understandable and relevant," there was a significant perceived relevance gap, with premium users rating the app content more relevant by >10 points compared to basic users, as detailed in Table 2. This discrepancy suggests that content relevance may play a substantial role in influencing engagement levels, particularly among different user groups.

Significant differences were also observed in the initial sample (N=2331) between the 2 groups in all motivational measures: the reasons for quitting smoking, the WAR scale, and the internalization level to quit smoking. Premium users, who were more likely to choose wellness and family planning as their primary reason for quitting, also showed greater willingness, ability, and readiness to quit smoking at baseline compared to basic users, who were primarily motivated by financial savings. Interestingly, there is a difference between the willingness to quit and the user's self-perception of their ability and readiness to quit. On average, both groups reported high levels of willingness to quit smoking (premium=7.78; basic=7.40) but a moderate perception of their ability (premium=7; basic=5.02) and readiness (premium=6.67; basic=6.23) to do so. In addition, higher levels of internalization were observed in the premium sample with fewer incomplete responses (premium=15.9%; basic=9%) and lower amotivation profile (premium=1.6%; basic=3.6%). They were more represented in profiles of identified (premium=9%; basic=6.4%) and intrinsic motivation (premium=28%; basic=20.4%).

In summary, while both groups reported being highly willing to quit smoking, premium users reported feeling more confident and prepared to start their smoking cessation process, more driven by internalized motivation and reasons to quit (ie, well-being vs savings), and more committed from the early stages of the program.

The Specific Attributes of the Mobile App User Experience

Despite being user centered and clinically guided, the 9s-Kwit's program design might contribute to user disengagement at specific points: (1) for both versions in the transition between the last activity of step 0 (s0a4) and the beginning of step 1 (s1a1); (2) for the basic version, between step 2 (s2a2) and step 8 (s8a1); and (3) for the premium version, between step 4 and step 5. The AIM-ACT framework helps explain this attrition: emotional and motivational mismatches (AIM) and attentional or contextual misalignments (ACT) could hinder user engagement, especially during key step changes. This suggests the need for aligning app activities more closely with users' affective states, goals, and contextual realities to reduce dropout rates [27].

The first problem arises in the transition of the app between the dashboard and the activity screen (Multimedia Appendix 2). When users complete all activities in a step, they are redirected to the dashboard, where an animation (an opening of a small padlock) indicates the next available step. This transition can create friction rather than facilitate smooth progression, potentially discouraging motivated users from starting new activities. Alternative design elements, such as more prominent visual cues (eg, a red circle above the start step) or direct navigation to the next activity screens, could improve user engagement. Second, for basic version users, the dashboard could be improved by more clearly indicating accessible steps, perhaps by visually distinguishing available and unavailable steps, thus reducing confusion and friction in progression. For example, it would have been possible to slightly blur the steps to which they did not have full access to highlight the user's path and decrease friction between step 2 and step 8.

The third issue involves the cognitive load of certain activities, particularly those that require more active engagement, such as reading or logging cravings for a long period. This could be the case for the dropout in between step 4 (s4) and step 5 (s5); 3 types of exercises were proposed in s4 to be performed for 24 hours, setting goals for craving management. The design of these activities, including their duration and nature, might impact users' perception of the effort-to-reward ratio as insufficient to continue engaging with the app program.

In general, using any game element, such as achieving certain milestones, will encourage learning new skills and knowledge by making learning more enjoyable and engaging and by enhancing self-esteem and motivation, which are highly associated with long-term smoking cessation [25,38]. The version of the Kwit app used in this review represents the first stage of an evolving series of modifications. This baseline version was designed to establish a solid evidence-based core, filling a gap where many mobile smoking cessation apps have lacked a scientific foundation [10,39].

The Standardized Attrition Rate for Smoking Cessation and mHealth Solutions

The dropout rate observed in this study could be because of the nature of tobacco use disorders and the selection criteria. Tobacco use disorders are well studied, with various effective treatments available; however, they typically exhibit dropout rates ranging from 10.8% to 77% in participants who had already defined a quit date as part of the selection criteria [20]. According to model developed by Prochaska and Prochaska [17], our participants would be at a lower stage because they would be just in the preparation phase.

Moreover, attrition is a known challenge in mHealth, with an average dropout rate of 43%, with higher rates in research under ecological conditions (98%) and lower rates in randomized controlled trials (up to 30%) [21].

In the case of studies on smoking cessation apps, the reporting of quit rates has yet to be standardized and is not always reported. This threatens the validity of some studies by introducing selection bias and making it difficult to compare the effect of such apps [11]. For instance, dropout rates in such studies range from 19.3% at 28 days [22] to 39.5% at 87.3 days of use [23] in controlled settings with English-speaking participants, while studies in ecological settings with French-speaking participants report rates of 65% at 30 days and 80% at 90 days of use [39] with a 1-year data collection period (vs less than a month for our study).

The Impact of the Program Completion on Users' Motivation Levels Toward Quitting

To estimate the program's impact on the motivation level, the analysis was based on 57 users who completed the activity s8a2 of the program: 2.2% of the users from the basic version (n=48) and 4.7% from the premium version (n=9). At the beginning of the program, both groups reported high levels of willingness to quit smoking, with an average willingness score of 7.46 out of 10. However, they reported only moderate levels of ability and preparedness, with average scores of 5.33 out of 10 for their perceived ability to quit and 6.30 out of 10 for their readiness to begin the quitting process.

After the program completion, substantial improvements in the WAR total score were observed in both groups, with different areas of improvement for each group. The premium users improved their willingness levels, whereas users with the basic version benefited in the ability and readiness category. Given the difficulty of assessing the effect of each individual component, we can only hypothesize about the program content's effect on WAR scores. It is worth noting that throughout her work, Michie has linked several techniques based on behavioral theories to different behavior change as smoking cessation to the point that there is now an ontology and a whole system that would allow this question to be answered in future studies [40,41]. Therefore, the content of the 9s-Kwit's program was mainly described through the taxonomy developed by Michie et al [32,33].

Given the intricate challenge of isolating and evaluating the effect of individual components within the program, our analysis regarding its impact on WAR scale scores must be approached with caution. As such, we posit that the program's influence on users' sense of competence and readiness likely stems from the implementation of various CBT techniques previously recognized as efficacious for smoking cessation in personal intervention settings [42].

Extensive research into personal interventions across varied demographics and environments has pinpointed specific CBT techniques—and their synergies—to be instrumental in elevating smoking cessation success rates. The 9s-Kwit's program incorporates these proven techniques, including goal setting for behaviors and outcomes, using problem-solving strategies, revisiting and refining behavioral goals, fostering commitment, delivering feedback on behavioral outcomes, enabling behavior substitution, facilitating behavioral practice and rehearsal, and reconfiguring both physical and social contexts to bolster behavior change efforts [42]. These components are strategically combined to amplify the probability of cessation among users.

Moreover, the program integrates principles from acceptance and commitment therapy right from the outset, urging users to align with their core values, such as family, well-being, or personal health. Using metaphors, these values are presented as guiding beacons during moments of temptation (cravings) [43]. The "plus" button feature distinctively separates sensations from actions, offering various strategies such as the 4Ds (Delay, Deep breath, Drink water, Do something else) and meditation to manage cravings effectively [44]. In the second stage, the Horn scale demystifies the multifaceted reasons behind smoking habits, proposing tailored strategies for each [6]. Culminating in stage 8, the program prompts users to confront their quitting fears, providing customized solutions to navigate these apprehensions successfully and asking them to set a quit date.

These results suggest that Kwit's preparation program can address ambivalence by increasing willingness to change, self-confidence, and readiness to quit among its users, especially those who felt less able to do so (users with the basic version). Self-efficacy or confidence in one's abilities has been identified as a determinant in long-term abstinence [45].

Strengths and Limitations

Strengths

The strength of this type of study is simultaneously one of its major limitations; being observational in an ecological context, it offers a unique "snapshot" of real-life behavior of a group of users of a mobile smoking cessation app, providing insight into how its use may impact motivation outcomes. This approach not only sheds light on the "science of attrition" by recognizing when intervention dropouts occur but also aids in identifying real-life adoption challenges, thereby facilitating the generation of hypotheses to enhance health care treatment adherence, particularly with the evolution of commercial mHealth apps [21,29]. To the best of our knowledge, only 2 other studies have explored using mHealth tools [46,47] to treat smokers who are ambivalent about quitting, and these studies focused on French-speaking smokers. This is the third study to examine this topic within an ecological context (ie, popular mobile apps) and with a large sample size [39,48].

Limitations

The low generalizability of the findings was a limitation for several reasons, outlined in the following sections.

Lack of Individual-Level Measures

The absence of detailed individual-level data, particularly on smoking habits, dependency levels, and mental health issues such as anxiety and depression, is a significant limitation. These factors are known to be associated with lower adherence to treatment [48,49]. In additional, the study did not collect detailed demographic information, such as age and gender, before the use of the 0-step preparation program. Conducted within an ecological context and adhering to General Data Protection Regulation, the study's data collection was limited to what was essential for app functionality, excluding pre-use demographic details.

Sample Size and Demographics

The study's sample is limited to iOS users, excluding Android users, who may differ in terms of quit attempts, quit date settings [50], and sociodemographics [51]. Given the global market share and diverse user base of Android, this limitation means the findings may not fully represent the broader population of smartphone users. The decision to focus on iOS users was driven by specific constraints at the time of the research design, making the results more reflective of the iOS user group.

Short Recruitment and Follow-Up Duration

The short duration of the recruitment phase and follow-up period is another limitation. Smoking cessation is a complex process often involving cycles of relapse and recovery. A brief follow-up may only capture a snapshot of this process, potentially overlooking critical data on sustained abstinence or long-term relapse rates. It may also fail to adequately assess dropout rates and reasons for disengagement, which are crucial for understanding and improving app efficacy.

Small Sample Size of Premium Users

The explanatory power of the study is also limited by the small sample size of premium users who completed the 9s-Kwit program. Although similar attrition rates have been reported in other ecological studies [39,48], the small number of premium users reduces the generalizability of the findings.

Future Perspectives

To address all these limitations and investigate user engagement over extended periods, we have established a new protocol in collaboration with the University Paris Nanterre, registered in ClinicalTrials.gov (NCT05318651). This initiative aims to provide a more comprehensive understanding of the program's impact over time.

Despite the limitations outlined, studies such as ours are critical for shedding light on 1 stage of the mHealth app design process. This research provided the Kwit design team with critical early insights that allowed for rapid iterative adjustments through A/B testing before launching the program on the Android platform and localizing it for different language audiences. As for 2024, the newly developed program integrates game-like features (awarding users points for successfully completing activities, offering different levels, and allowing for avatar customization), educational reading materials related to the topic of each step of the program, and a community design that was not previously accessible. It also introduces educational reading materials and a community design, which were not previously available on the platform. It remains to be seen how this proactive and responsive approach to app design not only optimizes user engagement but also avoids significant costs. It underscores the critical role of early and ongoing user feedback in refining mHealth interventions to ensure that they are both effective and engaging.

Rather than focusing on increasing abstinence as a stand-alone intervention, new studies should aim to improve the use of these and other interventions (as a complementary treatment rather than a comparative one) [48] and consider dropout rates as a measure of intervention quality. A meager retention rate highlights the current inability to satisfy users' expectations and needs of those seeking to quit [21]. To increase the duration and intensity of app use, qualitative studies are needed to obtain a user-centered perspective. In addition, small trials with users can help guide decision-making on design tweaks or new features. In contrast, through a quasi-experimental observational study based on the technology acceptance model, it would be possible to identify the determinants of engagement with a smoking cessation app [31].

Conclusions

This study on the first version of the 9s-Kwit's program provides crucial insights into the challenges and potential of mHealth apps in facilitating smoking cessation efforts. Despite a modest completion rate—with only 2.3% (57/2331) of the participants reaching the program's final step—the data unveil a significant difference in engagement levels between users of the basic and premium versions.

At the program's onset, participants displayed a strong willingness to quit, yet their self-assessed ability and readiness were only moderate. Notably, premium users reported feeling more capable of quitting than basic users—a sentiment that not only persisted but also intensified by the program's end. Subsequent evaluations indicated significant enhancements in willingness, ability, and readiness to quit across both user groups, with premium users showing an increased willingness and basic users experiencing considerable gains in self-assessed ability and readiness to quit.

These results imply that, despite the study's limitations, the 9s-Kwit's program may address user ambivalence, thereby enhancing willingness, confidence, and readiness to quit, particularly among those who initially felt less capable. Such improvements in self-efficacy are vital, as they play a pivotal role in achieving long-term smoking cessation success [45].

Ultimately, this research adds to the broader discourse on digital health interventions, underscoring the critical importance of adaptive design and user-centric approaches in developing effective mHealth solutions [24,26,27]. The observed attrition patterns highlight the intricate interaction between user characteristics, the cognitive demands of the app, and the inherent challenges of smoking cessation. This emphasizes the

essential need for early, iterative design processes that are informed by user feedback.

However, the study's conclusions must be approached with caution because of limitations such as the small sample size, the exclusive focus on iOS users, and the lack of comprehensive demographic data. By acknowledging these limitations, we have initiated a new research protocol with the University of Paris Nanterre (NCT05318651) to extend our investigation. This study aims to assess the long-term impact of the 9s-Kwit's program on a more diverse and extensive participant base.

Acknowledgments

The authors want to thank Mathias Lebot, Laurent Cruchet, Lucas Gallego and Edwan Rebuffe, who actively participated in the first phase of this study during their internship in their master's program in cognitive and behavioral clinical psychology. Mickael Ehrminger participated in the initial data curation. Lara Perez, user interface researcher and product designer, brought the content to life. The funders had no role in the study's design; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Conflicts of Interest

LAB undertook consultancy and research for a mobile app for smoking cessation (Kwit SAS) under a PhD contract involving the National Association of Research and Technology and the University of Paris Nanterre. All other authors declare no other conflicts of interest.

Abstract

Background: Personalized intelligent exercise prescriptions have demonstrated significant benefits in increasing physical activity and improving individual health. However, the health benefits of these prescriptions depend on long-term adherence. Therefore, it is essential to analyze the factors influencing adherence to personalized intelligent exercise prescriptions and explore the intrinsic relationship between individual behavioral motivation and adherence. This understanding can help improve adherence and maximize the effectiveness of such prescriptions.

Objective: This study aims to identify the factors influencing adherence behavior among middle-aged and older community residents who have been prescribed personalized exercise regimens through an electronic health promotion system. It also explores how these factors affect the initiation and maintenance of adherence behavior.

Methods: We used purposive sampling to conduct individual, face-to-face semistructured interviews based on the Transtheoretical Model (TTM) with 12 middle-aged and older community residents who had been following personalized exercise regimens for 8 months. These residents had received detailed exercise health education and guidance from staff. The interviews were recorded, transcribed verbatim, and analyzed using NVivo software through grounded theory. We then applied the TTM and multibehavioral motivation theory to analyze the factors influencing adherence. Additionally, the relationship between behavioral motivations and adherence was explored.

Results: Using the behavior change stages of the TTM, open coding yielded 21 initial categories, which were then organized into 8 main categories through axial coding: intrinsic motivation, extrinsic motivation, benefit motivation, pleasure motivation, achievement motivation, perceived barriers, self-regulation, and optimization strategies. Selective coding further condensed these 8 main categories into 3 core categories: “multitheory motivation,” “obstacle factors,” and “solution strategies.” Using the coding results, a 3-level model of factors influencing adherence to intelligent personalized exercise prescriptions was developed. Based on this, an implementation path for promoting adherence to intelligent personalized exercise prescriptions was proposed by integrating the model with the TTM.

Conclusions: Adherence to personalized exercise prescriptions is influenced by both facilitating factors (eg, multibehavioral motivation, optimization strategies) and obstructive factors (eg, perceived barriers). Achieving and maintaining adherence is a gradual process, shaped by a range of motivations and factors. Personalized solutions, long-term support, feedback mechanisms, and social support networks are essential for promoting adherence. Future efforts should focus on enhancing adherence by strengthening multibehavioral motivation, optimizing solutions, and addressing barriers to improve overall adherence.

exercise prescription; adherence behavior; qualitative; influence factors; Transtheoretical Model; multiple motivations of behavior

Introduction

Mounting evidence suggests that regular moderate physical activity significantly improves health-related quality of life, promotes community engagement and healthy aging, and may enhance cognition and mental health [1,2]. It also appears to mitigate the risk of at least 35 chronic diseases and reduce mortality [1,3-6]. Physical activity is currently recognized as a sustainable approach to promoting individual and community health and well-being [7]. Exercise prescription [8], a structured program designed to guide exercise for health promotion and the prevention and management of chronic diseases, has been applied to diverse populations, including healthy individuals, those with sports injuries, perioperative patients, individuals with chronic conditions, and those with disabilities [9-11]. However, many physicians struggle to provide physical activity guidance and prescribe scientifically effective exercise regimens due to a lack of knowledge, training, awareness, and understanding of exercise rehabilitation [3]. These challenges, combined with the absence of standardized implementation guidelines [12] and other barriers, hinder the promotion and integration of exercise prescriptions.

Most exercise guidelines [13-16] strongly recommend personalized and well-defined exercise prescriptions that specify the mode, intensity, frequency, and duration of exercise. Traditional exercise prescriptions often struggle to achieve scientific personalization, prompting the development of intelligent, personalized alternatives. By incorporating advanced technologies such as artificial intelligence and big data analysis, these modern approaches provide individuals with more precise, scientifically grounded, and customized exercise plans. For example, Netz et al [17,18] developed an innovative tool for remotely assessing balance, strength, and flexibility in middle-aged and older individuals, providing personalized exercise plans via smartphones. Lin et al [19] and Sun et al [20] created and validated distinct systems: a force gauge system that integrates exercise games with the Internet of Things and a cloud-based intelligent personalized exercise prescription system. Both systems are designed to deliver tailored exercise prescriptions for middle-aged and older individuals. Additionally, a multimodal data-driven artificial intelligence system has been developed and validated to generate personalized exercise prescriptions for patients with mental disorders [21]. These intelligent tools and systems effectively address the limitations of conventional exercise prescription methods. Beyond significantly improving exercise outcomes, reducing exercise-related risks, and enhancing individual health and quality of life, they also alleviate the burden caused by the shortage of professional sports rehabilitation resources, thereby improving the quality and accessibility of sports rehabilitation services [19-22]. Most research on intelligent personalized exercise prescriptions has focused on system design and development [23] and efficacy validation [17]. However, studies examining the factors that influence individual adherence behaviors and their underlying pathways are currently lacking. Recent systematic reviews and meta-analyses [24-26] suggest that while smart health interventions hold promise for improving exercise adherence, the specific factors and pathways driving adherence have not been fully explored or systematically explained. This gap makes it challenging for individuals to maintain long-term adherence. Therefore, it is crucial to further investigate and refine the factors, pathways, and theoretical frameworks related to adherence to personalized smart exercise prescriptions.

Motivation is a critical determinant in shaping individuals' behavioral intentions and driving behavioral changes, with various motivational factors regulating and influencing individual behavior [27-29]. Although motivation significantly impacts adherence behavior, theoretical limitations, a lack of empirical research, and the complexity of individual motivations contribute to a theoretical "black box" regarding how these motivations influence adherence to exercise prescriptions. The relationship between behavioral motivation and individual adherence behavior remains underexplored [30-32]. In health promotion, several theoretical models [33,34] have been used to study individual behavior. Among these, the Transtheoretical Model (TTM) has been widely applied in research on digital health behavior and behavior change [35-37]. By dividing behavior change into 5 stages—precontemplation, contemplation, preparation, action, and maintenance—the TTM provides a detailed framework for understanding the mechanisms and pathways of individual behavior change [38]. The TTM has shown promising results in various social studies focused on health behavior change and health promotion [39-41].

Therefore, this study uses qualitative methods to explore the factors influencing the adherence behavior of community-dwelling middle-aged and older residents who have followed personalized exercise prescriptions issued through an electronic health promotion system for 8 months. By integrating the TTM, the study analyzes behavioral intentions and changes at different stages of behavior change, identifies key factors in the adherence behavior change process, and constructs an implementation path model for adherence to intelligent personalized exercise prescriptions, driven by behavioral motivations and other influencing factors. This study reveals how behavioral motivations drive and sustain adherence to exercise prescriptions, expands the application of the TTM in digital health services, and provides insights for future research on adherence to intelligent personalized exercise prescriptions. Additionally, it offers practical strategies for enhancing and maintaining long-term adherence to these prescriptions. To our knowledge, this is the first qualitative study on adherence behavior to intelligent personalized exercise prescriptions.

Methods

Design

This study is part of a longitudinal research project aimed at examining the health impacts of intelligent personalized exercise

prescriptions on community-dwelling middle-aged and older residents. It uses a descriptive exploratory qualitative design, based on face-to-face semistructured interviews. The study strictly followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [42].

Participants

The participants in this study are a subsample from a longitudinal research project conducted by the research team, which aims to investigate the long-term effects of intelligent personalized exercise prescriptions on the health of middle-aged and older individuals. The inclusion criteria for the longitudinal study were age 50 years or older; no severe physical diseases or related complications; no cognitive or mental disorders among community-dwelling middle-aged and older residents; and exclusion of individuals with severe cardiovascular, pulmonary, or renal diseases, severe diabetes or related complications, fasting blood glucose of 13.3 mmol/L or higher with positive urine ketones, postprandial blood glucose of 19.4 mmol/L or higher, resting blood pressure of 180/110 mmHg or higher, or severe cognitive or mental disorders. Participants were initially recruited from the community via telephone and verbal invitations.

To investigate adherence behavior and the factors influencing adherence to intelligent personalized exercise prescriptions, we used purposive sampling to select participants for face-to-face semistructured interviews. The inclusion criteria were (1) community-dwelling middle-aged and older residents who had undergone home-based health checkups between 2021 and 2022 and received personalized exercise prescriptions through an electronic health promotion system administered by community staff; (2) participants who were provided with printed exercise materials and received detailed explanations and guidance from community staff; and (3) individuals whose exercise prescriptions had been active for at least 8 months. To gain a comprehensive understanding of exercise prescription adherence, we specifically recruited participants with neutral or negative attitudes toward intelligent personalized exercise prescriptions, as well as those who self-reported low adherence. The sample size was determined based on theoretical saturation, defined as the point at which no new issues or insights emerge and all relevant conceptual categories have been identified and explored [43]. Throughout the research process, the team continuously analyzed the dialogues and assessed the saturation level of the interview data at each stage. After the 12th interview, no new information emerged, all major concepts and categories had been thoroughly identified and explored, and theoretical saturation was reached. As a result, 12 eligible community-dwelling middle-aged and older residents participated in the face-to-face semistructured interviews.

Ethics Considerations

This study received ethical approval from the Human Research Ethics Committee of Bengbu Medical University (approval number 2022-103).

Intelligent Personalized Exercise Prescription Program

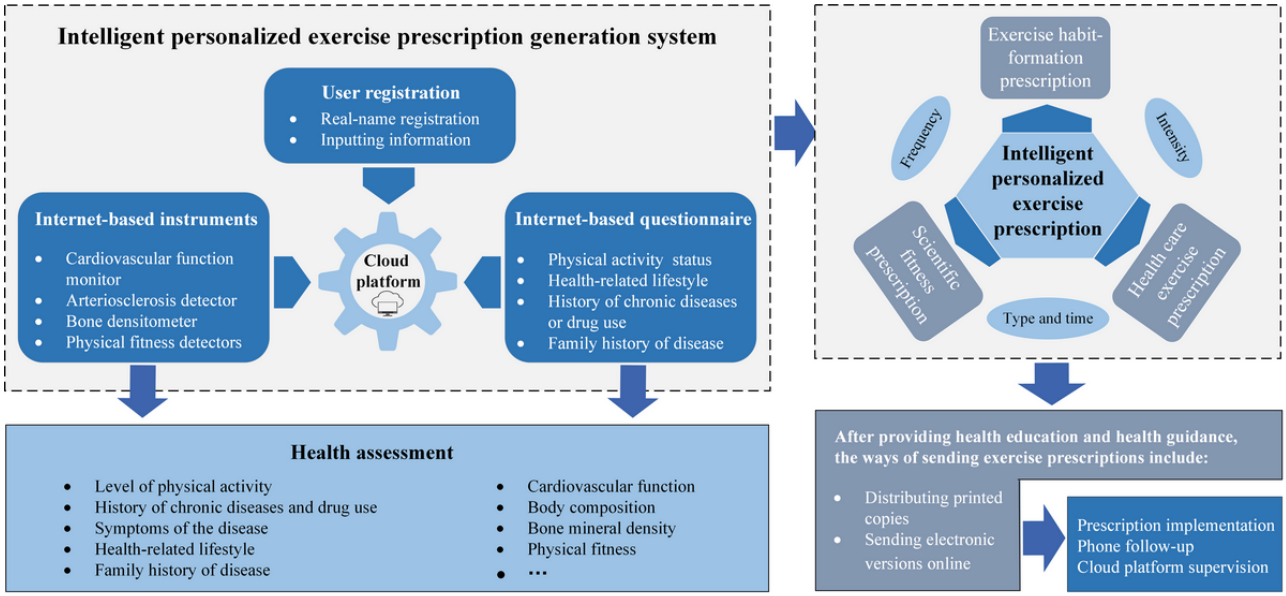
Details of the intelligent personalized exercise prescription system have been previously described [20]. The system generally consists of 4 components: user registration and information input, internet-based health monitoring devices, online questionnaire surveys, and a cloud platform.

Before generating a personalized exercise prescription, participants must register with their real names and provide personal information, including basic details (age, gender, height, and weight) and health history (past medical history and exercise habits). Next, participants' health data are collected using internet-based health monitoring devices. Additionally, participants must complete a series of online health questionnaires to provide the necessary data for generating personalized exercise prescriptions. Finally, all collected health data are uploaded to a cloud platform. The platform uses advanced data analysis techniques and artificial intelligence algorithms to evaluate participants' health data and generate personalized exercise prescriptions tailored to each individual.

Once the personalized exercise prescription is generated, community health service staff will provide face-to-face health education and guidance based on it. Depending on participants' needs, the prescription can be delivered in either electronic or paper form, promoting better adherence.

After the exercise prescription is implemented, community health service staff can access user information via the cloud platform and conduct regular follow-up calls. These calls aim to remind participants to adhere to the exercise prescription, answer their questions, and provide necessary support and guidance. Figure 1 illustrates the structure of the intelligent personalized exercise prescription system and the process of generating and applying the prescriptions.

Figure 1. Generation and application of intelligent personalized exercise prescription.



Procedures and Data Collection

This study strictly adheres to the COREQ [42]. To gather detailed data and gain a deeper understanding of participants' subjective experiences and true feelings, semistructured interviews were conducted. All interviews were carried out by 3 trained researchers, including the first author (XX), a graduate nursing student, and an undergraduate nursing student, between February and March 2023. Following purposive sampling to select interviewees, rapport was established between the interviewers and participants. Interviews were conducted in quiet, private spaces to minimize interruptions. Before the interviews, participants were briefed on the research objectives, methods, expected duration, and confidentiality principles. Informed consent was obtained, and participants signed consent forms. The interviews were audio-recorded by the interviewers, with additional on-site notes taken for further analysis. Additionally, interviewers observed and promptly documented participants' nonverbal behaviors, including tone, gestures, and facial expressions, during the interviews. Each interview lasted 20-30 minutes. Within 24 hours of completion, the recordings were transcribed into written transcripts and verified by the participants for content accuracy.

According to the main principles of the TTM, the occurrence and maintenance of individual behavior change occur across multiple stages. Therefore, before conducting the semistructured interviews, we determined the landmark events for each stage—"intention," "preparation," "action," and "maintenance"—based on the research objectives and the definitions and characteristics of these stages in the TTM. Relevant questions about stage transitions were formulated in the interview outline to ensure the interviews were systematic and scientifically rigorous. The interview outline included questions about the respondents' basic information; their perceptions and attitudes toward the intelligent personalized exercise prescription; factors that promote or hinder progression through specific stages of behavior change; and their activities, emotional states, needs, and suggestions within each stage. To ensure confidentiality, all participant information and data were anonymized and deidentified to prevent personal identification. Recordings and transcripts were stored in password-protected, secure files on the university server. The interviews concluded when no new information emerged.

Analysis

After the qualitative interviews were completed, the initial transcripts of the interview recordings—aligned with the interview questions corresponding to the 4 behavior change stages ("intention stage," "preparation stage," "action stage," and "maintenance stage") in the TTM—were imported into the qualitative analysis software NVivo 12 (Lumivero). The transcripts were then subjected to a 3-level coding process (Textbox 1) based on grounded theory [44,45] within the framework of the 4 behavior change stages.

Drawing on the TTM and the coding results, we analyzed the factors influencing the adherence behavior to intelligent personalized exercise prescriptions, proposed hypotheses for the pathways to achieving adherence, and developed an implementation path model for adherence to intelligent personalized exercise prescriptions. We validated the hypotheses through follow-up interviews with the 12 respondents and refined the theoretical model based on team discussions, ultimately finalizing it.

For clearer presentation and data referencing, the 12 participants were labeled P1 through P12. Data analysis and organization were primarily carried out by 5 researchers; 3 researchers (XX, GZ, and YX) sorted and classified the interview recordings for open, axial, and selective coding, while the remaining 2 (TS and HX) verified the phased collation and ensured accuracy and consistency in the 3-level coding process. The hypotheses and model framework for adherence behavior pathways to intelligent personalized exercise prescriptions were formulated by the research team, validated through follow-up interviews conducted by 2 researchers (XX and YX), and refined through group discussions.

Textbox 1. The 3-level coding process.

1. Open coding

This is the most basic level of abstraction in the coding process. Each interview transcript was read thoroughly, and the text was coded as it appeared, without unnecessary abstraction. By analyzing the text line by line, we identified and marked concepts and phenomena relevant to the research questions, ensuring that the coding remained original and authentic.

2. Axial coding

Building on open coding, we focused on the logical connections and relationships between the identified concepts. Through ongoing comparison and analysis, we refined these into higher-level main categories.

3. Selective coding

We further examined the relationships between the main categories, identifying a core category that served as the central focus of the coding system. This core category guided the analysis and discussion of the other categories.

Results

Overview

Effective interviews were conducted with 12 participants, and their general information is summarized in Table 1. The results of the 3-level coding process based on the 4 stages of behavior change in the TTM are as follows: (1) Open coding involves breaking down, reorganizing, and conceptualizing the transcribed interview materials. This process led to the identification of 21 categories (see Table 2), which highlight the direct factors influencing adherence to intelligent personalized exercise prescriptions. (2) In the axial coding stage, we examined the relationships and logical connections among the 21 categories identified during open coding. This led to the formation of 8 main categories (Table 3). (3) During selective coding, we integrated and refined the existing categories to extract a "core category." The categories of "hedonic motivation," "benefit motivation," "intrinsic motivation," "extrinsic motivation," and "achievement motivation" were consolidated into a single category, "multiple motivations of behavior." Similarly, "self-regulation" and "optimization solutions" were grouped under "problem-solving strategies," while "perceptual barriers" were categorized as "obstacle factors" (see Table 4). The open coding derived from the original interview data represents direct experiences and situational factors, forming the first level (bottom level). The 21 categories identified during open coding were organized into axial coding, which represents the preliminary classification of motivation and obstacle factors, making it the second level (middle level). Selective coding, which represents the core influencing factors derived from the systematic analysis of the main categories, forms the third level (top level). In summary, we constructed a 3-level model of factors influencing the adherence behavior to intelligent personalized exercise prescriptions, as illustrated in Figure 2.

Based on the TTM, Multiple Behavioral Motivation Theory, and the 3-level coding results from interviews on the 4 behavior change stages, we propose the following hypotheses for the path to adherence to intelligent personalized exercise prescriptions:

- Hypothesis 1: An individual's intrinsic motivations (such as disease susceptibility, perceived threat, and a sense of family responsibility) and extrinsic motivations (including family support, doctor's advice, recommendations from friends, and media publicity) contribute to the intention to adhere, leading to the "adherence intention stage."
- Hypothesis 2: Achievement motivation encourages the individual to reach the "adherence preparation stage," where they prepare for the actual adherence behavior to the exercise prescription.
- Hypothesis 3: Hedonic and benefit motivations drive the individual to enter the "adherence behavior stage," resulting in the initiation of actual adherence behaviors.
- Hypothesis 4: The presence of multiple motivations, coupled with problem-solving strategies, leads the individual to the "adherence maintenance stage," where they progress from partial to full adherence, achieving complete and sustained adherence to the exercise prescription.

The path hypotheses were verified and validated by 2 researchers (XX and YX) through follow-up interviews with the 12 respondents. Based on these findings, a model for the realization path of adherence behavior to intelligent personalized exercise prescriptions was further developed. This model consists of 4 stages of adherence: intention, preparation, action, and maintenance. In the intention stage, individuals are motivated by intrinsic and extrinsic factors, developing the intention to adhere, but without engaging in actual behavior. Driven by achievement motivation, they progress to the preparation stage, where they ready themselves for action and set goal expectations, though behavior has yet to occur. During the action stage, hedonic and benefit motivations play a key role in prompting individuals to take action and experience benefits, though full adherence may not yet be achieved. Finally, in the maintenance stage, supported by multiple motivations and problem-solving strategies, individuals transition from general adherents to complete adherents, fully adhering to the exercise prescription, as illustrated in Figure 3.

Table 1. General information on interviewees.

Number	Age (years)	Occupation	Gender	Educational level	Presence of chronic diseases	Type of exercise prescription	Previous exercise habits	Previous success or failure in health behavior change (eg, smoking cessation or weight loss)
P1	66	Shop assistant	Female	Junior high school	Yes	Scientific fitness mode	Yes	No
P2	71	Public official	Female	Junior high school	Yes	Scientific fitness mode	Yes	Weight loss success
P3	68	Teacher	Female	Vocational school	No	Health care mode	No	No
P4	72	Laborer	Male	Primary school	Yes	Scientific fitness mode	Yes	No
P5	63	Laborer	Female	Primary school	No	Health care mode	No	No
P6	68	Staff	Male	High school	No	Exercise habit–formation mode	No	Smoking and alcohol cessation success
P7	76	Staff	Male	Junior high school	No	Exercise habit–formation mode	No	No
P8	57	Pharmacy clerk	Female	High school	Yes	Scientific fitness mode	Yes	No
P9	60	Staff	Female	Junior high school	No	Exercise habit–formation mode	No	No
P10	69	Staff	Male	Junior high school	No	Health care mode	No	No
P11	72	Laborer	Female	High school	Yes	Scientific fitness mode	Yes	No
P12	68	Laborer	Male	High school	No	Health care mode	Yes	No

Table 2. Categories formed by open coding of interview content.

Behavior change stage, category, and initial concept	Representative original sentences
Intention stage	
Disease threat	
Encountering problems	*My cervical vertebra has some issues. Looking at my phone too much, due to my age, so I exercise to relieve the discomfort in my cervical vertebra.* [P5]
Worsening of symptoms	*My heart wasn't very good before. The doctor told me to try to increase the vitality of my heart. The lazier you are, the worse your heart condition gets.* [P7]
Susceptibility to disease	
Frailty due to aging	*As I've gotten older, my health has declined.* [P8]
Decline in function	*Now our physical functions are not as good as those of younger people. If we don't exercise more, it won't work.* [P8]
Hazards of prolonged sitting	*If you don't exercise and just lie down for a long time without moving, you'll definitely have health problems later on.* [P4]
Sense of family responsibility	
Reducing children's worries	*Although my children are grown up, I am still their support. If I am healthy, they will worry less.* [P9]
Promoting family health	*If I learn scientific exercise methods, I want to exercise with my family. Won't our family all be healthy then?* [P10]
Family support	
Support from children	*My children also strongly support me participating in this.* [P5]
Companionship of spouse	*Usually, my spouse and I play badminton together.* [P1]
Doctor's advice	
Doctor's notification	*The doctor told me to try to increase the vitality of my heart.* [P7]
Friend's recommendation	
Recommending participation	*My friend Yue ** joined first and spoke highly of your place, so she recommended me to join personalized exercises here.* [P6]
Media publicity	
Broadcasting publicity	*Initially, it was mainly through some radio broadcasts that I learned about the benefits of exercise.* [P5]
Preparation stage	
Technological awareness	
Scientifically expectations	*Your personalized exercise program must be well-organized and scientifically based.* [P1]
Organizing positive	*This exercise prescription must have benefits for the exercise of a specific body structure or physical fitness.* [P1]
Authoritative projects	*According to my daughter-in-law, she said, "Mom, there is a health program here in collaboration with a medical college and the University of Science and Technology of China. They provide free health checkups and tailor personalized exercise prescription for you. They also guide how to exercise. They are here to promote health. You should go and take a look. It's much better than those deceptive health products.*" [P2]
Exercise preparation	
Preparing sports equipment	*In order to adhere to the exercise prescription properly, I even prepared specific exercise clothing and shoes.* [P5]
Peer support	*At the beginning, I arranged to exercise together with a few people.* [P1]
Action stage	
Service hedonism	
Problem-solving	*It's great that you can explain any questions we don't understand so well.* [P3]
Thorough guidance	*You health providers are so thoughtful in explaining the examination reports and guiding us in exercise.* [P5]

Behavior change stage, category, and initial concept	Representative original sentences
Careful inspection	*Your staff are very meticulous in every examination, both before and after exercise.* [P4]
Professionalism of the service provider	*You have a lot of knowledge and explain things very well...* [P12]
Comprehensive reporting	*The reports you provide are very clear and comprehensive.* [P8]
Social hedonism	
Making friends	*During exercise, you can also make many friends (especially outdoors).* [P6]
Physiological benefits	
Symptom control	*Before, I had high blood sugar, but now my blood sugar is also very good.* [P6] *I used to have constipation, and it's still there, but the frequency has decreased...* [P5]
Physical improvement	*There has been an improvement in my body. I used to have high blood pressure and unstable blood pressure, but now it's very stable.* [P2]
Increasing physical activity	*Look, I can raise my arms very high now (demonstrating a posture).* [P2]
Psychological benefits	
Feeling relaxed	*After exercising, I feel my mood is more relaxed, my body feels better, and I have more energy than before.* [P3]
Energetic	*Now, both mentally and energetically, I am better than before.* [P2]
Experiencing well-being	*(After being guided on walking posture) When the heels touch the ground, I involuntarily straighten up, walking with chest out and stomach in, it feels particularly good, this kind of feeling...* [P6]
Personal benefits	
Acquiring knowledge	*Compared to before, I have learned how to exercise with proper posture, how to relax after exercising, and how to stretch...* [P2]
Free medical checkups	*They also conducted physical examinations for us, checking our bones and bone density, teaching us how to improve. They told me that my bone density had reached the bottom line and couldn't decline further, advising us to drink milk and eat eggs daily, as well as recommending specific vegetables. They explained it very thoroughly.* [P4]
Maintenance stage	
Self-management	
Perseverance	*I can persevere because that's my personality. Once I set my mind on something, I persist until I succeed, no matter what obstacles I face.* [P6]
Forming habits	*To develop a good exercise habit, I have to wake up at a certain time every day.* [P2]
Strict self-discipline	*I must be strict with myself and not make excuses like "it's cold today" or "it's windy" to forgive myself. I need to ensure that I accomplish what needs to be done.* [P2]
Flexibility adjustment	
Persisting to completion	*If I don't meet the planned exercise volume today, I'll make up for it tomorrow by sticking to the previous day's shortfall.* [P6]
Adapting flexibly	*I follow the exercise routine as advised by you. On rainy days, I use the treadmill at home, ensuring I meet the required exercise volume while exercising in a way I enjoy.* [P4]
Fulfillment of needs	
Adding videos	*It would be great if it could be turned into a video. The report is easy to misplace, and it's easier not to forget with a video, especially at our age...*[P1]
Enriching images	*I have a small suggestion. There are too few exercise images in our medical reports. It would be nice if they could be more varied. Otherwise, everything else is quite good.* [P10]
Positive feedback on results	
Good results upon retesting	*After exercising and reassessing my health, I found that I'm doing well. My grip strength is still good, and I'm almost reaching eighty kilograms. I'm still going strong. Hehehe (laughs happily).* [P4]
Ignition of exercise enthusiasm	
Eagerness to exercise	*After exercising for a while, I feel very enthusiastic about it, as if I'm eager to participate in sports from the bottom of my heart.* [P5]

Behavior change stage, category, and initial concept	Representative original sentences
Exercising voluntarily	*Having a workout plan makes me feel psychologically engaged. When it's time, I feel like I should exercise, and there's a sense of awareness, a kind of concern, that makes me want to work out.* [P6]
Pan-stage factors	
Personal limitations	
Struggling to persist	*Sometimes, doing exercise alone is difficult, so doing group activities helps.* [P7]
Lack of exercise interest	*However, later on, my legs felt better. Originally, I didn't like exercising and didn't do much exercise.* [P3]
Physical discomfort	*Because of my bad back, my legs hurt when I walk. So, I'm not good at walking and don't exercise much.* [P3]
Bodily fatigue	*Sometimes when I feel tired, I don't feel like exercising.* [P1]
Prone to forgetfulness	*I can't remember the exercise prescription because I'm old and forgetful. I used to stick to it at the beginning, but later, I did less, and I always forget the movements.* [P8]
External constraints	
Lack of resources	*There are no good places near my home. There is a small Friendship Square, but there is no track or facilities.* [P2]
Unable to free oneself	*The children need to come here for meals, buy groceries in the morning, and cook. It's usually fine, but sometimes it's overwhelming when I'm busy.* [P3]

Table 3. Main categories formed by interview content axial coding.

Behavior change stage, main category, and category	Definition
Intention stage	
Intrinsic motivation	
Disease threat	Perception of adverse health consequences resulting from one's current condition.
Susceptibility to disease	Adverse physical conditions, declining quality, and unhealthy lifestyle habits are more likely to trigger diseases.
Sense of family responsibility	Reduce the burden on the family and family members' worries and promote the health, harmony, and stable development of the family.
Extrinsic motivation	
Family support	Material or emotional support provided by family members.
Doctor's advice	Reasonable advice from doctors based on individual conditions to improve individual situations.
Friend's recommendation	Verbal introductions from friends that are hoped to be accepted and adopted.
Media publicity	Dissemination and transmission of information through information dissemination tools.
Preparation stage	
Achievement motivation	
Technological awareness	Understanding and familiarizing oneself with the intelligent personalized exercise prescription system.
Exercise preparation	Planning and preparing for upcoming exercise activities.
Action stage	
Hedonic motivation	
Service hedonism	Enjoy and experience high-quality, professional exercise testing and guidance services.
Social hedonism	Expand social connections, make friends, and enjoy the pleasure and benefits of social interaction.
Benefit motivation	
Physiological benefits	Control of adverse physiological symptoms of diseases and improvement in physical function or capability.
Psychological benefits	Improved mental state and psychological well-being, as well as increased energy.
Personal benefits	Personal access to free benefits, such as exercise and health knowledge, physical fitness, and health assessments.
Maintenance stage	
Self-regulation	
Self-management	Self-control and using inner strength for behavior change or habit formation.
Flexibility adjustment	Flexibly adjust according to individual circumstances within a certain range.
Optimization solutions	
Fulfilling needs	Fulfill the requirements arising from individual needs.
Positive feedback on results	Following the positive feedback from intelligent personalized exercise prescription to encourage better adherence.
Ignition of exercise enthusiasm	Stimulating or enhancing interest and enthusiasm for exercise through various means.
Pan-stage factors	
Perceptual barriers	
Personal limitation	Limitations imposed by individual conditions on accomplishing tasks.
External constraints	Limitations imposed by external factors beyond the individual on accomplishing tasks.

Table 4. Core categories formed by interview content selective coding.

Core category and main category	Definition
Multiple behavioral motivations	
Hedonic motivation	Behavioral motivation generated from the pursuit of the pleasant feelings brought by exercise.
Benefit motivation	Behavioral motivation arising from the actual benefits that can be obtained by following the exercise prescription.
Intrinsic motivation	Behavioral motivation originating from the individual's internal needs and perceptions.
Extrinsic motivation	Behavioral motivation resulting from the support and incentives of external factors.
Achievement motivation	Behavioral motivation arising from the expectation of achieving good performance or reaching specific goals by adhering to the exercise prescription.
Problem-solving strategies	
Self-regulation	Self-management and adjustment of an individual's behavior or thinking for better compliance with the exercise prescription.
Optimization solutions	Improvement measures and solutions for enhancing the compliance effect and adherence to the exercise prescription.
Obstacle factors	
Perceptual barriers	Difficulties and obstacles that an individual subjectively perceives as restricting their exercise in accordance with the exercise prescription.

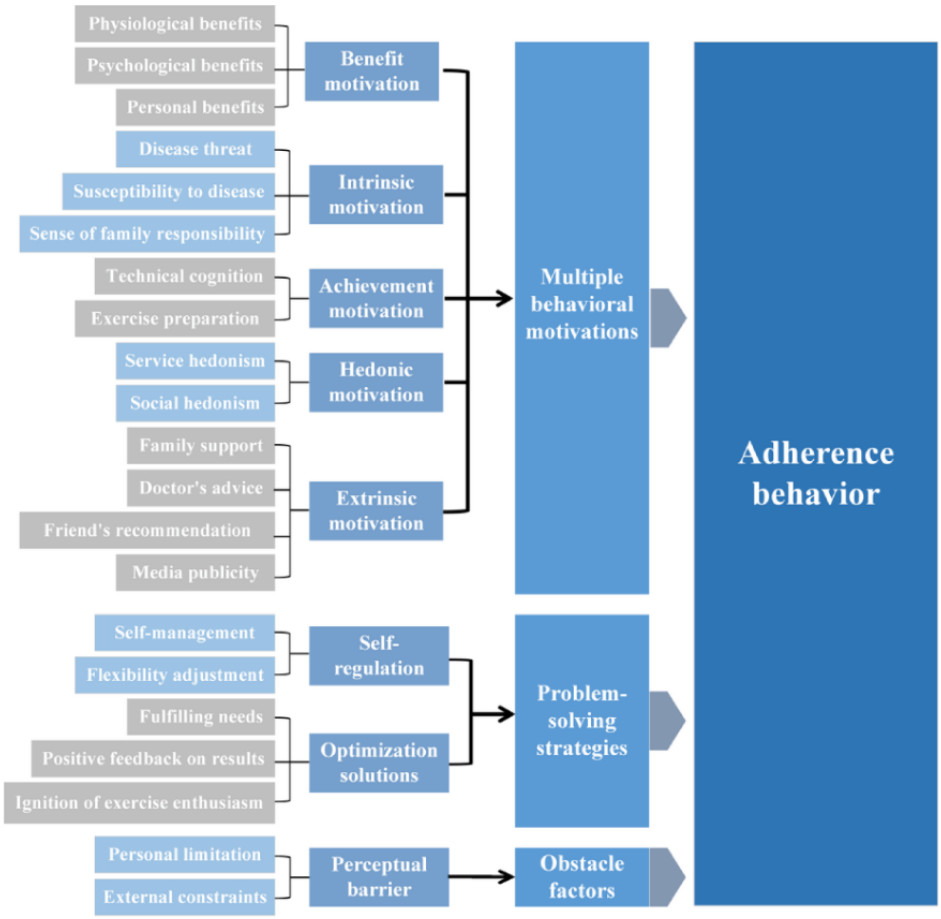

Figure 3. The implementation path model of adherence behavior to intelligent personalized exercise prescription based on the Transtheoretical Model and Multiple Behavioral Motivation Theory.

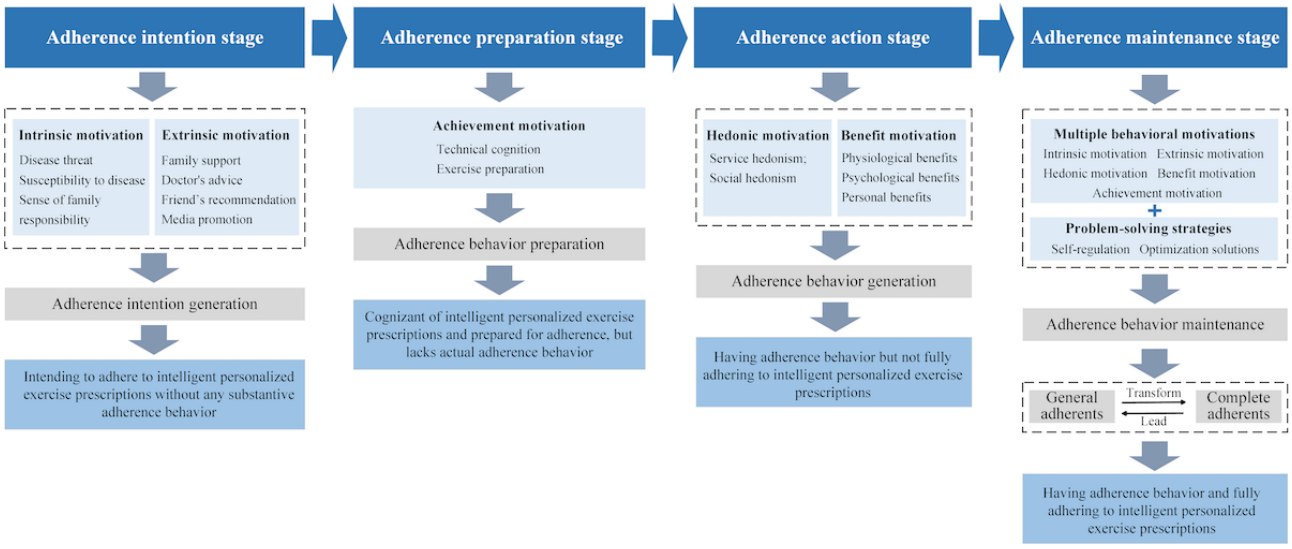

Factors Influencing Adherence Behavior With Intelligent Personalized Exercise Prescription and Pathways for Implementation

Multiple Behavioral Motivational Factors

Motivation is the central factor driving behavior change and serves as the intrinsic force behind individuals' actions [46,47]. This study explores how various motivations—hedonic, benefit, intrinsic, extrinsic, and achievement—affect participants' adherence to intelligent personalized exercise prescriptions. These motivations directly influence adherence behaviors [48]. (1) Intrinsic motivations (eg, perceived disease threat and susceptibility, sense of family responsibility) and extrinsic motivations (eg, family support, doctor recommendations, friend referrals, and media publicity) drive participants to develop an intention to adhere to the intelligent personalized exercise prescription. This phase, referred to as the "adherence intention stage," involves participants forming the intention to adhere, but without yet engaging in actual adherence behaviors. (2) After forming the intention to adhere, participants are driven by achievement motivation, aiming to reach self-set goals through adherence to the exercise prescription. At this stage, they begin preparing for adherence by seeking information about the exercise prescription and acquiring the necessary equipment. This phase, known as the "adherence preparation stage," builds upon the previous stage but does not yet involve actual adherence behavior. (3) When participants have a strong intention to adhere and are well-prepared, they enter the "adherence action stage" [49], where actual adherence behavior takes place. During this stage, high-quality health guidance, positive service experiences, and expanded social connections foster hedonic motivation. Additionally, the physiological and psychological benefits of adherence, increased health knowledge, and free health checkups provided by health care providers contribute to benefit motivation. Furthermore, hedonic and benefit motivations play a key role in sustaining and further developing adherence behavior during this phase. Therefore, the various motivations influencing participants in the context of intelligent personalized exercise prescriptions are crucial in the first 3 stages and serve as the primary drivers of adherence behavior.

Obstacles

"Perceptual barriers," or obstacles, are critical factors affecting adherence behavior. These barriers can undermine an individual's confidence and motivation, thereby hindering the sustainability of adherence. They negatively impact both the initiation and maintenance of adherence [50]. The findings by Kilgour et al [51] suggest that these obstacles stem from both individual limitations and external constraints. Individual limitations include disliking exercise, difficulty adhering due to personal traits, memory decline that causes the exercise prescription to be forgotten, and physical ailments or fatigue that prevent adherence. External constraints include insufficient exercise facilities, lack of necessary equipment, and a busy family life that interferes with following the exercise prescription. These factors impede the sustainability of adherence behavior and may lead participants to discontinue or abandon it. As obstacle factors do not occur exclusively in a specific stage of adherence behavior transformation but rather persist throughout each stage, they are classified as "pan-stage factors" during the coding process and the division of behavior change stages. These factors are independent of the 4 distinct stages of behavior change.

Solution Strategies

From the qualitative interview data, we extracted shared experiences, suggestions, and needs from participants, which were ultimately distilled into another key factor influencing adherence behavior: "problem-solving strategies." These strategies help promote the initiation and continuity of adherence behavior. "Problem-solving strategies" encompass participants' self-regulation and the optimization and enhancement of the exercise prescription intervention schemes. Participants can better promote adherence behavior through self-management, strict self-discipline, habit formation, resilience enhancement, and flexible adjustment of exercise time or location based on individual circumstances. Health service providers and intervention planners can address participants' needs by

incorporating relevant images and videos into the exercise prescriptions, thereby enhancing participants' motivation and enthusiasm for exercise. They can also regularly schedule or appropriately increase the frequency of health checkups, allowing participants to experience the positive health outcomes of adhering to the exercise prescription. This, in turn, generates positive feedback and promotes the sustained continuity of adherence behavior.

With diverse motivations and problem-solving strategies, adherence behavior progresses into the "adherence maintenance stage." In this phase, individuals who initially adhered gradually transition to full adherence. Fully adherent individuals then become role models, leading and motivating others to achieve complete adherence.

Discussion

Principal Findings

Overall, this study explores adherence behavior to intelligent personalized exercise prescriptions, identifies key influencing factors, and constructs a model that outlines the adherence pathway. The findings indicate that behavioral motivation is the primary driver of adherence, with motivations varying across stages. Intrinsic and extrinsic motivations predominantly influence the early stages, while benefit and hedonic motivations become more significant during the maintenance stage. This suggests that intervention strategies should be dynamically tailored to the individual's stage of behavior change. Additionally, self-regulation and optimization strategies play a crucial role in promoting adherence. Perceived barriers, such as individual limitations and external conditions, can hinder adherence. Moreover, diverse behavioral motivations drive the entire adherence process, facilitating the transition from intention to preparation, action, and ultimately to maintenance.

Enhancing Intrinsic and Extrinsic Motivations to Promote Adherence Intentions and Behavior Preparation

Consistent with the findings reported by Almagro et al [52], both intrinsic and extrinsic motivations contribute to the formation of adherence intentions, signaling the beginning of the intention stage. During this stage, individuals are motivated by intrinsic factors, such as perceived disease threat and susceptibility, as well as extrinsic factors, including support and encouragement from family and society, to adhere to intelligent personalized exercise prescriptions. However, individuals have not yet taken concrete action at this stage. To facilitate progression, it is essential to enhance health education and improve health literacy, thereby strengthening intrinsic motivation. Additionally, providing diverse forms of social support (eg, from family, friends, and doctors) can bolster extrinsic motivation [34,35]. Once individuals transition into the preparation stage, they develop a clearer understanding of their adherence goals and begin making preparations. At this stage, achievement motivation becomes the dominant driving force behind behavioral change.

Satisfying Individual Motivations and Aligning Feedback Mechanisms to Enhance the Maintenance of Adherence Behavior

When individuals begin to engage in adherence behavior, they enter the action stage. At this point, their hedonic and benefit motivations are partially fulfilled, which reinforces their adherence. However, full adherence may not yet be realized. Positive feedback from the outcomes of their behavior plays a critical role in sustaining adherence [53,54]. Therefore, it is essential to provide timely and encouraging feedback during this stage to support continued adherence. A positive feedback loop can enhance patients' exercise self-efficacy, thereby promoting sustained adherence. When individuals' diverse motivations are fulfilled and their adherence challenges are addressed through effective strategies, they transition fully from the action stage to the maintenance stage. In this stage, partial adherents gradually evolve into full adherents. These fully adherent individuals, in turn, can serve as role models, guiding and supporting those still in the action stage, helping them achieve full adherence.

Application of the TTM in Constructing Pathways for the Realization of Adherence Behavior

The precontemplation stage of the TTM refers to individuals who have no intention of changing their behavior within the next 6 months and are not considering any changes. This study, which uses a descriptive exploratory qualitative design within a longitudinal investigation of the effects of intelligent personalized exercise prescriptions on the health of middle-aged and older community residents, includes only participants who have already expressed an intention to change their behavior. Therefore, participants in the precontemplation stage are excluded from this study. As a result, the adherence pathway model developed for this research includes only the 4 stages of the TTM: intention, preparation, action, and maintenance. Additionally, integrating the Multiple Behavioral Motivation Theory with the TTM provides a comprehensive framework for understanding and enhancing adherence to exercise prescriptions. Future research should explore the interactions among various motivational factors and examine their specific effects on adherence behavior.

Enhancing Individual Self-Efficacy to Promote Effective Adherence Behavior

Through qualitative interviews and subsequent analysis, we found that participants with prior successful behavior change experiences (eg, quitting smoking, reducing alcohol consumption, or losing weight) exhibited a stronger intention to adhere to intelligent personalized exercise prescriptions. They also demonstrated better and more sustained adherence compared with others. This can be attributed to their previous successes, which enhanced their self-efficacy for behavior change [50,55,56]. Therefore, future interventions aimed at improving adherence should focus on boosting individual self-efficacy to facilitate effective and lasting adherence behaviors.

Strategies for Promoting, Implementing, and Optimizing Personalized Smart Exercise Prescription in the Community

To enhance the promotion, implementation, and optimization of personalized smart exercise prescriptions, we propose several strategies. First, targeted exercise health education and training activities should be organized within the community to improve exercise literacy and adherence intentions among middle-aged and older residents. Additionally, utilizing channels such as social media and community bulletin boards to disseminate information can help increase awareness and acceptance of personalized smart exercise prescriptions. Second, social cognitive methods have proven effective in promoting and maintaining health behavior changes [57]. Thus, using diverse social support strategies can enhance and sustain adherence to personalized smart exercise prescriptions. For example, creating a support network that includes family, friends, and health care providers can offer emotional support, encouragement, and supervision, helping individuals overcome challenges during exercise.

Additionally, establishing regular feedback mechanisms and offering appropriate incentives are crucial for enhancing adherence behavior [58]. Future efforts should consider utilizing smart health devices or apps to provide timely feedback on exercise performance and health improvements for individuals following personalized smart exercise prescriptions [59,60]. Based on this feedback, the exercise prescription can be continuously optimized and adjusted. For example, individuals without access to exercise spaces could be provided with home-based exercise plans. Additionally, adjusting the intensity, frequency, and type of exercises within the prescription can help overcome obstacles, enhance exercise achievements, and improve adherence to the personalized smart exercise prescription. Regarding incentives, implementing reward systems such as point-based rewards and fitness competitions [61] could stimulate both intrinsic and extrinsic motivations, thus promoting and maintaining adherence behavior. Finally, establishing a long-term tracking mechanism to regularly assess adherence to the personalized smart exercise prescription and overall health status is essential. Providing ongoing support and guidance is crucial for helping individuals maintain adherence behavior over the long term.

Study Limitations

First, this exploratory study has a limited sample size. Although small, the sample has reached theoretical saturation, meaning that adding more participants is unlikely to yield new insights. Second, despite using purposive sampling, selection bias may still be present, as participants with positive attitudes or better adherence to the personalized smart exercise prescription may have been more inclined to participate. To mitigate this, we specifically recruited participants with moderate to low attitudes toward personalized smart exercise prescriptions or those who self-reported low adherence. Additionally, the study focused exclusively on middle-aged and older community residents, excluding other potentially relevant groups, such as working adults or adolescents. This limitation affects the generalizability of the findings. Therefore, future research should include a broader range of populations for comparative analysis to provide a more comprehensive understanding of adherence behavior and its influencing factors across different groups.

Furthermore, qualitative research methods are inherently subjective. Although our study used rigorous qualitative analysis to minimize bias, incorporating quantitative methods could provide more objective data, thereby enhancing the credibility and scientific rigor of the results. Future research should adopt a mixed methods approach, combining both qualitative and quantitative data to gain a more comprehensive understanding. This study, as a qualitative component of a longitudinal investigation on the effects of intelligent personalized exercise prescriptions for middle-aged and older community residents, focuses on a specific cloud-based system. As a result, the generalizability of the findings may be limited. Future research should explore different intelligent personalized exercise prescription systems to validate the broader applicability of the findings. Additionally, the relatively low educational level of the participants may affect the representativeness of the results. Future studies should include participants with diverse educational backgrounds to ensure a more varied sample, gather comprehensive data, and enhance the representativeness of the findings.

Finally, the short duration of this study limited our ability to track long-term adherence behavior. Future research should incorporate long-term follow-ups to assess sustained changes in adherence and provide more comprehensive insights and practical guidance.

Conclusions

This study adopts a descriptive, exploratory, qualitative design nested within a longitudinal study examining the impact of intelligent personalized exercise prescriptions on the health of middle-aged and older community residents. Through individual, face-to-face, semistructured interviews with 12 participants who had adhered to the intelligent personalized exercise prescription for at least 8 months, received exercise health education materials, and received detailed explanations and guidance from staff, we identified 8 main categories and 3 core categories, integrating the TTM and various behavioral motivations. Furthermore, we developed a model illustrating the factors influencing adherence to intelligent personalized exercise prescriptions and the pathway of adherence behavior, based on the TTM and various behavioral motivations. This comprehensive approach deepens the understanding of both the positive and negative factors influencing adherence, as well as their implementation pathways. It also facilitates the development of targeted intervention strategies to enhance adherence, ultimately maximizing the health benefits of exercise.

Abstract

Background: Mindfulness practices, such as breathing meditation (BM), reduce stress and enhance mood. One such practice is mindful eating, where a practitioner focuses on the five senses while eating or drinking. A novel set of prototypes has been developed, incorporating principles of mindful eating. These prototypes include matcha green tea and a mobile app that provides audio guidance for meditation during the preparation and consumption of the beverage (hereafter referred to as guided tea meditation [GTM]).

Objective: This study assessed the feasibility and efficacy of GTM, evaluating meditation time, frequency, and prototype acceptability over 8 weeks, alongside changes in stress and mood. Additionally, other benefits of GTM were explored.

Methods: A comparator group was established in which participants performed traditional BM without an app or audio guide (active control). This unblinded randomized controlled trial involved 100 healthy American volunteers (n=49 GTM, n=51 BM). During the 8-week study period, participants were encouraged to perform either GTM or BM for 10 minutes daily. The meditation activity was self-reported the following day. Only the GTM group assessed the prototype acceptability. The Perceived Stress Scale-10 was used to measure stress levels, while the Two-Dimensional Mood Scale was used to evaluate mood changes. Other meditation benefits were explored using a questionnaire. All questionnaires were presented and completed via an app. An intention-to-treat analysis was performed.

Results: No significant between-group differences were found in total meditation time (P=.15) or frequency (P=.36). However, the weekly time and frequency of the GTM group remained above 50 minutes per week and 4 days per week, respectively. Over half of the GTM participants (≥28/49, ≥57%) accepted the prototype. The GTM group exhibited significant stress reductions at weeks 4 and 8 (both P<.001), similar to the BM group. Improvements in mood metrics were observed after a single GTM session on days 1 and 56, similar to the BM group. Moreover, increases in premeditation scores for relaxed and calm from day 1 to day 56 were significantly higher for the GTM group (P=.04 and .048, respectively). The majority of participants (≥25/49, ≥51%) assigned to GTM experienced positive changes in happiness, time management, quality of life, relationships, sleep, and work performance as they continued meditating. However, no significant between-group differences were found in these exploratory outcomes (P>.08).

Conclusions: We believe that GTM exhibits good feasibility. Meanwhile, GTM reduced stress, improved mood, and let the practitioners feel other benefits, similar to BM. Long-term practitioners of GTM may even feel more relaxed and calmer in the state of premeditation than those who practice BM.

Introduction

Background

Stress management or reduction is an important skill for many individuals because of the increasing occurrence of stress, anxiety, and depression. Indeed, approximately one-third of the global population experiences stress [1]. The United States is one of the most stressed nations in the world, with more than three-fourths of American adults reporting symptoms of stress, including headache, tiredness, and sleep problems [2]. This problem was exacerbated by the COVID-19 pandemic and people still struggle to adapt to the rapid changes caused by the pandemic [3-5]. Stress not only affects mood and mental health but also physical health, either directly by disturbing the autonomic nervous and neuroendocrine systems or indirectly by causing changes in health behaviors [6]. Thus, it is important to assess and encourage stress-lowering techniques to achieve well-being and tranquility in life.

Mindfulness-based approaches have been increasingly used to help individuals respond more effectively to stress and other negative internal experiences. Participation in an 8-week mindfulness-based stress reduction (MBSR) program lowered stress and anxiety symptoms [7,8]. Breathing meditation (BM; referred to as sitting meditation with awareness of breathing in the MBSR program) is the main technique that program participants are encouraged to practice daily [9]. During the meditation, a practitioner pays attention to bodily sensations that accompany breathing, and whenever they notice their mind wandering, they note what diverts their attention and subsequently redirect it to breathing [10]. Studies have demonstrated the positive effects of a 10-minute BM on emotion regulation and attention control [11,12].

MBSR programs provide a variety of mindfulness techniques other than BM and participants are encouraged to seek as many opportunities as possible to practice these techniques in their daily lives [10]. One such technique is mindful eating, in which a practitioner pays attention to the sight, smell, taste, texture, and temperature of food, as well as their thoughts and feelings while eating [13]. Several studies have shown a correlation between the degree of beneficial traits or effects that practitioners can obtain from meditative training and the total time or frequency of meditation [12,14,15]. Therefore, it seems reasonable to use time spent eating and drinking, which is an essential part of living, as an opportunity to practice mindfulness.

Japan has a long-standing tradition of tea ceremony where matcha green tea is served to guests. The ceremony has been shown to have a calming effect on participants [16,17]. Regarding taste, matcha green tea tastes sweet and umami (savory), as well as bitter [18]. We believe this differentiates matcha green tea from other beverages such as regular green tea and coffee, enabling practitioners to cultivate their awareness while focusing on the different tastes. Hence, we developed a dedicated matcha green tea for mindful eating as a prototype. Moreover, a prototype mobile app that provides audio guidance to perform meditation while making and drinking the beverage was developed. Hereafter, the whole program for stress management provided by the novel set of prototypes is referred to as guided tea meditation (GTM).

There are several commercial mindfulness apps that guide mindful eating. However, to the best of our knowledge, they are mainly intended for weight control [19]. Their efficacy on mental health, such as stress levels and mood, is limited [20], and no commercial products exist that incorporate an app and food for cultivating mindfulness.

Objective

This study aimed to investigate the feasibility and efficacy of GTM. To assess feasibility, the time and frequency of meditation using the prototypes were evaluated over 8 weeks. Additionally, the acceptability of the prototypes was evaluated. To assess efficacy, changes in stress levels over 8 weeks and changes in mood before and after single and multiple meditation sessions were investigated. Moreover, other benefits of GTM were explored using a questionnaire. The findings of this study may facilitate the collaboration between the two different fields, mobile health and food science.

Methods

Ethical Considerations

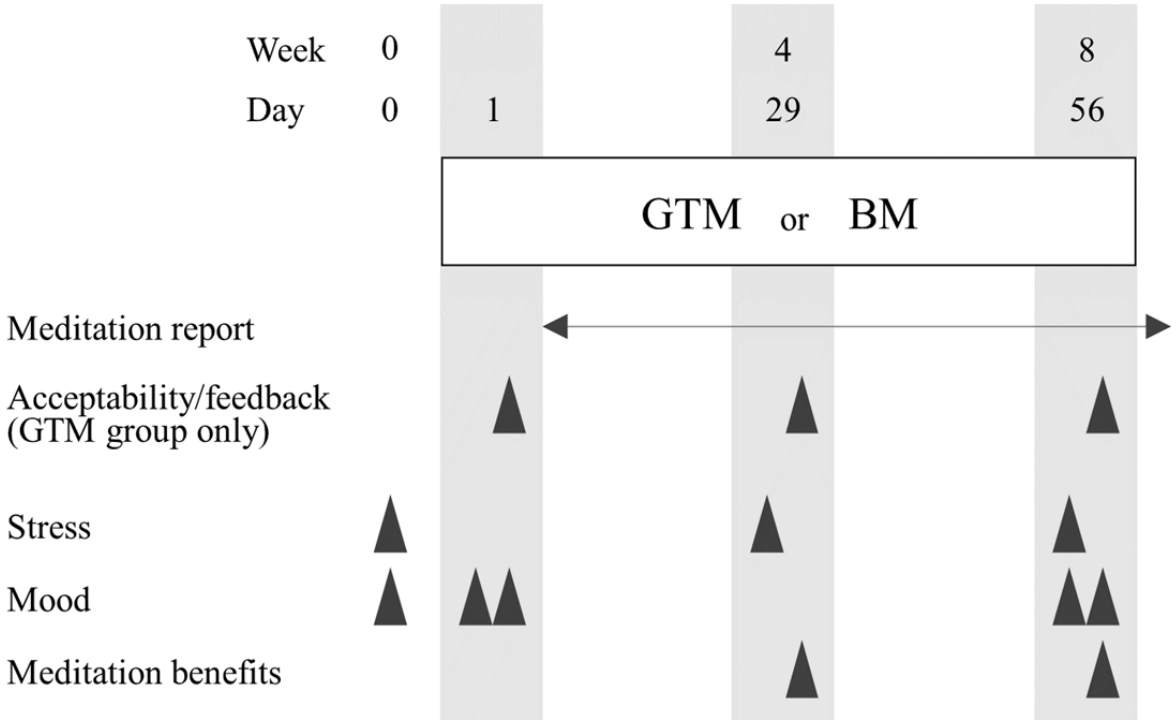
This study was approved by the Sterling IRB (Atlanta, Georgia; approval: 10829), registered at ClinicalTrials.gov (registration: NCT05832645), and conducted by Biofortis Clinical Research in accordance with the Declaration of Helsinki. All participants provided electronic consent before participating in the study. Data were anonymized and then analyzed. Email and Apple IDs were collected from the participants assigned to the GTM group for user authentication of the prototype app and stored with limited access. Other personally identifiable information was kept in strict confidence. Participants received a US $250 Visa gift card for completing all the surveys given below and were informed that the number and duration of the meditation sessions would not affect the stipend.

Trial Design

A comparator group was established in which participants performed traditional BM without an app or audio guide (active control), and this study used a randomized, unblinded, parallel-group design. Web-based screening was conducted to

assess eligibility and perceived stress levels. Given the results, eligible participants were asked to download the Castor Connect mobile app (Castor Connect) and allocated 1:1 to the GTM or BM group. Participants were encouraged to perform their assigned study intervention daily during the 56-day (8-week) intervention period. The duration was set according to the MBSR program. The meditation session performed on the previous day was self-reported by the participants via the mobile app. The acceptability of the prototypes was assessed and participant feedback was obtained only in the GTM group on days 1 (after the first use), 29, and 56 (after the last use). Perceived stress levels were assessed at weeks 0 (screening), 4 (day 29), and 8 (day 56). The mood was assessed before and after the first (day 1) and last (day 56) meditation sessions. A survey to explore the benefits of meditation was conducted at weeks 4 (day 29) and 8 (day 56). All questionnaires were presented and completed via the app. The study scheme and evaluation points are shown in Figure 1.

Figure 1. Study scheme. BM: breathing meditation; GTM: guided tea meditation.



Participants

The participants were recruited in May 2023 via email, websites, flyers, and Facebook. The main inclusion criteria were (1) aged 20-49 years; (2) born in the United States; (3) self-reported history of meditation, but no meditation within 30 days (one month) of screening; (4) access to an Apple ID, an email address linked to the Apple ID, and a dedicated smartphone (iPhone 8 or newer models with iOS 16 or newer versions) capable of downloading and running the app; (5) the ability to download, install, and update apps using a smartphone; (6) access to hot water to prepare the matcha green tea beverage; and (7) a willingness to maintain habitual diet (including supplements), lifestyle, and physical activity during the study. The third inclusion criterion was based on the product marketing strategy. The main exclusion criteria were as follows: (1) visual or hearing impairments that could not be corrected with glasses, contact lenses, or hearing aids; (2) self-reported taste or smell impairments within 30 days of screening; (3) a condition that prevented caffeine consumption (eg, caffeine sensitivity and underlying heart condition); and (4) contraindication, allergy, or sensitivity to any components in the study product or allergens present in the facility used to manufacture or pack the study product. A full list of the inclusion and exclusion criteria is available [21]. Based on their responses to the prescreening questionnaires, qualified participants proceeded to provide electronic informed consent for study participation. Eligible participants had a video call with the clinic staff to review the study instructions and confirm when to start the intervention.

Interventions for the GTM Group

Participants were instructed to perform GTM using the prototype, ekkomi center me (Otsuka Holdings Co Ltd). ekkomi center me consists of matcha green tea and a mobile app that delivers audio guidance to perform meditation while making and drinking the beverage. Audio guidance consists of three parts: (1) a guide for a relaxing introductory exercise, such as progressive muscle relaxation and guided imagery [22,23] (five variations); (2) a guide for meditation with matcha green tea (GTM); and (3) a guide for refocusing. Users could choose a voice actor out of three options and a background sound out of four options every time they used it. The total duration of all audio clips was designed to be approximately 10 minutes, considering time constraints. The contents of the app and audio clips were developed by a psychiatrist and mindfulness experts, as mentioned in the *Acknowledgments* section. Screenshots of the prototype app and an example of the audio script for GTM are provided in Multimedia Appendices 1 and 2, respectively. The flavor of matcha green tea was adjusted for a balanced taste profile with bitterness, sweetness, and umami, and the tea was

attached to a stick so that a user could easily make the tea beverage and pay attention to its complex but pleasant taste. The appearance of the prototype matcha stick is shown in Multimedia Appendix 3. The sticks were individually packed so that the participants could carry them.

Participants assigned to GTM received a packet that included the matcha sticks for 8 weeks and instructions to download the prototype app through TestFlight (attached to Multimedia Appendix 4). The participants were encouraged to perform GTM once a day for 8 weeks and were asked to report the time and frequency of meditation. Participants could choose when and where to meditate freely, and they were not prompted to meditate during the intervention period.

Interventions for the BM Group (as the Active Control)

Participants assigned to BM received a packet that included instructions to perform BM (Multimedia Appendix 5). They were encouraged to perform BM for at least 10 minutes per day according to the instructions. In traditional mindfulness-based programs such as MBSR, practitioners are encouraged to meditate for more than 45 minutes daily [9]. Therefore, the meditation time was not limited. Participants could choose when and where to meditate freely, and they were not prompted to meditate during the intervention period.

Outcomes

The total meditation time and frequency during the study period were calculated as the primary outcome measures based on the daily meditation reports of the participants. Frequency was defined as the number of days in which the participants completed at least one meditation session. Weekly meditation time and frequency were calculated and compared between the groups as secondary measures.

Changes in stress levels were assessed as secondary outcomes using the Perceived Stress Scale-10 (PSS-10) [24]. The total score ranges from 0 to 40, with higher scores indicating higher levels of stress. Mood metrics were also assessed as secondary outcomes using the Two-Dimensional Mood Scale [25]. In addition to the original 8 components (ie, calm, energetic, irritated, lethargic, listless, lively, nervous, and relaxed), measures of focus and anxiety were assessed using a 6-point Likert scale ranging from 0=Not at all to 5=Extremely. Changes from pre- to postmeditation scores and changes in premeditation scores over the study period were compared between groups. Other benefits of meditation were explored at weeks 4 and 8 by asking participants whether they noticed any positive changes in feelings of happiness, time management, physical discomfort, quality of life, relationships, sleep, and work performance. The answers were collected on a 5-point scale ranging from 1=Strongly Agree to 5=Strongly Disagree.

Sample Size

Because this was the first study to assess the feasibility and efficacy of GTM, the anticipated effect size was not available. We referred to two previous studies that evaluated mindfulness apps and recruited approximately 100 participants for two arms [20,26]. Under continuous outcome conditions with 100 participants (50 per arm), there was 80% power to detect an effect size of 0.57 using a 2-sided *t* test at a significance level of .05.

Randomization and Blinding

Participants were randomly assigned to one of the two intervention groups using a variable block randomization model with block sizes of 4 and 6 following an algorithm that automated randomization assignment in the Castor Platform. Randomization was 1:1 stratified by sex (male or female) and the screening score on the PSS-10 (0-17 [below-average stress] and 18-40 [above-average stress]). The average stress levels were based on a mean of approximately 17 in a sample of 2370 American men and women aged ≤45 years [27]. Hence, 100 eligible participants were enrolled in the GTM (n=49) or BM (n=51) group. The study staff and participants were unblinded to the group allocation.

Statistical Methods

An intention-to-treat (ITT) analysis was performed for all outcomes. The number of minutes of meditation over 56 days was compared between groups using a 2-tailed *t* test. Additionally, the response profile for all continuous outcomes measured over time (eg, stress levels and the weekly number of minutes meditated) was evaluated using a repeated-measures model. The outcome measured at each time point was included in the response vector, including the baseline. The covariance structure for the repeated measures was selected based on the minimization of the corrected Akaike information criteria. The model contained terms for time point, group, and time point by group interaction. Contrast or estimate statements were used to calculate the within-group change from baseline to each specified time point, as well as the between-group difference in the change from baseline. The frequency of meditation was evaluated using a generalized linear model following negative binomial regression and log link. The weekly frequency was explored using a generalized linear mixed model, where the model fit was similar to the repeated-measures model for continuous outcomes measured over time. To analyze within- and between-group changes in mood metrics, the Wilcoxon signed rank test and Wilcoxon rank sum test were used, respectively. Responses to the meditation benefit survey were recategorized (ie, strongly agree or agree, undecided, and disagree or strongly disagree) and compared between the groups using Fisher exact test.

In cases where meditation activity was not reported, the meditation time and frequency for the day were treated as zero. Missing data for stress and mood scores were not imputed, and only observed data were included in the analysis.

All tests were 2-sided and performed at a .05 significance level. Statistical analyses were performed using Statistical Analysis Systems Software (version 9.4; SAS Institute) and R (version 4.2.2; R Foundation for Statistical Computing).

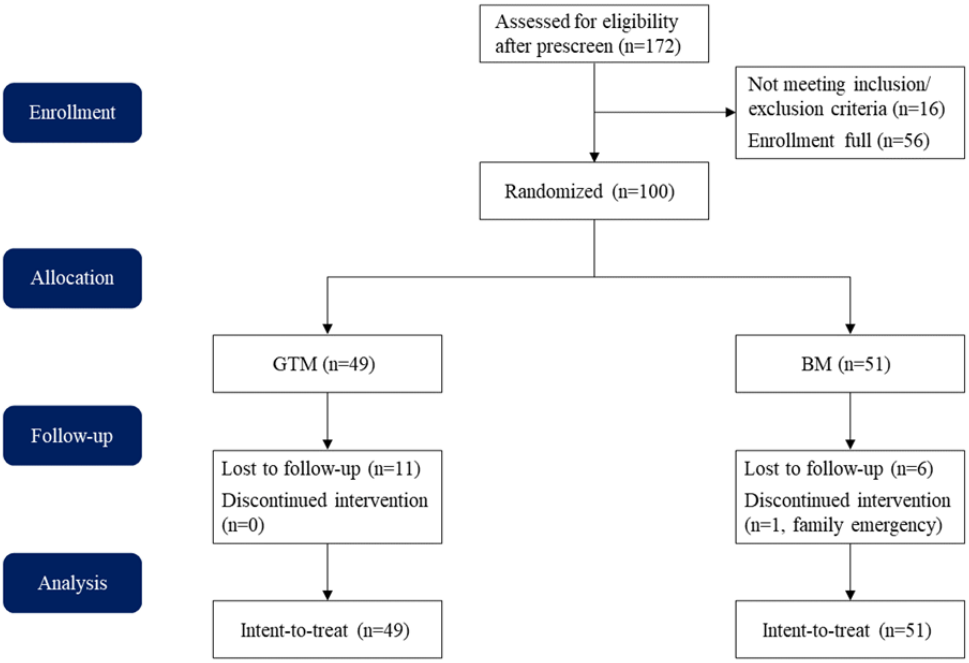
Results

Participants

The CONSORT (Consolidated Standards of Reporting Trials) participant flow diagram is shown in Figure 2, and the

CONSORT checklist is provided in Multimedia Appendix 6. The recruitment of test participants started in May 2023 and the follow-up ended in July 2023. Regarding retention, 38 (78%) out of 49 participants in the GTM group responded to follow-up surveys at 8 weeks, while 44 (86%) out of 51 participants responded in the BM group.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) participant flow diagram. BM: breathing meditation; GTM: guided tea meditation.



The participant demographics are presented in Table 1. Of the 100 participants, 81 (81%) participants were female and the average stress level was slightly higher than previously reported values for the US population (~17) [27]. Throughout the study, no adverse events were reported.

Table 1. Participant demographics.

Variable	GTM[a] (n=49)	BM[b] (n=51)	Overall (n=100)
Age (years), mean (SD)	34.5 (7.7)	33.3 (7.9)	33.9 (7.8)
Sex, n (%)			
Female	40 (82)	41 (80)	81 (81)
Male	9 (18)	10 (20)	19 (19)
PSS-10[c] group, n (%)			
Below-average stress	15 (31)	16 (31)	31 (31)
Above-average stress	34 (69)	35 (69)	69 (69)
PSS-10 screening score, mean (SD)	19.3 (4.9)	19.9 (5.5)	19.6 (5.2)

[a]GTM: guided tea meditation.

[b]BM: breathing meditation.

[c]PSS-10: Perceived Stress Scale-10.

Feasibility Assessment

Time and Frequency of Meditation (Prototype Use)

The total meditation time and frequency during the study period are presented in Table 2. Neither the time (mean 454.6, SD 219.4 minutes for GTM vs mean 521.0, SD 238.6 minutes for BM; *P*=.15) nor frequency (mean 37.4, SD 17.8 days for GTM vs mean 42.1, SD 16.1 days for BM; *P*=.36) significantly differed between groups.

Table 2. Total meditation time and frequency during the 8-week intervention period.

Variable	GTM[a] (n=49), mean (SD)	BM[b] (n=51), mean (SD)	Difference, mean (95% CI)[c]	*P* value
Time, total (minutes)	454.6 (219.4)	521.0 (238.6)	–66.5 (–157.5 to 24.6)	.15
Frequency, total (days)	37.4 (17.8)	42.1 (16.1)	0.9 (0.7 to 1.1)	.36

[a]GTM: guided tea meditation.

[b]BM: breathing meditation.

[c]The difference between groups is presented as the model-derived mean and 95% CI.

Weekly meditation time and frequency are listed in Multimedia Appendix 7. Regarding weekly meditation time, the interaction between week and group factors was significant (*P*=.02). There was a tendency that the weekly meditation minutes in the GTM group decreased in the latter half of the 8 weeks, whereas those of the BM group remained constant, and a significant difference was observed between the groups at week 5 (*P*=.04) and 8 (*P*=.045). Regarding frequency, no significant interaction between week and group was detected (*P*=.81), whereas a marginally significant difference was observed between groups at week 5 (*P*=.049).

Acceptability of and Feedback on the Prototypes

For the question "Was the app easy to understand and use?" 90% (n=44), 84% (n=41), and 71% (n=35) of the 49 participants answered "strongly agree or agree" on days 1 (after the first use of the prototype), 29, and 56 (after the last use), respectively.

For the question "Do you like the format and content of the audio guidance?" 82% (n=40), 69% (n=34), and 57% (n=28) of the participants answered "strongly agree or agree" on days 1, 29, and 56, respectively. Additionally, 45% (n=22) of the participants provided feedback that they would like more options in the audio clips.

For the question "Did you find the matcha green tea beverage tasty?" 80% (n=39) of the participants answered "strongly agree or agree" on day 1, with 59% (n=29) of them answering the same on days 29 and 56. Of the participants, 37% (n=18) gave feedback that they would like a sweeter taste, and 18% (n=9) commented that they would like more flavor options.

Efficacy Assessment

Perceived Stress Levels

Total PSS-10 scores are presented in Table 3. There was no significant interaction between week and group, indicating no significant difference in the response profiles between the groups (*P*=.29). Within the GTM group, a significant decrease in the PSS-10 score was detected between weeks 0 and 4 (estimate –4.8, 95% CI –6.5 to –3.1; *P*<.001) and between weeks 0 and 8 (–5.5, 95% CI –7.4 to –3.5; *P*<.001). Similarly, within the BM group, a significant difference was detected between weeks 0 and 4 (–4.5, 95% CI –6.1 to –2.9; *P*<.001) and between weeks 0 and 8 (–6.5, 95% CI –8.4 to –4.7; *P*<.001). No significant differences were detected between the groups in the changes from baseline to week 4 (*P*=.79) or week 8 (*P*=.44).

Table 3. Changes in perceived stress levels[a].

Week	GTM[b] (n=49), mean (SEM)	BM[c] (n=51), mean (SEM)	Between-group difference, mean (95% CI)[d]	*P* value
0	19.3 (0.7)	19.9 (0.8)	N/A[e]	N/A
4	14.3 (0.9)[f]	15.3 (0.9)[f]	–0.3 (–2.6 to 2.0)	.79

[e]Not applicable.

[f]*P*<.001 versus week 0.

Mood

The pre- and postmeditation mood scores and changes are presented in Table 4 (data at the first meditation session on day 1) and Multimedia Appendix 8 (data at the last meditation session on day 56). During the first meditation session, the within-group change from the pre to postmeditation time point was significant for all items in both groups, except for energetic (GTM, *P*=.34; BM, *P*=.71) and lively (GTM, *P*=.12; BM, *P*=.12). Similarly, during the last meditation session, the within-group changes in both groups were significant, except for energetic (GTM, *P*=.42; BM, *P*=.12), lethargic (GTM, *P*=.95), and lively (GTM, *P*=.98). No significant between-group differences were detected in premeditation or postmeditation scores or changes at the first or last meditation session.

Changes in premeditation mood scores from baseline (day 1) to day 56 are presented in Table 5. Significant between-group differences were observed in the relaxed and calm levels (*P*=.04 and .048, respectively; Figure 3).

Table 4. Changes in mood before and after the first meditation session on day 1[a].

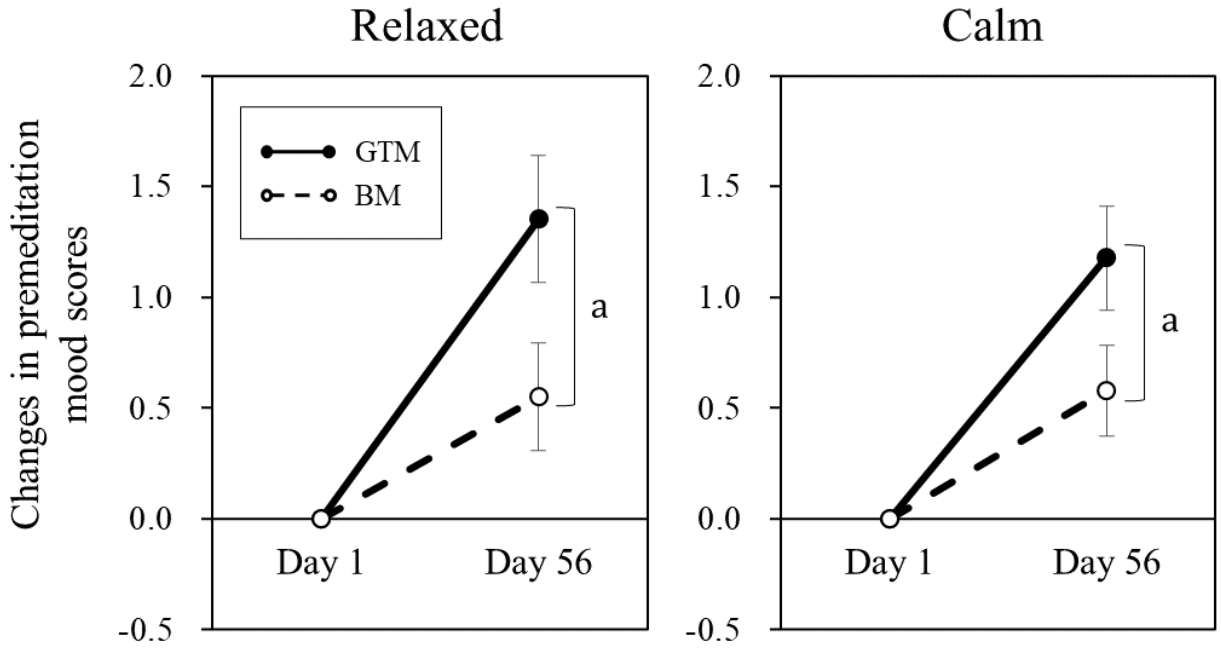
Figure 3. Changes in premeditation relaxed and calm scores from baseline (day 1) to day 56 were significantly greater in the GTM group. Mood was assessed using the Two-Dimensional Mood Scale. Data are presented as mean (SEM). a: *P*<.05. BM: breathing meditation; GTM: guided tea meditation.



Other Meditation Benefits

The categorized meditation benefit responses are shown in Multimedia Appendix 9. More than half of the participants in each group experienced positive changes in feelings of happiness (GTM: 32/49, 65%; BM: 34/51, 67%), time management (GTM: 25/49, 51%; BM: 37/51, 73%), quality of life (GTM: 37/49, 76%; BM: 39/51, 76%), relationships (GTM: 28/49, 57%; BM: 34/51, 67%), sleep (GTM: 26/49, 53%; BM: 33/51, 65%), and work performance (GTM: 30/49, 61%; BM: 31/51, 61%) at week 4. Similar results were observed at week 8. However, the groups displayed no significant differences in the distribution of responses at both time points (all *P*>.05).

Discussion

Principal Findings and Comparison With Prior Work

Although the performance of GTM was restricted to once (approximately 10 minutes long) a day, whereas the duration of BM was unrestricted, we expected that the meditation time and frequency in the GTM group would be equal to or higher than those in the BM group. As a result, the total meditation time and frequency did not significantly differ between the groups (Table 2), and weekly meditation time and frequency were even lower in the GTM group at weeks 5 and 8 (Table 3). However, the weekly time and frequency of the GTM group remained above 50 minutes per week and 4 days per week, respectively, throughout the study. Notably, these values, especially the frequency, are not lower than those reported for popular mindfulness apps on the market, although direct comparisons are not feasible due to differing test conditions between the studies [26,28-31]. On the other hand, the weekly meditation time in the BM group remained constant at approximately 65 minutes throughout the 8 weeks, although existing research consistently reports a decrease in engagement with mindfulness over time [32-35]. Moreover, the frequency in the BM group ranged from 5 to 6 times a week, indicating that the participants succeeded in performing BM almost every day as instructed. In general, meditating on a daily basis is considered difficult for most people due to several barriers [10,36]. However, it seemed that the population of this study, who had experience with meditation and discontinued it before study participation, did not perceive the daily implementation of BM as a burden. Although the BM group received only brief instructions on how to perform BM (Multimedia Appendix 5), none of the participants required additional instruction or assistance.

It should also be noted that 22% (11/49) and 14% (7/51) of the participants in the GTM and BM groups, respectively, were lost to follow-up or discontinued the intervention during the study. Although these attrition rates were not significantly higher than those of previous studies involving digital mental health interventions [20,36-38], attrition did affect time and frequency outcomes, as we adopted an ITT analysis. Considering participant feedback and decreases in weekly meditation time in the GTM group during the latter half of the 8 weeks, some participants may have become bored with the limited variety in the prototype offerings (5 types of audio scripts and 1 matcha flavor) and stopped using them. Downloading the prototype app through TestFlight (the procedures are shown in Multimedia Appendix 4) might be a hurdle for some participants. In addition, preparing for the environment to listen to audio, the matcha stick, and hot water might have been constraints for the GTM group. However, no obvious feedback was provided regarding this point, and more than half of the users showed acceptance of the prototype app, audio, and matcha throughout the 8 weeks. In conjunction with the meditation engagement data, we believe

that GTM exhibits good feasibility. However, further research is needed to expand the variety of offerings.

The effects of GTM on perceived stress levels and mood were investigated and compared with those of BM. The BM intervention that did not involve an app or audio guidance significantly reduced stress levels after 4 weeks. Similarly, GTM showed significant reductions in approximately 5 points of the PSS-10, which are similar to, or greater than, values reported by previous mobile health studies [26,28,39-41]. Direct comparisons with other mindfulness apps with audio guidance are desirable for future studies. A single session of BM significantly and consistently improved mood metrics after the first (day 1) and last (day 56) meditation sessions. Similar effects of GTM were observed and were sustained on day 56. Notably, the changes from day 1 to day 56 in the premeditation relaxed and calm scores were significantly greater in the GTM group. The greater changes in relaxed and calm levels observed in the GTM group may be attributed to the L-theanine contained in the matcha green tea. The relaxing effect of L-theanine has been demonstrated [42,43]. In the GTM group, the average premeditation score of relaxed and calm changed over 56 days, from 1.5 (SEM 0.2) to 2.9 (SEM 0.2) and from 2.0 (SEM 0.2) to 3.2 (SEM 0.2), respectively. In other words, the average participant in the prototype group experienced improvements in their relaxed and calm levels by more than one stage (eg, “somewhat” relaxed to “moderately” relaxed) in the state of premeditation. Elevated relaxed and calm levels may generate well-being and equanimity among practitioners, which needs to be investigated in future studies.

The majority of participants in both the BM and GTM groups experienced positive changes in happiness, time management, quality of life, relationships, sleep, and work performance as they continued the assigned meditation. However, these results should be interpreted with caution because the questionnaire used to assess these exploratory outcomes has not been validated. Future studies should conduct specific, validated surveys to assess each outcome.

Strengths and Limitations

A strength of this study is that a comparator group was set as the active control (traditional BM), whereas several relevant previous studies set a waitlist group as the control [26,38,44]. Another strength is that ITT analysis was applied to all outcomes, showing the stress-reducing and mood-improving effects of GTM. To the best of our knowledge, this is the first study demonstrating such effects of mindful eating–based practices by ITT analysis. Moreover, this study showed improvements in relaxed and calm levels following multiple GTM sessions were greater than those following multiple BM sessions.

This study does have some limitations. First, all data collected relied on a self-report method. Therefore, the reported meditation activity may not fully reflect actual activity, and data on the efficacy of meditation may be affected by expectation or placebo effects. After randomization, participants received information regarding whether their intervention was the intervention of interest (GTM) or the comparator. Second, correction for multiple comparisons was not conducted for mood metrics considering the exploratory nature of the study. To generalize the findings of this study, additional research needs to be conducted with a limited number of outcomes and a larger sample size. Third, matcha green tea consumption was limited to once a day, as this was the first long-term study to allow participants to consume the prototype matcha. Confirming the safety of the 8-week consumption of the matcha, we do not plan to limit the number of matcha consumption or GTM in commercial settings. Future studies should reflect real-world settings and be conducted with a longer evaluation period. Fourth, demographics such as the experience of meditation, the use of mindfulness apps, and socioeconomic status, which may have acted as confounders, were not investigated. Fifth, we did not assess trait mindfulness as our focus was on emotional state. Future studies should use validated questionnaires to assess mindfulness, such as the Five Facet Mindfulness Questionnaire and the Mindfulness Attention and Awareness Scale. Last, although the set of prototypes showed good feasibility and efficacy, we could not determine which parts of the offerings, to what degree, contributed to program adherence and efficacy.

Conclusions

Given the time and frequency of GTM and the acceptability of prototypes, we believe that GTM exhibits good feasibility. Meanwhile, GTM reduced stress, improved mood, and let the practitioners feel other benefits, similar to BM. Long-term practitioners of GTM may even feel more relaxed and calmer in the state of premeditation than those who practice BM. To further improve the feasibility and consolidate the efficacy of GTM, the offerings should be improved based on user feedback and compared with other mindfulness apps in future studies with a longer evaluation period.

Acknowledgments

The authors appreciate Dr Taisyu/Hironori Kawano for his insightful comments regarding the project and for creating the original version of the audio scripts. The authors thank Mindful Mamas for creating the audio clips for guided tea meditation and btrax, Inc for creating the initial prototype of the app. The authors also appreciate Adam Johnson, Todd Thompson, Renu Joshi, Sadia Zaidi, and other colleagues at Otsuka Precision Health, Inc for further development of the app, their cooperation in the study, and editing the manuscript. The authors thank Mr Taisei Kihara for creating the matcha stick. The authors are also grateful to Dr Dawn B Beckman and the clinical staff at Biofortis Clinical Research. This study was conducted using resources provided by Otsuka Holdings Co Ltd. The sponsor provided support in the form of salaries to KY and KH but did not have any additional role in the study design, data collection and analysis, or preparation of the manuscript.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

RT-K worked on conceptualization, methodology, investigation, and writing of the original draft. KY worked on conceptualization, creation and preparation of the matcha stick, and project administration. CMC worked on investigation, data interpretation, and writing, reviewing, and editing of the manuscript. TMB performed data curation and formal analysis. KDT administered this study. KH worked on conceptualization, methodology, project management, and writing, reviewing, and editing of the manuscript. All authors reviewed the final manuscript.

Conflicts of Interest

KY and KH belong to Otsuka Holdings Co Ltd, the owner of ekkomi center me. RT-K belongs to Otsuka Pharmaceutical Co Ltd, a subsidiary of Otsuka Holdings Co Ltd. CMC, TMB, and KDT were employees of Biofortis Clinical Research, a Contract Research Organization that received funding from Otsuka Holdings Co Ltd to conduct the study.

Abstract

Background: Smartphone apps and wearable activity trackers are increasingly recognized for their potential to promote physical activity (PA). While studies suggest that the use of commercial mobile health tools is associated with higher PA levels, most existing evidence is cross-sectional, leaving a gap in longitudinal data.

Objective: This study aims to identify app-use patterns that are prospectively associated with increases in and maintenance of PA. The primary objective was to test whether continued app use is linked to adherence to the recommended PA levels (ie, 23 metabolic equivalent task [MET] hours per week for adults or 10 MET hours/week for individuals aged >65 years) during a follow-up assessment. The secondary objective was to explore which functions and features of PA apps predict changes in PA levels.

Methods: A 2-wave longitudinal survey was conducted, with baseline and follow-up assessments separated by 6 months. A total of 20,573 Japanese-speaking online respondents participated in the baseline survey, and 16,286 (8289 women; mean age 54.7 years, SD 16.8 years) completed the follow-up. At both time points, participants reported their current PA levels and whether they were using any PA apps or wearables. Each participant was classified into 1 of the following 4 categories: continued users (those using apps at both the baseline and follow-up; n=2150, 13.20%), new users (those who started using apps before the follow-up; n=1462, 8.98%), discontinued users (those who had used apps at baseline but not at follow-up; n=1899, 11.66%), and continued nonusers (those who had never used apps; n=10,775, 66.16%).

Results: The majority of continued users (1538/2150, 71.53%) either improved or maintained their PA at the recommended levels over 6 months. By contrast, discontinued users experienced the largest reduction in PA (−7.95 MET hours/week on average), with more than half failing to meet the recommended levels at the follow-up (n=968, 50.97%). Analyses of individual app functions revealed that both energy analysis (eg, app calculation of daily energy expenditure) and journaling (eg, users manually entering notes and maintaining an exercise diary) were significantly associated with increases in PA. Specifically, energy analysis was associated with an odds ratio (OR) of 1.67 (95% CI 1.05-2.64, P=.03), and journaling had an OR of 1.76 (95% CI 1.12-2.76, P=.01). By contrast, individuals who maintained the recommended PA levels at the follow-up were more likely to use the goal setting (OR 1.73, 95% CI 1.21-2.48, P=.003), sleep information (OR 1.66, 95% CI 1.03-2.68, P=.04), and blood pressure recording (OR 2.05, 95% CI 1.10-3.83, P=.02) functions.

Conclusions: The results highlight the importance of continued app use in both increasing and maintaining PA levels. Different app functions may contribute to these outcomes, with features such as goal setting and journaling playing a key role in increasing PA, while functions related to overall health, such as sleep tracking and blood pressure monitoring, are more associated with maintaining high PA levels.

Introduction

Background

Physical inactivity is highly prevalent in modern society, with an average global prevalence of 31% [1]. It is associated with noncommunicable diseases such as stroke, hypertension, and diabetes [2] and is now the fourth leading risk factor for mortality [3]. To promote physical activity (PA), behavior change techniques (BCTs) have been developed [4], which can be delivered either in-person (eg, by health care professionals) or digitally (eg, through smartphones and wearable activity trackers). These digital mobile health (mHealth) interventions are expected to play a pivotal role in promoting PA, particularly during and after the COVID-19 pandemic, when in-person contact is highly restricted. These digital PA tools typically offer measurement and monitoring (eg, activity logs), information and analysis (eg, progress and individual exercise data), and support and feedback (eg, advice on PA and goal setting) [5]. The most frequently implemented BCTs include self-monitoring, providing feedback on performance, and goal-setting [6]. Observational studies have found that fitness app users are more physically active than nonusers [7], with app users having approximately twice the odds of meeting aerobic PA guidelines compared with nonusers, even during the COVID-19 pandemic [8]. One important limitation in the literature is that most studies on PA apps (and health care apps in general) have used a cross-sectional design, meaning longitudinal evidence is still lacking. We aimed to fill this gap and investigate whether, and how, daily use of PA apps and wearables (not necessarily as part of a clinical intervention or treatment) is prospectively associated with increased levels of PA.

How Effective Is an mHealth Intervention? Evidence From Clinical Trials

A large number of randomized and nonrandomized trials have been published on this topic, not limited to daily use of commercial PA apps and wearables. To our knowledge, 3 umbrella reviews have been conducted, focusing on digital interventions for improving PA. An early umbrella review [9] synthesized 11 systematic reviews and meta-analyses on eHealth or mHealth interventions targeting PA, sedentary behavior, and healthy eating for healthy individuals. The authors concluded that the majority of eHealth/mHealth interventions were reported as effective, although high heterogeneity was observed across multiple studies. Another umbrella review [10] focused on interventions using wearable activity trackers to improve PA. A synthesis of 39 systematic reviews and meta-analyses indicated a moderate effect size (standardized mean difference 0.3-0.6). A more recent umbrella review [11] identified 17 systematic reviews and meta-analyses on digital interventions specifically targeting PA and sedentary behavior to prevent or manage noncommunicable diseases. The results suggest that digital interventions have a small to moderate effect on increasing PA, although heterogeneity is documented across multiple reviews. For example, 3 systematic reviews concluded that mHealth interventions are effective, particularly those involving gamification [12], personalization [13], or delivery in workplace settings [14]. By contrast, a meta-analysis [15] found no significant effects of mobile interventions on total PA, moderate to vigorous PA, or walking. Similarly, a review of mHealth interventions equipped with social features found a nonsignificant effect on PA outcomes [16].

Researchers have also explored specific components or features of apps and wearables that are key to improving PA. Apps and digital interventions offering richer content and a larger number of BCTs are found to be more favored by users [17] and are associated with better health outcomes [18,19], although users also appreciate simplicity (eg, ease of use) [20]. Researchers have also found that certain app features and characteristics are more favored than others, such as data export, usability, and cost [20]; tracking (eg, steps, heart rate, and ovulation) [21,22]; and health information and medical reminders [23]. However, the umbrella reviews [9,11] concluded that the evidence for the effectiveness of specific BCTs or combinations of BCTs in digital PA interventions is largely mixed. In the search for successful digital implementations of BCTs, meta-regressions and systematic reviews highlighted the importance of behavioral goals and self-monitoring [24]; SMS text messaging, personalization, goal setting and planning, and graded tasks [25]; goal setting, prompts/cues, feedback on behavior, and action planning [26]; and personalized goal setting with motivational feedback [27]. By contrast, several meta-analyses reported no significant associations between intervention efficacy and the number or types of BCTs implemented [28,29].

Note that these analyses typically targeted clinical trials focused on specific populations, such as patients, older adults, and individuals with low socioeconomic status. Only a few studies have investigated how the spontaneous use of commercial apps and wearables can help improve PA in a community sample. Investigating app use in uncontrolled settings is particularly important to assess the potential efficacy of PA apps and wearables on the market. Studies have highlighted substantial differences in user behavior between controlled clinical contexts and real-world settings. For example, the average retention rate of mHealth interventions in published randomized controlled trials is about 91% [25], which is surprisingly high compared with the user engagement observed with commercial health care apps (eg, 4%, the median percentage of daily active users of mental health apps) [30]. An exceptional longitudinal study [31] investigated user engagement with a commercial app that rewards users with digital incentives for walking. The results showed that 60% of participants engaged with the app for at least 6 months. Interestingly, users who actively engaged with the app experienced larger increases in daily step count compared with less frequent users. These findings highlight the importance of continuous, long-term use of PA apps or wearables for users to fully benefit from these digital tools.

Study Overview

The general purpose of this study was to identify app-use patterns prospectively associated with increased levels of PA. To achieve this, we conducted a 2-wave longitudinal survey with a 6-month interval. At each survey point, participants reported their current levels of PA and whether they were using any PA apps or wearables. Each participant was classified into 1 of 4 categories: continued users (those who used apps or wearables at both baseline and follow-up), new users (those who started using apps before the follow-up), discontinued users (those who used apps at baseline but not at follow-up), and continued nonusers (those who had never used apps). We were particularly interested in (1) whether continued and new users would increase their PA levels or maintain high-level PA at the 6-month follow-up, and (2) whether any features of the PA apps would predict increases in PA.

Our recent cross-sectional study found that users typically engaged with a limited number of functions within an app (median 2 functions, IQR 1-4 functions). Physically active users tended to use functions such as sensor information (eg, step count and heart rate), goal setting (eg, setting a daily step goal), energy analysis (eg, estimating calories burned), journaling (eg, manually recording daily exercise), and global positioning system (GPS)/maps. We did not have a specific hypothesis regarding the prospective effects of individual app functions, so the overall analyses were conducted in an exploratory manner. However, we expected that sensor information (closely related to self-monitoring/tracking in the BCT taxonomy) and other functions implementing regulatory techniques [32] would be associated with increases in PA. Additionally, we expected that the number of functions might be linked to PA increases, as some studies have suggested that the amount of app content or the number of implemented BCTs is associated with the efficacy of mobile interventions [18,19].

Objectives

In this study, we had 2 objectives: the primary objective was to investigate whether new and continued users would increase PA or maintain high levels of PA over 6 months. The secondary objective was to identify the functions and features of PA apps that would predict increases in and maintenance of PA.

Methods

Participants and Procedure

Participants were recruited from the respondents who completed the first (baseline) survey, the results of which have been published elsewhere [33,34]. The baseline survey was conducted in 2023. Invitations to participate were sent to potential participants (residents of Japan who were registered in a database for online surveys) [33,34]. At baseline, 20,573 online respondents completed questionnaires regarding general health and health-related behaviors, including PA levels and use of mHealth apps. The only eligibility criterion was age (>18 years), with no additional criteria. Proficiency in Japanese was assumed, as the survey was written in Japanese. All participants were invited to the second (follow-up) survey, which took place approximately 6 months after the baseline survey. The follow-up survey, which included the same questions on PA and mHealth use, was completed by 16,286 of the 20,573 participants. Data from those who completed the follow-up were used for statistical analyses. Because of the online nature of the surveys, the reasons for dropout could not be tracked. Specifically, we had no means of reminding participants about the follow-up survey other than via email. Tracking dropouts was technically impossible, as they no longer responded to our emails. Participants received a small compensation for each survey (an online shopping voucher valued at approximately US $0.31).

Ethics Approval

The study protocol was approved by the Ethics Committee of the National Institute of Advanced Industrial Science and Technology (approval ID 2022-1279).

Measures

International Physical Activity Questionnaire-Short Form

At each survey, participants reported how many days and minutes per day they engaged in (1) walking, (2) moderate-intensity activity, and (3) vigorous-intensity activity over an average week [35,36]. The reported duration and frequency of each activity were then multiplied and converted into metabolic equivalent task (MET) hours per week. To determine whether each participant had a sufficient level of PA, the MET score was dichotomized to represent adherence to the national PA criteria recommended by the Ministry of Health, Labour and Welfare of Japan: 23 MET hours/week for adults aged <65 years and 10 MET hours/week for older adults [37]. Although there has been debate about dichotomization, we chose this approach because using an established cutoff helps clarify whether each participant achieved a clinically meaningful level of PA. Another advantage is that it explicitly distinguished those who maintained low or high levels of PA over time, which could not be separated using a simple numeric change score.

Stages of Change Questionnaire

Participants completed the Japanese version [38] of the Stages of Change questionnaire for PA, based on the transtheoretical model [39,40]. The questionnaire asked participants to select the most applicable statement from the following 5 statements: *I currently do not exercise and do not intend to start exercising in the future* (Precontemplation); *I currently do not exercise but I am thinking about starting to exercise in the next 6 months* (Contemplation); *I currently exercise some, but not regularly* (Preparation); *I currently exercise regularly, but have only begun doing so within the last 6 months* (Action); and *I currently exercise regularly and have done so for longer than 6 months* (Maintenance). Regular exercise was explicitly defined in the questionnaire instructions as engaging in PA for at least 20 minutes, twice or more per week.

Use of Apps and Wearables

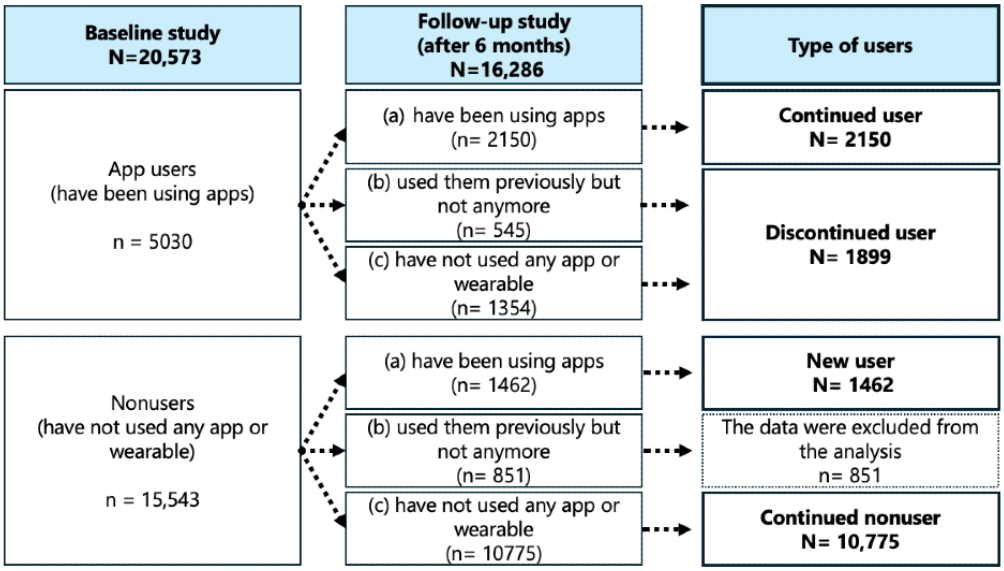
At baseline, participants provided a binary response indicating whether they used any apps or wearables to support their PA and exercise. Those who answered affirmatively were then asked for details on how they used the apps and wearables. The questions included the duration of app use, with the following

response options: <1 week, <1 month, <3 months, <6 months, <1 year, and ≥1 year. Participants were also asked about the functions and features of the apps they were using. They were presented with a list of 41 app functions (eg, sensor information, goal setting, and energy analysis) [33] and indicated any that applied to their usage [20,29]. However, as most of the listed functions were rarely used [33], we focused exclusively on the most frequently used functions for the current analysis: sensor information (eg, step count and heart rate), goal setting and progress tracking (eg, steps achieved), energy analysis (eg, estimated daily energy expenditure), weight recording, journaling (eg, manually entered diary or notes), GPS/maps, sleep information, reward points, and blood pressure recording.

At the 6-month follow-up, participants completed a similar questionnaire asking whether they were using apps and wearables. Unlike at baseline, participants were given 3 response options: (1) have been using apps and wearables for the past 6 months, (2) used them previously but no longer, and (3) have never used any app or wearable. Participants were also asked about the duration and frequency of app use (ie, how long and how often they had used/been using the app). However, questions regarding individual app functions and features were omitted due to limited space in the follow-up survey.

Responses from baseline and follow-up were interpreted as a 2×2 factorial matrix (user vs nonuser; baseline vs follow-up), classifying each participant into 4 categories (Figure 1): new users (those who began using apps before the follow-up), continued users (those who used apps or wearables at both baseline and follow-up), discontinued users (those who used apps at baseline but not at follow-up), and continued nonusers (those who never used apps). Participants who indicated at follow-up that they had used apps or wearables but were no longer using them (ie, those who selected option 2) were classified as discontinued users if they were identified as app users at baseline. If they were identified as nonusers at baseline, they were excluded from the statistical analyses for ease of interpretation. These participants were considered temporary app users—they may have used apps for a short period between baseline and follow-up but did not show significant changes in PA levels (P=.29; see Figure S1 in Multimedia Appendix 1 for details). We did not consider their usage comparable to that of the other participant groups.

Figure 1. Overview of user type classification.



Statistical Analyses

First, we explored demographic and descriptive differences between the 4 types of users based on gender, age, education level, household income, PA level, and readiness. Second, logistic regression analyses were conducted to examine how continued and discontinued app usage are associated with changes in PA levels. Two binary dependent variables were used to represent the following contrasts: (1) individuals who maintained underrecommended levels of PA (<23 or 10 METs) at the 6-month follow-up versus those who increased their PA to recommended or higher levels over time, and (2) individuals who maintained the recommended PA levels versus those who showed decreases and no longer met the recommended levels at follow-up. We also calculated simple change scores for PA (follow-up minus baseline) to clarify the magnitude of change experienced by each type of user over time. Finally, 2 independent logistic regression analyses were conducted to determine which app features were associated with changes in PA levels. The logistic regression models predicted the 2 binary dependent variables, specifically changes in (and maintenance of) adherence to the recommended PA levels, based on the individual 10 app features and functions used at baseline. All analyses were conducted using R (version 4.2.2; R Foundation) with the following specific packages: chisq.posthoc.test [41], finalfit [42], ggpubr [43], and tidyverse [44].

Results

Demographics

Table 1 shows the demographic characteristics for each type of app users (N=16,286). We identified 1462 (8.98%) new users, 2150 (13.20%) continued users, 1899 (11.66%) discontinued users, and 10,775 (66.16%) continued nonusers in the data set. A 1-way analysis of variance indicated significant age

differences between the user types (partial η^2=.009, *P*<.001), implying that new users were older than continued users and continued nonusers, and discontinued users were the youngest among the 4 types of users (*P*<.001; adjusted by the Tukey method). The descriptives per age group showed that, among older participants (eg, ≥60 years) who were identified as app users at baseline, 899 continued app use to follow-up, whereas 675 discontinued their use. Younger app users at baseline (eg, <30 years) were, however, more likely to discontinue than continue app use (n=250 vs 203). Chi-square tests revealed overall significant gender differences (*P*<.001). Residual analyses detected significant gender differences (*P*<.001) within continued users, men (1295/2150, 60.23%) versus women (855/2150, 39.77%). However, within continued nonusers, women (5770/10,775, 53.55%) were more dominant than men (5005/10,775, 46.45%; *P*<.001). Furthermore, continued users were the most prevalent among individuals with the highest household income (≥10 million JPY; 1 JPY=US $0.0065) and education level (university or above). At baseline, most continued users (1609/2150, 74.84%) reported that they had been using an app for longer than 6 months (1128/1899, 59.39%, for discontinued users). Similarly, most continued users (1654/2150, 76.93%) reported using a PA app once or more each day (1153/1899, 60.71%, for discontinued users).

Table 1. Demographic statistics of app users and nonusers.

Variable	Current app user		Current nonuser		Total (N=16,286)	*F* test or chi-square (*df*), *P* value

Relationship Between App Use and Adherence to the Recommended PA Level

Table 2 illustrates changes in PA levels for each user type over 6 months. Continued nonusers generally maintained underrecommended levels of PA over time (5259/10,775, 48.81%). Among the 4 types of users, new users had the largest proportion of individuals who increased their PA to recommended levels (178/1462, 12.18%), although achieving these levels was uncommon in the current sample. Continued

users typically maintained the recommended PA levels over time (1327/2150, 61.72%), while discontinued users had the largest proportion of individuals who failed to adhere to the recommended levels at follow-up (330/1899, 17.38%).

Table 2. The number of participants who increased, decreased, or maintained physical activity over 6 months as a function of the app user types.a

PA change category (baseline → follow-up)	Current user		Current nonuser	
	Continued user (n=2150), n (%)	New user (n=1462), n (%)	Discontinued user (n=1899), n (%)	Continued nonuser (n=10,775), n (%)
Maintained underrecommended level (not adhered → not adhered)	390 (18.14)	370 (25.31)	638 (33.60)	5259 (48.81)
Increased (not adhered → adhered)	211 (9.81)	178 (12.18)	159 (8.37)	931 (8.64)
Decreased (adhered → not adhered)	222 (10.33)	144 (9.85)	330 (17.38)	1269 (11.78)
Maintained recommended level (adhered → adhered)	1327 (61.72)	770 (52.67)	772 (40.65)	3316 (30.77)

[a]Adherence to the recommended physical activity level is equal to or larger than 23 metabolic equivalent task hours per week for adults or 10 metabolic equivalent task hours per week for older adults aged ≥65 years.

Logistic regression analyses were performed to examine how the 4 types of users were associated with adherence to the recommended PA levels (23 or 10 MET hours/week) over 6 months (primary objective). Discontinued users were used as the reference group, as they showed the largest proportion of individuals who decreased their PA to underrecommended levels at follow-up. Results (Table 3) showed that, compared with discontinued users, continued users (odds ratio [OR] 2.171, 95% CI 1.71-2.76, *P*<.001) and new users (OR 1.93, 95% CI 1.50-2.48, *P*<.001) were more likely to increase PA to the recommended levels at follow-up. Continued nonusers, compared with discontinued users, were more likely to maintain underrecommended PA levels at follow-up (OR 0.71, 95% CI 0.59-0.86, *P*<.001). Another logistic regression analysis showed that continued users (OR 2.56, 95% CI 2.11-3.10, *P*<.001) and new users (OR 2.29, 95% CI 1.84-2.85, *P*<.001) were more likely to maintain the recommended PA levels compared with discontinued users. Continued nonusers did not significantly differ from discontinued users (OR 1.12, 95% CI 0.97-1.29, *P*=.11).

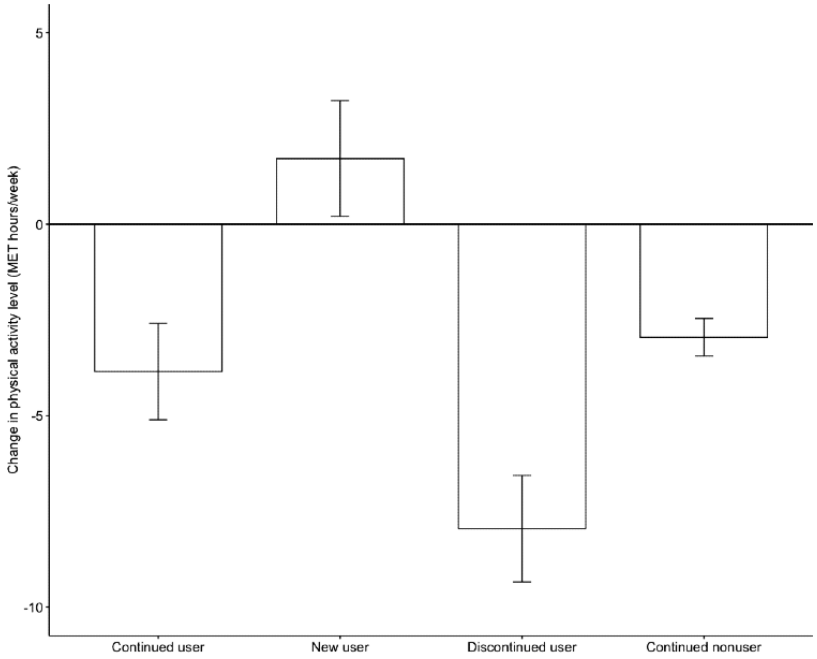
Table 3. Logistic regressions predicting physical activity changes based on 23 (or 10) metabolic equivalent task hours per week.

Outcome and predictor	Odds ratio (95% CI)	*P* value
Increased to versus maintained at below the recommended level (n=8136)		
Intercept (reference: discontinued user)	0.249 (0.209-0.297)	<.001
Continued user	2.171 (1.705-2.763)	<.001
New user	1.930 (1.504-2.477)	<.001
Continued nonuser	0.710 (0.589-0.857)	<.001
Maintained the recommended level versus decreased (n=8150)		
Intercept (reference: discontinued user)	2.339 (2.056-2.661)	<.001
Continued user	2.555 (2.109-3.096)	<.001
New user	2.286 (1.835-2.847)	<.001
Continued nonuser	1.117 (0.967-1.290)	.133

Changes in PA Level at the 6-Month Follow-Up

We then calculated the simple change scores for PA levels (ie, follow-up minus baseline in MET hours/week) to estimate the changes experienced by each user type over 6 months (Figure 2). New users were the only group to show increases in PA levels (mean 1.71, SD 57.76), which was significantly larger than the changes (decreases) observed in continued nonusers (mean –2.95, SD 50.76; $t_{1,780.5}$= 2.94, *P*=.003). Continued users showed a decrease in PA on average (mean –3.85, SD 58.53), while discontinued users exhibited even larger decreases (mean –7.95, SD 60.52; $t_{3,949.1}$=2.19, *P*=.03).

Figure 2. Change in physical activity level (in METs hours/week) at the 6-month follow-up among the 4 types of users and nonusers. The error bar indicates the SE. MET: metabolic equivalent of tasks.



Function-Wise Analyses Predicting Changes in PA

At baseline, app users most frequently reported using sensor information, followed by goal setting, goal progress, energy analysis, and weight recording (see Table S1 in Multimedia Appendix 1 for details). To explore which app functions are associated with increases in or maintenance of PA levels (secondary objective), we estimated 2 logistic regression models. These analyses targeted continued users exclusively (ie, individuals who reported using apps at both baseline and follow-up), with nonusers excluded. The results (Table 4) showed that energy analysis and journaling were significantly associated with increases in PA to the recommended levels (OR 1.67, 95% CI 1.05-2.64, *P*=.03 and OR 1.76, 95% CI 1.12-2.76, *P*=.01, respectively). Maintenance of the recommended levels (vs a decrease to underrecommended levels) was predicted by goal setting (OR 1.73, 95% CI 1.21-2.48, *P*=.003), sleep information (OR 1.66, 95% CI 1.03-2.68, *P*=.04), and blood pressure recording (OR 2.05, 95% CI 1.10-3.83, *P*=.02). We also tested the association between the number of app functions in use (at baseline) and changes in PA level (simple change score, ie, follow-up minus baseline) among continued users, which did not reach statistical significance (*r*=–0.02, *P*=.48).

Table 4. Logistic regression predicting physical activity change based on 23 metabolic equivalent task hours per week.

Outcome and predictor	OR (95% CI)	*P* value
Increased to versus maintained at below the recommended level (n=601)

Discussion

Principal Findings

This study investigated whether continued use of commercial PA apps and wearables over 6 months contributes to increasing or maintaining PA levels. Overall, the results emphasize the importance of continued app use in maintaining PA levels. Most continued users (1538/2150, 71.53%) either maintained or improved their PA to the recommended levels over 6 months, whereas 51% (968/1899) of discontinued users failed to meet the recommended levels at follow-up (compared with 797/1899, 41.96%, who were nonadherent at baseline). New users were found to experience the largest increase in PA levels, while discontinued users showed the largest reduction among the 4 types of users. These results suggest that individuals who recently started using apps and wearables saw the greatest improvement in their PA levels. By contrast, continued app use helped maintain PA levels (despite slight decreases), whereas discontinuation led to a substantial reduction in PA levels, equivalent to a decrease of more than 1 hour of vigorous PA per week [45].

Characteristics of Continued Versus Discontinued Users

More than half (2150/4049, 53.09%) of the app users identified at baseline reported continuing to use the app at the 6-month follow-up. While this retention rate may seem high compared with the reported daily engagement rates for health care apps [30], it is comparable to the 60% active user engagement rate observed in a longitudinal study of a commercial PA app over 6 months [31]. Our analysis of the demographic characteristics of continued (vs discontinued) users indicated that continued users were older, more likely to be men, and had higher education levels and incomes. Previous cross-sectional studies have found that mHealth/eHealth users tend to be younger, more educated, and have higher (digital) health literacy than nonusers [46-48]. Educational attainment is thought to reflect both literacy and skills (including confidence with digital and smart devices) as well as social norms related to the perceived value of health [47]. In general, women are the dominant users of health care apps (for diet, nutrition, and self-care), while fitness apps tend to be more popular among men [46]. Older adults typically avoid new technologies and mHealth services [49]. However, our results showed that continued users were more prevalent than discontinued users among older participants, suggesting that older users were more likely to continue using apps. We do not have data to readily explain this unexpected finding.

However, given that most of the continued users in our data had already been using PA apps for a long time (>6 months) at baseline, even older users may have developed high self-efficacy and perceived ease of use, which could reduce technology anxiety. Studies have identified various facilitators and barriers to technology adoption among older adults (eg, personal experiences and subjective norms) [50], which could serve as a basis for future research to explore how older users successfully adapt and integrate mHealth tools into their daily routines.

App Functions Predictive of an Increase in PA

We found that energy analysis and journaling were predictive of increases in PA to the recommended levels over 6 months. Additionally, goal setting, sleep information, and blood pressure recording were commonly used by individuals who maintained the recommended PA levels at follow-up. In a previous cross-sectional analysis, we reported associations between PA levels and individual app functions [33], which indicated that individuals with health-enhancing PA levels typically used functions such as sensor information (eg, step count and heart rate), goal setting, goal progress, energy analysis, journaling, and GPS/maps. The current prospective analyses emphasize the particular importance of energy analysis and journaling in improving PA over time. While sensor information was commonly used by PA app users (Table S1 in Multimedia Appendix 1), the findings suggest that, in addition to the automatically recorded PA data (eg, step count), users may benefit from additional analyses of physiological data (eg, energy expenditure calculations) and more deliberate engagement with the app, such as journaling and manually logging daily exercise and PA.

Interestingly, maintenance of the recommended PA level was associated with the use of sleep information, blood pressure recording, and goal setting. This suggests that users who are already sufficiently active may value functions that support general health care, rather than those focused solely on fitness and exercise. It is also possible that some users were prompted to use PA apps due to specific health concerns. Published meta-analytic studies have identified key app components that enhance PA, including self-monitoring, goal setting and planning, prompts/cues, feedback on behavior, and action planning [24-27], most of which are specifically designed to support PA. It may be important for future research to broadly explore app functions and features (not limited to PA-related functions) to identify more effective combinations, especially when the focus is on maintaining rather than increasing PA levels. This could reinforce the usefulness of the stages of change model [39,51] (eg, to guide the best interventions for those in the action or maintenance stages) and highlight the importance of tailoring digital behavior interventions.

Another interesting finding from this analysis is that the number of app functions reported as being in use was not significantly associated with increases in PA over 6 months. While several studies have suggested that the amount of app content or the number of implemented BCTs is linked to the efficacy of mHealth interventions [18,19], this association has not always been replicated [29]. As our analyses utilized self-report data rather than actual logs of user behavior, we cannot exclude the possibility that participants may not have accurately or exhaustively reported all the functions they used. However, our findings suggest that (1) users may not be fully aware of every function available in an app (or, at least, they do not consciously use them all), and (2) they may not necessarily benefit from multifunctionality. Instead, a limited number of functions (eg, goal setting and journaling) may be more effective in improving PA. Indeed, it is known that users appreciate the simplicity of an app [20], and as Michie et al [32] found, interventions that combine self-monitoring with at least one regulatory technique (eg, goal setting) can form the most cost-effective, minimal set of interventions.

Limitations

The results reported here should be interpreted with caution due to several important limitations. First, we targeted Japanese-speaking adults exclusively, which may limit the generalizability of the findings. The apps and products available on the Japanese eHealth/mHealth market may differ from those in other regions and countries. While there are similarities in user behavior between Japan and Western countries, exploring country- or culture-specific aspects would be an interesting direction for future research. Second, we cannot rule out the possibility of sampling bias. As reported elsewhere [33], the current sample exhibited higher PA levels than the general population in Japan, likely because the study was advertised as a survey on PA and health. Additionally, attrition could introduce bias, as some participants (4287/20,573, 20.83%) dropped out by the follow-up. Third, the follow-up survey did not include questions regarding how participants used specific app functions and features (assessed only at baseline). As this study was part of a larger project, there was a limit on the length of each survey. Future research should explore how changes in PA influence the use patterns of individual app functions, which could provide insights into how tailoring and personalization can be incorporated during app use adaptation. Fourth, we relied exclusively on self-reported PA, which may not always align with objective measures, such as accelerometers, due to self-reporting bias and other assessment artifacts. Similarly, user behavior and individual app function usage can be monitored automatically or made publicly available (eg, [52]). However, a downside of such an approach is that the analysis would be limited to a specific app or platform, potentially sacrificing the generalizability of the results. Finally, we cannot rule out the possibility of selection bias. As the surveys were administered online, participants were likely familiar with the internet and possibly mobile technology as well. This could explain the unexpected finding that older individuals were more likely to continue using the app.

Conclusions

This study demonstrated that continued use of apps and wearables contributes to both increasing and maintaining PA levels over 6 months. The results also revealed that app features associated with increases in PA differ from those linked to the maintenance of PA, highlighting the importance of tailoring apps to users' PA levels and readiness. We believe these findings make a meaningful contribution to the literature by highlighting

the continued use of apps and wearables as key factors in enhancing and maintaining high levels of PA. Additionally, it is noteworthy that more than half of the users continued using the apps through the 6-month follow-up, despite the poor retention rates and barriers commonly reported in the literature (eg, [53,54]). This may suggest that attitudes toward and the acceptability of mHealth apps are changing, with the COVID-19 pandemic potentially serving as an opportunity. Health care practitioners could increasingly rely on app-based approaches in their intervention repertoires, although integrating mHealth into routine practice remains a challenge [55]. Unfortunately, we did not assess the barriers preventing users from continuous engagement (eg, [56,57]), and these should be explored in future research to identify effective strategies for maintaining active user engagement.

Abstract

Background: Early detection of cognitive impairment or dementia is essential to reduce the incidence of severe neurodegenerative diseases. However, currently available diagnostic tools for detecting mild cognitive impairment (MCI) or dementia are time-consuming, expensive, or not widely accessible. Hence, exploring more effective methods to assist clinicians in detecting MCI is necessary.

Objective: In this study, we aimed to explore the feasibility and efficiency of assessing MCI through movement kinetics under tablet-based "drawing and dragging" tasks.

Methods: We iteratively designed "drawing and dragging" tasks by conducting symposiums, programming, and interviews with stakeholders (neurologists, nurses, engineers, patients with MCI, healthy older adults, and caregivers). Subsequently, stroke patterns and movement kinetics were evaluated in healthy control and MCI groups by comparing 5 categories of features related to hand motor function (ie, time, stroke, frequency, score, and sequence). Finally, user experience with the overall cognitive screening system was investigated using structured questionnaires and unstructured interviews, and their suggestions were recorded.

Results: The "drawing and dragging" tasks can detect MCI effectively, with an average accuracy of 85% (SD 2%). Using statistical comparison of movement kinetics, we discovered that the time- and score-based features are the most effective among all the features. Specifically, compared with the healthy control group, the MCI group showed a significant increase in the time they took for the hand to switch from one stroke to the next, with longer drawing times, slow dragging, and lower scores. In addition, patients with MCI had poorer decision-making strategies and visual perception of drawing sequence features, as evidenced by adding auxiliary information and losing more local details in the drawing. Feedback from user experience indicates that our system is user-friendly and facilitates screening for deficits in self-perception.

Conclusions: The tablet-based MCI detection system quantitatively assesses hand motor function in older adults and further elucidates the cognitive and behavioral decline phenomenon in patients with MCI. This innovative approach serves to identify and measure digital biomarkers associated with MCI or Alzheimer dementia, enabling the monitoring of changes in patients' executive function and visual perceptual abilities as the disease advances.

Introduction

Background

Mild cognitive impairment (MCI) is an intermediate stage between age-related cognitive decline and dementia, which affects the individual's cognitive, social, and mental aspects and can lead to emotional problems that affect daily living [1]. A recent study has revealed that the incidence of MCI is 6.7% for individuals aged 60 to 64 years, 8.4% for those aged 65 to 69 years, 10.1% for those aged 70 to 74 years, 14.8% for those aged 75 to 79 years, and 25.2% for those aged 80 to 84 years [2]. Previous evidence has shown that patients with MCI develop dementia or Alzheimer dementia (AD) at a rate of approximately 10% to 15% per year [3,4], significantly higher than the incidence of dementia in the general population, which is 1% to 2% per year. The increasing prevalence of dementia, coupled with a high conversion rate, presents challenges not only for those directly impacted by the condition, including individuals, caregivers, and families, but also for society.

Despite the high risk of dementia for people with MCI and the need for early intervention [5], there are currently no drugs or other treatments to modify the clinical course or delay the onset of dementia [6]. In clinical settings, the diagnostic process for MCI could be costly, often involving expensive and sometimes invasive or time-consuming examinations. In addition, the early symptoms of MCI are subtle, making it easy for patients to attribute them to the normal aging process rather than to cognitive impairment and leading to an early stage where patients may not undergo clinical examination. Therefore, achieving an effective MCI diagnosis remains one of the most challenging tasks in geriatric psychiatry [7].

Digital Drawing Tasks in MCI Detection

As a comprehensive activity, drawing requires various cognitive skills including orientation, selective and sustained attention, visual memory and reconstruction, visuospatial organization, and motor performance [8]. These requirements suggest that older adults may be susceptible to cognitive dysfunction, and an accurate assessment of their involvement in relevant activities might aid in identifying such disabilities [9]. With the development of portable devices and mobile computing, some researchers have attempted to improve drawing tests using digital methods to capture more information and influencing factors related to screening for MCI, such as working memory, attention allocation, cognitive flexibility, as well as visual and spatial processing. These factors play an essential role in the screening and assessment processes for MCI and help provide more comprehensive information about cognitive functioning, leading to a better understanding of cognitive health and possible problems in participants.

Recently, Müller et al [10] used a Windows Surface Pro 4 digitizer and a handheld stylus pen to evaluate the digital Clock Drawing Test (dCDT) and found a significant difference in time in air between the healthy older adults and the patient group. Afterward, Dion et al [11] discovered a difference in the "thinking time" percentage between the groups. The MCI group took 10 seconds longer to draw their clocks from memory, suggesting that the difference between those with and without MCI may lie in grouping and coordinating the necessary cognitive resources rather than severe drawing errors. Another study demonstrated differences in the time to completion, total pen stroke count, and higher-order decision-making latencies of dCDT between age groups, involving participants recruited as free of dementia and stroke [12]. As they transition from one part of the drawing to the next (eg, postclock delay), participants may use more diverse neurocognitive resources than simply processing speed. In addition to assessing the Clock Drawing Test (CDT), other drawing tasks were also studied. Kim et al [13] created a simplified Rey-Osterrieth Complex Figure Test (sRCFT) to assess digital pen strokes, spatial arrangement, and similarity of drawings in the drawing process, finding that these measures could serve as valuable digital biomarkers for studying visual structural dysfunction in AD. In addition, Müller et al [14] investigated the movement kinematics (ie, time in air, time on surface, and total time) of older adults with MCI when copying a 3D house to reflect their manual dexterity, visual space construction, and other cognitive abilities. Finally, in the digital tree drawing test, patients with MCI and early-stage AD used fewer colors and line widths, and their images displayed reduced contrast and heterogeneity [15].

Digital drawing tasks provide standardized test administration, more detailed feedback metrics, and automated scoring than traditional paper-based tests. However, these assessment tasks typically focus on the patient's overall performance, neglecting to capture detailed features (ie, clock face, numbers, and pointers in dCDT). In modern digital devices, tracking subtle cognitive changes in patients' selection of drawing areas, organization of shapes, and determining image sequences may offer a more practical approach to MCI detection.

Dual-Task Paradigm in MCI Detection

The dual-task paradigm is an experimental design approach for exploring the effects of multitasking on cognitive performance and brain function. In the dual-task paradigm, participants must perform ≥2 tasks simultaneously, involving different cognitive processes, such as attention, stimulus encoding, decision-making, working memory, response selection, and execution. This paradigm could detect changes in dual-task performance early in the progression of the most common neurodegenerative diseases [16]. Compared to other cognitive assessment tools, the dual-task paradigm is less influenced by the education level and is more applicable to participants with different educational backgrounds. In addition, the dual-task paradigm is quick, practical, and easy to apply in clinical practice, making it a promising method for cognitive assessment [17].

In studies related to the diagnosis of MCI, the analysis of dual-task gait tests has proven to be a valid method. The dual-task gait test is a commonly used clinical assessment that

requires participants to perform a cognitive task while simultaneously walking. In other words, participants must complete additional cognitive tasks such as counting, recalling words, or performing attention shifts while walking. For example, Montero-Odasso et al [18] conducted a dual-task gait test on 112 older adults with MCI and followed them for 6 years. Interestingly, high dual-task gait costs were associated with a 3.8-fold and a 2.4-fold increased risk of progression to dementia when counting backward and naming animals, respectively. Whitson et al [16] investigated gait-cognitive dual-task performance in 29 older adults and found that APOE 4 carriers exhibited more pronounced dual-task interference than low-risk participants. Compared to electronic sidewalks, Aoki et al [19] used a Kinect sensor to capture the whole-body movements of participants and extracted more substantial gait feature information by improving the motion performance capture method. Their findings revealed that a classifier based on dual-task gait features could detect older adults who scored low on the Mini-Mental State Examination (MMSE) test [20]. In addition, Ali et al [21] used the Vicon Nexus 2.8 motion capture system to obtain kinematic gait parameters such as velocity, peak knee extension angle, and dual-task cost for participants. Their study showed that the kinematic gait parameters of the dual-task peak knee extension angle for story recall gait could effectively differentiate the MCI group from the healthy control (HC) group.

Currently, methods for detecting MCI using the dual-task paradigm focus on gait-motor assessment or developing new screening tools. Commonly used screening methods for cognitive impairment in older adults (ie, CDT and Rey-Osterrieth Complex Figure Test [RCFT]) by neurologists, psychiatrists, and general practitioners still have good clinical outcomes due to their rapid administration, patient acceptability, and simple scoring rules [22,23]. Thus, integrating a dual-task paradigm into clinical screening tools may provide more alternatives to MCI detection.

Objective

We designed tablet-based “drawing and dragging” tasks, prototyped with clinically validated drawing tests, and explored the feasibility and efficiency of assessing MCI through movement kinetics under these tasks. In this study, the drawing task improves the traditional test clinicians use to fulfill the requirements for detecting richer cognitive domains. However, the dragging task is designed to meet the cognitive screening of older adults alone at home by providing a broader and more convenient means of self-examination and early warning. Finally, we hypothesized that movement kinetics features extracted from participants during drawing or dragging could effectively distinguish patients with MCI from healthy older adults.

Methods

Ethical Considerations

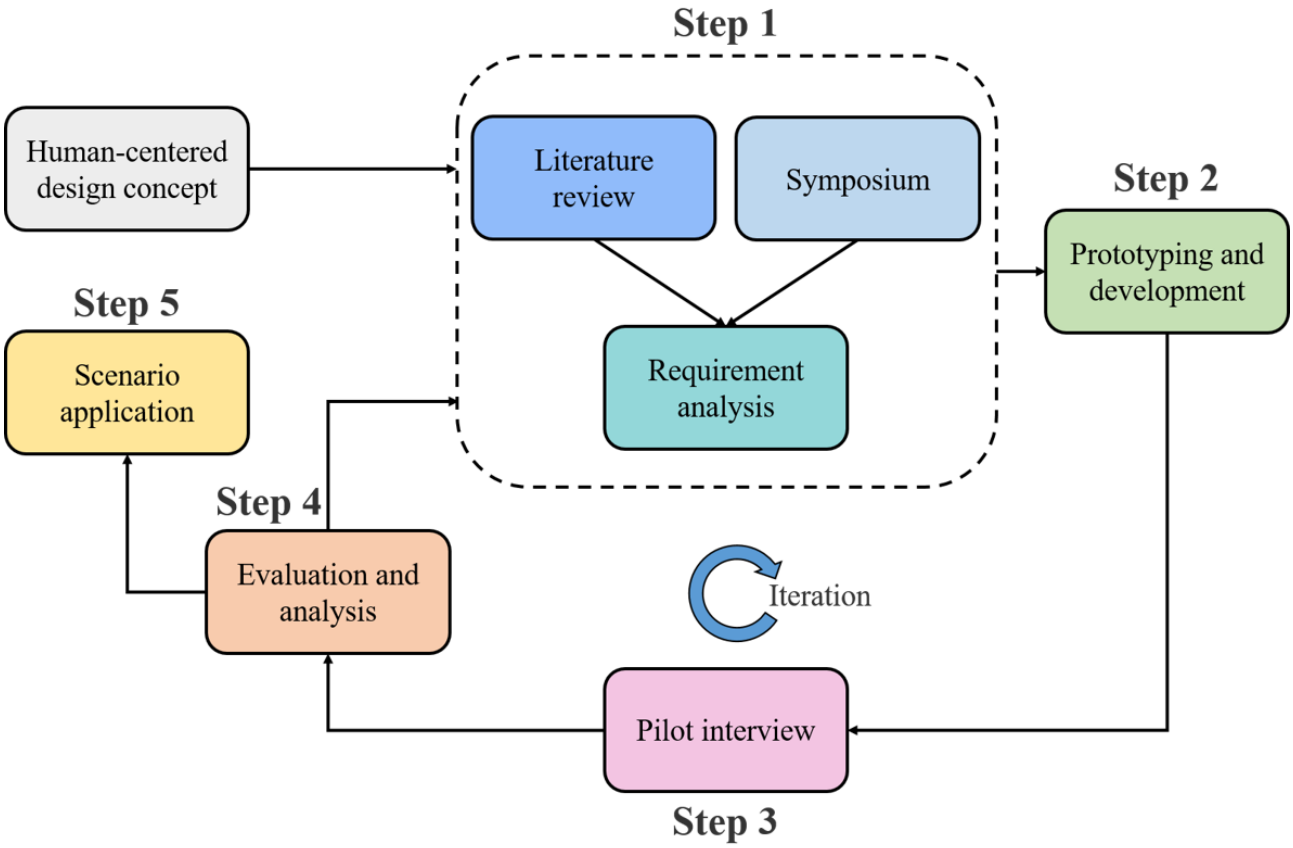
This research was reviewed and approved by the Biomedical Ethics Review Committee of Taiyuan University of Technology (20230118). The patients and participants provided their written informed consent to participate in this study. We provided US $10 to eligible older adults as compensation for participation.

Experimental Design

Design Overview

To design simple and effective “drawing and dragging” tasks for assessing hand motor function, we applied a human-centered design approach [24], as shown in Figure 1. Specifically, the approach included (1) a literature review and symposium to analyze the requirements of patients with MCI, (2) prototype design and development, (3) pilot interviews, (4) system evaluation and analysis, and (5) scenario application. In step 1, we surveyed approximately 100 previous studies and performed a detailed analysis of relevant studies. In addition, we conducted symposiums, mainly involving communication between patients with MCI, healthy older adults, caregivers, neurologists, nurses, and engineers regarding what to do and how to interact. These efforts were mainly aimed at extracting user requirements and applying them to our cognitive system. On the basis of these findings, the engineers designed and developed a task prototype in step 2. Then, in step 3, we conducted pilot interviews to better understand the different preferences and demands of patients with MCI. In other words, the interviews were semistructured exchanges, and the experimental prototype was tested among healthy older adults, patients with MCI, and caregivers to refine our task further. These first 3 steps constitute an iterative design circle to continuously improve and adapt the task to the requirements of patients with MCI. In step 4, we evaluated the extent to which the designed task could effectively differentiate between patients with MCI and HC participants and how well the user experience was. Step 5 is the scenario application, that is, the extension to home, community, and clinical settings. In the experimental design phase, the main focus is on steps 1, 2, and 3 and the iterations between them, while the evaluation and analysis (step 4) are described in the *Results* section.

Figure 1. The human-centered design approach is applied to the process of cognitive tasks, and the first 3 steps form an iterative design circle to improve and adapt the tasks continuously.



Stakeholders

The stakeholders engaged in the experimental design encompass our development team (2 neurologists, 2 nurses, and 3 engineers), patients with MCI, healthy older adults, and caregivers. Neurologists and nurses are from our partner hospitals and have been working for 10 years on diagnosing and treating neurological diseases. The engineers comprised 1 PhD and 2 MS students specializing in human-computer interaction. In addition, we recruited 49 patients with MCI, 49 healthy older adults, and 4 caregivers. They were mainly from the community, nursing home, and hospital. All older adults completed the Montreal Cognitive Assessment (MoCA) test [25], the Clinical Dementia Rating (CDR) test [26], and an informed consent form and underwent comprehensive medical evaluations conducted by experienced neurologists (including detailed medical history, systematic physical examination, and imaging studies). Furthermore, neurologists conducted clinical interviews with patients or their caregivers and collected self-reports to assess and diagnose MCI comprehensively. Among the 49 patients with MCI, all had MoCA scores <26 and CDR scores of 0.5. Brain magnetic resonance imaging or computed tomography scans revealed no other structural abnormalities associated with cognitive impairment. We provided the participants with a notebook and a pen

Prototype 1: Design and Iteration

Using clinically validated paper-based drawing tasks as screening elements, we conducted a comprehensive review of clinical MCI screening tools and invited 4 (8%) of the 49 patients with MCI and 4 (8%) of the 49 healthy older adults to participate in a symposium. We focused on the following points:

1. Which of the existing MCI diagnostic methods in the clinical setting involve hand motor function?
2. Does the screening tool address integrated cognitive abilities (ie, memory, attention, visuospatial, motor planning, and executive functions)?
3. Does the application of screening tools extend to hospitals, nursing homes, or households?
4. The psychology of older adults, considering their preferences and cognitive limitations

The symposium results identified the CDT and RCFT as the primary tasks for the cognitive assessment system. Subsequently, in step 2 (Figure 1), the engineers designed and developed prototype 1 based on these tasks. Prototype 1 consisted of a tablet-based dCDT and a digital RCFT. The dCDT required participants to complete three tasks in the clock drawing area: (1) draw a clock face, (2) write all the numbers in the correct position, and (3) use the pointers to indicate “10 minutes past 11-o’clock.” Similarly, in the digital RCFT, participants were prompted to copy the Rey-Osterrieth Complex Figure [ROCF] on the left side within the copy area. Next, to assess the feasibility of the 2 drawing tasks in prototype 1 among older adults, we conducted interviews (step 3; Figure 1) with 6 older adults (patients with MCI: 3/49, 6%; healthy older adults: 3/49, 6%) from the community. The interviews involved engaging the older adults in the tests and soliciting their feedback and

opinions. Some common dialogues from the study participants are as follows:

> *Experimenter: Could you share your thoughts on these tests?*
>
> *Patient with MCI: What time do the pointers indicate? I forgot.*
>
> *Patient with MCI: Do others have their minute pointers pointing at the number '2'? Am I the only one with the minute pointer pointing at the number '10'?*
>
> *Patient with MCI: This figure (RCFT) is too complex to complete, and I prefer not to continue.*
>
> *Healthy individual: Am I performing as well as others?*
>
> *Healthy individual: Does it matter that the number of positions are painted at different intervals?*
>
> *Healthy individual: RCFT is too time-consuming, and my eyes are tired.*

Prototype 2: Design and Iteration

Using the pilot study (step 3; Figure 1), we found that older adults were somewhat confused by the rules of dCDT (Figure 2A) but were generally receptive and engaged in its implementation. However, the digital RCFT was less than ideal. Participants thought that the ROCF was too complex and challenging to complete at first glance. In addition, it typically took ≥10 minutes to complete, which was not user-friendly to older adults. Hence, in the second symposium, we modified the original figure to a relatively simplified version while retaining its main framework. The modification work was collaboratively undertaken by 2 neurologists from our affiliated hospital, each with >10 years of experience, to ensure a balanced representation of global and local components. While the original RCFT comprises 18 components (4 global and 14 local components) [27], our simplified version of the RCFT consists of 5 global components and 4 local components, as illustrated in Figure 3.

In the global components section, we maintained the large rectangle with horizontal, vertical, and diagonal crossings; the large triangle (only the position has changed); and the 4 horizontal lines in the upper left panel, while the rest of the regions or local components have been simplified. Regarding the local components section, we made the following modifications: (1) squares replaced the diamonds, (2) the 3-point circle was moved to the bottom, and (3) three triangles staggered up and down instead of 5 parallel lines. We staggered the triangles up and down to allow participants to focus more on local components. Finally, some overlapping lines and detail parts outside the outline were removed in the simplified version. After the development, a raw copy of sRCFT is shown in Figure 2B.

Figure 2. Interactive interface of drawing and dragging tasks. (A) digital Clock Drawing Test (dCDT; single task), (B) simplified Rey-Osterrieth Complex Figure Test (sRCFT; raw copy), (C) dCDT (dual task), (D) sRCFT (delayed recall), (E) clock "drag and drop", (F) sRCFT "point and line".

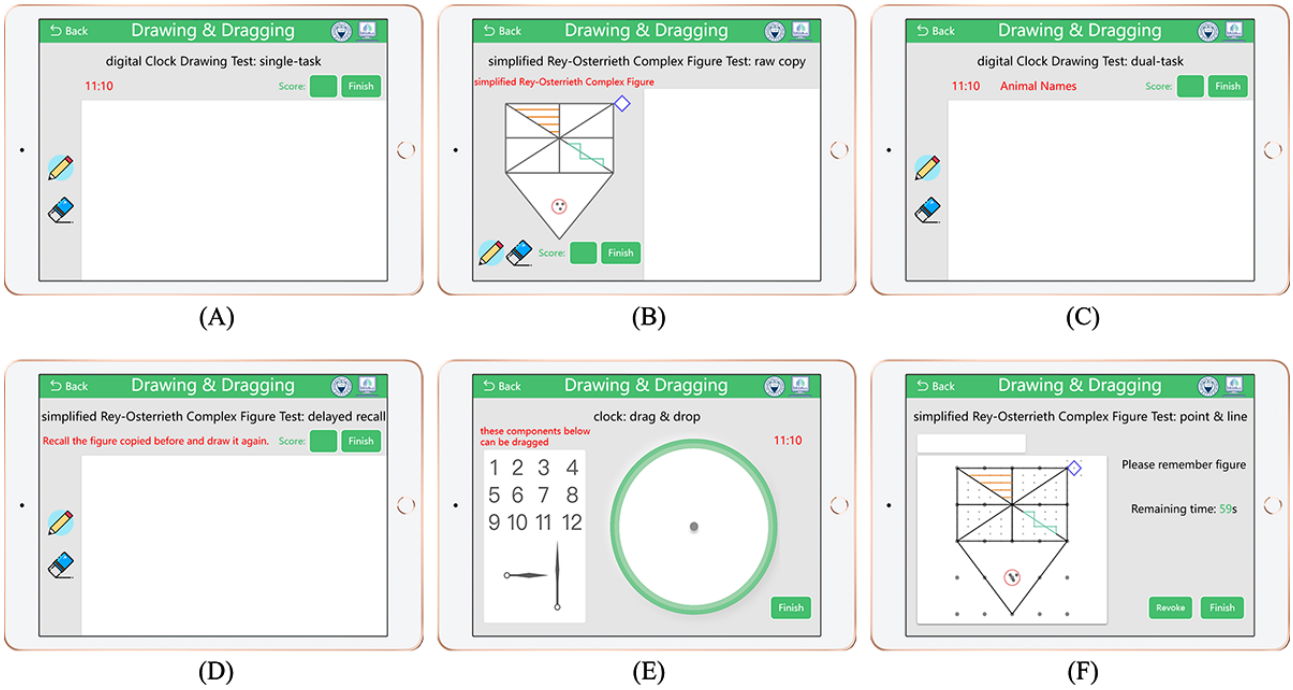


Figure 3. The simplified Rey-Osterrieth Complex Figure consists of 5 global and 4 local components.

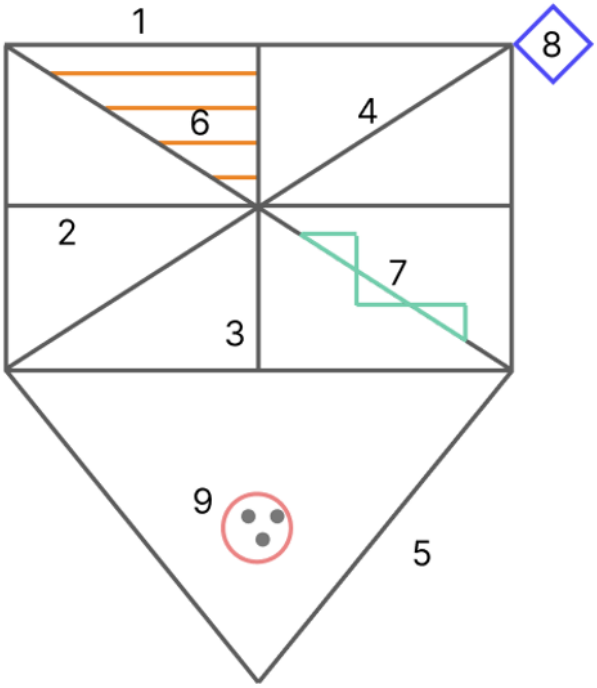


Global	1	Large rectangle
	2	Horizontal line
	3	Vertical line
	4	Diagonal cross
	5	Triangle
Local	6	4 parallel lines
	7	3 triangles
	8	Small square
	9	A smiley face

Subsequently, we conducted another pilot interview to investigate the performance of the sRCFT compared to the original RCFT on cognitive screening. We recorded the distribution of original RCFT and sRCFT scores for 24 (49%) out of 49 healthy older adults and 24 (49%) out of 49 patients with MCI in the raw copy and delayed recall (waiting 20 minutes to recall and draw the figure) tasks. The normality test for the score variables revealed that none of the groups met normality. Therefore, we used the median (IQR) for statistical description and the nonparametric Mann-Whitney *U* test for comparison between groups. As depicted in Table 1, the HC group scored significantly higher than the MCI group on the delayed recall task, while no significant difference was observed between the 2 groups in the raw copy task. Moreover, we examined the correlation between the raw copy and delayed recall scores of the original RCFT and sRCFT using Spearman correlation analysis. A positive correlation was noted between the original RCFT and sRCFT score (raw copy: r=0.812; P<.001 and delayed recall: r=0.816; P<.001; Figure 4).

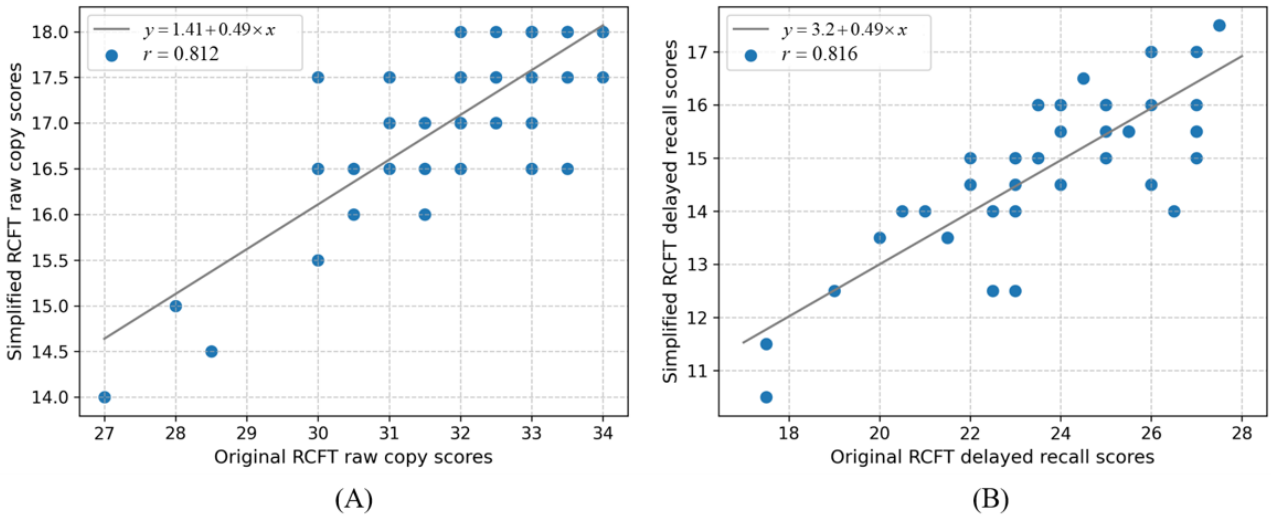
Table 1. Raw copy and delayed recall scores of healthy older adults and patients with mild cognitive impairment on the original and simplified Rey-Osterrieth Complex Figure Test (RCFT).

	HC[a] group (n=24)	MCI[b] group (n=24)	*P* value	*z* score
Original RCFT: raw copy (IQR 0-36)	32.5 (31.5-33.5)	32 (31-33)	.18	−1.350
Simplified RCFT: raw copy (IQR 0-18)	17.25 (16.5-17.5)	17 (16.5-18)	.94	−0.074
Original RCFT: delayed recall (IQR 0-36)	25.25 (24-27)	22.75 (21-24.5)	<.001	−3.639
Simplified RCFT: delayed recall (IQR 0-18)	16 (15-16.875)	14 (13.5-15)	<.001	−4.208

[a]HC: healthy control.

[b]MCI: mild cognitive impairment.

Figure 4. Correlation between raw copy and delayed recall scores on original and simplified RCFT: (A) raw copy and (B) delayed recall. RCFT: Rey-Osterrieth Complex Figure Test.



Prototype 3: Design and Iteration

As is well known, MCI encompasses changes in cognitive performance, including declines in short-term memory, working memory, logical thinking, verbal expression, spatial cognition, and executive function [24]. To comprehensively assess these aspects, we enhanced the drawing task during the third symposium, which involved adding 3 dual tasks to the dCDT and introducing a 10-minute delayed recall task in the sRCFT, as depicted in Figures 2C and 2D. In this prototype, 3 language function–related tasks include series 1 (low load: count backward from 100), animal names (medium load: name as many animals as possible), and series 3 (high load: subtract 3 from 100 and give the result) [28,29]. We combined the 3 language function–related tasks with the dCDT, resulting in 3 dual tasks. In the dual task, participants were required to perform a single dCDT task while completing a task related to language function. Series 1 was applied to test essential language functions, whereas series 2 and 3 focused on memory and logical thinking skills, respectively. Finally, according to the Schulman criteria, the dCDT score ranges from 1 point (ie, a perfectly accomplished CDT) to 6 points (ie, severe impairment and no identifiable clock) [30].

Performance in the delayed recall condition helps examiners assess visuospatial memory in declarative memory associated with the hippocampus and related areas of the right temporal lobe [31,32]. However, in the traditional delayed recall task, participants were asked to recall the previous figure 30 minutes after completing the RCFT raw copy task. Long waits are unwelcome and unpleasant for older adults. Therefore, we shortened the delayed recall time to 10 minutes [33] and adjusted the drawing sequence. The participants' performance in sRCFT will be scored in accuracy and location [34]. The score weights of the 9 components are equal, namely 2 (accurately drawn and correctly located); 1 (accurately drawn and incorrectly located or inaccurately drawn and correctly located); 0.5 (inaccurately drawn and incorrectly placed but identifiable); or 0 (inaccurately drawn, incorrectly located, and unidentifiable). Therefore, the possible range of raw scores is 0 to 18. A lower score indicates a more severe visual perception or construction function impairment.

In addition, during the nursing home interviews, 4 (8%) out of 49 healthy older adults mentioned that they were not accustomed to using the Apple Pencil for drawing and suggested incorporating a practice mode before initiating the test. Following discussions with the development engineers, we promptly integrated their feedback and added a practice mode, allowing free drawing without a time limit. At the same time, we assisted in teaching during the practice process to ensure that the participants could use the Apple Pencil in their experiments.

Prototype 4: Design and Iteration

To meet the demands for cognitive screening for older adults alone at home, we designed "drag and drop" and "point and line" tasks to indirectly assess their cognitive status by capturing subtle changes in hand motor function. Participating experimental designers included 4 (8%) out of 49 patients with MCI, 4 (8%) out of 49 healthy older adults, 2 (50%) out of 4 caregivers, and all our team members.

Similar to drawing, drag and drop is used to assess hand motor function and detect potential cognitive decline in patients with MCI [35,36]. So, we designed a clock "drag and drop" task, as shown in Figure 2E. The clock "drag and drop" task requires participants to drag or drop numbers and pointers from the drag area to the inside of the clock face, then rotate the pointers to point "10 minutes past 11." On the other hand, concerning sRCFT, we transformed the drawing task into a "point and line" task, as shown in Figure 2F. First, the participants were asked to memorize the simplified ROCF (including his position, belt, and all details) for 60 seconds. Then, the participant began recalling, connecting dots, and drawing lines to reproduce the target pattern. Specifically, the clock "drag and drop" task was scored on a scale of 0 to 3 (ie, numbers position, numbers order, and pointers indication; a high score indicates a perfect clock).

The sRCFT "point and line" task has the same scoring rules as the sRCFT drawing task (ie, a score between 0 and 18). In addition, during the pilot interviews, 4 (8%) out of 49 patients with MCI and 4 (8%) out of 49 healthy older adults from our partner hospitals completed the tests.

Experimental Participants and Procedure

Before initiating the study, we conducted a power analysis to estimate the sample size required to detect significant differences between the MCI and HC groups. This analysis considered an expected effect size of 0.3, a significance level of .05, and a statistical power of 0.8, requiring at least 82 participants per group [37]. Similar research in the field also informed our sample size, which typically used participant numbers within this range for comparable outcomes [38-41].

We rerecruited 207 participants from the geriatrics and neurology department research clinics at our collaborating hospitals who had not previously been involved in the design or development of the experiment. Participants were identified using a purposive sampling method [42], with the process being meticulously overseen by experienced neurologists. The inclusion criteria were that participants must (1) have normal hearing and vision or corrected to normal, (2) be aged >65 years, (3) have completed the MMSE test, (4) have completed the MoCA test, (5) have completed the CDR test, (6) be capable of moderate exercise without physical disabilities, (7) have no severe depressive symptoms or other mental illnesses, (8) be capable of using smart devices (eg, smartphones and tablets). Neurologists contacted potential participants during their clinic visits and explained the study's purpose, related procedures, and the possible impact of the research findings. Once potential participants expressed interest, neurologists conducted comprehensive medical evaluations, including detailed medical history collection; physical examinations; brain imaging (magnetic resonance imaging or computed tomography scans); and cognitive function assessments (using the MMSE, MoCA, and CDR scales). Of 207 participants, the MCI group comprised 108 (52.2%) participants who scored <26 on the MoCA and had a CDR score of 0.5, while the HC group included 99 (47.8%) healthy older adults without symptoms of cognitive decline. Brain imaging scans revealed no structural abnormalities causing cognitive impairment. Furthermore, all patients with MCI met the criteria proposed by the National Institute of Neurological and Communicative Disorders and Stroke and the Alzheimer's Disease and Related Disorders Association [43]. We also administered the habitual hand questionnaire [44], which consisted of 13 items, to all participants. The MCI and healthy groups were matched for age, gender, hand preference, education, average sleep duration (in general), exercise habit (regularly engaging in exercise or infrequently), and years of smart device use. Table 2 summarizes the clinical and demographic information for all participants.

Table 2. Clinical and demographic characteristics (n=207).

	MCI[a] (n=108)	HC[b] (n=99)	*P* value
Age (y), mean (SD)	71.34 (4.48)	70.11 (4.00)	.13
Gender, n (%)			.81
Woman	64 (59.2)	57 (57.6)	
Man	44 (40.7)	42 (42.4)	
Hand preference, n (%)			.43
Left	11 (10.2)	7 (7.1)	
Right	97 (89.8)	92 (92.9)	
Education years, mean (SD)	6.21 (3.28)	6.81 (2.89)	.31
Hours of sleep, mean (SD)	5.93 (1.20)	6.28 (1.06)	.11
Exercise habit, n (%)			.63
Yes	52 (48.1)	51 (51.5)	
No	56 (51.9)	48 (48.5)	
Smart device use years, mean (SD)	5.52 (2.54)	5.87 (2.52)	.47
MoCA[c], mean (SD)	24.09 (1.13)	27.04 (1.21)	<.001
MMSE[d], mean (SD)	25.31 (1.13)	28.00 (0.92)	<.001

[a]MCI: mild cognitive impairment.

[b]HC: healthy control.

[c]MoCA: Montreal Cognitive Assessment.

[d]MMSE: Mini-Mental State Examination.

We implemented digital "drawing and dragging" tasks on the Lenovo Qitian M530-A154 (AMD Ryzen 7 PRO 2700/16 GB). Our system introduction video can be found in Multimedia Appendix 1. Before the experiment began, participants could draw freely with an Apple Pencil until they were prepared to collect data. After the practice mode, given the sRCFT (delayed

recall) task rules, we clarified the execution sequence of digital drawing tasks, namely (1) sRCFT raw copy, (2) dCDT single task, (3) dCDT dual task, (4) sRCFT delayed recall, (5) clock "drag and drop," and (6) sRCFT "point and line." All tests were run on an iPad 2019 tablet (seventh generation, 3 GB/128 GB, with 10.2 inches and 2160×1620 touch screen), and Apple Pencil was configured for drawing and lining. The experimenter is engaged in the entire data collection process, clarifying the experiment's rules and procedures for the participants and documenting their feedback. At the beginning of the experiment, the experimenter explained the whole process to the participants and encouraged them to draw freely to familiarize themselves with the use of Apple Pencil. Once participants felt prepared, the test commenced.

Structured Questionnaire and Unstructured Interview

A structured questionnaire was used to investigate users' experiences of the overall cognitive screening process. The questionnaire is rated on a scale of 1 to 5, with higher scores indicating better performance in this area. The questionnaire consisted of four questions.

- Question 1: are the tasks easy to understand and interact with?
- Question 2: do the tasks evoke self-awareness and inspire them?
- Question 3: are the tasks are interesting?
- Question 4: would the tasks be used consistently in future daily life?

The unstructured interview was designed to gather user feedback on the digital cognitive tests, aiming to enhance the system further. The discussion centered on two primary themes:

(1) what are your thoughts on the "drawing and dragging" tasks?
(2) What aspects do you believe require optimization?

Data Processing and Feature Extraction

Tablet-based "drawing and dragging" tasks can assess the hand motor function and cognitive abilities of older adults. The data obtained from these tests were used for feature extraction, serving as a digital biomarker to distinguish individuals with MCI from those who were healthy. Therefore, we conducted data cleaning procedures before extracting the features, which involved removing outliers and ensuring data consistency. Next, we extracted 5 features related to hand motor function, including time, stroke, frequency, score, and sequence. All these features were extracted from the drawing or dragging tasks participated by older adults. A comprehensive overview of the details of these 5 categories of features can be found in Multimedia Appendix 2.

Statistical Analysis

Statistical analysis was conducted using SPSS software (IBM Corp) to analyze tablet device demographic characteristics and cognitive data. Age, years of education, sleep duration, years of smart device use, MoCA scores, and MMSE scores were described using means (SDs), while gender, hand preference, and exercise habits were presented as percentages. Furthermore, we conducted the Kolmogorov-Smirnov test to assess the normal distribution of all variables. For those variables conforming to a normal distribution, we applied 2-tailed *t* tests (for continuous variables) and chi-square tests (for categorical variables) to determine the significance of intergroup differences. For nonnormally distributed variables, we used the nonparametric Mann-Whitney *U* test to assess intergroup differences and estimated CIs using the Hodges-Lehmann estimator. In addition, logistic regression analysis was performed to evaluate the diagnostic value of the chosen variables in discriminating between healthy older adults and patients with MCI. The statistical significance level for all tests was set at $P<.05$.

Results

Analysis of Hand Motor Function Features

Table 3 exhibits the statistical comparison results between the MCI and HC groups concerning hand motor function features. In terms of MCI detection, the findings reveal discrepancies in the features selected across different tasks, indicating variations in the number of valid features among them. For instance, in the dCDT tasks (ie, dCDT single task, dCDT series 1, dCDT animal names, and dCDT series 3), the number of features with significant ($P<.05$) was 7, 7, 2, and 8, respectively. Furthermore, our analysis based on the number of selected features indicates that time- and score-based features outperformed stroke- and frequency-based features. Notably, features with significant ($P<.001$) were predominantly observed in time- and score-based features, while they were rare in stroke- and frequency-based features (only observed in sRCFT raw copy and clock drag and drop). Particularly, significant differences between the 2 groups were observed regarding time in the air, time on the surface, and time being dragged. Compared to the MCI group, the HC group exhibited significantly shorter times for switching between strokes and quicker drawing or dragging speeds. Similarly, the *P* values of the score features were mostly <.05, except for the sRCFT task (raw copy), which yielded the preferred features for subsequent logistic regression model construction. However, the dCDT animal names outcome was deemed unsatisfactory. During data collection, it was observed that most participants (151/207, 72.9%) were more accustomed to using the names of the 12 Chinese zodiac animals (Chinese folk culture), which may coincide with the clock numbers (1-12).

Table 3. Statistical comparisons were conducted for 4 categories of features between healthy older adults and patients with mild cognitive impairment.

Analysis of Drawing Sequences

We converted the drawing of the dCDT and sRCFT into pseudocolor images encoded by a series of colors in the order of strokes (Multimedia Appendix 3). In the dCDT single task, patients with MCI tended to rotate the tablet when writing numbers (making some numbers look upside down) and drawing lines to determine the 12 o'clock direction (MCI group: numbers 2 and 5 in Multimedia Appendix 3). Furthermore, upon analyzing the dCDT dual task, we noted that healthy older adults may exhibit errors in number positioning and slight gaps between numbers in series 1s due to increased cognitive load (HC group: numbers 2, 3, and 4 in Multimedia Appendix 3). As anticipated, both groups encountered challenges with the relatively complex series 3s. Notably, even some healthy older adults displayed significant gaps between numbers. However, in the spatial organization of the sRCFT, there was no discernible difference between the 2 groups (ie, global-first or local-first approach or top-first and bottom-second strategies). Particularly, healthy older adults exhibited good recall of figures, albeit with minor omissions in some details. Conversely, patients with MCI showed poor recall of figures, indicating deficits in visual memory and spatial construction abilities.

Diagnostic Value of "Drawing and Dragging" Tasks

To further explore the diagnostic value of the designed tasks in distinguishing patients with MCI from HC participants, we used a forward stepwise inclusion method in which the features extracted from the task were entered into a logistic regression model, where the diagnostic group (HC vs MCI) was considered as the dependent variable, and the task-extracted features were used as the independent variables, as shown in Table 4.

Table 4. Digital drawing and dragging tasks to construct logistic regression models with selected variables and their performance.

Model and selected variable	β	OR[a] (95% CI)	*P* value
dCDT[b]: single task			
Score	1.430	4.180 (2.070-8.441)	<.001
Number unpainted time	0.178	1.195 (1.075-1.327)	.001
Pointer unpainted time	0.326	1.385 (1.166-1.646)	<.001
dCDT: dual task			
Number painting time	0.415	1.515 (1.228-1.869)	<.001
Number unpainted time	0.092	1.097 (1.036-1.161)	.001
Number painting frequency	0.343	1.409 (1.080-1.837)	.01
sRCFT[c]: raw copy			
Figure painting time	0.141	1.152 (1.071-1.238)	<.001
Figure unpainted time	0.168	1.183 (1.085-1.290)	<.001
sRCFT: delayed recall			
Score	−0.689	0.502 (0.339-0.744)	.001
Figure painting time	0.149	1.161 (1.058-1.274)	.002
Figure unpainted time	0.096	1.101 (1.028-1.178)	.006
C lock: drag and drop			
Number drag time	0.135	1.145 (1.066-1.230)	<.001
Pointer drag time	0.260	1.297 (1.147-1.468)	<.001
Hand drag frequency	0.487	1.627 (1.268-2.087)	<.001
sRCFT: point and line			
Thinking time for the first stroke	−0.856	0.425 (0.259-0.696)	.001
Local drawing time	0.220	1.246 (1.032-1.506)	.02
Local components score	0.118	1.126 (1.063-1.192)	<.001

[a]OR: odds ratio.

[b]dCDT: digital Clock Drawing Test.

[c]sRCFT: simplified Rey-Osterrieth Complex Figure Test.

Furthermore, we used 4 metrics to measure the classification performance of the models, including accuracy, sensitivity, specificity, and area under the curve, as shown in Table 5. Receiver operating characteristic curves for logistic regression models were plotted, as depicted in Figure 5. Notably, the sRCFT delayed recall reached 88.4% (183/207) of the highest detection accuracy, while its specificity results were also the best (90/99, 91%). Meanwhile, the area under the curve indicating the authenticity of the detection method is the highest in sRCFT delayed recall, signifying superior performance. In the dCDT dual task, 88% (95/108) of all predicted patients with MCI were actual patients with MCI. In contrast, the sRCFT raw copy yielded lower classification results, with an accuracy of 82.1% (170/207). Our interpretation of these findings is that relatively complex tasks (eg, dCDT dual task and sRCFT delayed recall) are associated with integrated cognitive abilities, including executive functioning, language comprehension and expression, information extraction, and spatial visualization, making them more effective in detecting cognitive deficits.

Table 5. Diagnostic value of digital drawing and home dragging tasks in healthy older adults and patients with mild cognitive impairment.

Model	Accuracy	Sensitivity	Specificity	AUC[a] (95% CI)	*P* value
dCDT[b]: single task	0.845	0.861	0.828	0.904 (0.846-0.962)	<.001
dCDT: dual task	0.855	0.880	0.828	0.892 (0.830-0.954)	<.001
sRCFT[c]: raw copy	0.816	0.843	0.788	0.885 (0.820-0.950)	<.001
sRCFT: delayed recall	0.884	0.861	0.909	0.945 (0.903-0.986)	<.001
clock: drag and drop	0.845	0.861	0.828	0.904 (0.846-0.962)	<.001
sRCFT: point and line	0.855	0.861	0.848	0.912 (0.859-0.965)	<.001

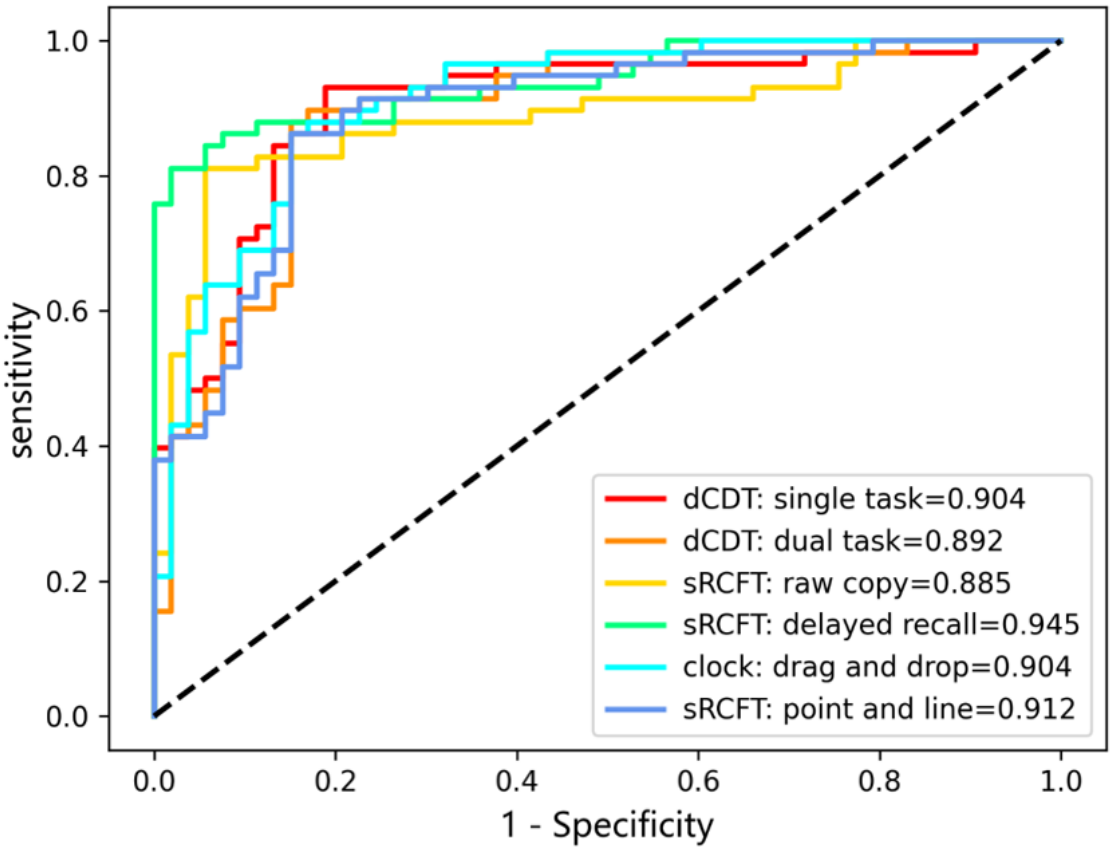
Figure 5. Receiver operating characteristic curves of our cognitive system. dCDT: digital Clock Drawing Test; sRCFT: simplified Rey-Osterrieth Complex Figure Test.



Comparison of Our Cognitive System With Existing Studies

We compared 4 aspects of sensitivity, specificity, administration time, and self-administration with digital cognitive tests identified in recent years to identify MCI and dementia, as shown in Table 6. For specificity and sensitivity, we averaged the results of the 4 drawing tasks and the 2 dragging tasks. The findings suggest that our cognitive system is equivalent to the best-performing Vigilance and Memory Test [45] in accurately discriminating patients with MCI. Similarly, in identifying healthy older adults, the performance on both types of tasks surpassed that observed in most recent studies, except for slightly lower performance than the screening system based on ROCF [46]. Although the total time for the digital drawing tasks was approximately 15 minutes, each task ranged from 3 to 5 minutes, aligning with the administration time (typically between <5 and 35 minutes) observed in most studies. Moreover, in the home dragging task, the time was generally shorter, and participants could achieve self-administration, a feature rarely observed in previous studies.

Table 6. Our cognitive system compared to existing mild cognitive impairment detection studies.

Test name	Study and year	Sensitivity	Specificity	Administration time (min)	Self- administration
Digital Tree Drawing Test	Robens et al [15], 2019	0.560	0.830	<5	—[a]
FACE[b]-memory	Alegret et al [41], 2020	0.734	0.721	30	Yes
Vigilance and Memory Test	Fung and Lam [45], 2020	0.861	0.753	15	No
Screening System based on ROCF[c]	Cheah et al [46], 2019	0.756	0.864	35	No
Digital Clock Drawing Test	Müller et al [47], 2019	0.854	0.775	<5	—
Smart Aging Serious Game	Cabinio et al [48], 2020	0.844	0.755	—	—
Virtual supermarket	Eraslan Boz et al [49], 2020	0.630	0.720	25	Yes

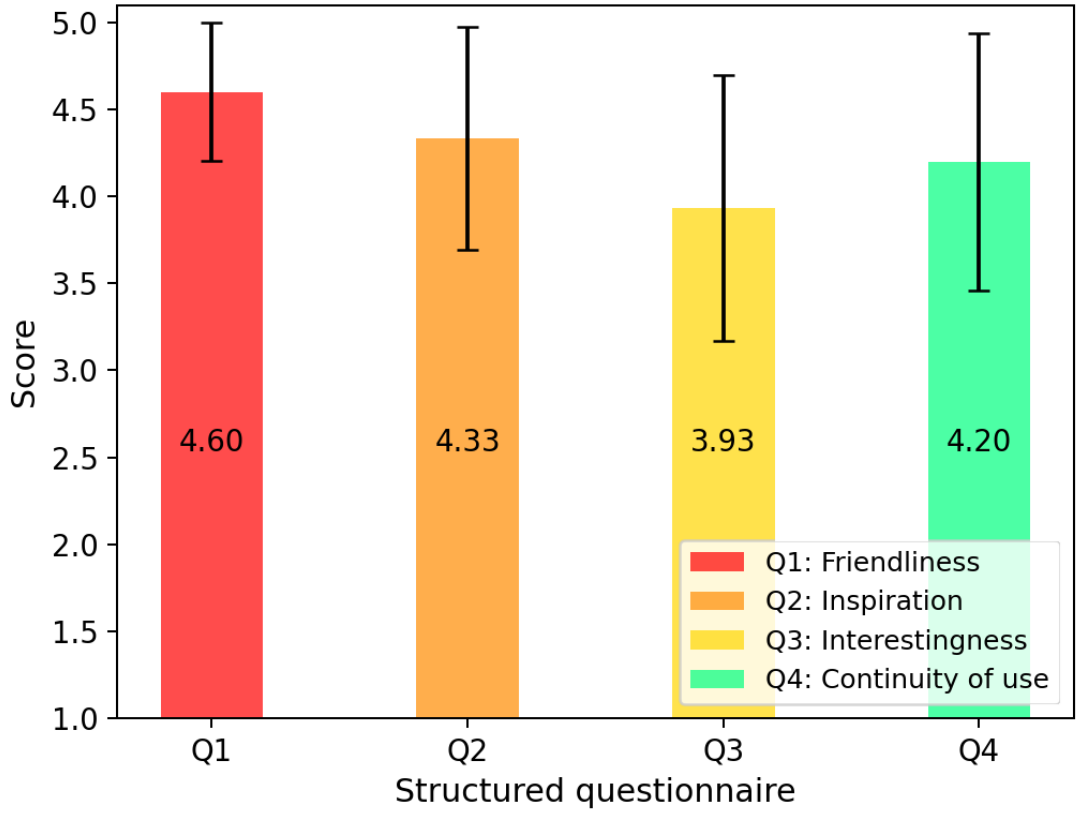
User Experience of Cognitive Screening Process

Figure 6 illustrates the results of the questionnaire experiment, where the error bars represent SD. All 207 participants rated the screening process highly across all aspects. The mean score for question 1 (4.60) was the highest among all questions, suggesting that our system was user-friendly, enabling most older adults to complete each test. However, the score for question 3 (3.93) was the lowest of all 4 questions, possibly due to the system's limited interaction, resulting in tasks being perceived as less engaging. Furthermore, most older adults (179/207, 86.5%) reported that our system engaged their cognition and helped identify cognitive deficits during self-screening (question 2: 4.33), expressing an interest in continued use in the future (question 4: 4.20).

Figure 6. User experience results with the structure questionnaire. Q: question.



Similarly, we gleaned valuable insights from unstructured interviews. All participants concurred that the screening tool is user-friendly and practical. Furthermore, older adults offered valuable suggestions for enhancing the screening tool: (1)

integrating social features to bolster user engagement and (2) providing instructional videos for each test to aid participants in comprehending the task requirements and procedures more effectively.

Discussion

Design Advantages Behind "Drawing and Dragging" Tasks

First, we digitized the traditional drawing test and assessed cognitive performance using a digital pen and tablet. The screening system recorded task-related data (eg, time, score, stroke, frequency, and sequence) and automatically uploaded these data to a remote cloud server where they could be analyzed and visualized through statistical analysis for easy access by neurologists and patients. Second, we captured the hand motor function features of each module (ie, clock face, number, and pointer) in dCDT to further explore the specific cognitive deficits of patients with MCI, which are rarely mentioned in the existing literature. In addition, the sRCFT was well received by older adults in practical testing settings and was easier to administer. Third, we introduced 3 tasks related to language function in the dCDT, expanding the assessment capabilities of the drawing system and increasing its potential application in detecting various cognitive impairments. Fourth, each task was time efficient, taking only 3 to 5 minutes. Older adults were willing to engage with and accept this, effectively avoiding the negative emotional impact of prolonged testing. Fifth, the screening system provides drawing and dragging interaction, which maintains the traditional drawing test requirements while meeting patients' needs for self-perception screening. In other words, the system can be applied to hospitals and clinics to facilitate physicians to understand patients' conditions in a timely and effective manner and can also meet the self-assessment of the cognitive level of older adults at home and provide an early warning means.

Detection Accuracy and Interpretability of Features

As for the cognitive assessment results, the 4 drawing and 2 dragging tasks performed well in discriminating abilities (average accuracy of 85.2%), comparable to the results of alternative state-of-the-art methods [47,50,51]. In addition, statistical hypothesis testing was conducted on the 5 categories of critical features acquired during the cognitive assessment. The analysis results provide three insights: (1) time features are the most prominent in cognitive assessment; (2) key features vary in different tasks; (3) most older adults strive for perfection in drawing or dragging tasks and ignore the features of movement kinematics, such as long-term stagnation in the air, multiple drawings to make the figure symmetrical, and slow drawing or dragging speed.

Regarding the digital pen stroke data analysis, we compared differences between the 2 groups in the dCDT. Typically, healthy older adults prioritized drawing the numbers 12, 6, 3, and 9 to divide the clock face area accurately and make the clock more perfect, partly reflecting their ability to generate adequate decision-making strategies [52].

In contrast, patients with MCI were accustomed to rotating the tablet to write numbers in sequence, counterclockwise to write numbers from 12, unable to indicate "10 minutes past 11 o'clock" and refine the scale between numbers 11 and 12. These behavioral patterns reveal deficiencies in patients with MCI's abilities related to time perception, numerical comprehension, and the organization and planning required for executing cognitive tasks [30,53]. On the other hand, when comparing drawing sequences between healthy older adults and patients with MCI in the sRCFT, most participants followed similar patterns: (1) from top to bottom, (2) from global to local, and (3) checking and filling in missing information. Some patients used unconventional methods, such as mirror drawing or completing the global structure last, possibly due to personal painting habits. Notably, patients with MCI scored lower and omitted many local features in delayed recall, suggesting a link between the loss of detailed features and visual-spatial dysfunction or deficits in visual-spatial working memory [54,55]. Furthermore, our study primarily focused on extracting local features, which may offer better identification of patients with MCI.

Experience of "Drawing and Dragging" Tasks

In terms of user experience, 207 participants rated the ease of use positively, with an average score of 4.60 (SD 0.398). In contrast, the average score for task enjoyment was 3.93 (SD 0.765), which is less desirable. The "drawing and dragging" tasks are designed as a serious game to maintain rigor while assessing participants' perceptions through teaching and training methods. However, this approach may be less conducive to generating enjoyment and may challenge user interest, leading to a perception of dullness and tedium. Moving forward, our focus will be on enhancing plot design and incentives and making it resemble a real game by incorporating interactivity and feedback mechanisms.

Limitations and Future Work

For our study, it is important to acknowledge several potential limitations and proposed solutions. First, our sample size was relatively small, comprising only 207 participants. To address this, we intend to conduct a longitudinal study to validate the efficacy of the developed MCI screening tool, aiming to recruit a larger and more representative sample. Second, considering the visual condition of older adults, the "drawing and dragging" tasks were performed on a 10.2-inch touchscreen tablet. Therefore, whether this study's experimental results can be extrapolated to smaller-screen smartphones remains to be determined. We will validate these smartphone tasks to fully evaluate their applicability, considering the user experience on different devices.

Conclusions

We present an MCI detection system based on the digital "drawing and dragging" by assessing the movement kinetics of older adults during various tasks. The interactive system comprises 4 digital drawing tasks and 2 home dragging tasks. We report how these 6 cognitive tasks are designed, optimized, and evaluated through research on traditional clinical screening tools, discussions with related neurologists, and user experience

feedback. Then, specific parameters were combined for different tasks, and different mixed models were constructed. The experimental outcomes demonstrate the efficacy of the proposed model in distinguishing patients with MCI from healthy older adults, garnering positive reception from multiple users. In a broader context, this study advances novel approaches for nuanced feature extraction of movement kinetics in individuals with MCI, offering tangible support for developing cognitive impairment detection systems.

Acknowledgments

This work was supported by the Central Guidance for Local Science and Technology Development Funds (YDZJSX2022C004) and National Natural Science Foundation Collaboration (U21A20469). In addition, the authors would like to thank all the volunteers for their participation in their experiment.

Authors' Contributions

AL contributed to paper writing, experimental design, and data analysis, while JL contributed to experimental design and system development. JC and WW collected and organized the data. SC proofread the paper for formatting and grammar. JZ and YQ were responsible for experimental design and system optimization.

Abstract

Background: Mobile health (mHealth) technologies are increasingly used in contact tracing and case finding, enhancing and replacing traditional methods for managing infectious diseases such as Ebola, tuberculosis, COVID-19, and HIV. However, the variations in their development approaches, implementation scopes, and effectiveness introduce uncertainty regarding their potential to improve public health outcomes.

Objective: We conducted this systematic review to explore how mHealth technologies are developed, implemented, and evaluated. We aimed to deepen our understanding of mHealth's role in contact tracing, enhancing both the implementation and overall health outcomes.

Methods: We searched and reviewed studies conducted in Africa focusing on tuberculosis, Ebola, HIV, and COVID-19 and published between 1990 and 2023 using the PubMed, Scopus, Web of Science, and Google Scholar databases. We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines to review, synthesize, and report the findings from articles that met our criteria.

Results: We identified 11,943 articles, but only 19 (0.16%) met our criteria, revealing a large gap in technologies specifically aimed at case finding and contact tracing of infectious diseases. These technologies addressed a broad spectrum of diseases, with a predominant focus on Ebola and tuberculosis. The type of technologies used ranged from mobile data collection platforms and smartphone apps to advanced geographic information systems (GISs) and bidirectional communication systems. Technologies deployed in programmatic settings, often developed using design thinking frameworks, were backed by significant funding and often deployed at a large scale but frequently lacked rigorous evaluations. In contrast, technologies used in research settings, although providing more detailed evaluation of both technical performance and health outcomes, were constrained by scale and insufficient funding. These challenges not only prevented these technologies from being tested on a wider scale but also hindered their ability to provide actionable and generalizable insights that could inform public health policies effectively.

Conclusions: Overall, this review underscored a need for organized development approaches and comprehensive evaluations. A significant gap exists between the expansive deployment of mHealth technologies in programmatic settings, which are typically well funded and rigorously developed, and the more robust evaluations necessary to ascertain their effectiveness. Future research should consider integrating the robust evaluations often found in research settings with the scale and developmental rigor of programmatic implementations. By embedding advanced research methodologies within programmatic frameworks at the design thinking stage, mHealth technologies can potentially become technically viable and effectively meet specific contact tracing health outcomes to inform policy effectively.

Introduction

Background

Mobile health (mHealth) technologies have become increasingly popular tools for facilitating data collection and delivery of health services worldwide [1,2]. The emergence of COVID-19 in 2020 increased interest in using mHealth technologies for contact tracing due to their ability to achieve case finding goals without the need for physical contact with an infected person [1,2]. Before COVID-19, mHealth technologies had already been used in Africa for contact tracing of infectious diseases such as Ebola [3-7], tuberculosis [8-11], and HIV, albeit with limited success. Compared to paper-based systems, the most apparent advantages of mHealth include its ability to reduce repetitive tasks and errors, systematic delivery of services, and improved monitoring due to efficient data processing in databases. Therefore, at face value, mHealth technologies have the potential to overcome challenges encountered when using traditional paper-based systems for contact tracing, thereby improving outcomes.

Contact tracing is a strategy for actively and systematically screening for symptoms among individuals exposed to someone with a transmissible disease to determine whether they require further diagnostic evaluation [12-14]. A key advantage of contact tracing is that, in principle, it reduces the time from when an individual falls ill with an infectious disease to when they are diagnosed, preventing further transmission to healthy persons. A contact, defined as any person living with or someone in a social circle who has regular contact with an individual with a transmissible disease, is at the highest risk of contracting the same disease due to their proximity to the infected person. Therefore, contacts are defined as a high-risk priority group for contact tracing [12]. The World Health Organization has long recommended and supported contact tracing for tuberculosis and Ebola [15,16] and promotes contact tracing as a critical intervention for tuberculosis control in high-burden countries [16].

Tuberculosis contact tracing can be seen as a cascade of activities that begins with finding an individual with the disease of interest, referred to as the index patient, and collecting information about their close contacts [12]. These activities are followed by a household visit to screen the enumerated persons for tuberculosis symptoms and may include collecting sputum samples from symptomatic contacts for laboratory testing—anyone testing positive for tuberculosis is referred to health facilities for linkage to care [12]. During household visits, contact tracing also serves as a pathway for accessing household contacts eligible for and initiating tuberculosis preventive therapy [14]. There are variations to contact tracing, with recent modalities using portable chest x-rays for identifying individuals eligible for tuberculosis testing [17,18] and oral swabs as an alternative to sputum samples [19,20]. In South Africa, contact tracing has now evolved from testing only symptomatic persons to universal testing of all household contacts and, in the process, initiating tuberculosis preventive therapy in eligible contacts [21].

The process for conducting contact tracing is rigorous. Each step in the contact tracing cascade requires documentation to enable contact follow-up, communication of results, linkage to care, and program monitoring and evaluation. Contact tracing programs rely significantly on efficient data collection to inform decision-making and patient management—in the absence of this, the process loses its cost-effectiveness and may become unattractive to national tuberculosis programs. Within Africa, countries have relied on inefficient paper-based data collection that overburdens outreach workers responsible for tracing household contacts but also results in poor data quality due to inevitable human error and inadequate accountability due to the manual processes required to collate field data [12,22-25]. These systems could be improved or overhauled by introducing mHealth technologies to optimize the documentation of activities in each step of the cascade.

Objectives

Despite the potential of mHealth to overcome traditional paper-based system challenges, there is evidence suggesting that improvements in contact tracing outcomes using mHealth technologies remain insufficient and “largely unproven” [24,26-28]. To address the evidence gaps, this systematic review assessed technologies on tuberculosis, Ebola, HIV, and COVID-19. While our focus remains predominantly on tuberculosis, we included these additional diseases due to similarities in contact tracing methods, enhancing the wider applicability of our findings. We aimed to synthesize information on the development, implementation, and evaluation of these technologies to better guide future work and enhancements. We hypothesized that synthesizing this existing information on the technologies will reveal valuable insights into the continuum of mHealth apps, their benefits, and limitations, thereby shaping improvements in future contact tracing efforts.

Methods

Literature Search

We conducted a systematic review of mHealth technologies used for contact tracing for selected infectious diseases and reported the results using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. We conducted an iterative search of all studies published in or translated into English from January 1, 1990, to December 31, 2023, in electronic databases, including PubMed (MEDLINE), Scopus, Web of Science, and Google Scholar (Multimedia Appendix 1). The year 1990 was chosen because it represents the earliest period during which the literature suggests that digital phones were introduced and available for use in health [29,30]. In addition, the 2023 cutoff allowed for the inclusion

of technologies that may have been used during the COVID-19 pandemic. The following search terms were applied within the selected databases: *tuberculosis*, *mHealth* or *mobile health*, *telehealth* or *telemedicine* and *case finding* or *contact tracing*/*investigation* or *tuberculosis screening* or *COVID-19* or *Ebola* or *HIV*. We used Medical Subject Heading (MeSH) terms to search in PubMed. We used subject headings and keywords in databases that do not use MeSH terms, such as Scopus, Web of Science, and Google Scholar. The search terms are presented in Multimedia Appendix 1. The Boolean operators "AND," "OR," and "NOT" were used to join words in all databases to improve the accuracy and relevance of the literature.

Inclusion and Exclusion Criteria

The following study inclusion criteria were applied: (1) studies conducted in Africa and published between 1990 and 2023 (2) that included an mHealth technology either as an intervention or part of procedures for contact tracing (3) used to screen for tuberculosis, COVID-19, Ebola, and HIV or find and screen contacts of people infected with these diseases.

The following studies were excluded: (1) mHealth modeling studies; (2) mHealth protocols and proposals; and (3) mHealth systematic reviews, commentaries, and scoping reviews.

Screening of the Literature, Extraction, and Analysis

The initial database search was conducted by DLM, and all references were uploaded to a reference management software library (EndNote version 20; Clarivate Analytics) for abstract and title screening. In total, 2 reviewers (DLM and HC) performed the initial review of all articles according to the inclusion and exclusion criteria. Where there was disagreement on the classification of a reference, a third reviewer (JN) conducted an additional review and confirmed the final classification.

A web-based data extraction tool was developed on Microsoft Office 365 Forms (Microsoft Corp; Multimedia Appendix 2). Extracted data elements included the study title, year of publication, country, location where the technology was implemented (community, facility, or both), study design, target disease, and type of technology used. The same form also contained sections to capture qualitative data about how the technologies were developed and their implementation processes, including challenges and the outcomes to measure effectiveness.

We summarized and synthesized the systematic review results using the Joanna Briggs Institute approach [31], and the data were presented in tables and narrative text. The themes used in the analysis were predetermined: development, implementation, and outcomes. The development theme described the steps taken in the development of the technologies. The implementation theme described how the technologies were deployed, what and how they collected contact tracing data, and challenges and successes. The final theme focused on the contact tracing outcomes measured when mHealth technologies were used.

Quality Assessments and Risk of Bias

The included studies were assessed for risk of bias using tools appropriate for each study type. The steps followed in assessing risk are detailed in Multimedia Appendix 3 [6,8,27,32-48]. The Cochrane Risk of Bias 2 tool was used for randomized clinical trials [49]. Technologies used in programmatic settings and pretest-posttest studies were assessed using the Quality Assessment Tool for Before-After (pretest-posttest) Studies With No Control Group developed by the US National Heart, Lung, and Blood Institute [50]. Finally, cross-sectional studies were assessed using the Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies also from the National Heart, Lung, and Blood Institute [50].

Definitions

The World Health Organization broadly defines eHealth as "the use of information and communications technology (ICT) in support of health and health-related fields, including health care services, health surveillance, health literature, health education, knowledge and research" [51].

mHealth is a branch of eHealth that refers to mobile wireless technologies to support public health objectives [51,52]. mHealth technologies are mainly used on portable devices such as phones and tablets [52,53] and allow for the ubiquitous provision of services such as public health surveillance, sharing of clinical information, data collection, health behavior communication, and the use of mobile technologies to reach health goals [54].

"Programmatic pretest-posttest" describes the use of technologies in programmatic settings to deliver an interventions to large populations targeting specific outputs and outcomes.

"In-house software platform" refers to bespoke technologies without using existing platforms. For example, many public health projects build forms on platforms such as Open Data Kit (ODK), Epi Info, and REDCap (Research Electronic Data Capture; Vanderbilt University), and in this review, these were not considered in-house software platforms.

"The effectiveness of an mHealth technology used in programmatic settings" is defined in the context of a project or program designed to implement an intervention with a target and without the use of research principles. Effectiveness in this sense is the achievement of a set target, such as the number of people screened using an mHealth technology.

"Effectiveness in a research project of an mHealth technology" is defined as the improvement of a contact tracing outcome before and after, such as the number of people diagnosed when screened using an mHealth technology.

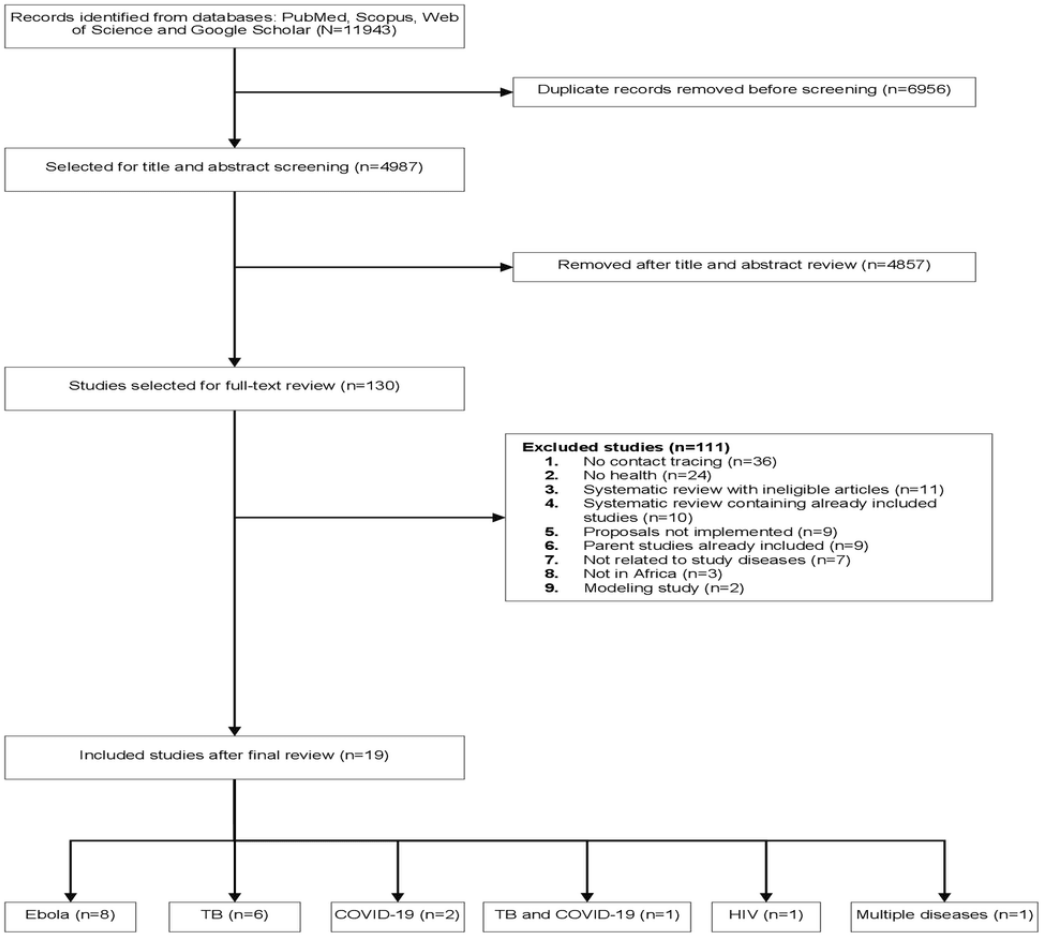
Results

Literature Search

Figure 1 provides a PRISMA flowchart for the literature search and review process. The initial literature search yielded 11,943 articles. After removing 58.24% (6956/11,943) of duplicates, 41.76% (4987/11,943) of the articles remained for screening. A review of titles and abstracts led to the exclusion of 97.39%

(4857/4987) of the articles, resulting in 130 articles being selected for full-text review. Only 19 studies were retained after the full-text review [6,8,27,32-47]. Of these 19 studies, 8 (42%) were on Ebola [32-39], 6 (32%) were on tuberculosis [6,27,40-43], 2 (11%) were on COVID-19 [44,45], 1 (5%) was on HIV [8], 1 (5%) was on tuberculosis and COVID-19 [46], and 1 (5%) was on multiple diseases in humans and animals [47]. No study needed translation.

Figure 1. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the systematic review. TB: tuberculosis.



Description of the Studies

Table 1 provides an overview of the key characteristics of the 19 studies that formed the basis of this systematic review. The studies covered a range of diseases, including Ebola, tuberculosis, COVID-19, HIV, and multiple diseases in humans and animals. In total, 74% (14/19) of the included studies were about technologies used for contact tracing of Ebola and tuberculosis. Ebola had the most studies with 42% (8/19), whereas tuberculosis had 32% (6/19). One other technology was used for both tuberculosis and COVID-19. The remaining 4 studies discussed technologies for the contact tracing of HIV (n=1, 25%), COVID-19 (n=2, 50%), and multiple diseases among humans and animals (n=1, 25%). Multimedia Appendix 4 [6,8,27,32-47,55-75] provides a detailed summary of each technology.

Table 1. Description of all retained studies.

Disease and target users	Technology type	Study	Country	Study design	Location
Ebola					
Health workers	Smartphone app, GIS[a], and BI[b] dashboard	Tom-Aba et al [34], 2015	Nigeria	Programmatic pretest-posttest	Community
Health workers	Smartphone app and BI dashboard	Sacks et al [32], 2015	Guinea	Programmatic pretest-posttest	Community
Contacts	SMS text messaging and phone calls	Jia and Mohamed [33], 2015	Sierra Leone	Programmatic pretest-posttest	Community
Health workers	Smartphone app	Adeoye et al [37], 2017	Nigeria	Programmatic pretest-posttest	Community
Contacts	Phone calls	Alpren et al [36], 2017	Sierra Leone	Programmatic pretest-posttest	Community
Health workers	Mobile tracking	Wolfe et al [35], 2017	Liberia	Programmatic pretest-posttest	Community
Health workers	Smartphone app	Danquah et al [38], 2019	Sierra Leone	Cross-sectional	Community
Health workers	Smartphone app	Whitesell et al [39], 2021	DRC[c]	Programmatic pretest-posttest	Community
Tuberculosis					
Health workers	Smartphone app and GIS	Chisunkha et al [6], 2016	Malawi	Cross-sectional	Community
Health workers	Smartphone app	Ha et al [40], 2016	Botswana	Pretest-posttest	Community
Contacts	USSD[d]	Diaz and Moturi [42], 2019	Tanzania	Programmatic pretest-posttest	Community
Health workers	Smartphone app	Davis et al [27], 2019	Uganda	Trials	Used or intended for use in both the facility and community
Health workers	Smartphone app	Szkwarko et al [41], 2021	Kenya	Cross-sectional	Facility
Both	Smartphone app	URC[e] [43], 2020	South Africa	Programmatic pretest-posttest	Used or intended for use in both the facility and community
COVID-19					
Contacts	Web application and USSD	Owoyemi et al [45], 2021	Nigeria	Programmatic pretest-posttest	Community
Contacts	Smartphone app	Mugenyi et al [44], 2021	Uganda	Pretest-posttest	Community
Tuberculosis and COVID-19					
Contacts	USSD and WhatsApp	Praekelt.org [46], 2021	South Africa	Programmatic pretest-posttest	Community

Health workers	Smartphone app	Rajput et al [8], 2012	Kenya	Programmatic pretest-posttest	Community
Multiple diseases					
Health workers	Smartphone app	Karimuribo et al [47], 2017	Tanzania	Programmatic pretest-posttest	Community

[a]GIS: geographic information system.

[b]BI: business intelligence.

[c]DRC: Democratic Republic of the Congo.

[d]USSD: unstructured supplementary service data.

[e]URC: University Research Co.

The type of mHealth technology varied across the selected studies. Exactly 42% (5/19) used communications platforms with SMS and phone calls accounting for 11% (2/19) [33,36] and unstructured supplementary service data or WhatsApp used in 16% (3/19) [42,45,46]. Smartphone apps were the most common, appearing in 68% (13/19) of the studies [6,8,27,32,34,37-41,43,44,47]. Among these smartphone apps, 25% (3/12) incorporated geographic information systems [6,34] or a business intelligence dashboard [32,34]. Only one out of the 19 (5%) used a mobile tracking system managed through cellphone tower technologies [35].

Most of the technologies (16/19, 84%) [6,8,32-40,42,44-47] were designed for use in the community during outreach visits, whereas 11% (2/19) were used in both the community [27,43] and the household and only 5% (1/19) were designed for use in a health facility [41]. Of all 19 technologies, 11 (58%) were designed for use by outreach workers to capture data during contact tracing [6,8,27,32,34,37-41,43,47], whereas 7 (37%) were designed for self-screening disease symptoms by the contacts [33,35,36,42,44-46] and only 1 (5%) could be used by both patients and outreach workers [43]. In contact-targeted technologies, contacts interacted with the system by sending messages, responding to built-in prompts, and making or receiving phone calls for contact tracing, whereas outreach workers used the technologies to facilitate data collection. Only 5% (1/19) of the studies used a technology to facilitate linkage to care of household contacts, a distal outcome from contact tracing [27].

Regarding study designs, 68% (13/19) of the studies that implemented technologies in programmatic settings used pretest-posttest designs. In these cases, the technology served as an intervention aimed at achieving specific contact tracing or case finding objectives within broad population programs, often without the technology of stringent research methodologies. The remaining 6 studies used various designs: 3 (50%) were pretest-posttest studies, 2 (33%) were cross-sectional studies, and 1 (17%) was a randomized trial.

The Uses of Technologies in the Included Studies

The uses of the technologies in the included studies are also presented in Table 1. As predetermined in the inclusion criteria, all technologies were designed to assist in contact tracing and infectious disease case finding. However, some were primarily designed for disease surveillance incorporating contact-tracing functionality [41,45,47,76]. The predominant contact tracing modality in the technologies involved identifying index patients, finding their contacts, and collecting data using mobile technologies instead of paper.

Other studies used unconventional contact tracing methods that did not necessarily require initial contact with index patients or arrangements with household contacts. For instance, in a study conducted in Malawi by Chisunkha et al [6], Google Earth, a publicly available software, was used to identify and visit households for recruitment into a chronic airway disease and tuberculosis trial even in the absence of previous knowledge of index patients. This approach involved the use of global positioning technology to locate households within a disease hot spot area on a map. Subsequently, data collectors were dispatched to these identified locations to recruit participants for the trial. While the system was not exclusively designed as a contact tracing project but rather as a tool to facilitate the location of participants within a study, the authors proposed that it could also serve contact tracing purposes in remote settings. This approach allowed for the swift identification of households before actual visits, thereby reducing costs and enhancing efficiency [6]. In Monrovia, Liberia, Wolfe et al [35] described an Ebola contact tracing system in which the government issued subpoenas to cell phone companies forcing them to provide locations of contacts that outreach workers could not locate. The authors reported that these subpoenas assisted in successfully locating 29 missing contacts [35]. In Sierra Leone, Alpren et al [36] described a repurposed call center, also for Ebola, in which the public acted as primary informants to authorities to report details and locations of known or suspected patients with Ebola (live alerts) and deaths (death alerts). The study showed >10,000 weekly alerts at the peak of the Ebola outbreak in October 2014. Cumulatively, between 2014 and 2016, the call center received 248,789 death alerts and 95,136 live alerts [36]. Finally, Mugenyi et al [44] developed and implemented the Wetaase app in a small pilot study to monitor the symptoms and movement of household members during the COVID-19 outbreak in Uganda. Unique to this technology was that household members downloaded and self-reported daily symptoms through Wetaase, and if symptomatic, they were tested for COVID-19 by workers visiting the household. Only 101 participants were enrolled, and out of an expected daily report of 8949 in 90 days, the app achieved 6617 reports, a use rate of 78%. Of these 6617 reports, only 57 (0.8%) self-reported COVID-19 symptoms, and no cases were diagnosed.

Development of mHealth Technologies for Contact Tracing

Type of Platform for Development

In total, 84% (16/19) of the technologies in the included studies were digital technologies developed to work on mobile phones. Of these 16 technologies, 11 (69%) were developed by customizing existing platforms such as ODK and CommCare, while 6 (38%) were developed as in-house software platforms. Of the 11 customized technologies, ODK was used to develop 5 (45%), and CommCare was used to develop 3 (27%) [27,32,38], while Unstructured Supplementary Service Data was used to develop 2 (18%) technologies and only 1 (9%) was developed using KoboToolbox. The remaining 16% (3/19) of the technologies used existing cellular network infrastructure such as SMS text messaging and phone calls. Of these 3 technologies that used existing cellular network infrastructure, 2 (67%) used phone calls, while 1 (33%) used cell phone tower technology.

Scope and Scale of Implementation

The scope and implementation scale of the technologies in the included studies varied depending on the intended use, that is,

in programmatic or research settings. Technologies used in programmatic settings of contact tracing activities had a larger scope aimed at targeting large sections of the population to meet contact tracing targets of the program. Large-scope technologies in the selected studies included the Surveillance Outbreak Response Management and Analysis System (SORMAS) in Nigeria, the Academic Model Providing Access to Healthcare (AMPATH) in Kenya, Tanzania's Tambua tuberculosis and Afyadata, tuberculosis HealthCheck in South Africa, and the Ebola contact tracing app in Guinea. For example, AMPATH in Kenya was developed to facilitate screening among >2 million individuals in 3 years [8]. Similarly, HealthCheck in South Africa was initially designed for population-wide self-screening of COVID-19 and expanded to tuberculosis at a national level [46]. In Tanzania, Afyadata, which veterinary specialists conceptualized, had a large scope for screening and reporting diseases in animals and humans [47,55]. Among humans, Afyadata has been used for finding diseases such as Ebola [47,77,78], COVID-19 [56,79], cholera [55,80,81], brucellosis [82,83], and an impetigo-like outbreak [47,55,84]. In contrast, technologies developed for research studies had a narrow scope, mainly built to demonstrate the value of mHealth in research settings or as research data collection tools, and had no evidence of uptake beyond the research. In Botswana, Ha et al [40] demonstrated that mHealth was better than paper by developing a mobile technology using ODK, but only 376 contacts were screened before the technology was probably retired. Chisunkha et al [6] developed a mobile technology using ODK to enumerate households for a tuberculosis contact tracing trial in Malawi and a small population. We did not find any further information about the tenure of this mHealth technology after the enumeration of the households. In Kenya, Szkwarko et al [41] developed PPTBMAPP to facilitate tuberculosis screening of 276 children in a health facility and demonstrated its superiority over paper, but no further use is documented. Also in Uganda, a randomized trial used an mHealth technology developed using CommCare as a data collection and screening tool and then evaluated the effectiveness of SMS text messaging to complete tuberculosis evaluation within 2 weeks. This technology screened only 919 contacts in the intervention and control arms [27].

Funding for Developing mHealth Technologies

Large-scale technologies developed for programmatic settings often received substantial funding for extensive development and implementation processes. For instance, SORMAS received €850,000 (US $929,509) from the European Union [85], Afyadata obtained US $450,000 from the Skoll Global Threats Fund [55], and the CommCare app for HIV screening was supported by a US $74.9–million US Agency for International Development–AMPATH program [86]. Tambua tuberculosis received government backing through Tanzania's National Tuberculosis and Leprosy Programme, which facilitated support and acceptance from end users [42].

In contrast, many research projects included in this review did not report their funding sources. This lack of reported funding highlights the resource disparities between technologies used in programmatic settings and research studies. Research projects often operated with limited financial resources, which impacted the scope and scale of their technology development processes. For example, in Botswana, Ha et al [40] evaluated a pragmatic mHealth technology for tuberculosis contact tracing. While the technology demonstrated promising outcomes compared to traditional paper-based methods, its application was limited to a pilot study across 7 urban and semiurban health facilities, and there is no record of its broader implementation, underscoring a challenge of limited scope in assessing the technology's full potential and scalability [40].

Participatory Development Processes as an Indicator of Successful Implementation

In total, 21% (4/19) of the technologies—SORMAS [57,76], Afyadata [47,55], AMPATH [8], and Tambua tuberculosis [42]—documented the use of design thinking frameworks in their development processes. Design thinking frameworks increase the likelihood of producing technologies that are fit for the intended purposes by using participatory processes to capture all the requirements and what outcomes the technology must deliver and how and also address the context in which the technology will be used [57,58]. Design thinking also involves extensive consultation with relevant stakeholders such as public health experts, government policy makers, health workers, and information technologists.

For example, Afyadata was intended to be a surveillance technology for use among humans and animals to monitor common diseases in the 2 fields. Professionals from human and animal health, as well as software developers, extensively collaborated to elicit project needs and goals. Relevant government officials were also involved and endorsed the technology throughout all its development and implementation stages. As a result, Afyadata is now widely used for surveillance purposes in Tanzania and has been used in the surveillance of cholera cases, monitoring of hygiene and sanitation practices, early detection of Ebola in neighboring Democratic Republic of the Congo, and surveillance of diseases occurring among animals. Afyadata was also adopted for the screening of COVID-19 in neighboring Mozambique.

Similarly, Nigeria's SORMAS followed a design thinking framework as a response to its precursor, the Sense Follow-up app. The Sense Follow-up app was an Android mobile technology rapidly developed in an emergency to support data collection during home visits following contacts of patients with Ebola for 21 days to document people who had been in contact with index patients with Ebola and support data collection during the first Ebola outbreak in Nigeria in 2014 [34,87]. However, the development was not sufficiently consultative because of time constraints imposed by the quick response time required to control Ebola. It was later deemed to have failed to meet the needs of the Ebola control team, specifically that it did not sufficiently support the bidirectional exchange of information; did not address case finding [57]; and had complex data manageability because of its modular architecture with separate systems for data storage, functions, and format and its interface [34,87]. The same team that developed the Sense Follow-up app then teamed up with philanthropists and public health and IT experts in designing SORMAS following a design thinking approach. The design thinking framework guided the SORMAS

development team to identify system, user, and technical requirements and addressed all the shortcomings of the Sense Follow-up app. Although there is limited evidence of its evaluation, SORMAS is now a widely used technology for contact tracing various diseases in Nigeria. In addition, because it is easily customizable, SORMAS was central in response to COVID-19.

Similar to Afyadata and SORMAS, the technology for HIV case finding in the AMPATH program with clear objectives was able to screen thousands as had been originally planned [8]. It was designed to be reliable in resource-constrained settings, scalable to allow for screening of >2 million people in 3 years, and open-source software; easily integrate with other systems and devices; and have GPS capabilities. As a result, public health experts, software technologists, and government stakeholders contributed to successfully developing a technology to screen >1 million HIV contacts.

However, in Guinea, the Ebola contact tracing technology was developed using participatory processes and design thinking but lacked government policy maker buy-in, which led to suboptimal implementation, and most of the intended results were not achieved [32]. Tuberculosis HealthCheck and COVID-19 alert technology in South Africa did not have documented participatory development, but government support led to their nationwide rollout [46].

All technologies used in research studies were developed by research teams and did not have any documented use of design thinking frameworks or participatory development. These technologies were used to reach research objectives, and their tenure did not extend beyond the project. However, the research team in Uganda that implemented the trial by Davis et al [27] conducted a post hoc analysis of the trial using an implementation science framework, the Consolidated Framework for Implementation Research, to understand the reasons for the poor performance of the mHealth technology on their main outcome [59]. While not explicitly mentioning design thinking as a framework to follow, the researchers conceded that the lack of consultation with local stakeholders was a critical gap in development that may have deprived them of a robust outer setting, which is a critical indicator for successful implementation even in smaller research studies.

Effectiveness of the mHealth Technologies and Reporting of Outcomes

Table 2 provides an overview of outcome reporting and technology development in the included studies. Technologies used in programmatic settings with a pretest-posttest setup were designed to reach specific targets and mainly reported outputs without comparisons, whereas research studies designed to answer a specific question reported both outputs and outcomes. Hence, effectiveness in the 2 approaches was defined differently. In technologies used for programmatic settings, effectiveness was defined as rolling out the technology to a large population and producing output. In research studies, effectiveness was defined as improving outcomes.

Table 2. Outcomes and app development.

Study title (design)	Output or outcomes	Development and evaluation

"Home-based tuberculosis contact investigation in Uganda: a household randomised trial" [27] (randomized study)	• Primary outcome: completion of tuberculosis evaluation within 14 days of enrollment among contacts requiring additional evaluation for tuberculosis
	• Secondary outcomes:
	  • Tuberculosis diagnosis and treatment initiation
	  • HIV diagnosis and linkage to HIV care
		The app was developed by public health professionals with experience in implementing and evaluating mHealth[a] technologies and by Dimagi CommCare specialists.

"Use of a mobile technology for Ebola contact tracing and monitoring in Northern Sierra Leone: a proof-of-concept study" [38] (cross-sectional study)	• Number of Ebola contacts identified and traced per arm • Time to find contact • Ebola cases detected per arm • Implementation feasibility	Developed by an information technologist in the United States working with the study team in Sierra Leone.
"Implementation of digital technology solutions for a lung health trial in rural Malawi" [6] (cross-sectional study)	• Number of households located on the map	No app development; Google Earth was used to identify households.
"Using a mobile technology to Improve paediatric presumptive Tuberculosis identification in western Kenya" [41] (cross-sectional study)	• Proportion of children recorded in the presumptive tuberculosis register • Proportion of children testing positive for tuberculosis	The app was developed in Bangladesh and customized for use in this study.
"Evaluation of a Mobile Health Approach to Tuberculosis Contact Tracing in Botswana" [40] (pretest-posttest study)	• Number of contacts screened using paper vs the app • Time to complete screening using paper vs the app • Missing and illogical data between paper and the app • User satisfaction with paper vs the app	Researchers partnered with an IT firm to produce the contact tracing app.
"Feasibility of using a mobile app to monitor and report COVID-19-related symptoms and people's movements in Uganda" [44] (pretest-posttest study)	• Household members using the technology • Household members reporting symptoms • Household members referred for testing • Household members diagnosed with COVID-19	Developed by a technology designer in consultation with officials from the Ministry of Health. No further details of the development process are given.
"The 117-call alert system in Sierra Leone: from rapid Ebola notification to routine death reporting" [36] (programmatic pretest-posttest)	• Number of live Ebola alerts • Number of death alerts • Confirmed new cases from alerts	No app development, and a call center was repurposed to report suspected Ebola cases.
"A Smartphone App (AfyaData) for Innovative One Health Disease Surveillance from Community to National Levels in Africa: Intervention in Disease Surveillance" [47] (programmatic pretest-posttest)	• Number of disease cases reported among humans and animals	Designed through a collaboration between public health and ICT[b] specialists and government personnel. They developed a theory of change to guide development and implementation.
"Ebola virus disease contact tracing activities, lessons learned and best practices during the Duport Road outbreak in Monrovia, Liberia, November 2015" [35] (programmatic pretest-posttest)	• The total number of contacts traced • Total households found • Total high- and low-risk contacts found • Total symptomatic contacts • Contact deaths recorded	No app development. The program used subpoenas to cell phone companies to provide location details of suspected Ebola contacts.
"Introduction of Mobile Health Tools to Support Ebola Surveillance and Contact Tracing in Guinea" [32] (programmatic pretest-posttest)	• Total number of Ebola contacts monitored on CommCare • IT and implementation challenges	An IT team developed it in the United States with local public health specialists in Guinea, local UN[c] partners, and the government.

Study title (design)	Output or outcomes	Development and evaluation
"USAID/South Africa Tuberculosis South Africa Project (TBSAP) Midterm Evaluation Report" [43] (programmatic pretest-posttest)	• Not reported	Not reported
"Development and implementation of the Ebola Exposure Window Calculator: A tool for Ebola virus disease outbreak field investigations" [39] (programmatic pretest-posttest)	• Exposure window for contact tracing to take place	Not reported
"Innovative Technological Approach to Ebola Virus Disease Outbreak Response in Nigeria Using the Open Data Kit and Form Hub Technology" [34] (programmatic pretest-posttest)	• Number of users downloading the app • Number of active users of the app	CDC[d], WHO[e], and DRC[f] field teams and Johns Hopkins teams developed the technology, and the government endorsed its use.
"Evaluation of an Android-based mHealth system for population surveillance in developing countries" [8] (programmatic pretest-posttest)	• Number of households visited for home-based counselling and testing and data collected using the app • Time to complete screening using the app vs PDA • App usability • Cost of development and implementation	Members of the AMPATH[g] project team developed the app in collaboration with staff from the Ministry of Health in Kenya. They had clear objectives for their scope and what they wanted the app to achieve.
"Evaluating the use of cell phone messaging for community Ebola syndromic surveillance in high-risk settings in Southern Sierra Leone" [33] (programmatic pretest-posttest)	• Suspected Ebola cases • Confirmed Ebola cases • Reported deaths	No app development
"Implementing Surveillance and Outbreak Response Management and Analysis System (SORMAS) for Public Health in West Africa- Lessons Learnt and Future Direction" [37] (programmatic pretest-posttest)	• Implementation outcomes from piloting the technology	Design thinking workshops were held in Nigeria and Germany to assess software requirements. Nigeria Centre for Disease Control and Prevention, Port Health, and other stakeholders were also involved in the design thinking methodology. Contact tracing requirements for other diseases, not just Ebola, were also considered in the design process.
"Using mHealth to self-screen and promote Tuberculosis awareness in Tanzania" [42] (programmatic pretest-posttest)	• Number of people screened using the technology • Number of presumptive cases screened using the app	Designed by the government and other implementors using the Ministry of Health mHealth platforms in a participatory process.
"TB HealthCheck puts tuberculosis self-screening in everyone's hands ahead of World TB Day" [46] (programmatic pretest-posttest)	• Not clearly stated	Not clearly stated
"Mobile health approaches to disease surveillance in Africa; Wellvis COVID triage tool" [45] (programmatic pretest-posttest)	• Risk of COVID-19 after self-screenings	The development process is not described in detail.

[a]mHealth: mobile health.

[b]ICT: information and communications technology.

[c]UN: United Nations.

[d]CDC: Centers for Disease Control and Prevention.

[e]WHO: World Health Organization.

[f]DRC: Democratic Republic of the Congo.

[g]AMPATH: Academic Model Providing Access to Healthcare.

Of all the included studies, only the trial from Uganda randomly assigned participants to different groups, comparing outcomes objectively. The trial had primary outcomes of contacts completing tuberculosis evaluation within 14 days and secondary outcomes of treatment initiation and linking patients to care [27]. Contacts were assigned to the control, and SMS text messaging–facilitated interventions were at a household level. The trial showed that the mHealth technology had no effect on the primary outcome.

In addition, although they did not randomize participants or calculate sample size as in the randomized trial, the cross-sectional surveys and pretest-posttest studies included in this systematic review attempted to evaluate the performance of the mHealth technologies by reporting outcomes such as proportions of contacts diagnosed, and some compared performance between groups. For example, a study in Sierra Leone compared the number of Ebola contacts identified and traced between the Ebola contact tracing app and a paper-based data collection system using a conveniently selected sample [38]. The researchers also evaluated completion, the proportion of cases detected, and implementation feasibility between the 2 arms. Similarly, the study by Ha et al [40] also compared outcomes in proportions before and after implementation and in contrast to a paper-based system. This pretest-posttest study compared the number of contacts screened, time to complete an evaluation, and data quality between using a contact tracing app and paper-based systems [40]. Other cross-sectional studies only reported outcomes in one conveniently selected group [6,41], and one pretest-posttest study only reported outputs [44].

Programmatic setting studies predominantly reported immediate outputs or implementation experiences of the mHealth technologies. SORMAS, AMPATH, and Afyadata, which were the largest and most comprehensively developed technologies, only reported absolute numbers of the people screened and implementation experiences rather than actual outcomes to determine the performance of the mHealth technology. In addition, Tambua tuberculosis in Tanzania reported immediate outputs on tuberculosis screening but did not have an evaluation done on implementation outcomes. In South Africa, ConnecTB and tuberculosis HealthCheck, both used to facilitate tuberculosis screening, did not provide sufficient details on the outputs or evaluation of the technologies. Nevertheless, these technologies in programmatic settings reached large populations for contact tracing.

Discussion

Principal Findings

We reviewed the continuum of mHealth technologies used for contact tracing and case finding. We synthesized this information to improve understanding of mHealth's value in contact tracing and inform how future projects can develop or implement it efficiently to improve contact tracing or implementation outcomes. Only 19 studies met the criteria and were included in the review. The technologies were developed by either customizing existing platforms or creating original software. Some technologies used to trace contacts did not require software development but used existing cellular network infrastructure. Technologies developed using design thinking frameworks with participatory activities had a higher likelihood of implementation fidelity. However, the effectiveness of these technologies was not sufficiently evaluated, and the outcomes of most technologies were only reported in small research studies.

Our search yielded a greater number of articles on studies using mHealth technologies for contact tracing than those obtained in previous reviews, likely reflecting the growing adoption of such technologies during the search period. In addition, our iterative search strategy, which featured relaxed criteria and encompassed a variety of infectious diseases, may have played a significant role in identifying this increased volume of articles. The review has also presented the entire pathway of using these technologies from the development stage until deployment and evaluation of outcomes. Our findings also confirm that mHealth outperforms traditional paper-based contact tracing regarding the timeliness of screening, data accuracy, and streamlining of the screening process. However, little evidence exists of mHealth's impact or incremental value on contact tracing outcomes compared to paper because of underreporting. Despite this challenge, our study underscores the potential of using validated design frameworks during the developmental phase, which is likely to enhance the overall effectiveness of such solutions. Future public health projects that intend to develop and implement mHealth technologies can consider these insights as a guide into some of the prerequisites for implementing useful technologies that can meaningfully improve outcomes.

Our systematic review suggests that a more systematic approach to development using design thinking frameworks with participatory development, including buy-in from policy makers, could help technologies in achieving the intended case finding outputs and outcomes when compared to an approach that does not use these frameworks. For example, SORMAS was developed in Nigeria following design thinking and participatory processes involving public health experts, information technologists, and government officials. SORMAS was responding to an earlier mHealth app, Sense Follow-up, which had failed at the implementation stage due to not meeting user requirements because of poor development. Similarly, Afyadata in Tanzania and AMPATH in Kenya both involved extensive consultative processes, increasing their outputs. Contrastingly, even a collaboratively built technology may fail at implementation without government backing. For example, in Sierra Leone, Sacks et al [32] reported poor outputs from the Ebola contact tracing program, partly due to the lack of government officials' commitment to supporting the program. In South Africa, ConnecTB did not document any design thinking frameworks or participatory development and was discontinued due to technical challenges despite having the policy makers' support. None of the research studies documented the use of a design thinking framework, which may have affected their results, most of which were suboptimal, with the technology failing to show an impact on case finding. A post hoc analysis of the trial by Davis et al [27] also recommended using design thinking frameworks even in research studies to ensure that they are impactful [59].

In addition to using established frameworks in the development stage, financial resources were a significant factor in determining the extent of development and implementation. For example, among the technologies used in programmatic settings, SORMAS received an initial funding of €850,000 (US $929,509) from the European Union [85], Afyadata received US $450,000 from the Skoll Global Threats Fund [55], and the CommCare app for HIV screening was developed under a US $74.9–million US Agency for International Development–AMPATH program [86]. In addition, Tambua

tuberculosis was government backed through Tanzania's National Tuberculosis and Leprosy Programme [42]. Government involvement also assisted in obtaining buy-in from the ultimate end users of the technologies. However, compared to studies implementing technologies in programmatic settings, most research studies included in this review did not have the financial resources to execute the extensive development processes required for a technology to succeed. However, the dilemma is that well-funded programs tend to develop and implement large and sustainable technologies but often overlook comprehensive evaluations and, hence, fail to inform any future work meaningfully. Research studies, on the other hand, while rigorously evaluating their technologies, undergo a suboptimal development process due to limited funding. Consequently, despite restricted resources, research studies tend to use more robust evaluation methods in their assessments. For example, in Botswana, Ha et al [40] evaluated a pragmatic mHealth technology for tuberculosis contact tracing, but it was only implemented in a few settings, possibly due to limited funding, and the researchers could not conduct a large study to fully evaluate the program. Therefore, nesting evaluations in large programs as implementation research processes may be a way to improve evidence of mHealth technologies' utility for contact tracing.

The primary focus of contact tracing programs is on improving case finding. However, there is also an expectation in some studies that improved case finding should also trickle down to the betterment of other outcomes down the tuberculosis care and treatment cascade, such as treatment initiation and completion [88,89]. However, using current evidence, it can be argued for mHealth technologies that, unless initially planned and incorporated in the design process, the desired contact tracing outcomes further down the cascade are inappropriate to determine the success of a contact tracing program and the effectiveness of mHealth technologies. Only 1 study in this review, a randomized trial, reported treatment initiation further down the contact tracing cascade [24,27], and the rest focused on outputs immediately after screening, such as numbers screened and testing positive. When using mHealth, immediate implementation outcomes such as technology development, implementation fidelity, feasibility, and acceptability could more appropriately measure effectiveness. This is because mHealth technologies can only measure what they are designed for. For instance, all technologies used in programmatic setting studies were designed to find and screen contacts but did not have modules developed for linkage to care, which would have allowed outcomes further down the cascade to be measured. Although this narrow focus on immediate outputs may limit the tenure of the technologies because they cannot demonstrate any value for the desired contact tracing outcomes, these outcomes are not determined only by finding the people with the disease. Instead, additional steps are required to optimize care linkage and treatment adherence. Small research studies with a limited scope cannot include all the steps from finding contacts, linking them to care, and showing a reduction in disease incidence, but without these steps, they may be too expensive and less likely to be adopted. Therefore, as discussed in the previous section, a participatory developmental process must be used to include such capabilities for mHealth and, where possible, develop the technology within a large well-funded program.

A cost analysis of the mHealth technology for contact tracing in Uganda found that this technology was underused because of its limited scope despite substantial investment in the development stages and initial implementation [90]. The authors suggested expanding the scope by increasing the volume of contacts served or expanding the use of the technology to the later stages of the contact tracing cascade. From this review, most technologies used to support Ebola contact tracing became defunct after the outbreak subsided, thus ultimately costing health programs because they were not used long enough to absorb or justify the costs of their development. Only SORMAS, which had an expanded scope beyond a single disease and activities beyond tracing, survived and continues to receive funding. Afyadata in Tanzania also has a large scope of contact tracing and surveillance activities in humans and animals and continues to be valuable to both health systems. Therefore, health programs should consider using technologies for contact tracing and case finding more broadly to capitalize on synergies and bring down costs to make them more sustainable. This will expand their scope and include multiple diseases or higher volumes of patients or expand the use of mHealth to all stages of the cascade, increasing the likelihood of the interventions' sustainability. Investment cases for future mHealth technologies may be supported if there is evidence of their cost-effectiveness, and this may be necessitated by exploiting economies of scale and scope. Health economics studies and models have also shown that unit costs of interventions may decrease and be optimized for cost-effectiveness by implementing at the appropriate scale, within the right scope [91,92], and without compromising quality by exceeding these bounds [93].

Limitations and Strengths of the Study

The primary limitation of our study stems from the context in which most of the reviewed mHealth technologies were deployed. Predominantly used within programmatic settings rather than through rigorous formal research, these technologies often lacked comprehensive outcome evaluations. Consequently, without these evaluations, our review faces challenges in definitively assessing the impact of mHealth technologies on enhancing contact tracing efforts. Despite this, the deployment of these technologies in well-funded programmatic settings offers valuable insights into the foundational requirements for successful contact tracing technologies, demonstrating how strategic funding can facilitate robust development and implementation.

In addition, our review faces limitations due to the unavailability of some key information, such as tenure of technology use beyond the initial studies, especially for technologies evaluated in research settings. The scarcity of detailed data in both primary literature and supplementary documents makes it difficult to assess whether the technologies were continued or discontinued after the research. This gap underscores the vital need for comprehensive documentation and rigorous reporting standards in the mHealth domain.

Recommendations and Conclusions

The essential ingredients for developing functional and impactful mHealth technologies, whether for contact tracing or other health care interventions, include using a participatory design thinking framework, securing adequate funding, and establishing a clear plan for evaluating the implementation outcomes of the technology.

Many projects, especially research projects, often face challenges of limited funds to fully develop and implement their technologies. In such cases, an alternative approach can be integrating the development of mHealth technologies within larger technologies used in programmatic setting projects. This integration can provide the necessary resources and infrastructure to sufficiently develop and efficiently evaluate the technology. However, such ideal scenarios may not always be feasible, and the use of participatory design thinking frameworks becomes a prerequisite for developing an effective mHealth technology. This approach emphasizes collaboration with end users, stakeholders, and experts to ensure that the technology aligns with user needs, is inclusive, and considers the context-specific requirements.

Authors' Contributions

The conception of this work was presented by SC and KV as part of DLM's PhD studies. Manuscript reviews were diligently conducted by HC and JN. JLD provided invaluable senior scientific guidance based on his extensive experience in contact tracing. TN collaborated with DLM to structure the systematic review chapters and review the written content drawing insights from their involvement in the Community and Universal Testing for tuberculosis project—a contact tracing cluster randomized trial—in which both are researchers dedicated to the development of a mobile health technology to support tuberculosis contact tracing.

Abstract

Background: As the most malignant type of cancer in the female reproductive system, ovarian cancer (OC) has become the second leading cause of death among Chinese women. Chemotherapy is the main treatment for patients with OC, and its numerous adverse effects can easily lead to malnutrition. It is difficult to centrally manage patients with OC in the intervals between chemotherapy. The use of WeChat, an effective mobile tool, in chronic disease management has been highlighted.

Objective: This study aimed to implement a continuous follow-up strategy and health monitoring based on the WeChat platform for patients with OC undergoing chemotherapy to ensure that each phase of chemotherapy was delivered on schedule and to improve the survival rate of patients with OC.

Methods: Participants were recruited and randomly assigned to either the WeChat-based nutrition intervention group or the usual care group. A self-administered general information questionnaire was used at enrollment to obtain basic information about the patients. The Patient-Generated Subjective Global Assessment (PG-SGA) Scale was used to investigate the nutritional status of the patients at 3 time points (T0=before the first admission to the hospital for chemotherapy, T1=2 weeks after the first chemotherapy, and T6=2 weeks after the sixth chemotherapy). The blood indices of patients were investigated through the inhospital health care system at 3 times（T0=before the first admission to the hospital for chemotherapy, T1=2 weeks after the first chemotherapy, and T6=2 weeks after the sixth chemotherapy). Patients in the intervention group were introduced to the nutrition applet, invited to join the nutrition management group chat, and allowed to consult on nutritional issues in private chats with nutrition management team members. Linear mixed models were used to analyze changes in each nutritional indicator in the 2 groups, with their baseline measurements as covariates; with group, time, and group-time interactions considered as fixed effects; and with patients considered as random effects.

Results: A total of 96 patients with OC undergoing chemotherapy were recruited into the study. Distribution was based on a 1:1 ratio, with 48 patients each in the nutrition intervention group and the usual care group. The attrition rate after the first chemotherapy session was 18.75%. The mixed linear model revealed that the group-based effect and the group-time interaction effect on PG-SGA scores were significant ($F_{38,38}$=4.763, P=.03; $F_{37,37}$=6.368, P=.01), whereas the time-based effect on PG-SGA scores was not ($F_{38,38}$=0.377; P=.54). The findings indicated that the group-based effect, the time-based effect, and the group-time interaction effect on nutrition-inflammation composite indices were significant ($F_{38,38}$=7.653, P=.006; $F_{38,38}$=13.309, P<.001; $F_{37,37}$=92.304, P<.001; $F_{37,38}$=110.675, P<.001; $F_{38,38}$=10.379, P=.002; and $F_{37,37}$=5.289, P=.02).

Conclusions: This study provided evidence that a WeChat-based, multidisciplinary, full-course nutritional management program can significantly improve the nutritional status of patients with OC during chemotherapy.

KEYWORDS

WeChat; nutrition management; ovarian cancer; chemotherapy; mobile health

Introduction

Ovarian cancer (OC) is the most malignant type of tumor in the female reproductive system, with a poor prognosis [1]. According to the latest statistics, there are 196,000 estimated OC cases, 45,000 estimated new cases, and 29,000 estimated OC deaths in China, making this disease become the second leading cause of death among Chinese women [2].

Approximately 90% of patients with OC receive chemotherapy. The carboplatin-paclitaxel combination as the first-line chemotherapy regimen for OC has shown considerable efficacy over the past 30 years [3]. Unfortunately, one of the major adverse effects of chemotherapy is malnutrition. Malnutrition is defined as a nutritional condition in which deficiencies of energy, protein, and other nutrients have measurable adverse effects on tissue or body form, function, and clinical outcomes [4]. The most common adverse effects of chemotherapy, including anorexia, altered taste and smell, food aversions, nausea and vomiting, mucositis, xerostomia, constipation, diarrhea, and early satiety, negatively affect nutritional status [5,6]. Malnutrition has been shown to be one of the leading causes of death in patients with OC [7-9]. It not only severely diminishes the efficacy of treatment but also leads to increased complications, decreased quality of life, prolonged hospitalization, increased health care costs, and shorter survival time [10]. Malnutrition may occur at any time during the perichemotherapy period, making it necessary to manage nutrition throughout the entire course of chemotherapy for patients with OC.

Surprisingly, there is less information available on nutritional management for patients with OC undergoing chemotherapy. Nutritional interventions in previous studies recommended to increase protein and calorie intake [11,12] or to modify the structure of the diet by adopting a Mediterranean diet [11]. The form of intervention was mainly counseled with a dietitian every 3 weeks through telephone [11]. The previous studies lacked real-time monitoring and timely guidance for patients, and there has been a lag in the nutritional management. In addition, they mentioned only guidance on energy intake and dietary patterns and lacked targeted nutritional guidance for chemotherapy-related adverse effects. The guideline provided more detailed dietary guidance for patients with OC undergoing chemotherapy, such as not using restrictive energy intake diets [13,14] and taking oral nutritional supplements according to the actual situation [15,16], which can help improve the nutritional knowledge of patients with OC. However, it did not mention in what way (eg, online or offline), and at what frequency and intensity, the intervention for patients treated with chemotherapy for OC is more conducive to their nutritional management. In addition, the difficulty of centrally managing patients recuperating at home between chemotherapy treatments should also be considered. Personalized nutritional guidance and education are the preferred methods of nutritional intervention for patients with OC treated with chemotherapy and should be carried out throughout the consultation [13]. Therefore, the construction of personalized nutritional management programs and the development of innovative telemedicine interventions for patients with OC undergoing chemotherapy have become urgent issues.

WeChat, a very popular social application in China, has more than 1 billion monthly active users. It is easy to operate and offers multiple functions such as text and voice messaging, free voice and video calls, group chats, subscriptions to public accounts and applets, and so forth. WeChat has been demonstrated to be an effective and more cost-efficient technological tool for chronic disease management [17,18]. Currently, the applications of WeChat in patients with cancer mainly focus on discharge follow-up [19], symptom management [20,21], cancer prevention [22], and intervention of psychological problems [23]. The effect of WeChat application in the nutritional management of patients with cancer has not been explored. Therefore, the aim of this study was to implement a continuous follow-up strategy and health monitoring based on a WeChat platform for patients with OC undergoing chemotherapy to ensure that each phase of chemotherapy was delivered on schedule and to improve the survival rate of patients with OC.

Methods

Study Design

We conducted a parallel, 2-armed, open-label, randomized controlled trial to examine the efficacy of the WeChat-based nutrition intervention compared with usual nutritional care and to explore preliminary effects of the intervention. The study was conducted between February 2023 and October 2023 at Peking Union Medical College Hospital, Chinese Academy of Medical Sciences in Beijing, China.

Participants

Patients were eligible if they were aged 18 years or older with pathologically confirmed OC [24]. The chemotherapy regimen was paclitaxel in combination with carboplatin. Patients had to have normal cognitive ability and proficiency in the use of WeChat. Patients were excluded if they had a malignant tumor of another system, a serious illness, or failure of vital organs (eg, the heart, lungs, liver, and kidneys) or if they were receiving enteral or parenteral nutritional support. All patients provided written informed consent (Multimedia Appendix 1).

Randomization and Allocation

Patients were randomly assigned (1:1) to receive the WeChat-based remote nutrition intervention or usual nutritional care. Randomization was stratified by disease stage (stages I and II vs stages III and IV) and surgical procedure (laparoscopy vs laparotomy) to balance treatment assignment. The random allocation sequence was generated by the study designers (XJT and YL, who were not involved in patient enrollment) by means of a table of random numbers, and the allocation was hidden by the envelope.

Study Procedure

Intervention Group

Establishment of Nutrition Management Team

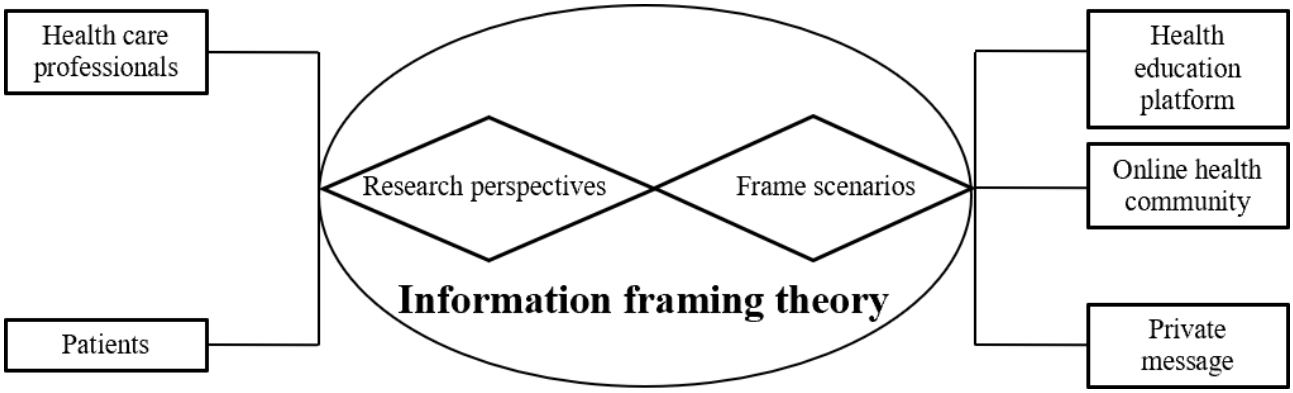
The nutrition management team consisted of a nursing administrator (bachelor's degree, associate nurse practitioner), 2 gynecologic oncologists (PhD, attending physician), 2 oncology specialist nurses (bachelor's degree, charge nurse practitioner), 1 nutrition specialist nurse (bachelor's degree, charge nurse practitioner), 1 dietitian (PhD, associate physician practitioner), and 2 master's degree students in nursing.

Design of the WeChat Platform

Overview

The construction of the WeChat platform relied on information framing theory [25], which emphasized the impact of information on human health behavioral decision-making and health outcomes. It focused the interaction process between people and information on the manifestation of information itself, while reinforcing the dominance of information in both research perspectives and research contexts. The WeChat platform constructed in this study considered the perspectives of both health care professionals and patients and set up 3 different scenarios based on the different needs of the 2 subjects: a health education platform (WeChat applet), a web-based health community (WeChat group chat), and a private question-and-answer session (WeChat private message), with the aim of realizing the maximum benefits of nutritional management. Specific relationships are displayed in Figure 1.

Figure 1. Information framing theory diagram.

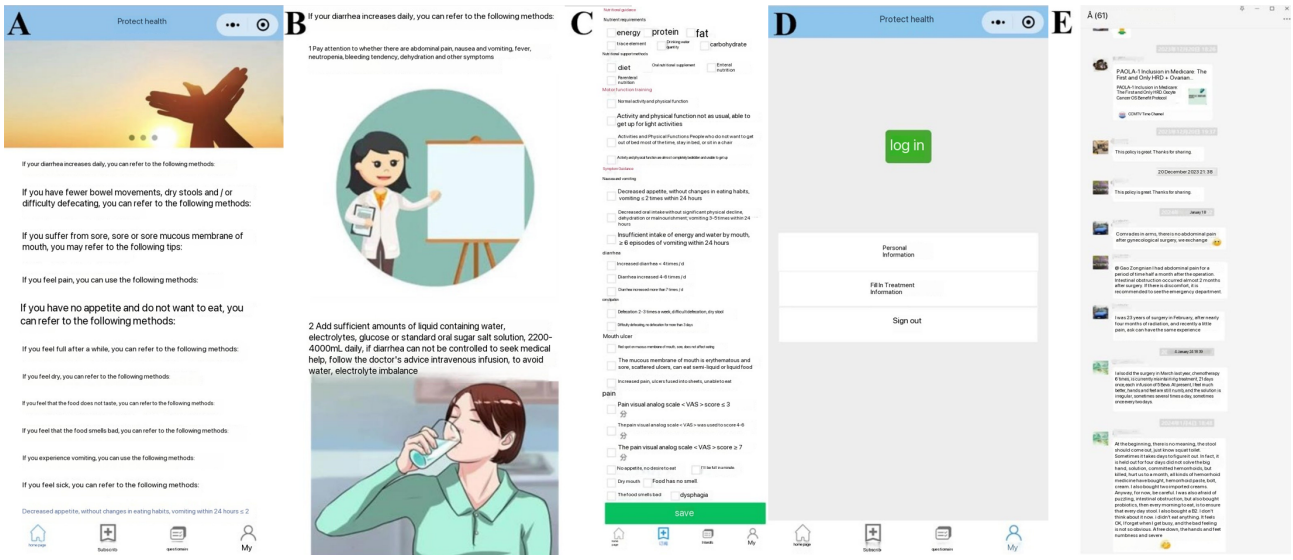


WeChat Applet

With regard to the development of the nutrition WeChat applet "Good Nutrition," it consisted of 2 ports: the computer side and the WeChat side. The computer side was operated and managed by health professionals. The WeChat terminal could be operated by patients with OC undergoing chemotherapy. Patient privacy and data security were protected through access control and permission control, patient data transfer and anonymization, redundant storage, and data backup. The applet was set up with 4 modules: health education column, subscription content column, questionnaire column, and personal information column (Figure 2A).

The content of the health education column was compiled based on a previously constructed multidisciplinary full-course nutritional management program (Table S1 in Multimedia Appendix 2) for patients with OC during chemotherapy, which mainly included chemotherapy symptom management (eg, diarrhea, nausea and vomiting, mouth ulcers), nutritional risk management (based on the Patient-Generated Subjective Global Assessment [PG-SGA] score), and physical activity management. This section provided comprehensive management measures based on symptom severity rating, nutritional risk level, and activity level. In addition, we used a combination of text and images in the presentation of the content, making it detailed and easy to understand (Figure 2B).

Figure 2. WeChat applet interface settings. (A) The applet was set up with 4 modules, namely, health education column, subscription content column, questionnaire column, and personal information column. (B) The content of the health education column. (C) The subscription content section summarized the 3 main sections of instructions: nutritional guidance, motor function training, and symptom guidance. (D) The personal information section was simple to set up and included basic patient information, treatment information, and an option to log out. (E) A group chat for patient-directed learning and encouraging patients to ask questions, share personal experiences, and discuss lifestyle topics.



The subscription content section summarized the 3 main sections of instructions: nutritional guidance (nutrient requirements and nutritional support methods), motor function training, and symptom guidance (nausea, vomiting, diarrhea, constipation, mouth ulcers, and pain). On the one hand, patients could subscribe to the content they were interested in according to their own situation, and the system would remind them to check whether the subscription content has been updated. On the other hand, members of the nutrition team could obtain the subscription status of the patients from the back end, so as to have a better understanding of the adverse effects of the individuals during chemotherapy and thus give more targeted guidance (Figure 2C).

Patients were briefly quizzed on a regular basis in the form of a questionnaire, and open-ended questions were included to ask whether they had any questions about the nutritional management process.

With regard to the log-in interface, the personal information section was simple to set up and included basic patient information, treatment information, and an option to log out (Figure 2D).

Group Chat

Throughout the intervention phase, we sent out evidence-based nutrition papers taken from WeChat applets in group chats for patient-directed learning and encouraged patients to ask questions, shared personal experiences, and discussed lifestyle topics. We also critically analyzed the public papers shared by patients to help them judge the quality of nutritional information (Figure 2E).

Private Message

Patients can always choose to have a private chat with a member of the nutrition management team via WeChat. For example, a patient with an aggravated chemotherapy reaction may seek help in a private chat, and our doctors would give some professional advice. In addition, for common problems, we also posted answers in the group for other patients' reference.

Implementation Procedure

Detailed and clear interventions are shown in Table 1.

Table . Interventions.

Time of intervention	Objectives of intervention	Interventions
1. The first admission for chemotherapy	To enable patients to master the nutrition management WeChat platform (WeChat applet, WeChat group chat, WeChat private message) function and operation use method	WeChat applet: 1. Searched for the "Good Nutrition" WeChat applet 2. Added it to My Applet 3. Opened the notification permission 4. Logged in the Applet 5. Introduced to the main functional sections Group chat: 1. Invited to join the group chat 2. Informed that throughout the intervention phase, evidence-based scientific papers would be sent to the group chat. Asking questions, sharing personal experiences, and discussing lifestyles were permitted. Group chat could help identify questionable nutrition information. Answer questions via private message: 1. Allowed private chats with nutrition team members if in doubt.
2. During each session of chemotherapy	Enable patients to understand in advance the possible adverse reactions related to chemotherapy and the countermeasures	Explained the complications associated with chemotherapy, and given a chemotherapy care booklet and a leaflet on diet and nutrition. Before discharge, the patients were given the nutritional guidebook again.
3. Each chemotherapy interval	Real-time monitoring of patients' chemotherapy adverse reactions and nutritional status, and timely resolution of patients' dilemmas in coping with chemotherapy-related adverse reactions	WeChat applet: 1. Updated the health education content every 2 months. 2. Checked the top 3 health education topics in the subscription content weekly, and sent relevant papers to the group chat for discussion and analysis. 3. Pushed the nutritional knowledge questionnaire weekly, according to the patients' answer situation in the group chat for nutritional guidance. Group chat: 1. Summarized nutritional knowledge questions once a week and answered centrally. 2. Summarized and corrected the misconceptions shared by patients during the day every night. Answer questions via private message: 1. One nutrition team member would be responsible for answering questions via private message and replying promptly after seeing the message every day.

Control Group

For patients in the usual care group, upon admission, patients were provided with admission counseling, given an explanation about the complications associated with chemotherapy, and given a chemotherapy care booklet and a leaflet on diet and nutrition. Before discharge, the patients were given the nutritional guidebook again. Responsible nurses made 1 telephone follow-up visit between chemotherapy sessions.

Data Collection and Outcomes

Self-reported sociodemographic characteristics (eg, age, BMI, marital status, education level, etc) and clinical disease features (eg, disease stage, surgical procedure, etc) were collected at baseline.

The primary outcome was assessed by the PG-SGA Scale to evaluate the nutritional status of patients at 3 time points (T0=before the first admission to the hospital for chemotherapy, T1=2 weeks after the first chemotherapy, and T6=2 weeks after the sixth chemotherapy). The PG-SGA was used as a prognostic tool developed specifically for patients with cancer to evaluate

the nutritional status [26]. It consisted of 2 subscales: the patient self-assessment scale and the medical staff assessment scale. The former integrated short-term weight loss, food intake (including amount eaten, type of food, manner of eating, etc), symptoms affecting eating, and activity or physical functioning. The latter included medical history, metabolic stress, and physical examination provided by medical staff [27]. Each item in the PG-SGA Scale has a score range of 0 - 4. The more severe the symptoms in relation to malnutrition, the higher the assigned value. The total score was compared and analyzed in three groups: (1) well nourished (0 - 1 point), (2) moderately or suspected of being malnourished (2 - 8 point), and (3) severely malnourished (≥9 point) [28]. A total score between 0 and 35 quantitatively informs the severity of malnutrition and types of intervention needed: 0 - 1 point indicates no need for any intervention, 2 - 3 points suggest education needs for the patients and the family, 4 - 8 points indicate the need for a referral to a dietitian, and a score of 9 or more recommends an action of critical nutritional intervention. The PG-SGA Scale had high validity (sensitivity 100%, specificity 88%) [29]. It had been accepted by the Oncology Nutrition Dietetic Practice Group of the American Dietetic Association as the standard for nutrition assessment for patients with cancer [26,30,31].

The secondary outcome was to compare the blood test indices of the 2 groups at the same 3 time points, including nutrition-related blood indices, such as total protein (g/L), albumin (g/L), prealbumin (g/L), and hemoglobin (g/L); inflammation-related blood indices, such as leukocytes (10^9/L), lymphocytes (10^9/L), neutrophils (10^9/L), and platelets (10^9/L); and nutrition-inflammation composite indices, such as the prognostic nutritional index (PNI) and systemic immunoinflammatory index (SII). The PNI reflected the chronic inflammation, immune status, and nutritional status of patients with cancer and can be used to predict the risk of postchemotherapy complications in patients with cancer. The PNI is calculated as "albumin (g/L) + 5 × lymphocyte (10^9/L)" [32]. The SII is a new scoring system proposed by Chinese scholars in 2014 to assess the functional status of the immune system in patients with tumor [33]. The SII is calculated as "platelet (10^9/L) × neutrophil (10^9/L)]/lymphocyte (10^9/L)," and the composite score combining the 3 indexes can better reflect the balance of the body's inflammatory response and immune status. The nutrition-related blood indices (total protein, albumin, prealbumin, and hemoglobin), inflammation-related blood indices (leukocytes, lymphocytes, neutrophils, and platelets), and nutrition-inflammation composite indices (PNI and SII) were collected from hospital electronic medical records.

Patient enrollment and baseline information collection were done by the member of the group responsible for recruitment, who was aware only of the patient inclusion and exclusion criteria and was not aware of the patient grouping. The assessment of the outcome indicators—PG-SGA and blood test indices—was done by the member responsible for efficacy assessment, who was also unaware of the patient subgroups. This study was open-labeled.

Statistical Analysis

Based on the primary outcome of PG-SGA score, a target sample size of 78 participants was estimated to provide 90% power with an α value of .05 to detect a difference between control and intervention groups. This calculation was calculated using PASS 15.0 (NCSS LLC), referring to data from previous study [34], taking into account a 20% dropout rate. Baseline characteristics were presented as medians (IQRs) or percentages and were compared using the chi-square test or the Mann-Whitney test, as appropriate. A linear mixed model was used to analyze these score changes, with their baseline measurements used as covariates. Group, time, and group-time interaction were treated as fixed effects, while the patient was treated as a random effect. Missing data due to loss to follow-up were assumed to be missing at random. The estimated within- and between-group differences were reported with their respective 95% CIs. A 2-sided *P* value of <.05 was considered statistically significant. All data analyses were performed using SPSS (version 25.0; IBM Corp) on an intention-to-treat basis.

Ethical Considerations

This study was approved by the Medical Ethics Committee of Peking Union Medical College Hospital, Chinese Academy of Medical Sciences (ZS-3411).

Results

Participant Flow and Baseline Characteristics

A total of 120 patients were notified of the study before they were admitted to the hospital for the first chemotherapy treatment, of which 18 patients did not fulfill the inclusion criteria and 6 patients refused to participate in the study. Therefore, 96 patients were involved in the random allocation, that is, 48 patients each in the intervention and control groups. During the follow-up, there was sample dropout in both groups: 1 (1/48, 2.1%) patient and 5 (5/48, 10.4%) patients in both groups who refused to continue participating in the study, in addition to 8 (8/48, 16.67%) patients and 4 (4/48, 8.3%) patients in both groups who went to other hospitals for chemotherapy. The flow diagram is shown in Figure 3. There were no statistically significant differences in demographic and clinical characteristics between the intervention and control groups, as shown in Table 2.

Nutritional Status—PG-SGA Score

Figure 4 demonstrates the PG-SGA scores of the intervention and control groups at T0, T1, and T6. Among the 3 time points, there was a statistically significant difference in PG-SGA scores between the 2 groups only at T6. By longitudinal comparison, we found that the difference of PG-SGA scores was statistically significant in the intervention group between T0 and T1 (P<.05), as well as in the control group, with scores lower than the T0 period. However, comparing T0 and T6, only T6 in the control group had a lower score than T0 (P<.05). The mixed linear model revealed that the group-based effect on PG-SGA scores was significant (F_{47}=4.763; P=.03), whereas the time-based effect on PG-SGA scores was not (F_{47}=0.377; P=.54). The group-time interaction effect on PG-SGA scores was statistically significant (F_{46}=6.368; P=.01) (Table 3).

Figure 4. Changes in PG-SGA scores at T0, T1, and T6 between intervention and control groups. T0=prechemotherapy; T1=after first chemotherapy; and T6=after sixth chemotherapy. *There was a significant difference between the intervention and control groups (P<.05). PG-SGA: Patient-Generated Subjective Global Assessment.

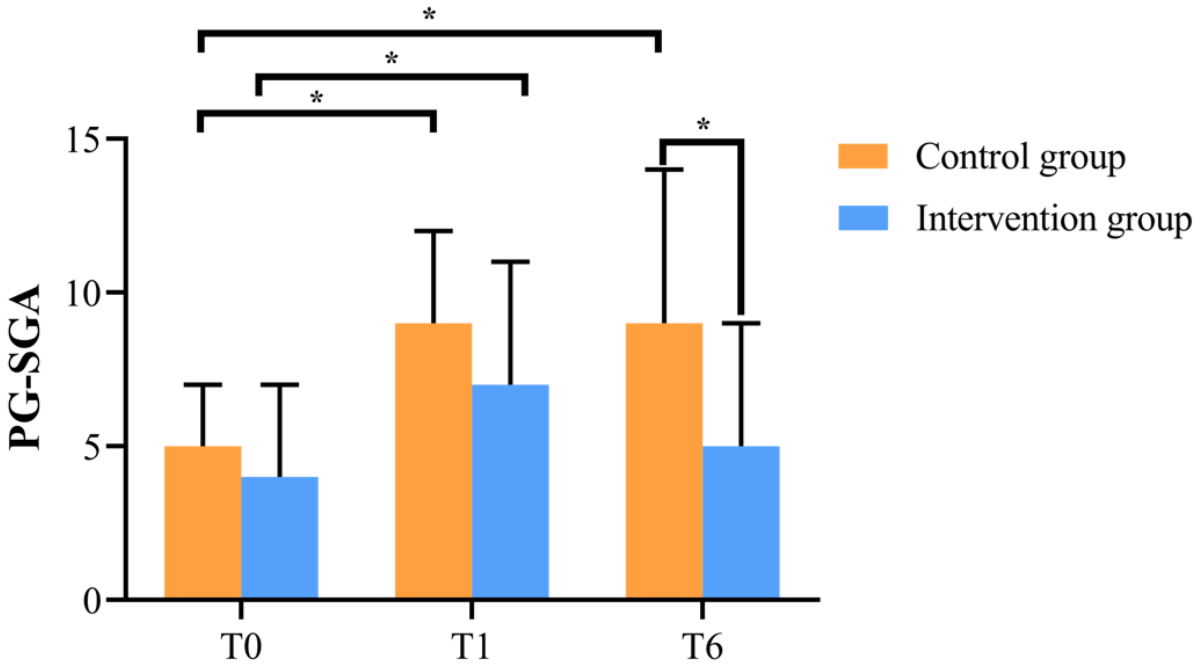

Table . Changes within groups and comparisons between groups regarding the Patient-Generated Subjective Global Assessment (PG-SGA) scores: linear mixed model analysis[a].

Groups	T0 (n=39)	T1 (n=39)		T6 (n=39)	
	Score, median (IQR)	Score, median (IQR)	Change from T0, median difference (95% CI)	Score, median (IQR)	Change from T0, median difference (95% CI)
Intervention	4.00 (3.00 to 7.00)	7.00 (4.00 to 11.00)	−3.00 (−4.00 to 0.00)	5.00 (3.00 to 9.00)	−1.00 (−2.00 to 1.00)
Control	5.00 (2.00 to 7.00)	9.00 (2.00 to 12.00)	−4.00 (−5.00 to 0.00)	9.00 (4.00 to 14.00)	−4.00 (−6.00 to −2.00)
Change between groups, median difference (95% CI)	1.00 (−1.00 to 2.00)	2.00 (−2.00 to 2.00)	N/A[b]	4.00 (1.00 to 5.00)	N/A

[a]Linear mixed model was used for the analysis of changes within group and comparisons between groups of the PG-SGA scores, with T0 measurement of the PG-SGA scores as covariate; group, time, and group × time interaction as fixed effects; and patient as random effect. PG-SGA: (group) F_{47}=4.763, P=.03; (time) F_{47}=0.377, P=.54; (group × time interaction) F_{46}=6.368, P=.01.

[b]N/A: not applicable.

Compound Immune-Nutritional and Compound Immune-Inflammatory Indicators in Blood

Among the 3 time points, there was a statistically significant difference in the PNI and SII between the 2 groups only at T6. By longitudinal comparison, there was a statistically significant difference in the comparison between all 3 time points for the PNI (Figure 5A) and SII (Figure 5B) in the intervention group, as well as in the control group (P<.05) (Figure 5). The mixed linear model revealed that the group-based effect on nutrition-inflammation composite indices was significant (F_{47}=7.653, P=.006; F_{47}=13.309, P<.001), as well as the time-based effect on nutrition-inflammation composite indices (F_{47}=92.304, P<.001; F_{47}=110.675, P<.001). The group-time interaction effect on nutrition-inflammation composite indices was statistically significant (F_{46}=10.379, P=.002; F_{46}=5.289, P=.02) (Table 4).

Figure 5. Changes in compound immune-nutritional and compound immune-inflammatory indicators in blood at T0, T1, and T6 between intervention and control groups. The line graphs show the differences and changes in prognostic nutritional index (**A**) and systemic immunoinflammatory index (**B**) between the intervention and control groups at T0, T1, and T6. *There was a significant difference between the intervention and control groups (P<.05). With regard to "a," "b," and "c," different letters at the 2 time points indicate that there is a significant difference in the blood indices of the intervention or control group at the 2 time points (P<.05).

[d]SII (systemic immunoinflammatory index): (group) F_{47}=13.309, P<.001; (time) F_{47}=110.675, P<.001; (group × time interaction) F_{46}=5.289, P=.02.

Nutrition-Related and Inflammation-Related Blood Indices

Changes in blood indices related to nutrition and inflammation at T0, T1, and T6 are shown in Figures 6 and 7, respectively. Figure 6 showed the differences and changes in total protein (Figure 6A), albumin (Figure 6B), prealbumin (Figure 6C), and hemoglobin (Figure 6D) between the intervention and control groups at T0, T1, and T6. Figure 7 showed the differences and changes in white blood cells (Figure 7A), lymphocytes (Figure 7B), neutrophils (Figure 7C), and platelets (Figure 7D) between the intervention and control groups at T0, T1, and T6. The mixed linear model displayed that the group-based effect on total protein (F_{47}=19.712; P<.001), prealbumin (F_{47}=10.029; P=.002), hemoglobin (F_{47}=6.225; P=.01), lymphocytes (F_{47}=3.921; P=.05), and neutrophils (F_{47}=72.058; P<.001) was significant. The time-based effect on total protein (F_{47}=75.642; P<.001), albumin (F_{47}=24.496; P<.001), prealbumin (F_{47}=5.054; P=.03), hemoglobin (F_{47}=27.744; P<.001), leukocytes (F_{47}=29.950; P<.001), lymphocytes (F_{47}=76.220; P<.001), neutrophils (F_{47}=182.218; P<.001), and platelets (F_{47}=9.350; P=.003) was statistically significant. The group-time interaction effect was statistically significant on total protein (F_{46}=5.626; P=.02), albumin (F_{46}=7.346; P=.007), hemoglobin (F_{46}=6.225; P=.01), leukocytes (F_{46}=3.328; P=.07), and neutrophils (F_{46}=45.555; P<.001). Detailed information is given in Table S2 in Multimedia Appendix 2.

Figure 6. Changes in nutritional indicators in blood at T0, T1, and T6 between intervention and control groups. The line graphs show the differences and changes in total protein (**A**), albumin (**B**), prealbumin (**C**), and hemoglobin (**D**) between the intervention and control groups at T0, T1, and T6. *There was a significant difference between the intervention and control groups (P<.05). With regard to "a, "b," and "c," different letters at the 2 time points indicate that there is a significant difference in the blood indices of the intervention or control group at the 2 time points, whereas the same letter indicates that there was no significant difference (P>.05).

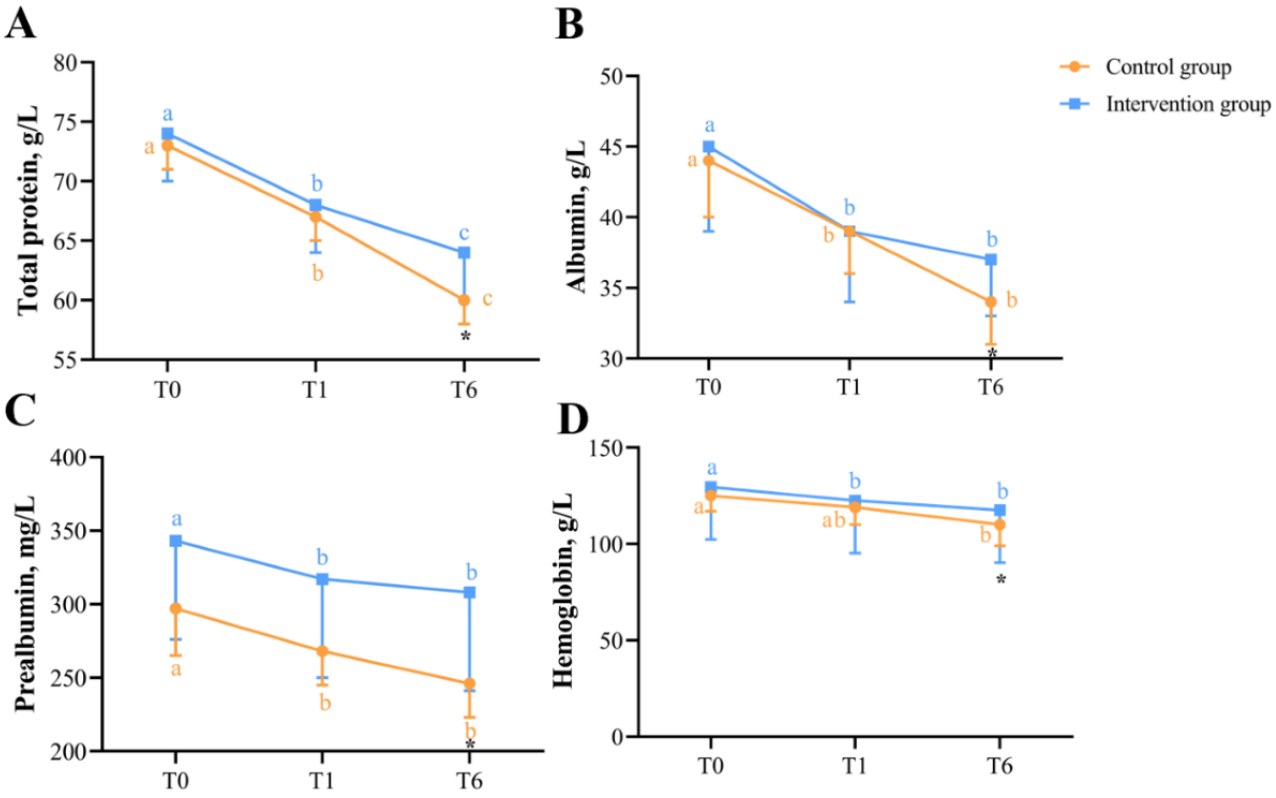

Figure 7. Changes in inflammatory parameters in blood at T0, T1, and T6 between intervention and control groups. The line graphs show the differences and changes in white blood cells (**A**), lymphocytes (**B**), neutrophils (**C**), and platelets (**D**) between the intervention and control groups at T0, T1, and T6. *There was a significant difference between the intervention and control groups (P<.05). With regard to "a," "b," and "c," different letters at the 2 time points indicate that there is a significant difference in the blood indices of the intervention or control group at the 2 time points (P<.05).

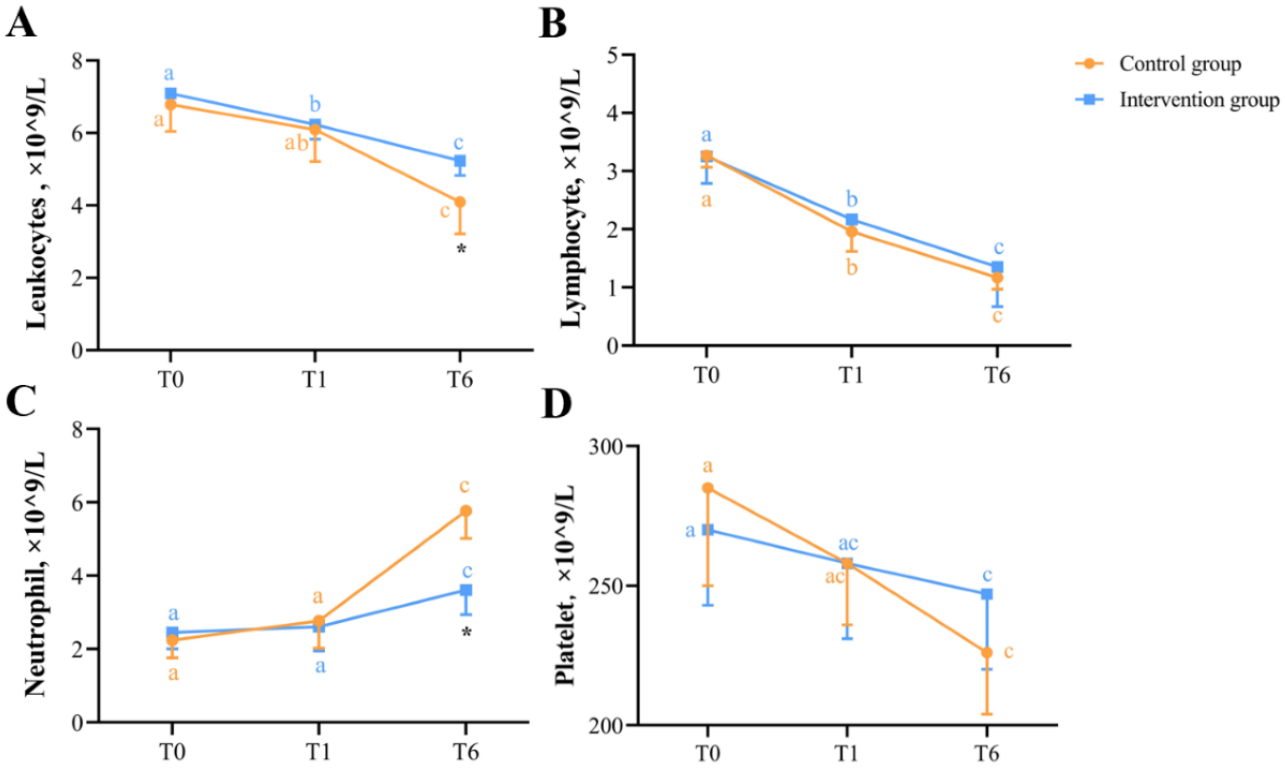

Discussion

Principal Findings

Owing to the difficulty of uniformly managing patients with OC undergoing chemotherapy during the chemotherapy intervals, remote and easily accessible alternatives are needed to improve the nutritional status of patients with OC undergoing chemotherapy. This study of patients with OC undergoing chemotherapy analyzed the effect of a full-course nutritional management program based on the WeChat platform on nutritional status. The results obtained showed that the interventions led to significant improvements in nutritional status in terms of reducing PG-SGA scores, increasing nutrition-related blood indices, and decreasing inflammation-related blood indices.

Comparison With Previous Work

Patients in both the intervention and control groups showed significant increases in the PG-SGA scores after the first chemotherapy compared with baseline, demonstrating that the nutritional status was markedly impaired in patients undergoing chemotherapy. This finding was consistent with those of other related studies [35-37]. The 2 main reasons are analyzed as follows. On the one hand, gastrointestinal symptoms such as nausea and vomiting caused by the paclitaxel-combined carboplatin chemotherapy regimen are the most pronounced and severe after the first chemotherapy session [38], which limits the patient's nutrient intake and absorption, resulting in a loss of body weight and muscle mass, and an elevated PG-SGA score. On the other hand, patients may also develop a cluster of peripheral neurological symptoms after the first chemotherapy session, affecting their motor function [39].

There was no significant difference in PG-SGA scores between the 2 groups after the first chemotherapy treatment, suggesting that the short-term benefits of nutritional intervention strategies have not yet been demonstrated. In addition to the adverse effects of chemotherapy, some patients may experience the following symptoms after their first chemotherapy treatment: anxiety, depression, pain, sexual dysfunction, fatigue, personality changes, and other symptoms [40]. Their normal adaptive mechanisms are challenged and their future planning is compromised, leading to a reduction in their disease self-efficacy [41].

At the sixth chemotherapy follow-up visits, the PG-SGA scores of the intervention group were not significantly different from those at baseline, indicating that the program helped patients gradually return to their prechemotherapy nutritional status during the sixth course of chemotherapy. Meanwhile, the PG-SGA scores of the intervention group remained significantly lower than those of the control group at sixth chemotherapy. This result was consistent with the study by Wang et al [42]. Similarly, we found significant differences between the 2 groups after the sixth session of chemotherapy for both indicators, the PNI and SII. After the sixth chemotherapy session, the intervention group had a higher PNI level and a lower SII level than the control group, which suggested that the nutritional intervention program during chemotherapy may further improve the long-term nutritional prognosis of patients after chemotherapy. The WeChat platform was divided into 3 main interventions: WeChat applet, WeChat group chat, and private

message. First of all, the health education content of the health education module in the WeChat applet was a comprehensive, detailed, and authoritative holistic nutritional intervention program during chemotherapy for patients to review and learn through literature review and expert correspondence, so as to enhance their nutritional literacy. The section was presented in the form of text combined with pictures to easily stimulate patients' interest in reading. The knowledge subscription section was for patients to subscribe to the content according to their own interests and symptoms after chemotherapy, so that patients could read and learn repeatedly anytime and anywhere. The questionnaire test was to regularly check the learning effect of patients, so as to provide targeted intervention. The joint intervention of the 3 sections improved patients' nutritional literacy during chemotherapy, thus realizing the improvement of nutritional status. Compared with Keum et al [43], who intervened in patients' nutritional status through a smartphone app, the WeChat applet in our study was more convenient and economical as it did not require downloads. Second, the WeChat group chat broke through the limitations of time and space to provide a platform for patients to communicate anytime, anywhere [44]. This platform enabled patients to share nutritional experiences, released negative emotions, and gained encouragement from each other [45]. In addition, nutritional team members would correct incorrect nutritional concepts and knowledge in the group chat in a timely manner. Relevant discussions in the group chat could be retained in the WeChat group for a long period of time, which facilitated repeated learning. Peer support from health care professionals and patients in the WeChat group chat also enhanced patients' trust and reliance on the nutrition intervention program [46]. The private massage provided a platform for patients to consult and took timely and effective countermeasures when they encountered nutritional problems [47].

Limitations and Strengths

There are some limitations in our study. First, to participate in the WeChat-based nutrition intervention program, patients must have mobile devices with web access, which suggested that the patients were younger or have supportive family members. Second, the sample size was small. A barrier to recruiting more participants is that most patients choose to go home for follow-up chemotherapy due to their financial situation, and it is difficult to access the nutritional status of patients. A larger sample size could enhance the knowledge gleaned about the efficacy of the intervention. In addition, our study captured only patients' self-reported objective physical outcomes such as weight and specific types of chemotherapy-related symptoms and did not assess patients' psychological perceptions of their nutritional status. In-depth qualitative interviews may be able to compensate for the bias in outcomes. Finally, the study was conducted in a public general tertiary care hospital, so it is necessary to test whether the good results observed can be generalized to other health care institutions.

This study also has some strengths. First, the study site was in a large general tertiary hospital that received patients from all over the country, so the study samples were representative of patients with OC undergoing chemotherapy with malnutrition conditions occurring in different regions of China. In addition, the nutritional assessment tool in the study has been internationally validated, thus allowing for replication and comparison with other studies. Another advantage was that the trial was conducted through a WeChat applet, which was easy to use and did not require downloading an additional application. In addition, the study included only those patients undergoing chemotherapy for OC, so the patient sample was more homogeneous than studies that included patients undergoing chemotherapy for gynecologic oncology.

Conclusions

In this study, a normative WeChat-based nutritional management program lasting for 6 chemotherapy intervals significantly improved nutritional status in patients with OC undergoing chemotherapy compared with conventional controls. Improving personalized nutritional intervention strategies in standard nutritional management protocols for patients with OC and introducing the WeChat platform as a mobile intervention model can enhance patients' nutritional status during chemotherapy and improve their quality of life.

Abstract

Background: Hypertension, a key modifiable risk factor for cardiovascular disease, is more prevalent among Black and low-income individuals. To address this health disparity, leveraging safety-net emergency departments for scalable mobile health (mHealth) interventions, specifically using text messaging for self-measured blood pressure (SMBP) monitoring, presents a promising strategy. This study investigates patterns of engagement, associated factors, and the impact of engagement on lowering blood pressure (BP) in an underserved population.

Objective: We aimed to identify patterns of engagement with prompted SMBP monitoring with feedback, factors associated with engagement, and the association of engagement with lowered BP.

Methods: This is a secondary analysis of data from Reach Out, an mHealth, factorial trial among 488 hypertensive patients recruited from a safety-net emergency department in Flint, Michigan. Reach Out participants were randomized to weekly or daily text message prompts to measure their BP and text in their responses. Engagement was defined as a BP response to the prompt. The k-means clustering algorithm and visualization were used to determine the pattern of SMBP engagement by SMBP prompt frequency—weekly or daily. BP was remotely measured at 12 months. For each prompt frequency group, logistic regression models were used to assess the univariate association of demographics, access to care, and comorbidities with high engagement. We then used linear mixed-effects models to explore the association between engagement and systolic BP at 12 months, estimated using average marginal effects.

Results: For both SMBP prompt groups, the optimal number of engagement clusters was 2, which we defined as high and low engagement. Of the 241 weekly participants, 189 (78.4%) were low (response rate: mean 20%, SD 23.4) engagers, and 52 (21.6%) were high (response rate: mean 86%, SD 14.7) engagers. Of the 247 daily participants, 221 (89.5%) were low engagers (response rate: mean 9%, SD 12.2), and 26 (10.5%) were high (response rate: mean 67%, SD 8.7) engagers. Among weekly participants, those who were older (>65 years of age), attended some college (vs no college), married or lived with someone, had Medicare (vs Medicaid), were under the care of a primary care doctor, and took antihypertensive medication in the last 6 months had higher odds of high engagement. Participants who lacked transportation to appointments had lower odds of high engagement. In both prompt frequency groups, participants who were high engagers had a greater decline in BP compared to low engagers.

Conclusions: Participants randomized to weekly SMBP monitoring prompts responded more frequently overall and were more likely to be classed as high engagers compared to participants who received daily prompts. High engagement was associated with a larger decrease in BP. New strategies to encourage engagement are needed for participants with lower access to care.

Introduction

Hypertension is the most important modifiable risk factor for cardiovascular disease and is more prevalent among Black and low-income people [1-3]. Given the ubiquity and inequities of hypertension, scalable approaches are needed to identify and treat Americans with hypertension.

One scalable approach may be by partnering with safety-net emergency departments (EDs)—hospitals where over 25% of patients are Medicaid recipients—to reach a medically underserved population to initiate mobile health (mHealth) interventions. There are over 136 million ED visits annually [4], and Black Americans and those with low incomes frequently use the ED [5].

mHealth is readily scalable as nearly all American adults (96%) have a mobile phone and over 80% use it for text messaging [6]. Text messaging is a leading form of communication partly because of its cost, ease, and low technical threshold. mHealth hypertension interventions have primarily targeted medication adherence, self-management (including diet and physical activity), and self-measured blood pressure (SMBP) monitoring. SMBP monitoring involves the regular measurement of BP by a patient outside the clinical setting. The outcomes of these mHealth hypertension interventions have had mixed results [7-10]. SMBP reduces BP, in part by promoting the habit of medication adherence and a healthy lifestyle, but little is known about SMBP in the Black and low-income population [11-15]. Additionally, more work is needed to understand engagement with mHealth text messaging interventions and how engagement relates to clinical outcomes.

"Engagement" has been conceptualized differently across fields and studies, but generally refers to users' use of and experience with the system [16]. Although engagement with an intervention is distinct from the performance of health behavior, as users may abandon the use of an intervention while continuing to perform the target behavior [17,18], engagement is associated with intervention efficacy in multiple health domains [19]. Engagement with an intervention may describe interaction with either push- or pull-based interventions [20]. The former describes a user responding to an intervention, for instance, by responding to a text message; the second describes the user calling on the intervention in response to their own needs, for instance, by opening a dashboard to review their past BP measurements. Although push interventions have the potential to increase users' performance of critical health behaviors, such as SMBP, they run the risk of burdening or annoying users, leading to disengagement [20]. Despite work to categorize and evaluate the efficacy of various engagement strategies for mHealth interventions [21], dropout rates remain high [22]. More work is needed to understand how users interact with mHealth interventions, their target health behaviors, and what factors contribute to engagement or disengagement with the intervention.

In this study, we examine engagement with a push intervention in which participants were asked to text SMBP measurements to the research team in response to a text prompt. We identify patterns of engagement with SMBP monitoring, factors associated with engagement, and the association of engagement with lowered BP.

Methods

Ethical Considerations

This study was approved by the University of Michigan Institutional Review Board (HUM00138470) and the ED site Institutional Review Board (1199877). All participants provided written informed consent. The original informed consent allowed for deidentified use in additional analyses and research studies. Participants of the Reach Out trial were given an automated BP cuff, US $20 at enrollment, US $25 after the completion of a 6-month follow-up visit, and US $30 after the completion of a 12-month follow-up visit. If needed, transportation was provided to follow-up visit(s).

Design

This is a nonprespecified secondary analysis of data from the Reach Out Trial. Reach Out was a randomized, controlled, 2×2×2 factorial design mHealth clinical trial to reduce BP among hypertensive safety-net ED patients seeking care for conditions likely to be discharged from the ED (identifier NCT03422718 on ClinicalTrials.gov) [23]. Enrollment occurred from March 2019 to March 2020. Participants were randomized to (1) prompted SMBP monitoring (daily vs weekly) with feedback, (2) tailored healthy behavior text messaging (daily vs none), and (3) facilitated primary care provider (PCP) scheduling and transportation (yes vs no) for 12 months. There were minimal differences across the intervention arms [24]. Among participants, BP declined over the 12-month intervention period. There was no difference in change in systolic BP among the 3 mHealth components [24].

Prompted SMBP Monitoring With Feedback

Participants were randomized to receive daily or weekly automated text prompts to take their BP and text the results to the study team. All participants were given a BP cuff at the time of enrollment. Sample prompts included the following: "This is your reminder to take your BP. REPLY with your BP to Reach Out!" Participants randomized to weekly prompted SMBP monitoring were sent up to 2 follow-up reminders over a 24-hour period if they remained unresponsive. Participants randomized to daily prompted SMBP monitoring were not sent follow-up reminders. All participants received an automated confirmation

text for each BP texted to the study team. Each week, all participants received a tailored feedback message comparing the participant's recent BP to goal BP, along with general encouragement. For example, if a participant reported an SMBP with systolic BP higher than the threshold but diastolic BP lower than the threshold, the following text was sent: "Your BP is 150/75. Your top number is above the normal range, but your bottom number is normal. Meds, eating healthy, and exercise can lower that top number!" Participants also received a monthly text that contained a graph of their self-reported BPs, with tailored interpretation. In this context, engagement was defined as a BP response to an SMBP prompt.

Covariates and BP

Covariates were chosen based on prior research suggesting an association with engagement in SMBP monitoring [13]. Age, race (self-reported Black vs non-Black), sex, education (no college vs any college), insurance type (eg, Medicaid, Medicare, private, uninsured, multiple, or other types of insurance), relationship status (living with someone or married vs living alone), and employment status were self-reported. We also queried access to hypertension care, including the presence of a PCP [25], diagnosis of hypertension, prior hypertension medication in the last 6 months, and inability to attend medical appointments due to lack of transportation (yes vs no). Finally, we queried medical comorbidities (eg, stroke, congestive heart failure, myocardial infarction, and kidney disease) [25].

Baseline BP measurements were the mean of the median of the remote systolic BPs received during the 3-week eligibility phase. All BP outcomes were intended to be measured in person. However, outcomes were assessed remotely for some participants at 6 months and for all participants at 12 months due to COVID-19 research restrictions. In-person BP assessments were conducted by trained research team members using an OMRON 7 Series Upper Arm BP Monitor and following standard procedures [26]. If performed remotely, participants were asked to provide 3 BP measurements, each 1 minute apart. Participants communicated these to the study team through phone calls or text messages. Participants were also asked to send a picture of their BP cuff on their arms to confirm the correct orientation.

Analysis

We used the k-means clustering algorithm and visualization to determine the pattern of SMBP monitoring engagement by SMBP prompt frequency. For both prompted SMBP frequency groups (weekly and daily), the optimal number of clusters of engagement via the elbow method was 2, which we defined as high and low engagement (Multimedia Appendices 1-4) [27]. For each daily and weekly prompted SMBP frequency group, we used descriptive statistics to describe engagement type and assessed the univariate association of demographics, access to care, and comorbidities with high engagement using logistic regression models. Finally, we sought to determine whether engagement was associated with a difference in systolic BP at 12 months using a linear mixed-effects model with 12-month systolic BP as the outcome variable and baseline BP, engagement type (high vs low), time measured in days from randomization to 1 year, and the interaction of time and engagement type as fixed effects, with a random participant effect. Systolic BP was estimated using average marginal effects from the fully adjusted model. K-mode clustering was performed using Python (version 3.11.2; Python Software Foundation), and all other analyses were conducted using SAS (version 9.4; SAS Institute).

Results

Participants

A total of 488 participants were randomized into the intervention; 241 (49.4%) were randomized to weekly monitoring and 247 (50.6%) were randomized to daily monitoring. Within this safety-net ED, of the 241 randomized participants, 117 (48.6%) used Medicaid. Demographics, access to care, and comorbidities for each prompted SMBP frequency group are included in Tables 1 and 2.

Weekly SMBP

Of the 241 participants randomized to weekly SMBP prompts, 189 (78.4%) were classed as low engagers, and 52 (21.6%) were classed as high engagers (Table 1). Low engagers had a mean response rate of 20% (SD 23.4), while high engagers had a mean response rate of 86% (SD 8.7). Participants who were low engagers decreased their engagement early in the trial (Multimedia Appendix 3). Participants older than 65 years (odds ratio [OR] 6.1, 95% CI 2.3 - 16.0; *P*<.001), married or living with someone compared to living alone (OR 2.3, 95% CI 1.2 - 4.5; *P*=.01), and those who attended some college (OR 2.6, 95% CI 1.4 - 5.1; *P*=.004) compared to those without college attendance were more likely to be high engagers. Participants with more access to care, including participants with Medicare (OR 7.6, 95% CI 2.8 - 20.4; *P*<.001) compared to participants with Medicaid, those with the care of a primary care doctor (OR 4.8, 95% CI 1.4 - 16.2; *P*=.01), and those taking antihypertensive medication in the last 6 months (OR 3.2, 95% CI 1.6 - 6.5; *P*=.001) had higher odds of high engagement. Participants who lacked transportation to appointments (OR 0.3, 95% CI 0.1 - 0.8; *P*=.02) had lower odds of high engagement. There was no association between engagement with PCP facilitation and healthy behavior text messaging. Participants who were high engagers had a greater decline in BP (−8.1 mm Hg, 95% CI −12.6 to −3.6), compared to low engagers (−2.4 mm Hg, 95% CI −6.6 to 1.9), and lower BP at 12 months (high engagers: 128.9 mm Hg, 95% CI 125.7 - 132.1 vs low engagers: 136.8 mm Hg, 95% CI 133.2 - 140.4; Figure 1 and Table 3).

[a]SBP: systolic blood pressure.

[b]BL: baseline.

Daily SMBP

Of the 247 participants randomized to daily SMBP prompts, 221 (89.5%) were classed as low engagers and 26 (10.5%) as high engagers (Table 2). Low engagers had a response rate of 9% (SD 12.2), while high engagers had a mean response rate of 67% (SD 8.7). Participants who were low engagers decreased their engagement early in the trial (Multimedia Appendix 4). Participants who were married or living with someone had a trend toward high engagement (OR 2.3 95% CI 1.0 - 5.2; *P*=.06), and participants with multiple insurance types were more likely to have high engagement (OR 6.2, 95% CI 1.8 - 22.0; *P*=.005) compared to Medicaid alone. Participants who were high engagers had a greater decline in BP (−9.0 mm Hg, 95% CI −14.5 to −3.5) compared to low engagers (−6.8 mm Hg, 95% CI −9.5 to −4.2) and lower BP at 12 months (high engagers: 122.2 mm Hg, 95% CI 118.4 - 12.1 vs low engagers 130.9 mm Hg, 95% CI 128.8 - 133.0; Figure 1 and Table 3).

Discussion

In this secondary analysis of a mHealth clinical trial among participants recruited from a safety-net ED, we identified 2 distinct patterns of SMBP engagement.

High and Low Engagement: Interpretation and Implications

In both daily and weekly reminder conditions, participants could be clustered into high and low engagers. A larger proportion of participants randomized to weekly SMBP monitoring prompts were high engagers and had greater engagement overall compared to participants who received daily prompts. All engagement groups had a decline in BP, even low engagers in the daily condition who exhibited a very low response rate.

In both daily and weekly conditions, many of the factors associated with high engagement were factors also associated with better health outcomes in general: high engagers generally had attended college, had treated their hypertension with an antihypertensive medication in the last 6 months, had Medicare, and had more access to care (ie, they had reported a PCP at enrollment or reported having transportation to medical appointments). Perhaps due to these factors, high engagers had slightly lower baseline systolic BP than low engagers in both conditions (Table 3). High engagers also exhibited a greater decrease in BP than low engagers. This may be related to their baseline characteristics, which could promote a habit of medication adherence and a practice of a healthy lifestyle (through SMBP) [11-15]. Another possible explanation for this finding, which would require further study, is that high engagers learned more about what impacted their BP from frequent monitoring. In this case, researchers should explore strategies for promoting engagement to turn low engagers into high engagers.

We found that engagement levels declined quickly and did not recover, suggesting re-engagement attempts should begin early on. Re-engagement strategies could take the form of direct outreach from the study team. However, for the sake of scalability, researchers should also explore techniques for re-engaging participants through the intervention itself. Although there is not yet a good evidence base for re-engagement strategies for mHealth interventions, existing research suggests that when users re-engage, it is for the same health motivations that brought them to the system in the first place [28]. Work examining the adoption and re-adoption of wearables has also found that the visual appeal of new devices is also associated with re-engagement [29]. These findings suggest that reminding users of their health goals and prompting them to monitor their BP could be an effective re-engagement technique. Although researchers have little control over the general visual appeal of text messages, future interventions could explore whether varying the form of reminders to include more graphical elements, for instance, by sending images as text messages, could promote engagement or re-engagement.

Another possible explanation of our findings is that high engagers were more likely to engage in SMBP because they were better able to act on their BP. For instance, high engagers may have been able to talk to their PCP about their recorded measurements [30]. By contrast, low engagers, who overall had less access to care, may have been less able to consult clinicians about what additional management was needed, leading to discouragement and disengagement. This interpretation suggests that SMBP alone is unable to mitigate the impact of decreased access to care. Additional strategies, such as connecting participants to primary care—which was initiated in the Reach Out trial but ended due to COVID-19, the addition of community-health worker support, or activating social networks may be needed.

Prompt Frequency, Engagement, and BP

Participants in the weekly condition exhibited higher engagement, and higher engagement was associated with a greater decrease in BP. The lower engagement observed in the daily condition could be due to habituation, as observed in other mHealth contexts [17,31]—users may simply have gotten used to the notifications and begun ignoring them. Lower engagement could signal frustration or dissatisfaction with the intervention, impacting real-world use. Other studies had similar findings—higher engagement was linked to improved outcomes [32,33]. More work is needed to evaluate the reasons for higher engagement. To get better insight into the effect of each message, future work could analyze not just the response rate but also the rate at which messages are read and the rate at which particular behaviors associated with hypertension management, such as medication taking, are performed. Such granular data could enable researchers to get more insight into how different doses of the intervention function. Future works could also focus on the efficacy of prompt frequency alongside habituation to better inform how to optimize engagement.

Limitations and Conclusions

Our study has limitations. This was a nonprespecified secondary analysis of clinical trial data. Reach Out was a single-center trial; thus, results may not be generalizable to other safety-net ED populations, particularly those with non–English-speaking populations. Finally, we cannot exclude that a small subset of participants completed SMBP monitoring but did not text in their BPs, and as a result, we may be overestimating the

proportion of low engagers. If high engagers were misclassified as low engagers, this should bias our findings toward the null.

In conclusion, about 16% of safety-net ED participants were highly engaged in prompted SMBP monitoring with feedback. Participants in the weekly condition overall exhibited higher engagement compared to daily prompts. BP decreased among all participants, but those with higher engagement had a greater decline in BP overall, supporting weekly rather than daily BP prompts. New strategies to encourage engagement are needed for participants who were not taking antihypertensive medication and had lower access to care.

Abstract

Background: The effectiveness of timely medication, physical activity (PA), a healthy diet, and blood pressure (BP) monitoring for promoting health outcomes and behavioral changes among patients with hypertension is supported by a substantial amount of literature, with “adherence” playing a pivotal role. Nevertheless, there is a lack of consistent evidence regarding whether digital interventions can improve adherence to healthy behaviors among individuals with hypertension.

Objective: The aim was to develop a health behavioral digital intervention for hypertensive patients (HBDIHP) based on an intelligent health promotion system and WeChat following the behavior change wheel (BCW) theory and digital micro-intervention care (DMIC) model and assess its efficacy in controlling BP and improving healthy behavior adherence.

Methods: A 2-arm, randomized trial design was used. We randomly assigned 68 individuals aged >60 years with hypertension in a 1:1 ratio to either the control or experimental group. The digital intervention was established through the following steps: (1) developing digital health education materials focused on adherence to exercise prescriptions, Dietary Approaches to Stop Hypertension (DASH), prescribed medication, and monitoring of BP; (2) using the BCW theory to select behavior change techniques; (3) constructing the intervention's logic following the guidelines of the DMIC model; (4) creating an intervention manual including the aforementioned elements. Prior to the experiment, participants underwent physical examinations at the community health service center's intelligent health cabin and received intelligent personalized health recommendations. The experimental group underwent a 12-week behavior intervention via WeChat, while the control group received routine health education and a self-management manual. The primary outcomes included BP and adherence indicators. Data analysis was performed using SPSS, with independent sample *t* tests, chi-square tests, paired *t* tests, and McNemar tests. A *P* value <.05 was considered statistically significant.

Results: The final analysis included 54 participants with a mean age of 67.24 (SD 4.19) years (n=23 experimental group, n=31 control group). The experimental group had improvements in systolic BP (–7.36 mm Hg, *P*=.002), exercise time (856.35 metabolic equivalent [MET]-min/week, *P*<.001), medication adherence (0.56, *P*=.001), BP monitoring frequency (*P*=.02), and learning performance (3.23, *P*<.001). Both groups experienced weight reduction (experimental: 1.2 kg, *P*=.002; control: 1.11 kg, *P*=.009) after the intervention. The diet types and quantities for both groups (*P*<.001) as well as the subendocardial viability ratio (0.16, *P*=.01) showed significant improvement. However, there were no statistically significant changes in other health outcomes.

Conclusions: The observations suggest our program may have enhanced specific health outcomes and adherence to health behaviors in older adults with hypertension. However, a longer-term, larger-scale trial is necessary to validate the effectiveness.

Introduction

Hypertension and Health Behavior Interventions

Hypertension, as a high-prevalence chronic disease, has become an important risk factor for many diseases (eg, stroke, renal disease) and a major contributor to the global burden of disease [1,2]. Approximately one-third of older adults with hypertension fail to achieve their blood pressure (BP) control goals [3]. The reasons for the low rate of hypertension control are related to high-risk lifestyles such as poor dietary habits and low levels of physical activity (PA).

Relevant studies have shown that adherence to recommended health behaviors can significantly reduce systolic blood pressure (SBP) by an average of 4.0 mm Hg to 5.6 mm Hg and diastolic blood pressure (DBP) by an average of 4.1 mm Hg to 5.3 mm Hg in individuals with hypertension [4]. Engaging in a wide range of exercise training can lead to average reductions of 4.08 mm Hg to 8.24 mm Hg in SBP and 2.5 mm Hg to 4.0 mm Hg in DBP [5]. Regular BP monitoring behaviors result in average reductions of 2.53 mm Hg to 4.7 mm Hg in SBP and 1.45 mm Hg to 2.4 mm Hg in DBP [6,7]. Adherence to Dietary Approaches to Stop Hypertension (DASH) not only reduces SBP and DBP by approximately 5.5 mm Hg and 3 mm Hg, respectively, but also reduces the chance of developing hypertension by 26% [8,9]. High medication adherence, combined with comprehensive interventions like diet and exercise management, leads to improved BP control [10,11]. It is evident that comprehensive health behavior interventions can achieve effective BP control, with adherence playing a pivotal role.

In recent years, several studies exploring intelligent health promotion systems that incorporate advanced technologies like artificial intelligence, wearable devices, and mobile communication have consistently shown their efficacy in managing chronic diseases [12-14]. In addition, numerous studies support that independent mobile health (mHealth) apps play a vital role in community-based patient management [10,12,14-16]. WeChat, China's predominant social communication mobile app, serves as one platform for mHealth interventions. It boasts a staggering daily user count of up to 902 million people and over 1 billion monthly active users spanning all age groups [17]. Several studies have indicated that mHealth-based interventions can enhance health outcomes, quality of life, and self-care among patients with chronic diseases [18,19]. BP monitoring adherence (BPMA), dietary habits, and self-efficacy behaviors of patients with hypertension have been somewhat improved by these interventions based on mHealth [20-22]. However, other studies have shown no significant change or little improvement in BP, medicine, exercise, and DASH adherence [20,23-25].

Theoretical Framework

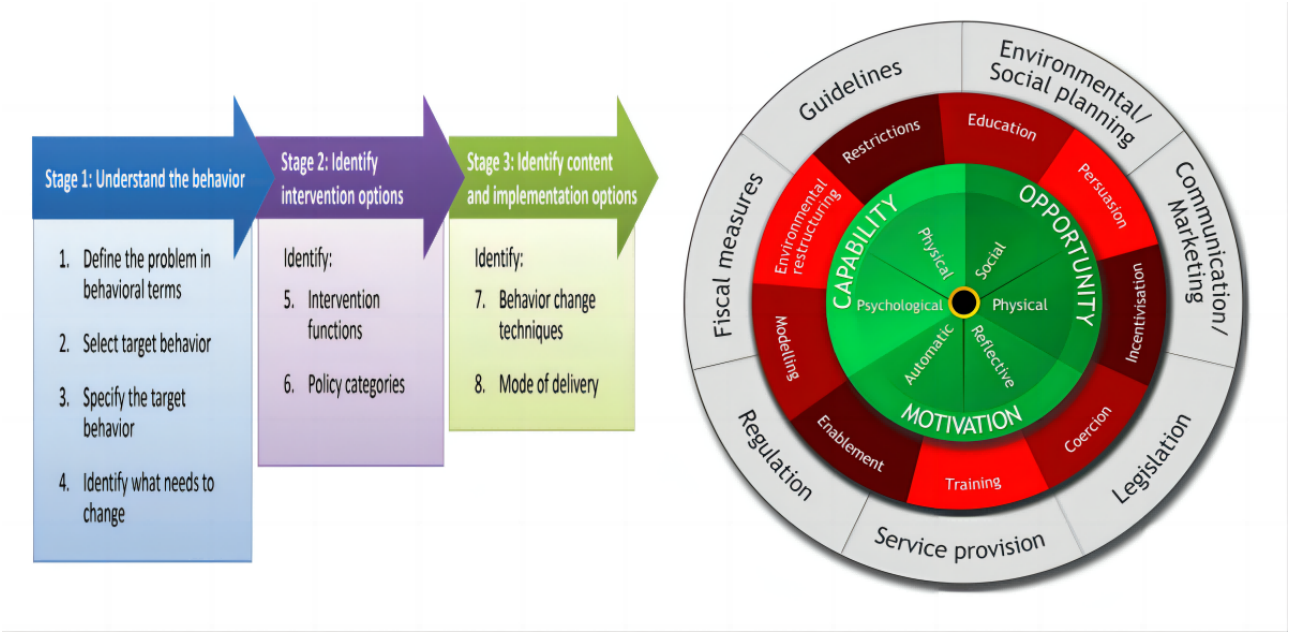
The behavior change wheel (BCW), which integrates 19 relevant theoretical frameworks for behavior change, was first proposed by Michie et al in 2011 [26]. As Figure 1 illustrates, it consists of 3 tiers. The inner tier is the Capability, Opportunity, Motivation-Behavior (COM-B) model, which is used to identify barriers to intervening in the target behavior. The second tier comprises the following 9 intervention categories intended to tackle identified behavioral obstacles: education, persuasion, motivation, coercion, training, restriction, environmental restructuring, demonstration, and empowerment. The outermost tier encompasses 7 policy categories (eg, regulation and legislation) that aid in the implementation of macrolevel interventions [27]. This theory consists of 3 steps: understanding the behavior, identifying intervention options, and identifying content and implementing the options (ie, behavior change techniques [BCTs]). Michie et al [28], along with other scholars, developed “The behavior change technique taxonomy of 93 hierarchically clustered techniques,” which contains 93 BCTs and provides names, definitions, and examples. In the final step, researchers can select the necessary BCTs from this taxonomy list.

Scholars have applied this theory to community health promotion, health care management, and nursing care, resulting in positive outcomes [29-32]. Additionally, some researchers have extended its application to digital and mHealth interventions [33]. The effectiveness of this lies in its ability to aid interveners in the systematic and scientific identification of intervention functions and specific BCTs for behavior change problems. Despite this, the theory does not provide much insight into the components of the intervention. The BCW can be supplemented by the digital micro-intervention care (DMIC) model [25,34].

In 2020, the DMIC model proposed by Baumel and colleagues [34] provided a reference paradigm. This theoretical model promotes shorter, more focused interventions, known as micro-interventions. They can be highly focused on implementation in people's daily lives to help intervention recipients achieve desired short-term goals (the basis for achieving long-term goals). The DMIC comprises the following 3 core concepts: events (in-the-moment attempts at change or impact toward the overall target of the intervention), decision rules (guiding which events are deployed and when), and proximal assessments (assessing the impact of the event). Events are similar to specific BCTs, while decision rules deploy events in a meaningful way based on time, user status, or environmental

information, allowing interveners to dynamically adjust the content of micro-interventions. Overall outcome assessment, proximal event outcome assessment, and assessment of user participation in the micro-intervention are 3 types of impact assessment for digital micro- interventions. Based on the results of the overall and proximal assessments and the continuous recording of the user engagement experience (ie, measuring the quality of attention, engagement, and immersion during the use of the program), it is possible to identify individuals with low levels of engagement and later search for the causes, modify the intervention decision rules, and re-engage the user. This theoretical framework advocates for interventions that aim to achieve specific objectives through in-the-moment intervention elements. These elements may not be directly tied to the attainment of a broader clinical goal [34]. Each intervention in every event represents an immediate attempt to modify or influence the overall goal of the intervention. This implies that, in order to achieve a clinical objective, interventions should be broken down into numerous small steps and regulated through proximal assessments, ultimately leading to the attainment of the overall outcome.

Figure 1. Behavior change wheel.



Goal of This Study

Therefore, our objective was to develop a health behavioral digital intervention for hypertensive patients (HBDIHP) based on BCW and DMIC and assess the effectiveness of this program in 2 groups after 3 months of intervention. This program involved exercise, diet, BP monitoring, and medication adherence intervention strategies. Consequently, we aimed to assess the effectiveness of this approach for enhancing outcomes for older adults with hypertension.

Methods

Development of HBDIHP

Community-Oriented Intelligent Health Promotion System

The Intelligent Health Promotion System is a cloud platform–based system that leverages health sign data and health questionnaire responses to generate intelligent health reports, personalized exercise prescriptions, and other tailored health recommendations. It also tracks and monitors individual health data. This system comprises the following 3 main layers: perception layer, decision layer, and application layer (see Figure 2).

This system is installed in the Intelligent Health Cabin at community health service centers (see Figure 3). It currently supports a range of connected instruments, including cardiovascular function monitors, arteriosclerosis detectors, body composition monitors, bone densitometers, and physical fitness detectors. After completing assessments with these instruments, the system sends those collected data to its central cloud platform database. Participants need to continue to fill out various questionnaires, such as chronic disease history questionnaires, medication profiles, and family medical history surveys. The system then uses both instrument data and questionnaire responses to activate the intelligent decision-making and inference engine, which generates comprehensive reports. These reports provide a comprehensive evaluation of an individual's health status and offer personalized, evidence-based recommendations, namely personalized intervention plans.

Figure 2. Intelligent health promotion system architecture diagram.

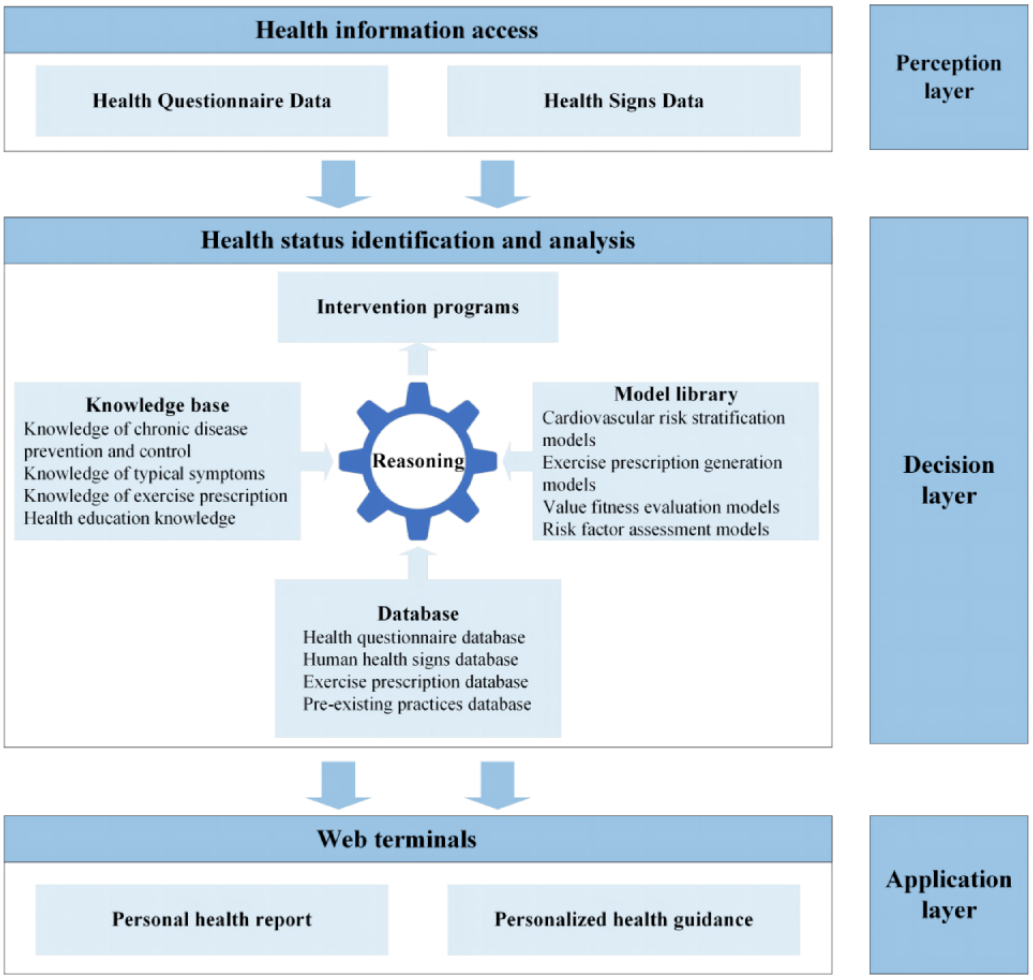


Figure 3. Intelligent Health Cabin.

Assessment of Health Outcomes and Risk Prediction

The comprehensive report provides an overview of participants' health, identifying health issues in areas such as the cardiovascular system, lipid metabolism, musculoskeletal system, lifestyle, and physical fitness, while explaining the meaning of abnormal indicators. In the cardiovascular assessment, the system not only evaluates participants' cardiovascular systems based on instrument results but also predicts participants' heart age and the risk of cardiovascular disease using a machine learning model.

Personalized Health Advice

The comprehensive report offers personalized health advice to each resident, which includes exercise prescriptions, dietary recommendations, and suggestions for behavior correction. The exercise prescription, based on the design principles of the American College of Sports Medicine guidelines (frequency, intensity, type, time, volume, and progression [FITT-VP])

combined with the Transtheoretical Model, delineates intervention plans tailored to the health care stage, exercise habit formation stage, scientific fitness stage, and exercise habit maintenance stage. After being processed by the intelligent decision module, the system generates exercise prescriptions customized for individual residents (see Figure 4), considering the exclusion of exercise contraindications. These prescriptions encompass exercise recommendations, principles, weekly plans, exercise correction, precautions, and exercise guidance (see Figure 5) [13].

A dietary guidance and behavior correction database was constructed using technical strategies such as expert systems and knowledge graphs. In practice, the system provides dietary recommendations and behavior correction suggestions (eg, health advice for sedentary individuals to change their unhealthy habits) based on diet-related questionnaires, medical history collection, and physical examination results (see Figure 6).

Figure 4. Exercise prescription generation flowchart.

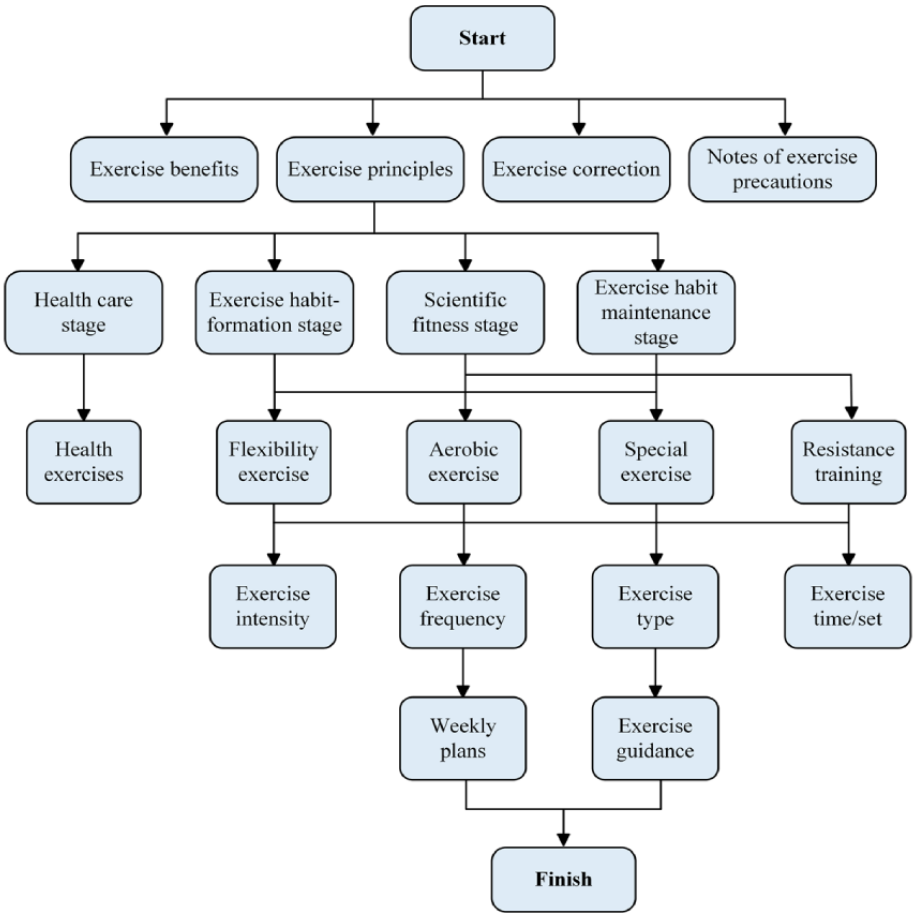

Figure 5. Personalized exercise prescription.

Figure 6. Dietary recommendations and behavior correction suggestions.

Development of the Health Behavioral Digital Intervention

A multidisciplinary working group for digital health intervention strategies was established during the entire intervention program design process. This group included 3 patients with hypertension, 1 clinical expert in hypertension, 1 management expert, and 1 behavioral psychology expert. Group-focused interviews were carried out at every stage of development. At this stage, experts evaluated intervention strategies using their professional knowledge, while patients with hypertension assessed the acceptability and utility of the interventions from their perspective. After finalizing the intervention scheme, experts who were not involved in the development were invited to assess its structural validity.

Defining Health Behavior Management Targets and Health Education Content

The identification of the 4 key health behavior management targets and associated health education content for hypertension (see Table 1) was based on existing literature and previous research findings.

Table 1. Health education targets and content.

Health behaviors	Targets	Health education content
Physical activity (exercise)	Recommended exercise levels according to exercise prescription	Relevant knowledge and exercise skills for personalized intelligent exercise prescriptions
Healthy diet	Choose types and quantities of food according to the DASH[a] principles	Knowledge related to DASH and techniques for assessing simplified DASH grading diet index score
Taking medication	Adherence to prescribed medication	Knowledge of medications
Monitoring of blood pressure	The recommended frequency of home blood pressure monitoring according to clinical guidelines	Knowledge and skills in blood pressure monitoring

[a]DASH: Dietary Approaches to Stop Hypertension.

Development of Digital Health Education Materials

Patient health education needs for the 4 targets were gathered through focus group interviews. Subsequently, evidence-based principles were used to develop textual materials related to exercise, diet, medication taking, and BP monitoring. These materials underwent content validity assessments by experts before being transformed into health education videos. For diet, in addition to creating health education videos based on the DASH guidelines, the research team developed a simplified DASH grading diet index score. The scoring system included items for evaluating daily meals, such as grains, vegetables, fruits, protein sources, cooking oil, and compliance with recommended food types and quantities. Items 1 through 7 represented positive scoring criteria for each recommended food category and quantity, while items 8 through 10 incurred deductions. The aim was to educate patients on recommended dietary behaviors through the acquisition of DASH knowledge and proficiency in using the simplified DASH grading diet index score. For exercise, in addition to providing general knowledge about exercise, the research team augmented the guidance materials (eg, videos on how to perform recommended exercise types) without altering the existing elements of the intelligent exercise prescription. Medication adherence and BP monitoring were primarily addressed through instructional videos that imparted relevant knowledge and skills. All relevant videos were accompanied by textual materials that were ultimately compiled into the “hypertension self-management manual.” See Figure 7 for an overview.

Figure 7. Hypertension self-management manual.

Development of Digital Intervention Scheme Based on BCW and DMIC

We used the systematic workflow of the BCW to identify appropriate intervention categories and suitable BCTs. Details of this process have been published in other papers [35]. Based on the identified BCTs, we developed corresponding textual content, which, along with the previously mentioned digital health education materials, collectively form the foundational elements of the DMIC theory. Subsequently, additional elements of the DMIC theory, namely proximal assessment indicators and decision rules, were determined based on literature review and expert opinions.

First, the BCW theory was used to identify barriers related to capability, opportunity, and motivation affecting adherence to health behaviors by patients with hypertension. Intervention categories were chosen to address these barriers, including methods like education, persuasion, and incentivization. Figure 8 illustrates the process of developing the mHealth intervention scheme for improving adherence.

Second, BCTs, such as feedback on behavior, prompts, self-monitoring of behavior, and verbal persuasion about capability, were selected from the BCT taxonomy, which had already been coded and organized by researchers like Michie et al [28]. Furthermore, based on the selected BCT, specific textual content was prepared (eg, BCT: focus on past success; text: “You have successfully quit smoking in the past, and we believe you can also develop a scientific exercise habit! Keep it up!”).

Third, following the DMIC model, we classified the textual content corresponding to BCTs and digital health education materials as “events.” Subsequently, we established decision rules that determined when and in what order interventions for these events should take place. Additionally, we established proximal assessment indicators (eg, knowledge level) for tailoring intervention strategies to individual patients and their corresponding events (eg, continue learning if qualified, relearn if not). Events, proximal assessment, and decision rules were integrated into intervention units organized by chronological stages, including assessing and preparing, committing and planning, and reinforcing behavioral habits. Notably, health education was primarily implemented during the assessing and preparing phase (first week).

Fourth, the intervention scheme was validated by an expert panel through 2 rounds of Delphi surveys. The panel of 15 experts included 6 nutrition experts, 2 clinical cardiologists, 3 clinical nurses and nursing teachers, and 4 exercise experts. The content validity index (CVI) was calculated and assessed using the item-level CVI (I-CVI) and a 4-point scale, respectively. The first round of assessments using the I-CVI ranged from 0.6 to 0.8. After adjusting the content based on the feedback and comments from the experts, the I-CVI reached 1 in the second round.

Finally, all intervention logic and guidance content were compiled into an intervention manual. This manual included daily intervention tasks (eg, questionnaires, text based on BCTs, and the order of videos to be sent), communication guidelines, and personalized guidance strategies (eg, after assessing the extent of the patient's knowledge and skills, the approach to providing personalized guidance can be provided).

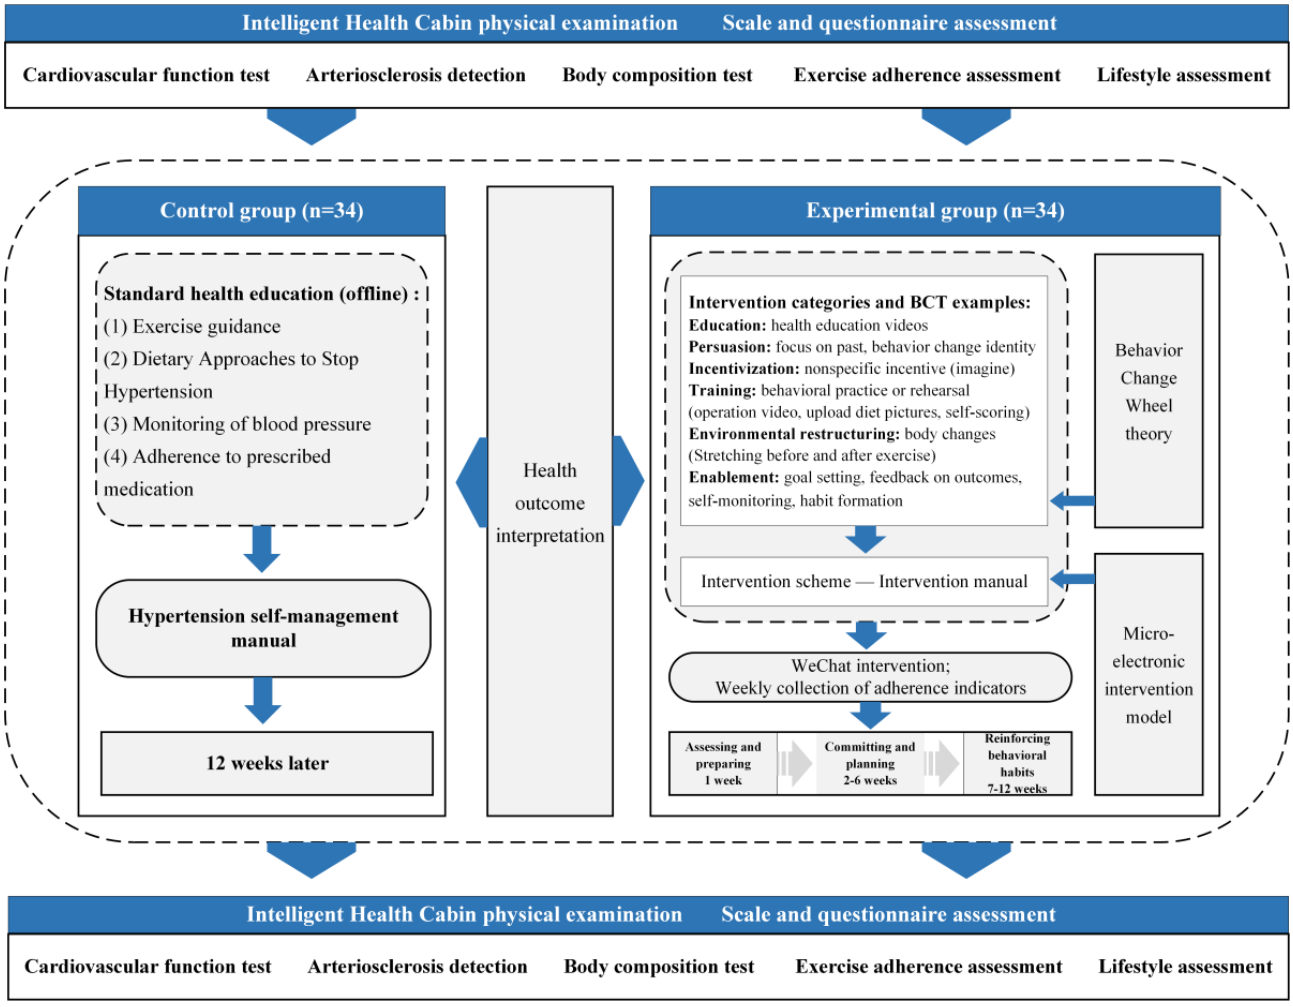
Study Design

Trial Design and Setting

The study protocol was previously published [35]. This was a randomized controlled trial. The experimental group received the health behavioral digital intervention based on an intelligent health promotion system and WeChat for 12 weeks, while the control group received routine health services and was provided with a "Hypertension Self-Management Manual" to guide daily health behaviors (refer to Figure 9). The trial was conducted at 2 community health centers, both located in Anhui Province: Sanxiao Kou Community Health Service Center and Dongfeng Community Health Service Center.

Figure 9. Trial design.



Patients

The staff at the community health service centers recruited eligible patients with hypertension within their jurisdiction through phone calls or verbal invitations using a convenience sampling method. The inclusion criteria for participants were as follows: (1) diagnosed with primary hypertension or currently taking antihypertensive medication; (2) aged >60 years; and (3) proficient in using smartphones and the WeChat application. The exclusion criteria were as follows: (1) patients with hypertension undergoing nonpharmacological treatment; (2) those with diabetes, kidney disease, or other conditions requiring special dietary and exercise considerations; (3) individuals participating in or having participated in other health management projects; and (4) those unable to measure BP in a home environment.

Sample Size

The sample size for this study was determined based on the effect size. According to a previous meta-analysis comparing the BP-lowering effects of mHealth interventions and other traditional methods used by patients with hypertension, the mHealth experimental group demonstrated a significant reduction in BP, with an effect size of 0.7 [36]. The sample size for this study was calculated using GPower 3.1, assuming α=.05 and β=.2 and accounting for a 20% dropout rate, resulting in a final sample size of 68 participants.

Randomization, Allocation, and Blinding

Prior to randomization, a researcher unfamiliar with the experimental design used SPSS (version 23; IBM Corp) to generate 68 random numbers. Subsequently, using the visual binning method, these numbers were divided into 2 groups (experimental group and control group). The paper slips containing the labeled random numbers were placed into sealed envelopes, and another researcher unaware of the experimental design was responsible for assigning participants to either the experimental group or control group. This researcher sequentially opened the envelopes and assigned participants to the experimental group or control group based on the numbers. Additionally, during the data collection phases before and after the experiment, we trained and employed 2 nursing graduate students unfamiliar with the study design. The data collection for the experimental group intervention process was conducted by 5 nursing undergraduates who were also unfamiliar with the experimental design.

Outcomes

Primary Outcomes

Before and 12 weeks after the intervention, we used a cardiovascular function monitoring device (BX-CFTI-100, Intelligent Machine Institute) to measure participants' BP. Measurement details have been published [13]. Through WeChat, 5 undergraduate students unfamiliar with the experimental design collected adherence indicators from the experimental group participants weekly. These indicators included exercise adherence, calculated as the ratio of actual weekly exercise time meeting the prescribed intensity to the total prescribed weekly exercise time; dietary adherence, assessed using the weekly average score of the simplified DASH grading diet index score (see protocol paper for details [35]); medication adherence, assessed using the weekly average score of the Modified Morisky Scale (Chinese version-MMS-8, Certificate Number: 8538-1877-1559-6025-5310) [37-39]; and BPMA calculated as the ratio of the actual weekly frequency of BP monitoring to the total recommended weekly frequency.

Secondary Outcomes

Secondary outcomes were assessed before and after the intervention. Heart rate and subendocardial viability ratio (SEVR) were measured using the cardiovascular function monitor; brachial-ankle pulse wave velocity was measured using an arterial stiffness monitor (BX-AS-100, Intelligent Machine Institute); weight was measured using a body composition analyzer (BX-BCA-100, Intelligent Machine Institute); and lifestyle was assessed through an online questionnaire administered to participants pre- and postintervention. Participants were questioned about health-related behaviors, including the frequency of smoking, drinking, diet, and PA. For smoking, the lifelong smoking quantity of participants was calculated based on the quantity and weekly frequency of cigarettes smoked. For those who had quit smoking, this calculation also included their smoking history before quitting. The alcohol content in one bottle of the most popular alcoholic beverages in Anhui Province is as follows: beer (500 mL, 3.2% alcohol): 17.5 g; white liquor (450 mL, 42% alcohol): 210 g; and wine (750 mL, 13.5%-14% alcohol): 97.5 g. Daily alcohol consumption was calculated using these values. Missing values for smoking and drinking data were set to zero. Participants were asked about the types, duration (in minutes), and frequency (per week) of PA they engaged in. PA time was determined in minutes per metabolic equivalent (MET) per day (min/MET/day) based on activity codes and MET intensities in the "Compendium of Physical Activities." Weekly exercise time (MET-min/week) and weekly PA time (MET-min/week) were calculated, with missing values set to the median [40].

Statistical Analysis

Data analysis was carried out using SPSS, with independent sample *t* tests and chi-square tests used to evaluate the significance of differences between the 2 groups. Paired *t* tests and McNemar tests were used to compare differences within the same group before and after the 3-month intervention. A *P* value <.05 was considered statistically significant.

Ethical Considerations

The study was approved by the Ethics Committee of Bengbu Medical College in June 2022 under approval number 2022-103, and the study began after informed consent was obtained from patients with hypertension and all participants allowed their data to be used anonymously. An independent data manager conducted weekly checks on the database to ensure its integrity and security. The implementation of data lockup aims to prevent any postmodification. All exported data must undergo anonymization by the data manager before statistical analysis can be conducted to safeguard the participants' information. Each participant who underwent the intervention and data collection at the community health center was given a gift of daily necessities valued at approximately US $6.87.

Results

Participants

Between September 5, 2022, and September 19, 2022, a total of 68 patients with hypertension were recruited through phone or verbal invitations from the 2 community health centers in Anhui Province. Participants were re-invited to the community health service center for health data and information collection between December 20, 2022, and January 5, 2023. A total of 54 participants (30 women and 24 men; mean age 67.24, SD 4.19 years) were included in the final analysis: 23 in the experimental group and 31 in the control group. Exclusions were due to various reasons, including hospitalization for illness (2 individuals), inability to complete the postintervention assessment (3 individuals), health conditions deteriorating to the point of hindering PA (4 individuals), voluntary withdrawal from the study (4 individuals), and a change in antihypertensive medication (1 individual). Other patients did not change their hypertension medication during the intervention.

Baseline Data

No statistically significant differences in health outcomes (eg, SBP, SEVR), adherence indicators (eg, exercise time, PA time, medication adherence), and learning performance were observed between the experimental group and control group at baseline.

Intervention Effect

Table 2 displays the baseline and posttest results for both groups regarding health outcomes, adherence indicators, and learning performance. Significant changes were observed in SBP (–7.36 mm Hg, P=.05), SEVR (0.16, P=.01), exercise time (856.35 MET-min/week, P=.03), medication adherence (0.56, P=.02), BP monitoring frequency (P=.046), and learning performance (3.23, P<.001) in the intergroup comparison after 12 weeks. The PA time increased for the experimental group in the before-and-after comparisons (P=.045). Both groups experienced a reduction in weight after the intervention (experimental: 1.2 kg, P=.002; control: 1.11 kg, P=.009). Furthermore, the Cohen d values reflecting effect size were greater than 0.5 for all variables except PA time, indicating at least an intermediate effect size. Among these variables, the health outcomes of SEVR, recommended diet types (eg, meeting recommendations occasionally, sometimes, often), recommended diet quantities (eg, meeting recommendations occasionally, sometimes, often), BP monitoring frequency (eg, measure daily, measure 1-3 times a week, measure whenever remember), and learning performance had Cohen d values >0.8, suggesting a large effect size.

Table 2. Effects of the health behavioral digital intervention for hypertensive patients (HBDIHP) effects (N=54).

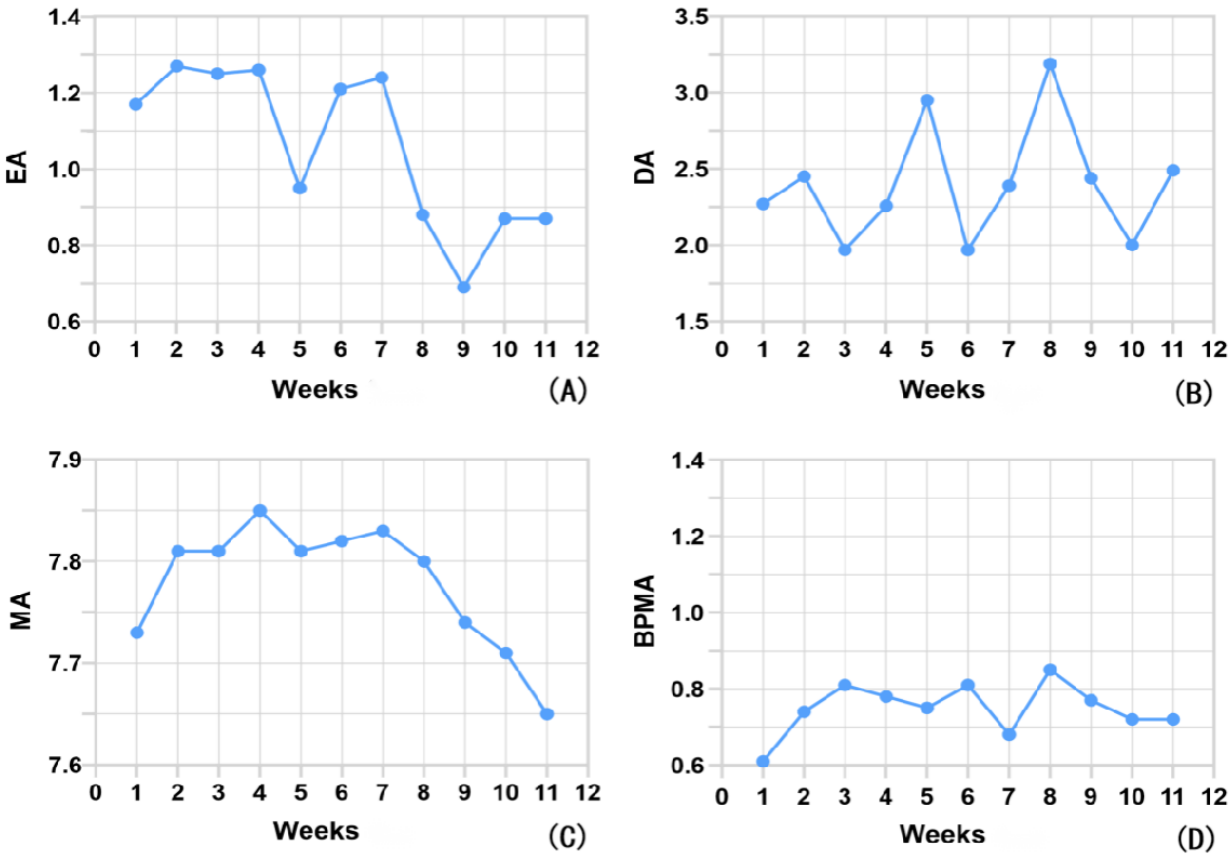
Changes in Weekly Adherence Indicators in the Experimental Group

The experimental group collected weekly average adherence indicators from the first week after the assessing and preparing phase (the second week of the project) through the eleventh week (the twelfth week of the project), as depicted in the curve shown in Figure 10. From weeks 1 to 4, the exercise adherence curve indicated that this phase was when the intervention participants were most actively engaged in PA. They exceeded the prescribed exercise volume (>1). By week 5, the participants showed lower exercise adherence, followed by 2 weeks of rebound. Subsequently, exercise adherence sharply declined, reaching a stable state in weeks 10 and 11. The dietary adherence curve indicators exhibited the most noticeable fluctuations, reaching peaks in weeks 4 and 8 and valleys in weeks 6 and 10. Medication adherence gradually increased from week 1 to week 4, experienced fluctuations, and then steadily declined starting at week 7. Among the 4 indicators, the BPMA curve had smaller fluctuations. It steadily increased from week 1 to week 3, reached a low point in week 7, and remained relatively stable at 0.72 thereafter.

Figure 10. Average adherence indicators by week in the intervention: (A) exercise adherence (EA), (B) dietary adherence (DA), (C) medication adherence (MA), (D) blood pressure monitoring adherence (BPMA).



Discussion

Health Outcomes

We observed varying degrees of positive impacts on health outcomes for patients with hypertension through this health behavioral digital intervention. The intervention demonstrated a significant effect on SBP control. It may also be effective at improving SEVR (with statistical differences observed between the 2 groups after the intervention). However, there is insufficient evidence to conclude that a WeChat-based digital intervention is more effective than a conventional intervention for weight improvement. Based on the current results, both interventions appear to have a positive effect on weight reduction. No statistically significant differences were found in other health outcome indicators.

The improvements in BP after our program's intervention were similar to previously published findings. Using methods such as text messaging, electronic reminders, and sharing health education links, both SBP and DBP can be reduced [20-22]. However, our project only demonstrated a significant reduction in SBP and not DBP, consistent with the results found by some scholars [41-43]. The reduction in BP may have resulted from the intervention measures we designed based on BCW and the DMIC model, which enhanced patients' knowledge and adherence to healthy behaviors. Several behaviors interacted dynamically and influenced each other, such as increased disease knowledge leading to regular BP monitoring at home [8]. Regular attention to BP can assist individuals with better managing their condition [44], ultimately enhancing BP control. Both the DASH diet and exercise, either alone or in combination, can relax the smooth muscle of blood vessel walls to some extent, promoting blood circulation and consequently

lowering BP [45,46]. Older adults with decreased vascular elasticity may have a tendency for elevated SBP and decreased DBP (as seen in our study with high mean SBP and normal mean DBP) [47]. They may be more sensitive to reductions in SBP. Another possible reason for the reduction in SBP, but not DBP, could be attributed to variations in study populations, interventions, age groups, and medication usage. Regardless, the results of this study were generally consistent with the antihypertensive effects reported in the guidelines [48]. Additionally, the exercise prescription aligned with the guideline recommendations of engaging in at least 30 minutes of moderate-intensity dynamic aerobic exercise per week (such as walking, jogging, cycling, or swimming) and a minimum of 2 to 3 days of resistance training per week. Simultaneously, the formulation of personalized behavior change strategies has further increased patient adherence to the exercise prescription.

SEVR, a reliable indicator of myocardial oxygen supply and demand [49], may be more closely associated with exercise. Our previous study demonstrated an improvement in this indicator after an exercise intervention [13], and other researchers have also observed significant enhancements in SEVR across different age groups (18-80 years) following exercise interventions [50]. Regarding weight, there was a reduction observed in both groups of patients with hypertension when comparing pre- and postintervention data. This reduction aligns with the results of our previous 1-arm before-and-after study [13]. However, the WeChat-based intervention did not demonstrate superiority, possibly due to the limited sample size with this experiment. There were no statistically significant differences observed in heart rate and brachial-ankle pulse wave velocity. This finding contradicted our 1-year study results, which may be attributed to the small sample size and the relatively short duration of the study. Some scholars pointed out that exercise training to improve atherosclerosis requires higher exercise intensity and longer duration, while the participants in this study were older adults with chronic diseases and the exercise prescriptions mostly provided lower exercise intensity [51].

Adherence Indicators

This program enhanced the health knowledge of community-based patients with hypertension and fostered compliance with medication, BP monitoring, exercise, and dietary guidelines, which was consistent with the findings in some previous literature [20-22]. The improvement in knowledge highlighted the efficacy of educating patients with hypertension, serving as the cornerstone of healthy behavior change.

The improvement in medication adherence in our research supports the findings of other research [52-54]. This study indicated that the Morisky scores before and after the intervention (6.77-7.65) were within the moderate range, with slightly better outcomes compared with the results reported by Morawski et al [55] (same assessment tool: 12 weeks, 6-6.3). Medication education and adherence reminders based on video, text messages, and other mobile app functions were some of the most common interventions for medication adherence in cardiovascular diseases [56]. These were key BCTs in our project. Foreman et al [57] suggested that medication text reminders reinforcing medication adherence can lead to higher oral medication adherence among patients with hypertension. Information reminders also help patients maintain higher compliance over time. However, long-term, high-frequency reminders may result in response fatigue in patients [58]. This may explain why our research showed that medication adherence was highest during weeks 2 to 6 (commitment and planning stage) but significantly declined after week 7 (behavioral habit consolidation stage). This highlights the need for researchers to adopt additional behavior change strategies to address patient fatigue during this phase. The effectiveness of electronic reminders and health education in improving patient compliance with BP monitoring has also been confirmed [53]. Based on our research findings, the curve for BPMA showed the least fluctuation. This suggests that BPMA is relatively stable for patients. It is crucial to emphasize the importance of BP monitoring to patients and establish corresponding health behaviors, particularly during the initial phase of the intervention. Additionally, monitoring BP is often the first health behavior action adopted by patients, and it plays a pivotal role in the transition to other health behaviors [44]. Therefore, it should receive special attention during the initial stages.

Most studies have consistently demonstrated the impact of various exercise types and intensities on BP improvement. Research involving mHealth or telehealth interventions through smartphones for patients with coronary heart disease or hypertension has also reported their positive effects on exercise compliance [22,59], which were consistent with our results. Our research revealed a significant rise and reduction in the exercise prescription adherence curve. This indicator was highest during weeks 2 to 6, but it significantly declined starting from week 7. This suggests that emphasis should be placed on maintaining exercise habits. The effectiveness of DASH in improving BP is unquestionable. However, the results of a systematic review indicated only weak evidence supporting the use of smartphone apps to enhance DASH dietary adherence and reduce BP [60]. From our study's perspective, there was significant fluctuation in DASH dietary adherence. This variability may be attributed to the complexity of dietary management compared with other health behaviors, making it difficult to implement and provide feedback [61]. This poses a greater challenge for researchers in designing interventions to improve dietary compliance among patients with hypertension.

In this study, considering the decline in participant adherence indicators after a certain period of intervention, effective strategies may help alleviate participant adherence fatigue, thereby sustaining and enhancing patient engagement. For exercise adherence, research indicates that the effectiveness of interventions is not necessarily correlated with longer intervention periods or higher frequencies. Therefore, tailoring interventions to individual preferences, using different proven therapeutic intervention types for specific target populations, maintaining intervention frequencies above once per week, and ensuring a moderate planned duration may be crucial factors in promoting intervention adherence [62]. Additionally, involving professionals from different disciplines (such as psychologists, doctors, and nurses), having professionals supervise the

implementation of intervention plans, and actively engaging in social interactions with staff and other participants have proven effective in enhancing participant adherence and increasing engagement [62]. Regular home visits [63], actively implementing strategies to increase participant self-efficacy [64], and incorporating gamification elements into interventions [65] are also effective strategies to address participant compliance fatigue. During the intervention implementation process, dynamically assessing and understanding the drivers and barriers of adherence based on the participant's stage and providing personalized decision support and motivation can effectively enhance participant adherence and engagement [66,67].

Notably, there is a lack of research on behavior change interventions for hypertension based on the BCW and DMIC. Therefore, a more intricate experimental design and thorough investigation are required to understand the precise mechanisms underlying the effectiveness of this project, including which components and specific BCTs are effective.

Limitations

This study has several limitations. First, we were unable to implement blinding for the personnel involved in the hypertensive health behavior interventions. To mitigate this, we established standardized intervention procedures, provided intervention strategies tailored to different patient types, edited intervention guidance language based on BCTs, incorporated the aforementioned content into the intervention manual, and conducted training for all intervention personnel. Second, the generalizability of our trial's results may be limited for populations of patients with hypertension residing elsewhere, as they may possess sociodemographic and comorbidity characteristics distinct from those of our study participants. Third, some measurement indicators relied on patient self-report, which could potentially affect the credibility of the results. Fourth, considering the workload, this study did not assess changes in compliance indicators in the control group nor did it collect more comprehensive dietary-related information. This requires correction in future experiments of app-based hypertension health behavior interventions.

Conclusions

The observations suggest that our program may have improved specific health outcomes and adherence to health behaviors in older adults with hypertension. In terms of health outcomes, participants observed significant improvements in SBP, SEVR, and weight. Moreover, there were noteworthy changes in adherence indicators, such as exercise duration, medication adherence, PA duration, frequency of BP monitoring, and learning performance. However, due to our small sample size and short intervention duration, a larger sample size and longer randomized controlled trial are needed to validate the intervention's effects, explore its mechanisms, and identify the specific design elements that are effective. Additionally, among the 4 adherence behaviors, dietary adherence is the most susceptible to external influences, and more BCTs targeting dietary adherence should be considered in intervention design.

Abstract

Background: Young women often face substantial psychological challenges in the initial years following cancer diagnosis, leading to a comparatively lower quality of life than older survivors. While mobile apps have emerged as potential interventions, their effectiveness remains inconclusive due to the diversity in intervention types and variation in follow-up periods. Furthermore, there is a particular dearth of evidence regarding the efficacy of these apps' intelligent features in addressing psychological distress with these apps.

Objective: This study aims to evaluate the effectiveness of a mobile app with intelligent design called "*AI-TA*" on cancer-related psychological health and ongoing symptoms with a randomized controlled design.

Methods: Women aged 18 to 45 years diagnosed with breast cancer were randomly assigned to the intervention or control group. The intervention was *AI-TA*, which included 2-way web-based follow-up every 2 weeks. Both intention-to-treat (ITT) and per-protocol (PP) analyses employed repeated measurement analysis of variance. The participants' background features, primary outcomes (psychological distress and frequency, self-efficacy, and social support), and secondary outcomes (quality of life) were measured using multiple instruments at 3 time points (baseline, 1-month intervention, and 3-month intervention).

Results: A total of 124 participants were randomly allocated to the control group (n=62, 50%) or intervention group (n=62, 50%). In total, 92.7% (115/124) of the participants completed the intervention. Significant improvements in psychological symptoms (Memorial Symptom Assessment Scale-Short Form) were observed in the ITT group from baseline to 1-month intervention relative to the control group (ITT vs control: 1.17 vs 1.23; P<.001), which persisted at 3-month follow-up (ITT vs control: 0.68 vs 0.91; P<.001). Both the ITT and PP groups exhibited greater improvements in self-efficacy (Cancer Behavior Inventory-Brief Version) than the control group at 1-month (ITT vs PP vs control: 82.83 vs 77.12 vs 65.35; P<.001) and 3-month intervention (ITT vs PP vs control: 92.83 vs 89.30 vs 85.65; P<.001). However, the change in social support (Social Support Rating Scale) did not increase significantly until 3-month intervention (ITT vs control: 50.09 vs 45.10; P=.002) (PP vs control: 49.78 vs 45.10; P<.001). All groups also experienced beneficial effects on quality of life (Functional Assessment of Cancer Therapy-Breast), which persisted at 3-month follow-up (P<.001).

Conclusions: The intelligent mobile app *AI-TA* incorporating intelligent design shows promise for reducing psychological and cancer-related symptoms among young survivors of breast cancer.

Introduction

Background

Breast cancer is a significant health concern for women globally, particularly in China, where the incidence and mortality rates have been steadily rising, accounting for 12.2% and 9.6%, respectively, of the total cases in the world [1,2]. In 2020, alone, approximately 416,371 women were newly diagnosed with breast cancer [3]. Moreover, the peak prevalence of breast cancer among Chinese women occurring between 45 and 55 years, which is younger than that of their Western counterparts [2-4].

Life after breast cancer, especially for younger survivors, often entails adverse psychological consequences [5]. Young survivors of breast cancer have greater psychologic morbidity than older women and age-matched women with no cancer history; this includes elevated levels of psychological distress and frequency of persistent disease for at least 2 years after diagnosis [6]. A substantial proportion of younger women experience long-term iatrogenic effects, including fatigue, persistent pain, lymphedema, and infertility, all of which may negatively affect psychological health [7,8]. Other cancer-related symptoms, such as psychosocial maladjustment, have also been reported during both cancer treatment and rehabilitation [9]. A lack of confidence and preparedness to cope with cancer can intensify survivors' distress, hinder their reintegration into society, reduce their self-efficacy, and cause significant impairment in quality of life [10,11]. Understanding the dynamic demands of young survivors of breast cancer is crucial for providing targeted and culturally sensitive support. Our previous research on young survivors of breast cancer indicated that psychological support is desired early in diagnosis, and there is more focus on information provided during treatment [12]. Thus, recognizing the unique characteristics of young survivors of breast cancer is vital for delivering tailored and comprehensive psychosocial care.

Research indicates that young survivors of breast cancer have more complex and dynamic needs and face challenges related to cultural norms, psychological disturbances, and a decreased quality of survivorship [13]. Web-based programs that leverage the accessibility, availability, and cost-effectiveness of the internet have been widely used in breast cancer interventions [14,15]. However, most programs aimed at improving well-being in survivors of cancer are not tailored to the specific functions, components, or characteristics of the target population. Information is often generalized and looped and does not accurately align resources with individual needs, rendering them ineffective for many patients. This means that there is no coordinated, personalized, or supportive care; rather, there is only a 1-way relationship between programs and patients.

Incorporating artificial intelligence (AI) into interventions offers a promising avenue to address these challenges. AI, as a major component of the internet, can enhance technical interventions and interactions through the use of a sophisticated blend of human-computer and human-human techniques [16]. Specifically, AI algorithms can analyze user input and provide tailored advice or support based on the user's history and preferences. This personalized interaction increases user engagement and satisfaction, effectively bridging psychological gaps and facilitating a deeper understanding of user needs. At the humanistic level, AI can significantly enhance communication and collaboration. For example, AI-driven platforms can facilitate social support networks or groups, connecting individuals with similar interests or experiences. This approach is particularly useful in therapeutic contexts or web intervention. In health care, AI can analyze patient data in real time to provide up-to-date, personalized health recommendations or alerts, empowering users to access relevant information and engage in dynamic dialogues [17]. Building on previous studies and feedback from interventionists, young survivors of breast cancer, and health care professionals, we developed an intelligent interactive mobile app called "*AI-TA*" (a WeChat Mini Program) guided by a person-centered care (PCC) framework [12,18,19]. The PCC emphasizes collaborative partnerships between patients and health care providers [20]. It has been shown to enhance patients' convictions to engage in desired activities and take responsibility for disease management and clinical outcomes [21-23]. Informed by our pilot study results, we have made necessary adjustments to the intervention strategy and module design [24]. In this study, we expand the sample size to further enhance the effectiveness and generalizability of the findings, hypothesizing that users of *AI-TA* will experience significant improvements in psychological symptoms.

Objective

The purpose of this study is to comprehensively assess the impact of an innovative mobile app, "AI-TA," which features intelligent design elements, on the psychological health and ongoing symptoms experienced by young survivors of breast cancer.

Methods

Study Design

This study was designed as a multicenter, 3-month, parallel group, single-blind, 2-arm randomized controlled trial conducted in 3 university-affiliated hospitals from January 2022 to December 2022. This study investigated the effectiveness of "*AI-TA*" on psychological and related symptoms of young survivors of breast cancer from baseline (T0) to 2 follow-up points (1 month [T1] and 3 months [T2]; Multimedia Appendix 1). The trial was approved by the Chinese Clinical Trial Registry (ChiCTR2200058823).

Recruitment

Participants were recruited through convenience sampling, aligning with findings from prior studies [25-27], and

considering the menopausal age of women. The inclusion and exclusion criteria for the participants are provided below in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Chinese females
- Aged 18-45 years
- Diagnosed with stage 1-3 breast cancer
- Able to access the internet using computer or mobile devices
- Able to read and write in Chinese (traditional or simplified)
- Provided informed consent

Exclusion criteria

- Chronic or acute physical conditions that significantly impair daily functioning or require intensive medical care and supervision that could detract from intervention participation or measurement of outcomes
- Serious cognitive or communication barriers (including but not limited to medical diagnoses of advanced dementia, severe aphasia, or other neurological conditions significantly impairing understanding or expression)
- Recurrent or metastatic breast cancer
- Concurrent involvement in other studies

Randomization

To ensure the quality of the entire study and prevent selection and information bias, our researchers received unified training and were divided into different group roles: (1) recruiter: 2 breast clinical nurses will strictly recruit young survivors of breast cancer according to the inclusion and exclusion criteria and record recruitment information; (2) an independent master candidate randomly assigned participants to 2-armed parallel groups at a 1:1 ratio via a computer-generated digital sequence; (3) intervener: an experienced researcher conducted the interventions, with another researcher serving as the intervention companion, who was responsible for supervision and evaluation; and (4) data collectors: collect and analyze all participants' data and the results of the intervention by double checking. During the process, blinding was applied to the recruiters and data collectors.

Procedure

The participants in the control and intervention groups received oral and written instructions on how to use the *AI-TA*, which combines a mobile app with fortnightly web-based follow-up. Each participant used her own WeChat ID to register and log in with a unique or random number for access to *AI-TA* and was told not to discuss the research with other patients so that no identifying information would be linked to them and to reduce contamination. At first enrollment, they were required to complete and return electronic questionnaires, which included sociodemographics, cancer-related characteristics, and psychological and accompanying symptoms in *AI-TA* after informed consent was obtained. The initial baseline evaluation of symptoms was classified at T0. Data collection and assessments of outcomes took place over 2 time points in the follow-up period. T1 assessment took place at 1 month after allocation (intermediate period of intervention), and T2 assessment took place at 3 months after allocation (end point of the intervention). Follow-up assessments were collected via *AI-TA*–assisted self-reported surveys. Each result was saved and available for participants to view their own result at any time. In addition, all participants were awarded CNY 100 (US $13.80) upon completing all the assessments. In addition, there was a questionnaire to assess participants' interaction of and satisfaction with the *AI-TA* mobile app program for further improvements in the following research (Multimedia Appendix 2).

Intervention

AI-TA consisted of several modules designed to support young survivors of breast cancer in various aspects of their survivorship. The mobile app stored reliable resources uploaded by health care professionals occasionally from time to time and covered psychological counseling, coping effectiveness, symptom management, social security, etc in text, image, and animation formats. It also allowed participants to synchronously save their log-in, comments, likes, history, duration, and traces. In addition, the health care professionals invited breast clinical experts to hold salon lectures, focusing on common problems in treatments involving diet guidance, functional exercise, tube maintenance, and other guidance. Question and answer sessions were incorporated, and recorded videos were made available for review. Visual representations of *AI-TA* are shown in Figure 1. Additional details relating to the intervention construction can be found in Figure 2.

Figure 1. Visual representations of AI-TA.

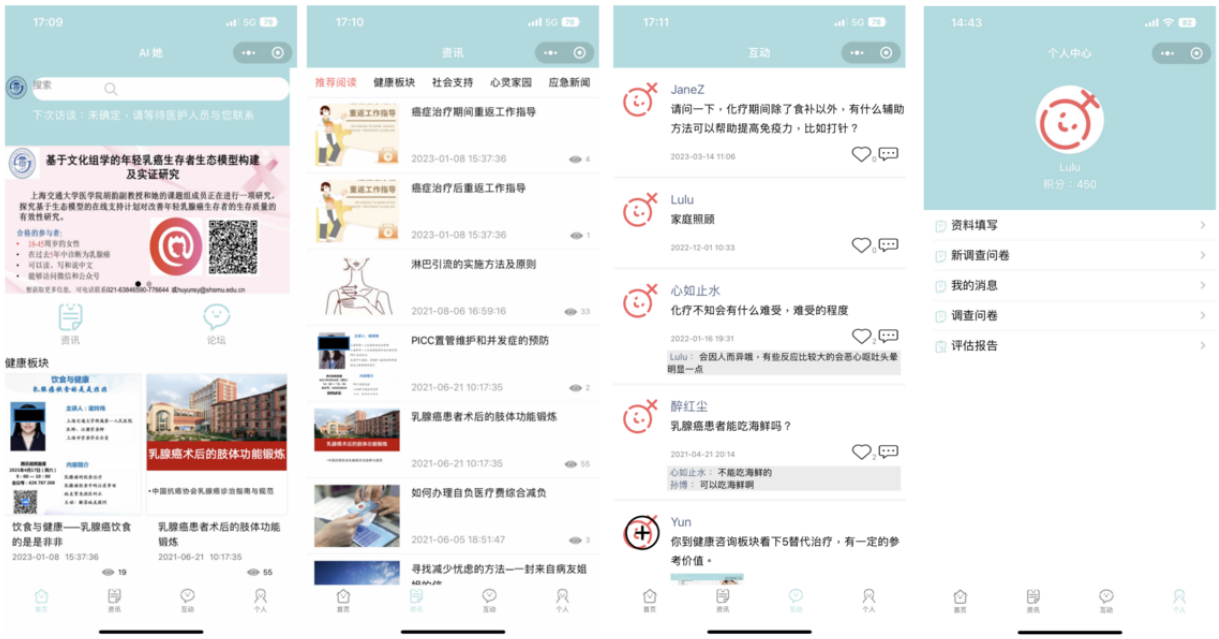

Figure 2. Frame diagram for the intervention design.

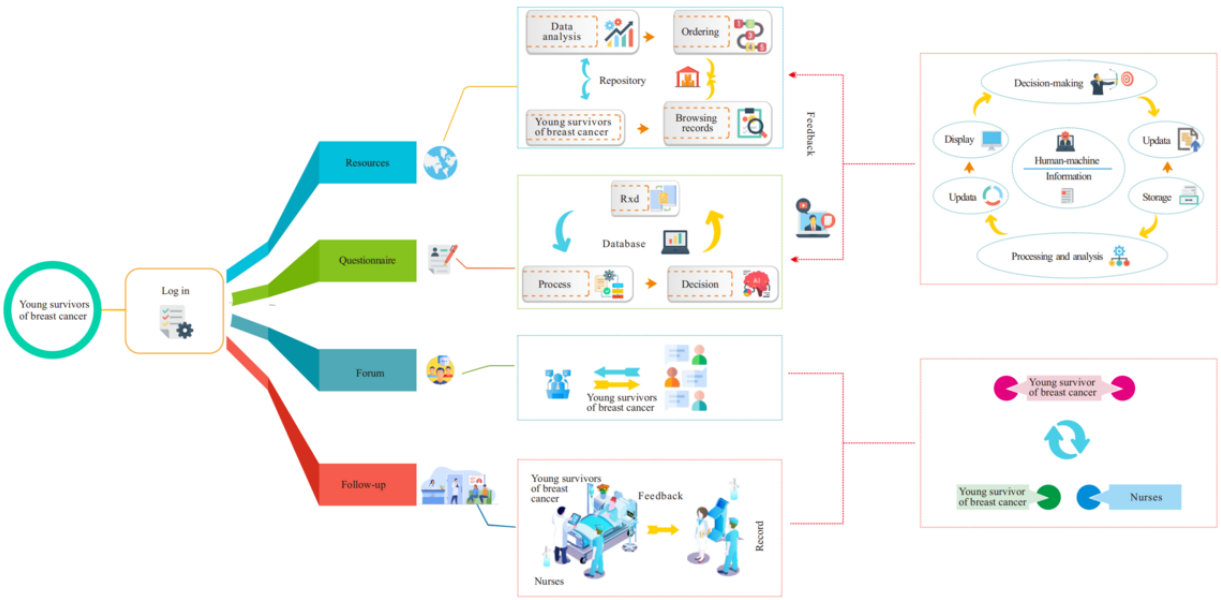


AI-Driven System

An AI-driven system is central to our intervention, using text extraction techniques and behavioral data analysis to provide personalized recommendations. This innovative approach significantly enhances user engagement and retention by tailoring content to individual preferences and interests. The following functions were undertaken: (1) personalized content delivery (the AI system analyzes responses from questionnaires to prioritize issues and deliver tailored content; for instance, if young survivors of breast cancer reported low physical activity and poor sleep quality, keywords such as “physical,” “exercise,” “activity,” and “sleep” were used to recommend relevant articles), (2) symptom tracking and management (the system regularly tracks survivors’ symptoms and allows health care professionals to update and tailor content based on their browsing preferences, enhancing the relevance and effectiveness of the information provided), (3) data monitoring and evaluation

(AI algorithms can calculate and monitor assessment progress as well as synchronous storage in the server backend), (4) social support network (AI can enable the formation of connections in forums with independent YBCS; it fosters a supportive web-based environment through interactive question and answer sessions, experience sharing, and emotional support), and (5) privacy and security (adhering to health care data regulations, the AI system uses encryption measures to ensure the utmost privacy and security of user data; AI-driven system is a vital link that enables the exchange and feedback of information in peer-to-peer interactions between young survivors of breast cancer and health care professionals and enhances the interactive experience). This dynamic approach ensures that the intervention remains relevant, engaging, and supportive of the unique needs of survivors.

2-Way Web-Based Follow-Up

Furthermore, the intervention program included fortnightly web-based follow-up using 2-way communication through private messages or calls. This approach encouraged narration from young survivors of breast cancer and aimed to establish a partnership using PCC communication skills such as open-ended questions, reflections, and summaries. In the initial conversation, health care professionals focused on listening to survivors' narratives about daily life events and customs (diet, motion, pressure, hobbies, relationships, and sharing) to build trust relationships. The subsequent step entailed the anticipation and cocreation of a health plan jointly based on their feedback through discussion and agreement, including goals, resources, and needs. The contents regarding what participants had talked about, how they felt, what goals they had, and what they wanted to accomplish will be the points for the forthcoming conversations to consider. During the 3-month intervention, participants were also free to get in touch with the health care professionals during office hours. Each follow-up was recorded and uploaded to the platform.

General Information Support

The control group was granted access to general information on the mobile app, with all modules available in *AI-TA* except for forums and intelligent recommendations. This meant that they could not participate in the forum and obtain recommendations provided by the system based on questionnaire results. In addition, young survivors of breast cancer in the control group also had no follow-up conversations.

Measures and Instruments

A comprehensive set of questions was used to assess participants' sociodemographic and health characteristics, including age, height, weight, habitation, educational attainment, marital status, employment, income, offspring, parent, cancer stage (stages 1-3), cancer type, diagnosis time, and treatment.

Primary Outcome Measures

Psychological Distress and Frequency

The Memorial Symptom Assessment Scale-Short Form (MSAS-SF) was used to assess the frequency and severity of psychological symptoms during the past 7 days [28]. The distress level of each symptom was rated on a 5-point Likert scale (0="not at all," 1="a little bit," 2="somewhat," 3="quite a bit," and 4="very much"). If the symptom was not present, a value of 0 was assigned. The frequency of psychological symptoms is rated from 1 to 4 (1="rarely" to 4="almost constantly").

Self-Efficacy

The Cancer Behavior Inventory-Brief Version (CBI-B) developed by Heitzmann et al [29] was adopted to rate self-efficacy for coping with cancer. It is used to assess four factors: (1) maintaining independence and positive attitude, (2) participating in medical care, (3) coping and stress management, and (4) managing affect. There are 12 items in total (rated on a 9-point Likert scale, ranging from 1="not at all confident" to 9="totally confident"); a score≤36 is considered low, a score between 37 and 72 is considered moderate, and a score between 73 and 108 is considered high.

Social Support

The Social Support Rating Scale (SSRS) is a 10-item questionnaire developed by Xiao [30] for measuring social support, including objective social support, subjective social support, and use of social support. A higher score indicated more social support. The SSRS has been widely used and has shown acceptable reliability and validity in the cancer population. An SSRS score≤22 is considered poor social support, a score between 23 and 44 is considered moderate social support, and a score between 45 and 66 indicates adequate social support.

Secondary Outcome Measures

The Functional Assessment of Cancer Therapy-Breast (FACT-B) translated and adapted by Wan et al [31] was used to evaluate the quality of life of patients with breast cancer. The 5 dimensions included physical well-being, social or family well-being, emotional well-being, functional well-being, and additional concerns (cancer type–specific questions). A total of 36 items were scored on a 5-point Likert scale (0="not at all," 1="a little bit," 2="somewhat," 3="quite a bit," and 4="very much"). Among them, 19 items were scored in a reverse manner. Higher scores represent better quality of life.

Sample Size

This study used G*Power (version 3.1; HHU) to calculate the necessary sample size. On the basis of a similarly designed study, mobile app support reduced the psychological symptoms among survivors of breast cancer with an effect size of 0.77 [32]. Considering the conservative estimate and the variability of previous pilot research [24] as well as the statistical power [33], we estimated that 66 participants were needed to compare between-group differences and present a large effect size (d=0.8) in the primary outcome after intervention, with an α level of .05 (2-sided test), 80% statistical power, 1:1 allocation rate, and 20% attrition rate. Thus, a final sample of 124, with 62 (50%) individuals in each group, was adequate.

Ethical Considerations

The trial complied with the ethical guidelines of the Declaration of Helsinki and was approved by the ethics committee of Public Health and Nursing Research, School of Medicine, Shanghai

Jiao Tong University (SJTUPN-201803). All participants provided electronic informed consent before enrollment in the study. All data and information were anonymized according to the established guidelines, and a password-protected document containing participants' personal information was stored on secure servers.

Statistical Analysis

Data analysis was performed using SPSS (version 26.0; IBM Corp). Descriptive and comparative statistics were used to characterize the study groups (eg, percentage or mean and SD). A total of 2-sample *t* tests (2-tailed) and chi-square or Fisher exact tests were used where appropriate, and these tests assessed demographic variable differences between the intervention and control groups. Before performing the *t* test, the continuous variables were checked for normality using the Shapiro-Wilk test, and all the data were revealed to be normal ($P>.05$). To confirm the improvements in psychological symptoms, the baseline and postintervention results of the dependent variables were analyzed using the paired *t* tests, whereas the 2-sample *t* tests were used to detect differences between the intervention and control groups at each time point. To estimate the effects of the intervention on the outcomes over time, a linear mixed effect model for repeated measurements was performed. The main effects of group, time, and group×time interaction effects were examined. The significance level was set at $P<.05$ (2 sided).

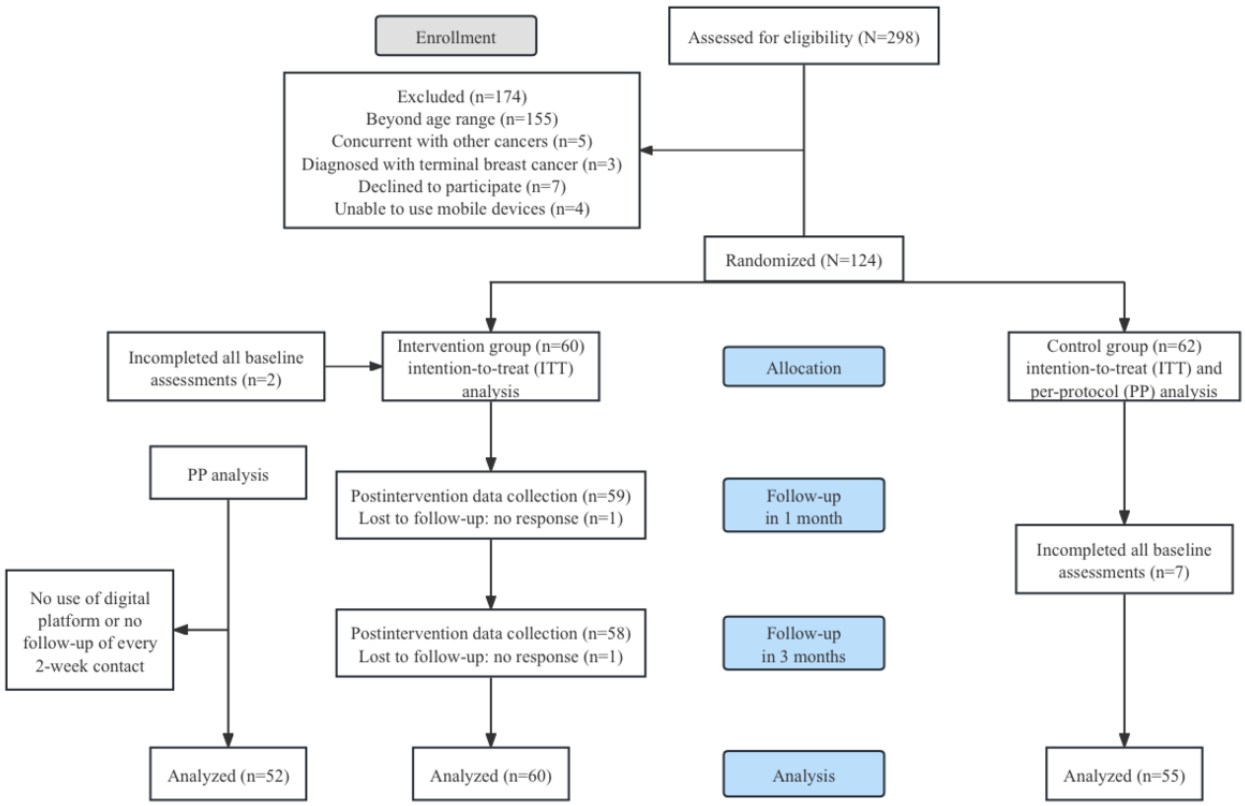
For this study, both intention-to-treat (ITT) and per-protocol (PP) analyses were conducted. The primary analysis used an ITT approach, which can reflect the results of all participants randomly assigned to receive intervention; missing fields were imputed with the expectation-maximization algorithm. Post hoc sensitivity analyses for missing data were performed to ensure the integrity and reliability of the trial outcomes (Multimedia Appendix 3 [24]). The PP group analysis included participants who fully followed the intervention protocol. The primary end points for evaluating the efficacy of *AI-TA* were MSAS-SF, CBI-B, and SSRS to assess psychological symptoms (distress and frequency), self-efficacy, and social support, respectively, at T2. Secondary end point was FACT-B measures of quality of life.

Results

Participants

Data were collected through questionnaires at T0, T1, and T2. Approximately 7.3% (9/124) of participants (2/62, 3% in the intervention group and 7/62, 11% in the control group) did not complete all baseline assessment at T0. At T1 and T2, 1.7% (2/115) of participants did not return their questionnaires despite being reminded. A flowchart of the study participants is given in Figure 3.

Figure 3. A flowchart of the study participants.



Overview

Table 1 provides an overview of the sociodemographic and health characteristics of young survivors of breast cancer at T0. In this study, the participants had an average age of 40.21 (SD 4.24) years, a mean height of 161.16 (SD 4.24) cm, and a mean weight of 55.9 (SD 8.56) kg. The average time since diagnosis

was 1.42 (SD 0.3) years. Approximately 89.6% (103/115) participants were living in urban areas and about 90.4% (104/115) were married. Approximately 93.9% (108/115) had children, and 81.7% (94/115) of the participants' parents were in good health. A total of >50% were employed, and their monthly income was >CNY 10,000 (US $1379.44). In addition, participants tended to be highly educated; approximately 50.4% (58/115) were college graduates and some had graduate degrees. Almost 94.8% (109/115) had invasive breast cancer, and approximately 65.2% (75/115) were diagnosed with stage 2 or stage 3 breast cancer. A total of 11.3% (13/115) only underwent surgical treatment, 42.6% (49/115) only received adjuvant treatment, and 46.1% (53/115) had both. No significant differences were observed in the demographic characteristics between the intervention and control groups, except that the time since diagnosis of participants in the control group was significantly longer than that in the intervention group (P=.03). However, this difference did not remain when comparing the control and PP groups (P=.18).

Table 1. Participant characteristics at baseline (N=115).

Characteristics	Control group (n=55)	ITT[a] group (n=60)	ITT group, *P* value	PP[b] group (n=52)	PP group, *P* value

[a]ITT: intention-to-treat.

[b]PP: per-protocol.

[c]Includes radiotherapy, chemotherapy, endocrine therapy, etc.

The Effects on Primary Outcomes

Table 2 presents the overall test results of the intervention effect on psychological symptoms through repeated measures analysis. There were statistically significant group effects, time effects, and group×time interaction effects on the changes in the MSAS-SF and CBI-B scores. Significant time effects ($F_{2,108}$=236.123; P<.001) and group×time interaction effects ($F_{2,108}$=36.639; P<.001) were found in the ITT analysis for the SSRS score, but only a significant time effect ($F_{1.767,95.423}$=231.187; P<.001) was found in the PP analysis.

As demonstrated in Table 3, there were no significant differences in any of the variables between groups at T0, which supported successful randomization. At T2, psychological distress (ITT vs PP vs control: 0.40 vs 0.41 vs 0.93; P<.001) was significantly different among the groups. In addition, each group exhibited significant differences (ITT vs PP vs control: 92.83 vs 89.30 vs 85.65; P<.001) in self-efficacy; however, compared with those in the control group, the ITT group (P=.002) and PP group (P<.001) did not show significant increases in social support scores until T2.

The Effects on Secondary Outcomes

First, the analysis highlighted a statistically significant group effect (*P*=.02), time effect (*P*<.001), and group×time interaction effect (*P*<.001) for quality of life in both the ITT and PP groups (Table 2).

The results at T1 (ITT vs PP vs control: 106.68 vs 105.73 vs 100.33; *P*<.05) and T2 (ITT vs PP vs control: 124.47 vs 126.04 vs 113.50; *P*<.001) indicated that there was significant improvement in overall quality of life. Notably, significant differences between and within all groups were found in functional well-being and additional concerns both in T1 and T2. Compared with those in the control group, the ITT and PP groups did not show significant increases in physical, social or family, and emotional well-being until T2 (*P*<.05; Table 4).

Table 4. Changes in quality of life over time between each group.

Discussion

Principal Findings

This randomized controlled trial examined the effectiveness of an internet-enabled, mobile, intelligent interactive intervention for young survivors of breast cancer over a 3-month period. The findings demonstrated the benefits of using a mobile app and engaging in 2-way web-based follow-up. Significant improvements were observed in psychological symptoms, including distress and frequency, indicating the positive impact of the intervention. In addition, there was a noticeable trend toward improvement in quality-of-life outcomes, with both the ITT and PP analyses showing consistent overall outcomes.

We observed that the MSAS-SF score decreased from moderate to mild in all groups, and psychological distress also significantly decreased by 1.08 in the ITT group and 0.96 in the PP group from baseline; these findings were more pronounced than those of American survivors of breast cancer [32] and survivors of lung cancer [34]. In addition, a significant reduction between groups in the frequency of psychological problems was found (eg, sadness, worry, irritability, and nervousness), with 0.83 in the ITT group and 0.77 in the PP

group at T2. Clinical evidence has confirmed that survivors of cancer who approach people considered isolated and marginalized with stigmatized conditions and underserved populations to confide negative emotions and relieve themselves may become stuck in a psychological trap [35]. *AI-TA* adopted multiple approaches to alleviate psychological distress and reduce the frequency of psychological symptoms. For example, individuals could connect and offer spiritual support to each other in a private forum, allowing young survivors of breast cancer to openly share experience and advice, thereby overcoming the hesitation often caused by traditional cultural norms. Web-based follow-up enables continuous care between health care professionals and survivors, providing targeted educational contents such as information about stress relief, emotional management, and other relevant information [36]. By integrating the assessments from AI-driven system with qualitative insights from interviews, the follow-up can be more accurate to address the nuanced needs of young survivors of breast cancer, ensuring that the care provided is both relevant and effective. In this study, young survivors of breast cancer had a lower frequency of psychological symptoms at baseline and therefore had little margin for improvement at T1 and T2 in the ITT group; conversely, the PP group demonstrated notable enhancements. This disparity may relate to the duration or intensity of the intervention [37]. In addition, the greater increase in physical and global distress in the intervention group identified the necessity of intelligent interactive support for young survivors of breast cancer.

The findings reported in this study align with the literature, indicating that the intervention program *AI-TA* had a positive effect on increasing self-efficacy levels, as reported previously [32]. In particular, the ITT and PP groups had already reached a high level of self-efficacy at T1, which was faster than the control group. Among them, coping and stress management showed a borderline significant trend between groups at T1, and it became better at T2. This is likely because these survivors lacked motivation and familiarity with *AI-TA* at first, resulting in insufficient in-depth effects on young survivors of breast cancer [38]. Although the intervention group exhibited more favorable changes in several self-efficacy variables, all the groups experienced positive changes, which indicated that the general information support also played a certain role in promoting young survivors of breast cancer.

In this study, the changes in symptoms among survivors of breast cancer were similar to changes in their levels of self-efficacy. Several explanations have been proposed to account for the relationship between syndrome and self-efficacy: patients with cancer with high self-efficacy have a high level of health beliefs, which may promote the recovery from symptoms; in contrast, those with low self-efficacy are prone to negative emotions such as anxiety and depression, which are not conducive to recovery from psychological and physical symptoms [39,40]. AI-driven system and fortnightly web-based follow-up encouraged young survivors of breast cancer to actively engage with the provided content, enhancing their participation and initiative. This interactive process improved their confidence and self-efficacy in managing their symptoms, as the AI continually adapts to their evolving needs and responses.

Furthermore, while all groups' total social support scores were sustained and reached adequacy by T2, no significant effect was observed across any dimension at T1. This initial absence can be attributed to the challenges faced by young survivors of breast cancer. Frequently undergoing treatments and grappling with severe side effects, young survivors likely found themselves with limited energy to engage with the AI-driven tool (*AI-TA*) or to communicate effectively with health care professionals [41]. Besides, research has identified several factors that affect the perception of social support of survivors of cancer. Specifically, young patients with a collectivist orientation who value in-group solidarity and interdependence may feel alienated from or resist joining groups perceived as outside their usual social circles in a short term [42]. Initially, *AI-TA* may not show a significant impact. The novelty of such apps and their integration into survivors' lives requires time to manifest tangible benefits. However, as these AI-driven systems evolve to more accurately assess and respond to daily symptoms, their potential to significantly enhance health management and symptom control for young survivors with breast cancer grows. Over time, continued engagement with *AI-TA* is likely to foster social support, deeper understanding of the disease, and overall better well-being for them. The gradual accumulation of these positive effects underscores the promise of long-term interventions to bolster survivors' outcomes.

This work revealed that the *AI-TA* mobile app has been shown to work effectively in improving quality of life. The findings in physical, social or family, and emotional well-being of these survivors did not increase until T2. Previous literature has also been published in the field of internet-based or computer-based interventions for survivors of breast cancer, and the results indicate that internet support has no significant impact on quality of life in recently diagnosed survivors of breast cancer [43]. Particularly in the early postoperative period and before and after chemotherapy, the recovery of physical well-being and role function was slower [44]. In addition to confronting the challenges of disease itself, young survivors of breast cancer often experience negative emotions associated with work, childbirth, support, and other pressures as well as feelings about being abandoned by the medical system [45]. The integration of web-based follow-up through AI-driven system fosters continuous interaction and support, which is crucial for these survivors managing sensitive and often underdiscussed topics such as sexual health. These not only allow real-time monitoring and assistance but also facilitate a space for them to seek guidance and share experiences securely and comfortably.

Limitations

There are several limitations to this research that weaken the generalizability of these findings and warrant further investigation. Firstly, because of the relatively small population size and heterogeneity of treatment, a small study may not detect significant effects on outcomes related to the whole psychological symptom. Secondly, it is possible that young survivors of breast cancer with different types of cancer would react differently to the content of this intervention. Furthermore,

the duration of this study was short; thus, in the future, long-term interventions could be carried out to detect differences between groups.

Conclusions

The mobile app *AI-TA* demonstrated significant benefits in addressing the psychological health needs of young survivors of breast cancer during their survivorship journey. The consistent duration, intelligent support, and ease of interaction and web-based follow-up facilitated through digital platforms contributed to the success of the intervention. Specifically, AI-driven features such as personalized content delivery based on user feedback, symptom tracking and management, and interactive support networks have proven crucial for enhancing self-efficacy and social support among these survivors. Emphasis should be placed on optimizing the frequency of interaction and content delivery during an intervention to sustain user engagement without inducing fatigue. The observed effect size on psychological and related symptoms warrants further exploration, prompting future research to expand and investigate the efficacy of such AI-driven interventions in larger trials and across diverse populations over extended periods.

Acknowledgments

The authors would like to thank the involved clinical specialists, nurses, and other technicians for their assistance and active guidance throughout the study. This study was supported by the National Natural Science Foundation of China (71804112), the Nursing Talent Team Construction Project of Shanghai Jiao Tong University, the School of Medicine (SHSMU2021-21), and the Shanghai Sailing Program (21YF1422400).

Abstract

Background: Chinese immigrants experience significant disparities in tobacco use. Culturally adapted tobacco treatments targeting this population are sparse and the use is low. The low use of these treatment programs is attributed to their exclusive focus on individuals who are ready to quit and the wide range of barriers that Chinese immigrants face to access these programs. To support Chinese immigrant smokers at all levels of readiness to quit and address their access barriers, we developed the WeChat Quit Coach, a culturally and linguistically appropriate WeChat (Tencent Holdings Limited)–based peer group mobile messaging smoking cessation intervention.

Objective: This study aims to assess the feasibility, acceptability, and preliminary effects of WeChat Quit Coach.

Methods: We enrolled a total of 60 Chinese immigrant smokers in 2022 in New York City for a pilot randomized controlled trial (RCT) and a single-arm pilot test. The first 40 participants were randomized to either the intervention arm (WeChat Quit Coach) or the control arm (self-help print material) using 1:1 block randomization stratified by sex. WeChat Quit Coach lasted 6 weeks, featuring small peer groups moderated by a coach, daily text messages with text questions, and chat-based instant messaging support from the coach in response to peer questions. The next 20 participants were enrolled in the single-arm pilot test to further assess intervention feasibility and acceptability. All 60 participants were offered a 4-week supply of complimentary nicotine replacement therapy. Surveys were administered at baseline and 6 weeks, with participants in the pilot RCT completing an additional survey at 6 months and biochemical verification of abstinence at both follow-ups.

Results: Of 74 individuals screened, 68 (92%) were eligible and 60 (88%) were enrolled. The majority of participants, with a mean age of 42.5 (SD 13.8) years, were male (49/60, 82%) and not ready to quit, with 70% (42/60) in the precontemplation or contemplation stage at the time of enrollment. The pilot RCT had follow-up rates of 98% (39/40) at 6 weeks and 93% (37/40) at 6 months, while the single-arm test achieved 100% follow-up at 6 weeks. On average, participants responded to daily text questions for 25.1 days over the 42-day intervention period and 23% (9/40) used the chat-based instant messaging support. Most participants were satisfied with WeChat Quit Coach (36/39, 92%) and would recommend it to others (32/39, 82%). At 6 months, self-reported 7-day point prevalence abstinence rates were 25% (5/20) in the intervention arm and 15% (3/20) in the control arm, with biochemically verified abstinence rates of 25% (5/20) and 5% (1/20), respectively.

Conclusions: WeChat Quit Coach was feasible and well-received by Chinese immigrants who smoke and produced promising effects on abstinence. Large trials are warranted to assess its efficacy in promoting abstinence in this underserved population.

Trial Registration: ClinicalTrials.gov NCT05130788; https://clinicaltrials.gov/study/NCT05130788

smoking cessation; tobacco; mHealth; social media; Chinese American; immigrant; smoking; smoker; mobile messaging; randomized controlled trial; tobacco use; feasibility; acceptability; nicotine replacement therapy

Introduction

The prevalence of smoking has declined significantly in the United States over the past 50 years [1]. However, smoking rates remain disproportionately high in socioeconomically disadvantaged populations, including Chinese immigrants (foreign-born Chinese Americans). In New York City (NYC), the city with the largest Chinese immigrant population in the United States, 28% of Chinese American men smoke compared with 18% of the total NYC men [2]. Chinese immigrants, accounting for 68% of the NYC Chinese American population, are more likely to smoke than US-born Chinese Americans (New York City Department of Health and Mental Hygiene, unpublished data, 2018).

Culturally adapted tobacco treatments for Chinese immigrants are sparse [3,4] and the use is low. For example, the National Asian Smokers' Quitline (ASQ) engages only about 2000 Asian American callers nationwide annually (the number of Chinese-speaking callers is unknown) [5]. The low use of tobacco treatment programs is attributed to 2 major reasons. First, current tobacco treatment programs are designed to offer cessation support to individuals who are ready to quit smoking (ie, they plan to quit within a month). However, only 6%-33% of Chinese Americans who smoke are ready to quit [6-8]. This is largely due to the limited knowledge about the harms of smoking, strong attachment to traditional Chinese prosmoking norms, lack of behavioral capability for quitting, limited social support to facilitate cessation, and low self-efficacy [9-13]. Current tobacco treatment programs often provide no support to move the vast majority of individuals not ready to quit to the stage of being ready to quit. Second, Chinese immigrants have limited access to evidence-based tobacco treatments. Access barriers include limited awareness of treatment resources, skepticism about treatment effects, and time and economic constraints [9-11,14,15]. Less than 20% of Chinese American smokers who attempt to quit use pharmacotherapy or behavioral interventions [7,16]. Research is needed to explore intervention strategies that can engage a broad group of Chinese immigrant smokers, including those not ready to quit, and address the wide range of barriers to cessation.

Over the past decade, social media has been increasingly studied as a tool for tobacco treatment. Social media can reach large populations, allow users to access at their own time of convenience with low or no cost, and may alleviate access barriers to tobacco treatment. A total of 2 systematic reviews have provided evidence supporting the feasibility and acceptability of social media–based smoking cessation interventions [17,18]. In addition, 2 randomized controlled trials (RCTs) conducted among English-speaking smokers compared social media–based tobacco treatment with other cessation support [19,20]. Both interventions feature peer group messaging support, with mixed findings, for example, a Facebook (Meta)–based intervention resulted in abstinence rates comparable to the control at 3, 6, and 12 months [19], whereas a Twitter-based intervention yielded a higher abstinence rate than the control on day 60 [20].

A total of 3 RCTs among Chinese-speaking smokers in Hong Kong [21] and mainland China [22,23] compared WhatsApp (Meta)–based or WeChat (Tencent Holdings Limited)–based interventions with usual cessation care or no tobacco treatment, all using a one-on-one intervention model. A WhatsApp-based intervention led to higher abstinence than the control at 6 months (8% vs 5% biochemically validated 7-day point prevalence abstinence) [21]. A WeChat-based intervention also produced higher abstinence than the control at 26 weeks (12% vs 3% biochemically validated continuous abstinence) [23], but the trial only included individuals ready to quit. Another trial of a WeChat-based intervention did not report any abstinence outcomes [22]. Thus far, the impact of using social media to engage and treat smokers, particularly those not ready to quit, is still unclear.

To reduce tobacco use among Chinese immigrants, our multidisciplinary team developed a culturally and linguistically appropriate social media intervention named WeChat Quit Coach for Chinese immigrants who smoke, across all levels of readiness to quit. Informed by the social cognitive theory and the socioecological model, WeChat Quit Coach addresses multilevel barriers to cessation [24]. The intervention features small, private peer groups moderated by a coach, daily WeChat text messages with text questions, and chat-based instant messaging support from the coach responding to peer questions. By using WeChat, the most widely used social media platform among Chinese with approximately 1.3 billion monthly active users worldwide [25], WeChat Quit Coach holds the potential to reach a large population of Chinese immigrants. In our previous study, we found that 94% of Chinese immigrants who smoke in NYC use WeChat, and that WeChat is used more frequently than other platforms, including Facebook, Twitter, WhatsApp, Line (Line Corporation), and short messaging [10]. This study sought to assess the feasibility, acceptability, and preliminary effects of WeChat Quit Coach among Chinese immigrants who smoke.

Methods

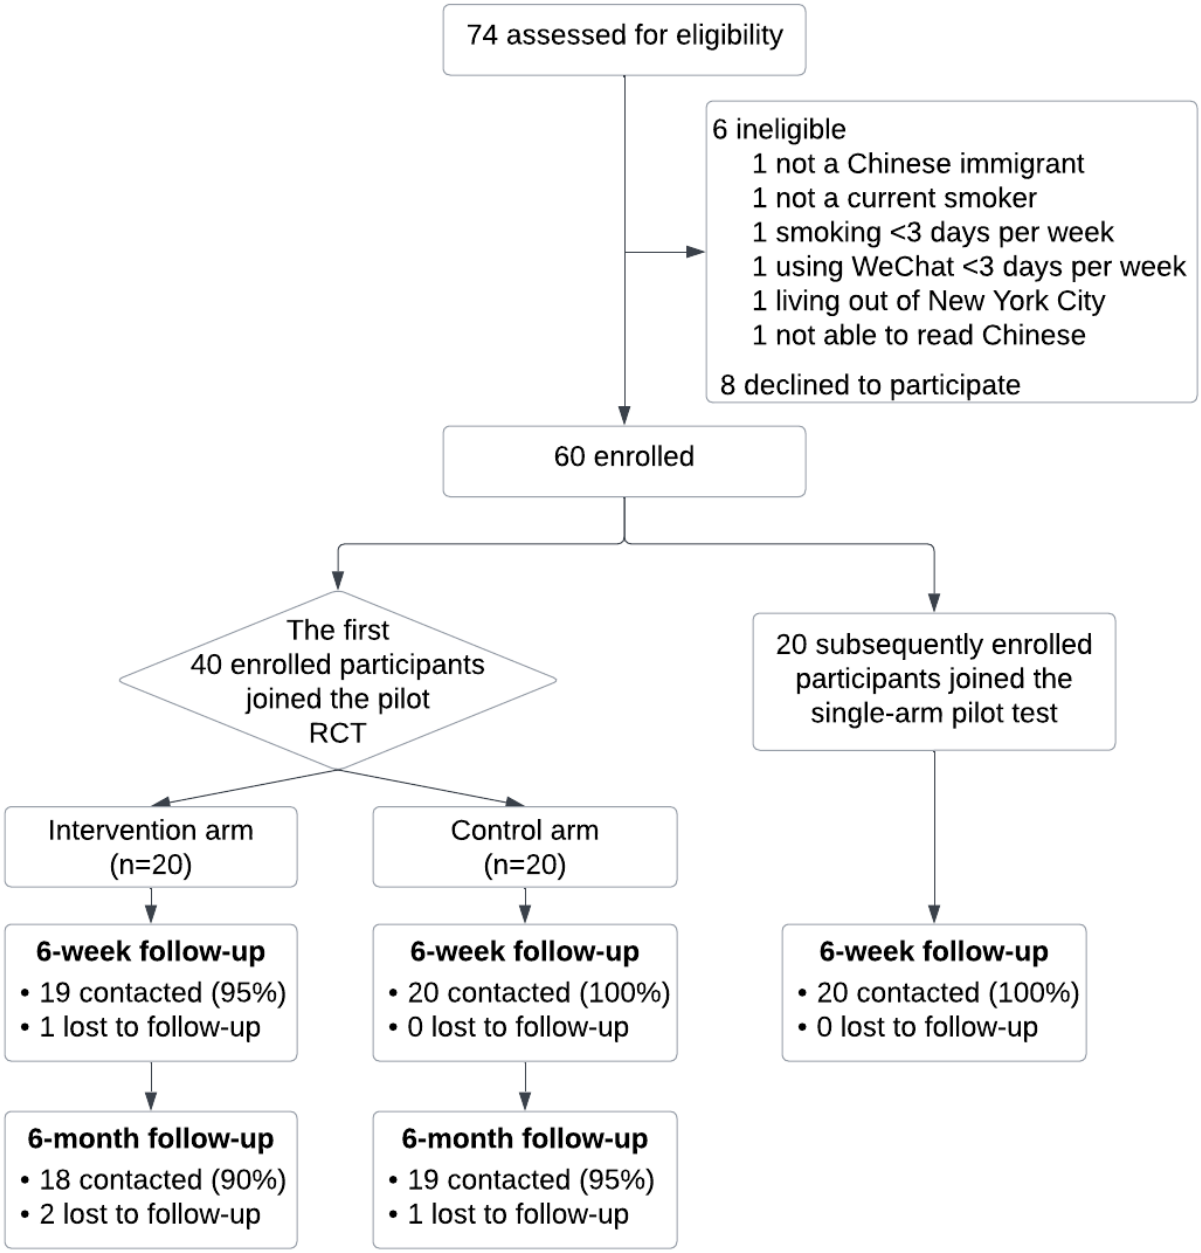
Ethics Approval

The study was approved by the Institutional Review Board of New York University Grossman School of Medicine (i20-01959) and preregistered at ClinicalTrials.gov (NCT05130788).

Study Design

As shown in Figure 1, we conducted an open-label, 2-arm pilot RCT and a single-arm pilot test among 60 participants. The first 40 participants were enrolled in the pilot RCT. To obtain more data on feasibility and acceptability, we enrolled an additional 20 participants in a single-arm pilot test.

Figure 1. Study schema. RCT: randomized controlled trial.



Participants in the pilot RCT were randomized in a 1:1 ratio to the intervention (6-week WeChat Quit Coach) or control arm (self-help print material). Both arms received a 4-week supply of nicotine patches and lozenges by request. Research staff conducted in-person baseline assessment and follow-up phone assessments at 6 weeks and 6 months postintervention initiation and performed biochemical validation through exhaled carbon monoxide (CO) tests at both time points. Participants in the single-arm pilot test received the same treatment as the intervention arm (6-week WeChat Quit Coach and nicotine replacement therapy [NRT]) and completed an in-person baseline survey and a phone survey at 6 weeks. Participants received a US $20 gift card for each survey completed and an additional US $20 for completing each biochemical validation test, irrespective of the test result.

Participants and Recruitment

Participants were recruited from February to December 2022, primarily in 3 NYC communities that have high concentrations of Chinese immigrants, including Flushing (Queens, NY), Sunset Park (Brooklyn, NY), and Chinatown (Manhattan, NY). Inclusion criteria included (1) self-identified as a Chinese immigrant; (2) age ≥18 years; (3) had smoked at least 100 cigarettes in their lifetime; (4) smoked ≥3 days per week; (5) used WeChat ≥3 days per week; (6) able to read Chinese; (7) lived in NYC; and (8) was somewhat interested in quitting, which was assessed by a question, "Which statement best describes your intention to quit? (A) I don't want to quit at all; (B) I may quit at some point, but not within the next 6 months; (C) I plan to quit within the next 6 months; (D) I plan to quit within the next 30 days; (E) I am trying to quit." People who chose an answer other than "A" were considered to be somewhat interested in quitting. Exclusion criteria included (1) current participation in other tobacco treatments, (2) pregnancy or breastfeeding, and (3) inability to connect with research staff through WeChat.

In collaboration with community-based organizations (CBOs), we disseminated study flyers at community events (eg, CBOs' workshops, health fairs, and immigrant resource fairs) and posted flyers in CBOs' offices and on their WeChat accounts. The flyer contained information about the study purpose, a study WeChat QR code, and a study phone number. In addition, CBOs and study participants referred potential participants to the research staff.

Potential participants contacted our research staff by scanning the study WeChat QR code or calling the study number. The research staff conducted eligibility screenings over the phone and arranged an in-person study visit for eligible individuals. At the visit, the research staff administered the written consent process and a paper-and-pencil baseline survey. The first 40 participants were enrolled in the pilot RCT. The subsequent 20 participants were enrolled in the single-arm pilot test.

Randomization

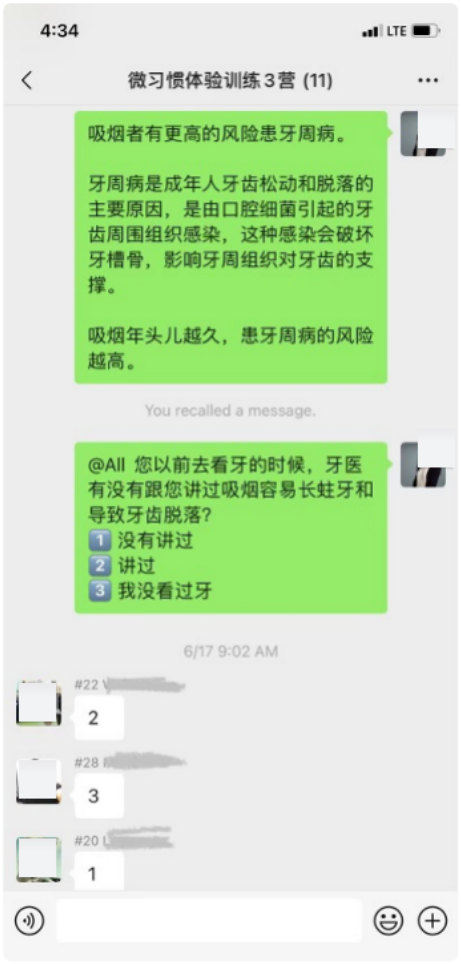
A total of 40 participants were randomized to the intervention or control arm (n=20 per arm) using block randomization stratified by sex (male or female). A randomization module was created and uploaded into REDCap (Research Electronic Data Capture). The research staff performed the allocation. Participants and research staff were unblinded to the assignment.

Intervention Arm

The research staff created a WeChat peer group every other month. Each group comprised of participants newly enrolled during the 2-month period who were either randomized to the intervention arm or enrolled in the single-arm pilot test (4-10 participants per group), along with a coach (NJ) and a research assistant. During the 6-week intervention period, the coach sent a WeChat text message to the group every day at 9 AM. The messages aimed to (1) enhance motivation to quit by building awareness about the health effects of smoking, quitting methods (eg, quitting preparation and relapse prevention) and cognitive or behavioral tips (eg, coping and refusal strategies), and available Chinese-language tobacco treatment programs (eg, ASQ and local smoking cessation programs); (2) challenge social norms that perpetuate smoking by denormalizing cigarette sharing culture and highlighting the fact that most Chinese immigrants do not smoke; (3) improve self-efficacy through motivational contents and tips for handling slips; and (4) encourage NRT use by addressing misconceptions. Details about the development process of WeChat Quit Coach are available elsewhere [24].

Following the daily WeChat text message, a text question was sent to the WeChat group each day to promote engagement (eg, "What is the longest period you've stayed abstinent in previous quit attempts?"). Participants were encouraged to respond daily and ask their own questions either in the group or directly to the coach, who responded within 24 hours. Figure 2 shows a screenshot of the intervention. If a participant did not respond for 3 consecutive days, a reminder message was sent to him or her through WeChat by the research assistant. Each participant received up to 3 reminders during the intervention. Participants could comment on others' responses and withdraw from the intervention at any time. The research assistant moderated peer interactions and monitored engagement.

Figure 2. A screenshot of the WeChat Quit Coach intervention.



Smokers have higher risks of developing gum diseases compared to nonsmokers.

Gum diseases, infections in the gums that affect the bone structure supporting teeth, are the primary cause of tooth loss among adults.

The longer one smoke, the greater the risk of developing gum diseases.

Question: Have you ever been told by a dentist that smoking increases the risk of tooth decay or loss?

1. No
2. Yes
3. Never visited a dentist

Control Arm

Participants allocated to the control arm received a leaflet with information about pharmacotherapy and behavioral interventions for smoking cessation, including the ASQ and local Chinese-language tobacco treatment programs.

NRT Supply

All 60 participants were offered a 4-week supply of free nicotine patches and lozenges. The participants could request NRT medications by texting the study WeChat account or calling the study number, with research staff screening for contraindications over the phone. If no contraindication was reported, participants were recommended a combination of nicotine patches and lozenges with doses as per package instructions. Participants could choose the form (eg, patch, lozenge, or both) and request

a lower dose. NRT medications and an instruction sheet (Chinese version) were then delivered by mail or in person.

Key Measures

Primary outcomes included feasibility, engagement, and acceptability. Feasibility was measured by eligibility rate (defined as the proportion of individuals screened who were eligible), enrollment rate (the proportion of eligible individuals who enrolled), follow-up rate (the proportion of participants who completed follow-up assessment at each time point), and the number of withdrawals. Engagement and acceptability were assessed at 6 weeks among participants from the intervention arm and the single-arm pilot test. Engagement was defined as the number of days participants responded to text questions and the number of participants who posted their own questions for instant messaging support. Acceptability was assessed through Likert scale questions regarding participants' perceptions about the intervention (eg, the timing of text messages and length of the intervention), helpfulness of intervention components (ie, text messages, text questions, and chat-based instant messaging support), overall satisfaction, and willingness to recommend it to others.

Secondary outcomes, assessed at 6 weeks and 6 months in the pilot RCT, included self-reported and biochemically verified 7-day point prevalence abstinence (yes or no). Participants reporting abstinence in the past 7 days were invited to participate in an exhaled CO test administered by research staff. A CO concentration of ≤6 parts per million indicated biochemically verified abstinence [26]. Additional outcomes encompassed quit attempts (yes or no; defined as no smoking for at least 24 hours because of trying to quit), change in smoking knowledge score, progression to a more advanced stage of change (yes or no), NRT use (yes or no), and use of other tobacco treatment (yes or no). Smoking knowledge was assessed using a 5-item measure adapted from the Global Adult Tobacco Survey [27], "Based on what you know, does smoking cigarettes cause (1) respiratory diseases, (2) lung cancer, (3) coronary heart disease, (4) stroke, (5) diabetes?" (0="no" or "not sure"; 1="yes"). The score of smoking knowledge was the sum of the points (ranging between 0 and 5). The stage of change was assessed by a question "Which statement best describes your plan about quitting?" with answer options of 1="I am not interested in quitting at all" (precontemplation), 2="I may quit in the future, but not in the next 6 months" (precontemplation), 3="I plan to quit within the next 6 months" (contemplation), 4="I plan to quit within the next 30 days" (preparation), and 5="I am trying to quit now" (action). Participants reporting a more advanced stage of change at follow-up, compared with baseline, were deemed to have transitioned to a more advanced stage.

Other measures included sociodemographic characteristics (eg, age, gender, education, birth country, years of residence in the United States, marital and employment status, and household income level), smoking behaviors (eg, age of smoking initiation, number of smoking days per week, cigarette consumption per day, time to first cigarette in the morning, and current use of other tobacco products), quitting experience (eg, quit attempts in the past 12 months, reasons for past quit attempts, and quitting methods ever used), and smoke-free home rule ("Which statement best describes the rule about smoking inside your home? (1) Smoking is not allowed anywhere in my home [complete rule]; (2) Smoking is allowed in some places or at some times in my home [partial rule]; (3) Smoking is allowed anywhere in my home [no rule]; (4) There are no rules about smoking in my home [no rule]" [28]).

Statistical Analysis

We performed descriptive statistics to summarize the variables of interest. Secondary outcomes were assessed using an intention-to-treat approach, with missing data treated as no change compared with baseline. To compare the differences between intervention and control arms, effect size estimates were computed, including odds ratios for categorical variables (eg, self-reported and biochemically validated abstinence) and Hedges *g* for the continuous variable (ie, smoking knowledge score) and their 95% CIs. For variables containing zero count cells, odds ratios and 95% CIs were not reported. All data analyses were performed using Stata 17 (StataCorp LLC).

Results

Feasibility

Of the 74 potential participants screened, 68 (92%) were eligible, and 60 (88%) enrolled, with no withdrawals. For the pilot RCT, follow-up rates were 98% (39/40 participants) at 6 weeks and 93% (37/40) at 6 months. The single-arm test achieved 100% follow-up at 6 weeks.

Sample Characteristics

On average, participants were 42.5 (SD 13.8) years old and had resided in the United States for 13.1 (SD 7.7) years (Table 1). Most were male (49/60, 82%), born in mainland China (58/60, 97%), and employed full-time (41/60, 68%). Out of 60, 15 participants (25%) had a middle school education (comparable to US 9th grade) or lower, and 28 participants (47%) reported an annual household income of US $55,000 or less.

Table 1. Characteristics of study participants at baseline (N=60).

Characteristics	Pilot RCT[a]		Single-arm pilot test (n=20)	Total (N=60)

[a]RCT: randomized controlled trial.

[b]Multiple responses, do not add up to 100%.

In total, 47 out of 60 participants (78%) reported daily smoking. On average, participants started smoking at 17.9 (SD 5.9) years old, smoked 12 (SD 8) cigarettes per day, and had a smoking knowledge score of 2.1 (SD 1.6). Participants were predominantly not ready to quit (42/60, 70% in precontemplation or contemplation stage). While 23 out of 60 participants (38%) reported current e-cigarette use, no participants reported current use of hookah, cigars, or smokeless tobacco (data not shown). Out of 60, 32 participants (53%) reported having a complete smoke-free home rule, 23 participants (38%) reported past 12-month quit attempts, and 11 participants (18%) had used evidence-based tobacco treatment, including 10 participants (17%) used NRT, 1 participant (2%) consulted a doctor, and 1 participant (2%) sought help from a smoking cessation program. None reported ever calling a quitline.

Engagement and Acceptability

On average, participants responded to WeChat text questions on 25.1 (SD 11) days out of 42 days (median 26.5, IQR 19-33 days). Reportedly, 9 out of 40 participants (23%) sent their own questions to receive chat-based instant messaging support from the coach. In total, 3 out of 40 participants (8%) interacted with peers. One of the participants commented on another's responses to a text question, while 2 participants each posted a message to communicate with the entire peer group.

Of the 39 participants who completed the 6-week follow-up assessment, 36 participants (92%) were satisfied or very satisfied with the intervention (Table 2). Participants predominantly agreed that WeChat Quit Coach enhanced their motivation to quit (35/39, 90%), increased awareness about how to quit (34/39, 87%), and promoted confidence in quitting (32/39, 82%). Most (32/39, 82%) would recommend the intervention to others, while 8 out of 39 participants (21%) indicated the intervention duration was too short. When asked about perceptions about the intervention, 34 out of 39 participants (87%) agreed that text messages were helpful, 33 participants (85%) indicated that text questions were helpful, and 25 participants (64%) found it enjoyable to answer text questions. Of the 9 who sent their own

questions for instant messaging support, 7 participants (78%) reported such support was helpful.

Table 2. Acceptability of WeChat Quit Coach among participants (n=39).

Satisfaction with the intervention	
Satisfied or very satisfied	36 (92)
Neither satisfied nor dissatisfied	3 (78)
Dissatisfied or very dissatisfied	0 (0)
Agree or strongly agree with the statements	
"It makes me want to quit smoking."	35 (90)
"It is helpful for quitting smoking."	32 (82)
"It makes me feel more confident that I can quit."	32 (82)

Perceptions	Participants, n (%)
"It makes me feel I knew how to quit."	34 (87)
"It makes me want to try again if a quit attempt is unsuccessful."	30 (77)
Length of the intervention (6 weeks)	
Appropriate	30 (77)
Too short	8 (21)
Too long	1 (2)
Would recommend the intervention to others	
Definitely yes	13 (33)
Probably yes	19 (49)
Probably no	5 (13)
Definitely no	2 (5)

[a]Among participants who sent in their own questions to receive chat-based instant messaging support (n=9).

Cessation Outcomes

At 6 weeks, 20% (4/20) of intervention participants reported 7-day point prevalence abstinence and were validated biochemically (Table 3). None of the control participants reported abstinence. At 6 months, 25% (5/20) of intervention participants reported abstinence and were validated, while 15% (3/20) of control participants reported abstinence and only 5% (1/20) were validated.

Table 3. Intention-to-treat analyses of preliminary effects of WeChat Quit Coach (n=40).

	6 weeks			6 months		
	Intervention arm	Control arm	Effect size estimates[a], OR[b] or Hedges *g* (95% CI)	Intervention arm	Control arm	Effect size estimates[a], OR or Hedges *g* (95% CI)

[a]For categorical variables, we computed the odds ratio and its 95% CI; for the continuous variable, we computed the Hedges *g* and its 95% CI.

[b]OR: odds ratio.

[c]Not applicable.

[d]Compared with baseline.

[e]NRT: nicotine replacement therapy.

Compared with baseline, intervention participants showed an average increase of 1.6 (SD 1.6) points in smoking knowledge at 6 weeks, while the score remained unchanged (mean -0.3, SD 1 points) for control participants. At both follow-up time

points, more intervention participants reported quit attempts and progressed to a more advanced stage of change, while more control participants requested NRT during the study period than intervention participants (17/20, 85% vs 16/20, 80%; data not shown in tables) and reported NRT use at both follow-ups (14/20, 70% vs 11/20, 55%).

Discussion

This is the first study of a social media–based smoking cessation intervention targeting Chinese immigrants. The sociodemographic characteristics of our participants correspond to the overall population traits of Chinese immigrants in NYC, including low income and low education [29]. The study demonstrates the feasibility and acceptability of a WeChat-based smoking cessation intervention and shows promising early efficacy on biochemically verified abstinence at 6 months.

It was found that 70% (42/60) of the participants were in the precontemplation or contemplation stage at enrollment. It suggests that the intervention is attractive to participants, including those not determined to quit in the near term. WeChat Quit Coach targets individuals at all levels of readiness to quit and is implemented through a platform deeply integrated into the daily lives of Chinese immigrants. The intervention has the potential to extend the reach of tobacco treatment within this population.

WeChat Quit Coach created favorable user experiences, as indicated by high levels of acceptability and engagement. Participants were overwhelmingly satisfied with the intervention. The interaction feature (daily text questions) was deemed enjoyable and helpful overall, resulting in a high engagement level compared with other social media peer group cessation interventions [20,30]. It is encouraging that participants post their own questions to receive instant messaging support, resulting in a usage rate (23%) comparable to that of a WhatsApp-based one-on-one cessation intervention for smokers in Hong Kong, which also features instant messaging support (17%) [21]. The results suggest that our intervention generally aligns with the needs of Chinese immigrant smokers. In total, 8 of the 39 participants (21%) reported the intervention was too short, highlighting opportunities for further refinement.

WeChat Quit Coach appears to be promising in promoting abstinence, with a biochemically verified abstinence rate of 25% at 6 months, which is higher than those reported in previous trials of social media interventions for Chinese-speaking smokers in Hong Kong (8% vs 5% biochemically validated 7-day point prevalence abstinence at 6 months [21]) and China (12% vs 3% biochemically validated continuous abstinence at 26 weeks [23]). Other outcomes, including quit attempts and smoking knowledge, were also higher in the intervention arm than control. Larger trials are needed to evaluate the impact of such intervention on abstinence among Chinese immigrants.

A noteworthy finding is that 55% (11/20) of intervention participants and 70% (14/20) of control participants reported NRT use. The high use of NRT could be attributed to the availability of complimentary NRT and the convenient process to request NRT. Chinese immigrants have limited awareness and hold widespread misconceptions about NRT despite its over-the-counter availability [10,14]. Moreover, Chinese immigrants have a high poverty rate compared with immigrants overall in the United States [31]. These factors contribute to the underuse of NRT. Our study indicates that Chinese immigrant smokers are receptive to using NRT when access barriers (eg, cost) are minimized. Our intervention might be more successful in promoting NRT use if cues to try NRT were added to our message library.

This study has several strengths. It is the first to explore a social media–based smoking cessation intervention for Chinese immigrants, a disadvantaged population with high smoking rates. It tests an innovative intervention using a culturally appropriate platform. The study fills gaps in research on tobacco-related disparities and the application of mobile technology for tobacco treatment. It also benefits from the inclusion of both individuals who are ready to quit and those not ready to quit, high follow-up rates, biochemically validated abstinence, and provision of NRT. This study has several limitations. First, as a pilot study aiming to test the feasibility, acceptability, and preliminary effects of our intervention, it was not adequately powered to assess treatment efficacy on abstinence. Second, participants were recruited from NYC, thus limiting the generalizability of our findings to other geographic regions.

This study supports the feasibility of a WeChat-based smoking cessation intervention for recruiting Chinese immigrant smokers across different levels of readiness to quit. The high levels of engagement, acceptability, and promising abstinence outcomes suggest that the intervention may be viable for this population. Larger trials are warranted to determine its efficacy.

Acknowledgments

We sincerely thank Professor Brian D Elbel (New York University Grossman School of Medicine) for the crucial support in securing approval from the Institutional Review Board for this research project. This work was supported by the National Institute on Minority Health and Health Disparities at the National Institutes of Health (K01MD014165) and New York University Grossman School of Medicine's Department of Population Health (Global Health Pilot Grant Funding Award). The funding organizations played no role in study design, data collection and analysis, manuscript writing, or the decision to submit the paper for publication.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors contributed to the writing-review and editing. NJ, APC, and SES performed conceptualization. AZ and NJ performed and contributed to the investigation, data curation, and writing the original draft. KS and NJ performed formal analysis. SES and NJ performed the methodology and supervision. NJ handled the funding acquisition, project administration, validation, and visualization, and managed resources and software.

Abstract

Background: Globally, students face increasing mental health challenges, including elevated stress levels and declining well-being, leading to academic performance issues and mental health disorders. However, due to stigma and symptom underestimation, students rarely seek effective stress management solutions. Conversational agents in the health sector have shown promise in reducing stress, depression, and anxiety. Nevertheless, research on their effectiveness for students with stress remains limited.

Objective: This study aims to develop a conversational agent–delivered stress management coaching intervention for students called MISHA and to evaluate its effectiveness, engagement, and acceptance.

Methods: In an unblinded randomized controlled trial, Swiss students experiencing stress were recruited on the web. Using a 1:1 randomization ratio, participants (N=140) were allocated to either the intervention or waitlist control group. Treatment effectiveness on changes in the primary outcome, that is, perceived stress, and secondary outcomes, including depression, anxiety, psychosomatic symptoms, and active coping, were self-assessed and evaluated using ANOVA for repeated measure and general estimating equations.

Results: The per-protocol analysis revealed evidence for improvement of stress, depression, and somatic symptoms with medium effect sizes (Cohen d=−0.36 to Cohen d=−0.60), while anxiety and active coping did not change (Cohen d=−0.29 and Cohen d=0.13). In the intention-to-treat analysis, similar results were found, indicating reduced stress (β estimate=−0.13, 95% CI −0.20 to −0.05; P<.001), depressive symptoms (β estimate=−0.23, 95% CI −0.38 to −0.08; P=.003), and psychosomatic symptoms (β estimate=−0.16, 95% CI −0.27 to −0.06; P=.003), while anxiety and active coping did not change. Overall, 60% (42/70) of the participants in the intervention group completed the coaching by completing the postintervention survey. They particularly appreciated the quality, quantity, credibility, and visual representation of information. While individual customization was rated the lowest, the target group fitting was perceived as high.

Conclusions: Findings indicate that MISHA is feasible, acceptable, and effective in reducing perceived stress among students in Switzerland. Future research is needed with different populations, for example, in students with high stress levels or compared to active controls.

Introduction

Background

Stress is rapidly becoming a major issue affecting adults in high-income countries, especially during periods of uncertainty and worry. Chronic stress is closely related to mental illnesses such as anxiety disorders and depression, leading to various symptoms such as sleep disturbances, pain, dizziness, cardiovascular and digestive problems, as well as fatigue [1,2]. Younger individuals, particularly students [3-7], are experiencing a decline in mental health on a global scale [8,9]. Studies indicate that approximately 11% of students experience impairments such as anxiety, depression, exhaustion, and burnout-like symptoms [1,10]. Furthermore, a high level of stress can have a negative impact on academic performance, resulting in changes in study direction, prolonged studies, and even dropout [11,12].

Students encounter distinct challenges during their academic journey, including the need to assimilate a substantial amount of content, effectively manage their time, cope with performance expectations, and handle examination pressure [13]. In addition, the developmentally sensitive period associated with this age group, combined with the academic environment, can contribute to increased stress levels [6]. Furthermore, compared to previous generations, today's students appear to exhibit lower stress tolerance and inadequate stress coping mechanisms, which further exacerbate the situation [1,14,15]. Notably, a recent study by Ehrentreich et al [16] reported that stress levels among students have increased by nearly 40% due to the impact of the COVID-19 pandemic.

To prevent students from experiencing chronic stress and its long-term effects, the implementation of appropriate prevention programs is crucial. These programs aim to promote students' self-management and stress management skills, including learning and time management techniques, to help them effectively cope with stress and to counteract increasing stress levels in the target group [10,17]. Studies have demonstrated the positive impact of interventions such as behavioral therapy–based approaches, relaxation and mindfulness exercises, psychoeducation, and time and study management strategies in reducing stress among students [10,18,19]. Typically, evidence-based stress management programs combine psychoeducational sessions with relaxation exercises [20-22]. Importantly, stress management programs should be specifically tailored to the needs of students. By considering the target group's real-life context, these programs facilitate the transfer of acquired skills into everyday life [23].

Despite the importance of stress management programs for students, successful uptake remains challenging [24]. Unfortunately, individuals experiencing stress often do not make use of stress management techniques for several reasons. These include the fear of being stigmatized [25], underestimation of the impact of stress, limited availability of therapy options, and high cost, particularly for young people in education [26,27].

Low-threshold, mobile health (mHealth) interventions such as smartphone apps could potentially bridge this gap. A meta-analysis by Weisel et al [28] highlighted the advantages of apps, including location and time independence, reduced stigmatization, and low costs [29]. Initial evidence suggests that smartphone apps can effectively reduce perceived stress, distress, depression, and anxiety and improve quality of life, psychological health, well-being, and self-regulation among student populations [30-32]. However, reported disadvantages of digital interventions, such as low adherence, legal concerns, lack of therapist relationship, and arbitrary scheduling, may diminish their effectiveness [29,33].

Conversational agents (CAs), commonly known as chatbots, are designed to simulate humanlike conversations and are increasingly used in clinical and nonclinical settings [34-36]. Initial findings demonstrate the feasibility, acceptance, and effectiveness of CAs in various health domains [37,38], including promoting physical activity [39]; managing pain [40]; reducing substance abuse [41,42]; improving depression, distress, and stress [43]; enhancing general wellness and pain [44]; and facilitating self-adherence and psychoeducation [38]. Although large language model (LLM)–based CAs have recently gained increasing attention [45], they are still subject to basic research in computer science because of several severe shortcomings, such as hallucinations and nonconscious bias, among others [46]. Therefore, LLM-based CAs are not yet appropriate for safe and ethical delivery of several-week health interventions [47]. Hence, we decided to implement an established, safe, and transparent approach to using CAs and used a rule-based CA [39,40,48-51].

Studies investigating the effectiveness of stress management interventions delivered by a CA specifically tailored to the needs of students are still lacking. While recent studies have explored interventions such as Stressbot, developed with Meta's Messenger (Meta Platforms, Inc) and CA Atena, accessible via Telegram messaging app (developed by the Digital Health Lab at Fondazione Bruno Kessler FBK research center), their focus has been limited to short-term outcomes or specific topics. For instance, while Stressbot aimed to reinforce coping self-efficacy, its intervention period was only 7 days [52]. Similarly, CA Aetna's positive psychology and cognitive behavioral approaches with a tailored focus on the unique needs of the COVID-19 pandemic rather than the life context of students led to inconclusive outcomes regarding anxiety and stress reduction [53]. Furthermore, a previous study evaluating an artificial intelligence (AI)–based chatbot that provided self-help interventions for students to reduce depression lacked detailed descriptions of evidence-based intervention designs, leaving uncertainty about the elements implemented [54]. However, evidence-based design is vital in developing CA-based coaching intervention programs [34] and stress management interventions

for specific groups such as students [23]. To our knowledge, there is no study describing the development and evaluation of the effectiveness of a CA-delivered stress management coaching program lasting several weeks and adapted to the specific context of students in their everyday lives.

Consequently, we have developed an evidence-based, scalable, and CA-delivered stress management coaching intervention for students called MISHA. It combines the following components: (1) providing psychoeducation about stress, mindfulness, and relaxation; (2) fostering participant motivation for self-reflection on stress and stress reactions; and (3) guiding participants in the regular practice of mindfulness and relaxation techniques. This comprehensive approach addresses key aspects of stress management, including knowledge acquisition, self-reflection, and practical application of mindfulness and relaxation techniques [19,55]. By focusing on these evidence-based intervention components, MISHA aims to empower students with effective tools and strategies to reduce stress and its long-term effects.

Objectives

The goal of this pilot study was twofold: (1) to develop a scalable, evidence-based coaching intervention specifically designed for students and delivered via a CA and (2) to assess the coaching intervention's effectiveness, engagement, and acceptance.

Methods

Intervention

App Development

MISHA was developed in collaboration with the ETH Zurich using the open-source software platform MobileCoach [56], designed for rule-based digital health interventions [48,57-59]. MISHA features a chat-based interface with multimedia elements and regular notifications to engage users. The app includes a chat channel, an audio library with relaxation exercises, psychoeducational illustrations, and frequently asked questions (Figure 1). Communications takes place via predefined but dynamic answer options or by providing free-text input. Study participants were provided with access to a beta version of the MISHA app for Android (Google LLC) devices through Firebase [60] and for iOS (Apple Inc) devices through TestFlight [61].

Figure 1. Screenshots of the MISHA app (coach selection, chat interface, reminder, and audio library). Translation from German to English, screenshot Select coach: "Choose a coach"; screenshot Chat with coach: "Effective time management can support you and prevent or reduce stress. Shall we discuss this?", "Yes, I'm interested.", "Great, you're on board. Today, we'll focus on reflecting on your personal thought and behavior patterns related to time management. Remember, time management is primarily self-management.", "Really?", "Perhaps you've experienced this yourself or observed it in others…"; screenshot Reminder: "Have you relaxed today? See you tomorrow", "Dear Isabelle, tomorrow I'll show you a relaxation exercise"; screenshot Audio library: "Progressive Relaxation - Introduction (long)", "Progressive Relaxation - Brief", "Progressive Relaxation - Extended", "Seated Meditation", "Footprints in the Snow", "Waterfall".

Coaching Concept of MISHA

The intervention concept for MISHA draws inspiration from an effective face-to-face prevention program [62], adapting its content and topics to suit a CA-delivered approach. MISHA's chat messages and notifications are aligned with the health action process approach (HAPA) model, emphasizing both motivational and volitional processes in behavior change [63].

MISHA integrates evidence-based strategies from cognitive behavioral therapy (CBT), mindfulness, and psychoeducation to provide information about stressors and coping techniques [55,64]. The stress management program includes fundamental elements derived from CBT, such as cognitive restructuring, identification, evaluation, and modification of maladaptive thought patterns [65]. In addition, techniques such as behavioral activation and activity monitoring from CBT were applied to

directly support the participants in their desired goals in a collaborative approach. For further details on CBTs and session elements, refer to Multimedia Appendix 1. The overall aim is to empower participants to reflect on their daily stressors and effectively manage their stress with new coping techniques.

Coaching Content

MISHA offers a consecutive 12-session coaching program based on the stress management manual by Kaluza [20]. Sessions cover psychoeducation on stress, relaxation techniques, and student-specific topics such as examination anxiety. Topics are personalized, for example, setting goals, individual appointments with the CA, or selecting a CA. Participants can schedule sessions every 2 to 4 days, completing the program in 24 to 54 days (refer to Multimedia Appendix 1 for an overview of sessions and a detailed description of the content). Throughout the coaching, participants receive personalized feedback on the progression of the coaching, motivational reminders, and reminders in case of inactivity (refer to Multimedia Appendix 2 for detailed information on reminders). Personalization on an individual level is essential in promoting trust, engagement, adherence, and effectiveness to digital health interventions [66,67].

Study Design and Procedure

We conducted an unblinded, 2-armed, pilot randomized controlled trial in a population of university students in Switzerland. Study participants were allocated either to a 4-week to 7-week coaching intervention or to a 40-day waitlist control group. This research project was registered at the German Clinical Trials Register accredited by the World Health Organization (DRKS00030004). The trial was conducted following CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines. No significant content changes were made to the coaching intervention during the study period.

After downloading the MISHA app, participants were greeted and provided with information about the study procedure and coaching program. They were explicitly informed that the app does not serve as a substitute for psychotherapy and were given guidance on where to seek further help if needed. Study information was displayed within the app. To proceed, participants had to provide electronic informed consent by confirming that they had read and understood the study information. Subsequently, inclusion criteria were checked, and participants were directed to the baseline self-assessment at preintervention (time point 1; T1) using the app's in-built LimeSurvey platform (LimeSurvey Project). The MobileCoach software automatically randomized participants into either the intervention or the waitlist control group by a 1:1 allocation using random numbers (0 to 1), with numbers <0.5 assigned to the intervention group. Participants from the intervention group started the coaching program immediately. Upon program completion (1) by working through all the modules or (2) after 54 intervention days, participants were directed to the postintervention survey (time point 2; T2) before moving to the final goodbye session. During the intervention, further self-reported outcomes (eg, goal achievement) and use data (eg, total minutes spent on in-app relaxation) were gathered.

Participants from the waitlist control group received short weekly chat messages from MISHA, informing them about the remaining duration of their wait and encouraging them to continue their participation in the study. After 40 days of waiting, they were presented with the postintervention survey (T2) and given the opportunity to participate in the coaching program.

There was no human involvement throughout the study; however, participants had the option to contact the study team via email if they encountered technical issues or encountered problems with app download.

Ethical Considerations

The Cantonal Ethics Committee of Zurich (KEK-ZH, BASEC-Nr. Req-2020-01038) reviewed the research project and confirmed that the study did not fall within the scope of the Human Research Act. All participants gave informed electronic consent by selecting a checkbox before enrolling in the study and were informed about their right to opt out at any time. Their data were deidentified. Participants who completed the postintervention survey had the opportunity to win a voucher worth CHF 200 (US $224.73). In addition, students of applied psychology at Zurich University of Applied Sciences had the opportunity to earn 5 test person hours.

Recruitment

From October 6, 2021, to the end of October 2021, flyers were distributed via email to students at the University of Zurich, the Zurich University of Teacher Education, University of Applied Sciences Northwestern Switzerland School of Education, the University of Teacher Education in Special Needs Zurich, and the Zurich University of Applied Sciences. In addition, the flyer was posted on Facebook (Meta Platforms, Inc) and LinkedIn (Microsoft Corp). The app could be downloaded via flyer by following a web link. Eligibility was determined within the MISHA app by self-report and included the following: (1) being aged ≥18 years; (2) possession of and basic knowledge in the use of a smartphone; (3) sufficient knowledge of the German language; and (4) being a student at a Swiss university, university of applied sciences, university of teacher education, or college of higher education.

Outcomes

Primary Outcome

To measure the effectiveness of the program, we assessed perceived stress at preintervention (T1) and postintervention (T2) time points using the German version of the Perceived Stress Scale, a self-report questionnaire consisting of 10 items [68]. Participants rated their responses on a scale ranging from 0 (never) to 5 (very often).

Secondary Outcomes

We measured secondary outcomes, including depression, anxiety, somatic symptoms, and active coping, at preintervention and postintervention time points by self-report. Multimedia Appendix 3 presents all outcomes and time points.

Depression, Anxiety, and Somatic Symptoms

We used the Patient Health Questionnaire Somatic, Anxiety, and Depressive Symptom Scales [69] to detect depressive symptoms, anxiety, and somatic symptoms, which consists of the Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7, and the Patient Health Questionnaire-15. The PHQ-9 is a 9-item questionnaire assessing depressive symptoms [70]. Participants rate the frequency of each symptom over the past 2 weeks, ranging from 0 (not at all) to 3 (nearly every day). The Generalized Anxiety Disorder-7 is a 7-item questionnaire that measures anxiety symptoms [71]. Participants rate the frequency of each symptom over the past 2 weeks, ranging from 0 (not at all) to 3 (nearly every day). The Patient Health Questionnaire-15 is a 15-item questionnaire measuring psychosomatic symptoms [72]. Participants rate the severity of each symptom over the previous 4 weeks, ranging from 0 (not bothered at all) to 2 (bothered a lot). For this study, items 14 (trouble with sleeping) and 15 (ie, low energy or tiredness) were collected in the PHQ-9 (similar in both questionnaires) but had to be converted according to the manual [73]. By combining these individual components, the PHQ Somatic, Anxiety, and Depressive Symptoms Scales provide a comprehensive assessment of depressive symptoms, anxiety, and somatic symptoms.

Active Coping

According to the HAPA model [74], we evaluated participants' engagement in stress management activities by asking them to rate how often they had actively taken steps to reduce stress in the past 5 days. The question was assessed on a rating scale ranging from 1 (never) to 4 (regularly). This allowed us to understand the participants' level of proactive involvement in managing their stress.

Predictor: Self-Efficacy Expectancy

Various health behavior change models, including the HAPA model [74], consider self-efficacy expectancy to be a key aspect of health behavior change. However, research findings on the impact on stress interventions are mixed [75-77]. To address this, we assessed self-efficacy expectancy using the General Self-Efficacy Scale [78]. Before the intervention, participants rated their agreement with statements on their ability to handle tasks effectively on a 4-point Likert scale ranging from 1 (not at all true) to 4 (exactly true). The total score of the General Self-Efficacy Scale ranges from 10 to 40, with higher scores indicating higher self-efficacy.

Exploratory

Working Alliance

To assess the interaction between participants and MISHA, we used the German version of the Working Alliance Inventory-Short Revised [79] after the intervention. This self-report questionnaire comprises 12 items that capture the quality of the therapeutic relationship and collaboration between participants and the CA via 3 dimensions: goal, task, and bond. Responses were rated with an adapted scale from 1 (I do not agree at all) to 6 (I completely agree) after the intervention.

Subjective Stress Expertise and Goal Achievement

Throughout the coaching period, we assessed participants' goal achievement 3 times (sessions 1, 6, and 11) using a scale of 1 to 10, where 1 referred to the goal as clearly not achieved and 10 referred to the goal as fully achieved. We further measured participants' stress expertise 3 times (sessions 2, 5, and 13) using a similar scale, ranging from 1 (no idea how stress manifests itself in me) to 10 (I know exactly how I react when under stress).

Engagement and Acceptance

The extent to which a participant has to engage with the intervention to derive the maximum benefits is termed intended use [80]. For MISHA, we defined intended use for participants as completing the postintervention assessment, regardless of completing all sessions. This definition was based on the fact that participants may have varied goals and desired outcomes, leading to differences in their use of MISHA's features, including frequency and duration [81,82]. It also implies that participants do not necessarily need to interact with all available intervention components. Furthermore, participants might discontinue using the intervention upon achieving their personal goals, indicating that nonuse is not due to loss of interest [83,84]. In addition, we ground this approach on the self-determination theory, where autonomy by providing choice is essential [85].

To assess participants' engagement in the coaching program, we analyzed use data from the intervention group by calculating the ratio of replied conversational turns based on the number of SMS text messages sent by MISHA in relation to SMS text messages replied by participants. Furthermore, we tracked the number of sessions completed by participants and the number of reminders sent to participants in cases of inactivity (ie, if participants stopped interacting during a session). In addition, we tracked the number of minutes of audio files played by participants throughout the intervention.

We evaluated the feasibility and acceptance of MISHA using the user version of the Mobile App Rating Scale (uMARS) [86] after the intervention. The uMARS is a validated questionnaire that assesses the dimensions of engagement, functionality, esthetics, information, perceived quality, and perceived impact. All subscales use a 5-point Likert scale ranging from 1 to 5, where higher scores indicate a more favorable judgment. In this study, 19 items were translated from English to German to assess engagement (eg, entertainment, interest, customization, interactivity, and target group of the app), information (eg, quality of information, quantity of information, visual information, and credibility of source), perceived quality (eg, recommendation, use, payment, and overall rating), and perceived impact (eg, awareness, knowledge, attitudes, behavior change, seeking help, and intention to change). In addition to the uMARS, participants had the opportunity to provide feedback in free text prompted by the following questions: "What did you like most about the MISHA app?" and "What would you improve in the MISHA app?"

Sample Size Calculation

The sample size was estimated for a generalized estimating equation (GEE) based on a repeated-measure (within-between

interaction) ANOVA. A small to medium time by group interaction effect size (Cohen *f*=0.15) for the primary outcome perceived stress due to prior results [87] was expected. The G*Power (Heinrich-Heine-Universität Düsseldorf) analysis [88] revealed that a sample size of 90 participants would be sufficient with a power of 0.80 and a correlation of *r*=0.5 between measurements. Owing to the high percentage of dropouts observed in earlier studies, the target sample was increased to 180 participants [89].

Data Analysis

Descriptive statistics, independent 2-tailed *t* tests, and chi-square tests were conducted to analyze baseline differences in demographics and outcomes between the intervention and control groups.

In our analysis, we examined the effectiveness of the intervention by assessing changes in the primary outcome perceived stress scores over time within each group (intervention and control) and comparing these changes between groups. We first conducted a per-protocol (PP) analysis, including only participants who completed both surveys. This was done using a repeated-measure ANOVA with perceived stress as the dependent variable, time as the within-subject factor, and group as the between-group factor. Secondary outcomes, including depression, anxiety, psychosomatic symptoms, and active coping, were analyzed accordingly.

In compliance with the CONSORT (Consolidated Standards of Reporting Trials) guidelines, we also conducted an intention-to-treat (ITT) analysis wherein all randomized participants were included, regardless of their adherence to the coaching intervention. This analysis was performed using GEE. In model 1, we conducted an unadjusted evaluation with time (T1 and T2), group (intervention and control), and treatment (group by time interaction) as independent variables, with perceived stress as the dependent variable. The incorporation of time allows the examination of the dependent variable stress over different time points, the incorporation of group allows for comparison of stress between groups, and the interaction between group and time allows for an examination of whether the changes in outcomes over time differ between the intervention and control groups. In model 2, we did an adjusted analysis with the inclusion of the covariate general self-efficacy for the primary outcome perceived stress. The same independent variables were considered as in model 1. Secondary outcomes were evaluated accordingly. A log link function, gamma distribution, and unstructured covariance structure were applied. This modeling approach provided the best fit with the outcomes and allowed us to avoid restrictions on the covariance structure. To reduce the impact of influential observations and outlier effects, we used a robust estimator, which is consistent with standard procedures when using GEE.

Using GEE [90] offered several advantages. First, it allowed us to consider the correlations between the measurement times in longitudinal data, which is important for analyzing repeated measures. In addition, GEE allowed us to include incomplete data sets using an estimating equation to handle missing data. GEEs use all available data and estimate missing outcome values under the assumption of missing completely at random (MCAR). To assess the assumption of MCAR, we conducted the Little MCAR test. Calculations of between-group effect sizes (Cohen *d*) were based on the pooled SD and labeled as small (Cohen *d*=0.2), medium (Cohen *d*=0.5), and large (Cohen *d*=0.8). Furthermore, we explored the potential relation of working alliance and perceived impact on treatment outcomes using a correlation. All statistical analyses were performed using SPSS software (version 28; IBM Corp). We applied qualitative content analysis [91,92] using thematic maps [93] to answer the open-ended questions.

Results

Demographics and Baseline Scores

In total, 230 individuals downloaded the app. Of the 230 individuals, 148 (64.3%) were assessed for eligibility and completed the baseline survey. Before randomization, of the 148 participants, 8 (3.5%) discontinued using the app and 140 (60.9%) were randomized into intervention (70/140, 50%) and waitlist control (70/140, 50%) groups. The complete participant flow is depicted in Figure 2.

Participants had a mean age of 26.71 (SD 6.29) years. While 23.6% (33/140) of the participants identified as men, 73.6% (103/140) as women, and 2.1% (3/140) as nonbinary, 0.7% (1/140) declined to provide information about their gender (Table 1). Regarding relationship status, 59.3% (83/140) of the participants reported being married or in a relationship, while 40.7% (57/140) were single. Regarding educational background, most participants (90/140, 64.3%) had an apprenticeship or vocational or high-school diploma. A substantial proportion of the participants (37/140, 26.4%) had a university degree at the bachelor level or higher vocational education or training, while 8.6% (12/140) had other qualifications. Regarding their field of study, most participants (131/140, 93.6%) were studying at a university of applied sciences or university, while 5% (7/140) were studying at other institutions. The participants had a degree in (applied) psychology (124/140, 88.6%), social sciences (6/140, 4.4%), or other fields (7/140, 5%). There were no differences between groups for any of the outcomes at baseline.

Effectiveness

To evaluate the effectiveness of the intervention and to take missing data into account, a PP analysis of the time by group interaction was conducted followed by an ITT analysis. For the PP analysis (Table 2), we found evidence of a treatment effect (group by time interaction) from pre- to postintervention time points between the intervention and control groups for stress (P=.001; Cohen d=−0.60), depressive symptoms (P=.003; Cohen d=−0.50), and psychosomatic symptoms (P=.010; Cohen d=−0.36) but not for anxiety and active coping behavior.

In the ITT analysis for the unadjusted model (model 1), we found evidence of a treatment effect (group by time interaction) from pre- to postintervention time points between the intervention and control groups for stress (P<.001), depressive symptoms (P=.003), and psychosomatic symptoms (P=.003). No treatment effect was found for anxiety (P=.13) and active coping (P=.09).

After adjusting for the covariate self-efficacy expectancy (model 2), we found evidence of treatment effect sizes similar to model 1 (Table 3). Furthermore, there was evidence for an effect of self-efficacy expectancy on perceived stress (P<.001), depression (P<.001), anxiety (P<.001), and psychosomatic symptoms (P<.001) but not on active coping.

Table 2. Preintervention and postintervention means, results of the per-protocol (PP) repeated-measure ANOVA analysis, and between-group effect sizes (Cohen *d*) of primary and secondary outcomes (n=98).

Measure	Preintervention, mean (SD)	Postintervention, mean (SD)	Between-group effect sizes (intervention group vs waitlist control group after the intervention)

Exploratory

Regarding the working alliance, participants in the intervention group reported a mean working alliance score of 4.23 (SD 0.89) after the intervention. When exploring the potential influence of the working alliance on changes in outcomes from pre- to postintervention time points, we did not find evidence for correlations on any of the outcomes (Pearson correlation *r* ranging from −0.021 to 0.223). The participants rated their subjective stress expertise and goal achievement throughout the coaching program (3 times). For goal achievement, we observed a significant increase from the first to the third measurement with a large effect size (Cohen *d*=−1.07). Table 4 provides further details.

Table 4. Means for subscales bond, task, and goal of working alliance and results of a paired *t* test for stress expertise and goal achievement.

	Start of the intervention, mean (SD)	End of the intervention, mean (SD)	*t* test (*df*)	*P* value[a]	Cohen *d* (95% CI)
WAI-SR[b](n=42)					
Total	—[c]	4.23 (0.89)	—	—	—
Bond	—	4.20 (1.01)	—	—	—
Task	—	4.18 (0.82)	—	—	—
Goal	—	4.30 (0.84)	—	—	—
Stress expertise (n=45)	7.51 (1.47)	7.64 (1.60)	0.47 (44)	.64	−0.07 (−0.36 to 0.22)
Goal achievement (n=24)	3.88 (2.54)	6.71 (2.14)	−5.24 (23)	<.001	−1.07 (−1.57 to −0.56)

[c]Not applicable.

Engagement and Acceptance

In the intervention group, 60% (42/70) of the participants finished the coaching program by completing the postintervention survey (completers) and used the intervention as intended. Although the Little test indicated that values were MCAR for perceived stress (χ^2_1=0.5; *P*=.47), depression (χ^2_1=0.2; *P*=.63), anxiety (χ^2_1=2.0; *P*=.16), psychosomatic symptoms (χ^2_1=0.6; *P*=.80), and active coping (χ^2_1=0.1; *P*=.82), we conducted a dropout analysis due to the potential risk of differential attrition, particularly with significantly higher dropouts observed in the intervention group [94]. The analysis revealed no significant differences in outcomes (eg, stress and depression) or demographics (ie, gender and age) between completers and dropouts.

Overall, 45% (19/42) of the completers worked through all 13 sessions, played a mean of 86.52 (SD 120.54) minutes of relaxation audios, and received a mean of 115.88 (SD 5.06) reminders; Table 5 provides further information. On average, MISHA sent 400 (SD 205.61) SMS text messages and participants answered a mean of 297.54 (SD 169.80) SMS text messages, resulting in an average engagement ratio of 74.3%.

The participants in the intervention group (42/70, 60%) rated the subscale information highest, with a mean of 4.26 (SD 0.46), followed by engagement (mean 3.42, SD 0.70), perceived impact (mean 3.35, SD 0.87), and subjective quality of the app (mean 2.99, SD 0.87). Regarding engagement, individual customization was rated lowest with a mean of 2.71 (SD 0.84), while the target group fit was perceived as high (mean 3.95, SD 0.90). The participants liked the visual information of the CA and rated it high regarding correctness, clarity, and logic (mean 4.45, SD 0.55). Only a few participants (2/42, 2%) showed a high willingness to pay for the app (mean 2.10, SD 0.91) or anticipated high future use (mean 2.98, SD 1.05). The recommendation of the app to others was good, with a mean of 3.43 (SD 1.19) within the subjective app quality scale.

Table 5. Indicators of engagement: intended use, session completion, relaxation, and reminders.

Indicators of engagement	Values, n (%)	Relaxation applied, mean (SD)	Reminders received, mean (SD)[a]
Completers (intended use[b])	42 (100)	86.52 (120.54)	15.88 (5.06)
Completed all sessions	19 (45)	97.11 (71.43)	14.89 (5.75)
Stopped interacting after session 12	3 (7)	299.33 (377.33)	17.67 (1.15)
Stopped interacting after session 11	3 (7)	29.00 (26.91)	17.67 (0.58)
Stopped interacting after session 10	1 (2)	12.00 (0.0)	27.00 (0.0)
Stopped interacting after session 9	2 (5)	46.00 (26.87)	21.00 (1.41)
Stopped interacting after session 8	4 (10)	53.50 (42.45)	16.00 (3.92)
Stopped interacting after session 7	3 (7)	89.33 (82.25)	18.00 (1.73)
Stopped interacting after session 6	3 (7)	56.00 (73.53)	17.00 (1.0)
Stopped interacting after session 5	1 (2)	26.00 (0.0)	14.00 (0.0)
Stopped interacting after session 4	1 (2)	16.00 (0.0)	9.00 (0.0)
Stopped interacting after session 3	2 (5)	4.00 (4.24)	8.50 (2.12)
Stopped interacting after session 2	0	—[c]	—
Stopped interacting after session 1	0	—	—

[a]Reminders in case of inactivity during sessions.

[b]Intended use is defined by completing the postintervention survey, regardless of number of sessions that were completed.

Qualitative Feedback

The participants in the intervention group had the opportunity to provide free-text responses regarding their positive feedback on the CA intervention (Figure 3) and suggestions for improvement (Figure 4). The number of responses is displayed within the circles.

Figure 3. Thematic map of positive participant feedback.

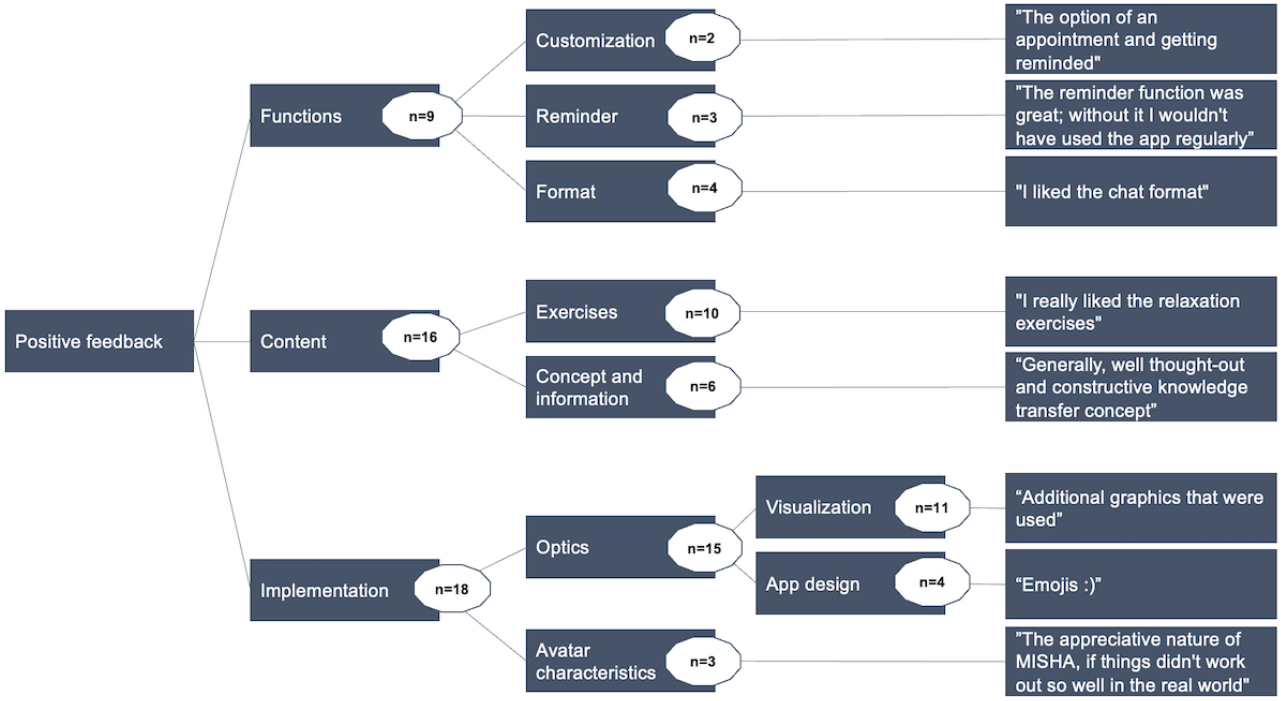

Figure 4. Thematic map of negative participant feedback.

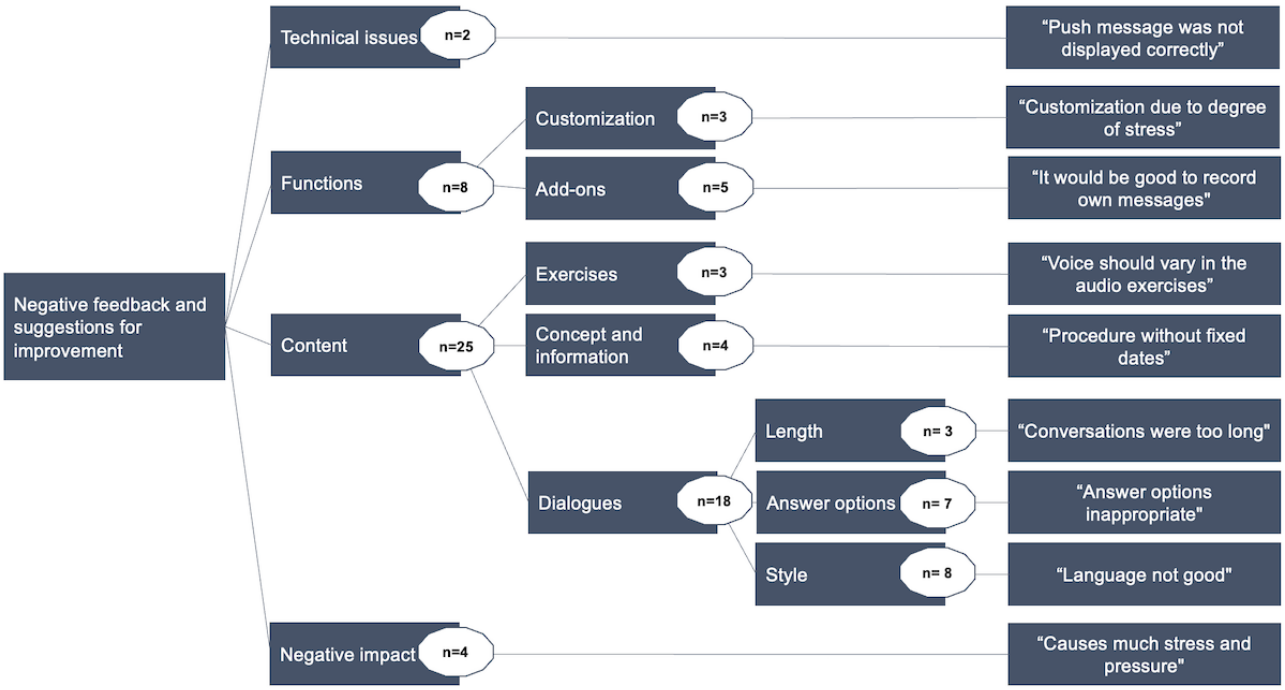

Discussion

Principal Findings

This study aimed to describe the development and evaluation of the effectiveness of the MISHA app, a rule-based, CA-delivered stress management coaching intervention specifically tailored to the living environment of students. We described the MISHA app's evidence-based design and systematic evaluation. In both the PP and ITT analyses, we found evidence of decreased stress levels among participants in the intervention group compared to those in the control group, with a medium to large between-group effect (PP: Cohen d=−0.60). In addition, we observed evidence of a reduction in depressive symptoms with a medium to large effect (Cohen d=−0.50) as well as in psychosomatic symptoms with a small to medium effect (Cohen d=−0.36), while anxiety and active coping did not change. In the ITT analyses, a weak relation was found between self-efficacy and perceived stress, depression, anxiety, and psychosomatic symptoms, while the treatment effect persisted for stress, depression, and psychosomatic symptoms.

Our findings are consistent with other studies evaluating CA effectiveness in nonclinical populations. For instance, a study on CA Shim [95] among young adults with stress, despite a small sample size, reported stress reduction and improved psychological well-being, mirroring our results. Another study by Maciejewski and Smoktunowicz [52] assessed Stressbot, a 7-day messenger CA intervention aimed at enhancing coping self-efficacy among university students. Initial results showed reduced stress levels and improved self-efficacy postintervention. A large single-arm study evaluated Viki, an instant-messenger platform-based intervention [96], and found reduced stress and depressive symptoms. However, unlike our study, they reported a significant decrease in anxiety. In our study, the concurrent COVID-19 pandemic situation or upcoming examinations may have triggered increased uncertainties and fears. In a study involving CA Atena [53], the overall reduction in anxiety and stress levels may not have been substantial; however, the intervention showed promise in supporting individuals with high stress levels during the COVID-19 pandemic. Another study evaluated an AI-driven CA with the aim of reducing depression in university students by reflecting on their emotions, thoughts, and behavior [54]. The authors found reduced levels of depression and anxiety in the intervention group.

With its strong focus on goal setting, a crucial element in coaching [97], and being based on a behavior change model [74], the MISHA coaching intervention appears to effectively help students manage their stress. Toward the end of the coaching program, participants significantly rated their goal achievement higher with a large effect (Cohen d=−1.07), indicating the intervention's effectiveness in this regard. However, some participants expressed a desire for customization options, particularly regarding stress levels.

Regarding evidence from mHealth interventions for students, a study by Yang et al [30] found positive effects on stress and overall well-being in a 30-day app-based intervention on stress management through mindfulness meditation among medical students. A systematic review confirmed that digital interventions for the enhancement of mental well-being among college students can be effective in improving depression, anxiety, and mental well-being [98].

Given the mixed findings regarding the impact of self-efficacy expectancy on stress interventions targeting students [75-77], we explored whether self-efficacy was related to perceived stress. We found only a weak relation, while the treatment effectiveness remained unchanged. Therefore, in this study,

self-efficacy does not seem to have influenced the treatment's effectiveness in reducing stress.

In line with other studies [30,99,100], participants formed a working alliance with CA MISHA. Qualitative analyses revealed participants' appreciation for MISHA's supportive nature, especially during challenging moments. Most participants enjoyed interacting with MISHA, found the information provided appropriate, and expressed increased intention to change their behavior related to stress. Some desired additional features (eg, voice recording), found answer options or language style to be inappropriate, and disliked the lengthy dialogues. The various exercises, reminders, and visualizations were perceived as positive, and the constructive knowledge transfer was appreciated. In summary, it appears that a CA could be a well-accepted medium for stress prevention measures among students.

Limitations

This study has several limitations. First, despite statistically significant findings, it is essential to recognize that the absolute improvement in perceived stress, depressive symptoms, and psychosomatic symptoms was small. However, these improvements may still hold clinical relevance, and students experiencing even slight relief from perceived stress can benefit from CA-based coaching. Medium effect sizes indicate practical significance but may not always translate into substantial clinical change, and results should be interpreted with caution and in light of the context. Furthermore, all participants were self-selected, which limits the generalizability of our findings and introduces the potential for self-selection bias. Participants may have a particular interest in the subject and, therefore, cannot be considered a representative sample. It is important to note that their preexisting characteristics may differ from those in the broader population, and caution should be exercised when generalizing these findings to a wider context. Furthermore, this study is based on a convenience sample and should not be considered representative of all students. In particular, our sample, with most studying psychology (123/140, 87.9%) and predominantly woman participants (103/140, 73.6%), does not accurately reflect the student population in Switzerland, which shows an approximately even gender distribution (53% woman) [101]. Therefore, questions remain regarding the accessibility of the intervention to individuals who may not have an interest in psychological content and whether men and women can be equally reached by a mindfulness-focused chatbot such as MISHA.

Second, regarding engagement, we have analyzed use data from the intervention group, including completion rates, session completion, SMS text message response rate, reminders, and use of media player for relaxation. These objective measures offer valuable insights into participants' interactions with the coaching program and help ensure the robustness of our findings. However, it is difficult to measure how devoted participants were when using the app. To date, there is no consensus on measuring engagement in digital interventions [81]. According to Perski et al [102], engagement can be defined as a multidimensional construct that can be measured using self-reported outcomes, use data, or even psychophysical parameters. Future research should assess participants' time and motivation for offline engagement with exercises, while considering aspects of attention, interest, and emotions. Furthermore, in-depth use data should be gathered to assess the association between engagement, effectiveness, and optimal intended use.

Third, in this study, participants established a working alliance with the CA. However, it is important to acknowledge that CAs lack humanlike empathy or emotions [103]. They may struggle to understand the nuances of human language and lack the emotional intelligence and personal experience of a human, even if they can express empathy-like utterances. A recent study demonstrated that human-AI collaboration outperformed human-to-human collaboration, leading to a 19.6% increase in empathy in peer-to-peer text-based mental health support conversations [104]. While AI can mimic empathy and generate appropriate responses in text-based conversations, it is important to remember that these are still artificial constructs.

Fourth, various technical limitations need to be listed. At the beginning of the intervention, there were technical difficulties related to the audio files of the relaxation exercises. Some exercises could not be played. In addition, several participants indicated that the app was not updating properly; however, this issue was resolved within a few days. Furthermore, there was a 2-day interruption at the beginning because a technical adjustment had to be made to ensure that the system could recognize completed sessions. It remains unclear whether these technical issues led to more dropouts, frustration, or nonuse of the exercises. Notably, the recording of the minutes of listened audio files did not function flawlessly. While audio minutes were measured, they must be interpreted with great caution due to uncertainty in measurement. In addition, if the display of push notifications on the mobile phone was not set as the default, some SMS text messages were displayed without text. The number of people for whom this was the case and whether it negatively affected adherence cannot be conclusively determined. Any reported bugs in MISHA were addressed by a member of the study team within a 24-hour timeframe. There were no reported instances of server downtime.

Fifth, it is important to recognize the potential for improvements to enhance interaction in MISHA. The nature of the current CA is rule based: while allowing for evidence-based program development, the flexibility of interaction is limited by predefined answer options. While participants appreciated various aspects such as visualization, reminders, or exercises, personalized input via text input was missing, and some answer options were perceived as inappropriate. AI-based technology such as LLMs or natural language processing could be considered to improve text processing in MISHA. Natural language processing and LLM enable the CA to interpret user inputs more dynamically with increased natural interactions [105,106]. AI-based CAs are increasingly applied in health care to provide education and disease management. The literature on AI-based CAs indicates high overall performance and satisfactory user experience, high engagement, and positive health-related outcomes [107]. However, to date, CA interventions in the field of mental health are almost entirely rule based [108]. Ethical considerations concerning AI

technology should be addressed to mitigate potential misjudgments and risks. Research highlights the critical issue of inadequate transparency in data input and algorithms, undermining the reliability and validity of results [107,109]. Currently, both rule-based and LLM-based CAs are suitable for administering script-based interventions such as CBT elements, including psychoeducation, goal setting, or reflective tasks. While in the future, LLM-based interventions may be able to deliver more complex interventions in the field of psychology, it is crucial to consider the potential risk and limitations of implementing these technologies [110].

Sixth, it is important to acknowledge the possibility of a digital placebo effect [111]. In an unblinded trial, participants might attribute their improvements to the mere use of an mHealth intervention rather than its specific components. Expectations and engagement could introduce positive bias into the outcomes. Future research should carefully plan control conditions, which might include active control groups or sham interventions [111].

Conclusions

This paper outlines the evidence-based development of MISHA, a scalable coaching intervention specifically designed for students in their everyday life. The results of this study confirmed that CA-based coaching can be successfully delivered and is effective in reducing stress in students. It could not be confirmed that self-efficacy is related to the treatment effect. The establishment of a strong working alliance between participants and the CA, along with their perceived goal achievement, further reinforces the potential effectiveness of this intervention. Future research should involve students from diverse academic backgrounds, analyze effectiveness over time, incorporate active control groups, and improve user interaction. Overall, providing psychoeducation on stress, coupled with relaxation techniques, seems to empower students with effective tools and strategies for stress reduction.

Abstract

Background: Conversational chatbots are an emerging digital intervention for smoking cessation. No studies have reported on the entire development process of a cessation chatbot.

Objective: We aim to report results of the user-centered design development process and randomized controlled trial for a novel and comprehensive quit smoking conversational chatbot called *QuitBot*.

Methods: The 4 years of formative research for developing QuitBot followed an 11-step process: (1) specifying a conceptual model; (2) conducting content analysis of existing interventions (63 hours of intervention transcripts); (3) assessing user needs; (4) developing the chat's persona ("personality"); (5) prototyping content and persona; (6) developing full functionality; (7) programming the QuitBot; (8) conducting a diary study; (9) conducting a pilot randomized controlled trial (RCT); (10) reviewing results of the RCT; and (11) adding a free-form question and answer (QnA) function, based on user feedback from pilot RCT results. The process of adding a QnA function itself involved a three-step process: (1) generating QnA pairs, (2) fine-tuning large language models (LLMs) on QnA pairs, and (3) evaluating the LLM outputs.

Results: We developed a quit smoking program spanning 42 days of 2- to 3-minute conversations covering topics ranging from motivations to quit, setting a quit date, choosing Food and Drug Administration–approved cessation medications, coping with triggers, and recovering from lapses and relapses. In a pilot RCT with 96% three-month outcome data retention, QuitBot demonstrated high user engagement and promising cessation rates compared to the National Cancer Institute's SmokefreeTXT text messaging program, particularly among those who viewed all 42 days of program content: 30-day, complete-case, point prevalence abstinence rates at 3-month follow-up were 63% (39/62) for QuitBot versus 38.5% (45/117) for SmokefreeTXT (odds ratio 2.58, 95% CI 1.34-4.99; *P*=.005). However, Facebook Messenger intermittently blocked participants' access to QuitBot, so we transitioned from Facebook Messenger to a stand-alone smartphone app as the communication channel. Participants' frustration with QuitBot's inability to answer their open-ended questions led to us develop a core conversational feature, enabling users to ask open-ended questions about quitting cigarette smoking and for the QuitBot to respond with accurate and professional answers. To support this functionality, we developed a library of 11,000 QnA pairs on topics associated with quitting cigarette smoking. Model testing results showed that Microsoft's Azure-based QnA maker effectively handled questions that matched our library of 11,000 QnA pairs. A fine-tuned, contextualized GPT-3.5 (OpenAI) responds to questions that are not within our library of QnA pairs.

Conclusions: The development process yielded the first LLM-based quit smoking program delivered as a conversational chatbot. Iterative testing led to significant enhancements, including improvements to the delivery channel. A pivotal addition was the inclusion of a core LLM–supported conversational feature allowing users to ask open-ended questions.

Trial Registration: ClinicalTrials.gov NCT03585231; https://clinicaltrials.gov/study/NCT03585231

Introduction

Background

Cigarette smoking accounts for 8 million premature deaths and 25% of all cancer deaths annually [1,2]. Despite advancements in government policies, antismoking campaigns, and shifting societal norms, existing smoking cessation interventions continue to have limited treatment engagement and cessation rates [3-9]. While this is a problem for the general population of people who smoke, the issue is particularly pronounced in communities considered marginalized, synonymous with groups considered vulnerable or disadvantaged, which are segments of society facing systemic disadvantages and barriers in accessing resources and opportunities. Populations considered marginalized, marked by factors such as racial or ethnic minority status, sexual or gender identity differences, low education and income levels, higher unemployment rates, or an increased prevalence of mental illness, encounter discrimination, social exclusion, and limited influence in decision-making processes.

Challenges in treatment engagement and cessation efficacy across all communities of people who smoke are compounded by a scarcity of trained clinicians and significant barriers, including cost and lack of insurance, hindering access to existing clinician-delivered interventions [10-14]. Given that 1.3 billion people in the world smoke cigarettes, with 70% of them wanting to quit, it would be impractical to have enough trained clinicians to help people quit smoking [15,16]. Indeed, only 5% of cessation attempts are aided by a health professional [17]. Consequently, there is an enormous need for high-impact, cost-effective, population-level interventions for smoking cessation.

A well-documented finding from research on clinician-delivered treatments has emphasized the significance of therapeutic conversations as powerful drivers of patient engagement [18-21]. Therapeutic conversations, which form a social-emotional bond with the user, have predicted treatment engagement and, subsequently, health outcomes across various treatments and settings [12,18,22]. A new technology provides an opportunity to leverage engaging therapeutic conversations. Advances in machine learning, large language models (LLMs), and cloud computing are now making it possible to create and widely disseminate conversational chatbots for behavior change coaching.

Unlike the chatbots used in customer service contexts, conversational chatbots for behavior change coaching are designed to form long-term social-emotional connections with users, even as they are made aware that chatbots are merely computer software that use language to communicate with users [23,24]. Conversational chatbots for coaching are designed to be supportive and empathic, offering reflective listening, personalized responses, and timely advice aligned with the user's individual needs [25,26]. In the context of cessation, conversational chatbots can enhance engagement through an informal therapeutic conversational style tailored to users' unique barriers to quitting smoking [27]. Conversational chatbots only require a text response to operate, making them ideal for all individuals who smoke, including those with low technology literacy [26]. Overall, conversational chatbots offer a cost-effective communication platform, accessible at any time, and have the potential for high population-level reach, making them a valuable tool in smoking cessation interventions.

To date, research on conversational chatbots for smoking cessation is scarce. Existing literature revealed a limited number of empirical studies, often exhibiting low methodological quality [28]. There is a notable paucity of randomized controlled trials (RCTs) focusing on conversational chatbots for smoking cessation, and while promising results have emerged, they have been limited by low quit rates [29]. Several conversational chatbots for smoking cessation in the public domain include Florence (World Health Organization) [30], Bella (Solutions4Health) [31], and Alex AI (Alex Therapeutics) [32]. However, we are not aware of publications on their efficacy, with only the Florence app having reported user's receptivity results [33]. Critical to creating useful and engaging conversational chatbots is following a user-centered design development process [34]. Similar to most chatbots, the development of the chatbots listed above lacks context for how they were designed and any user-centered design that involved conducting a needs assessment or including user feedback during the development process [28,35]. The few studies that have provided development details only describe early design phases, such as coding 30 quit coaching calls for prototype development, without empirical efficacy data [28,35,36]. In sum, the literature on chatbots for smoking cessation offers only partial accounts on how they were developed or report on initial stages of development.

Objective

To address these gaps, this paper describes the comprehensive 4-year, 11-step user-centered design development process for a novel quit smoking conversational chatbot named "QuitBot." This single report aims to summarize the entirety of the QuitBot development process.

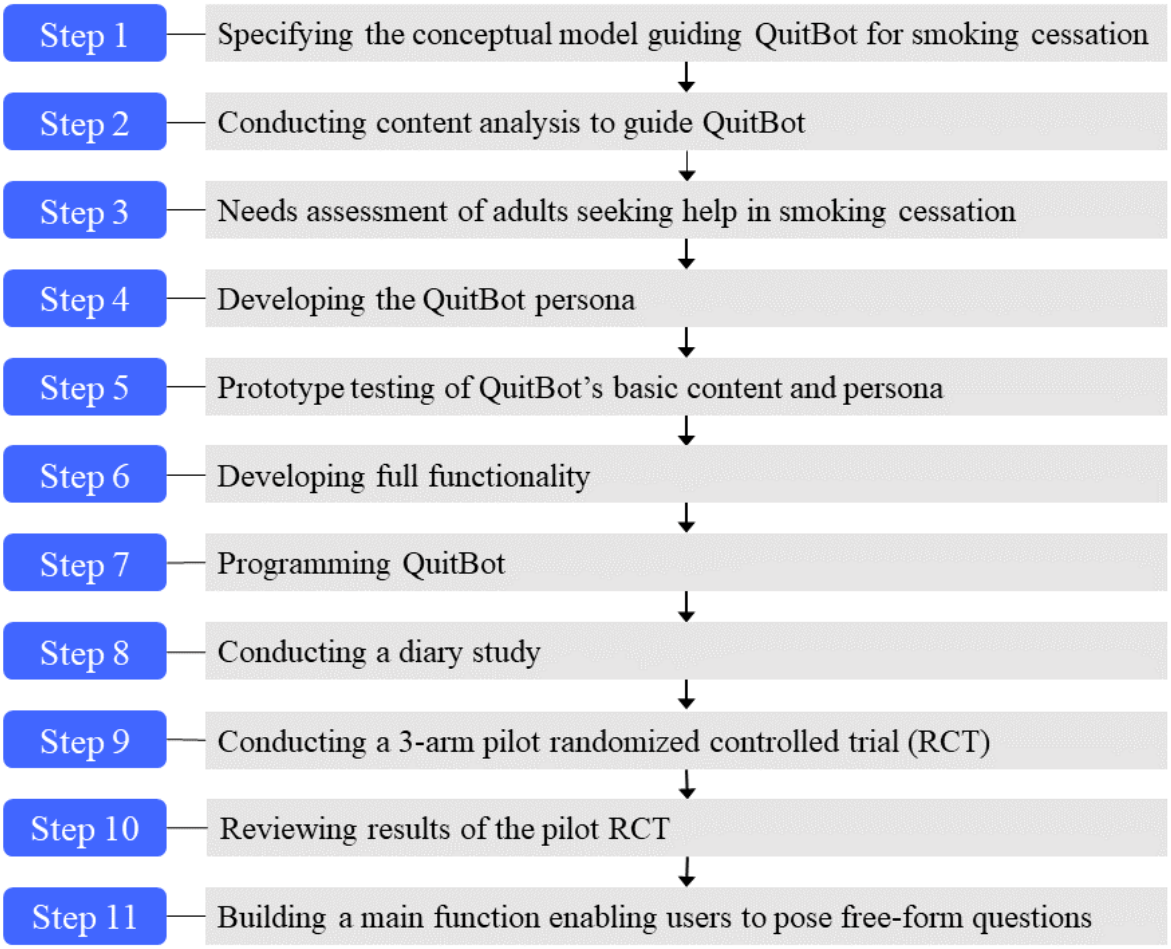
Methods

Overview of the Formative Research Process

The 4 years of formative research for developing QuitBot followed an 11-step process, consistent with a user-centered design framework (Figure 1) [37,38].

The steps were as follows: (1) specifying a conceptual model to guide the QuitBot intervention targets; (2) conducting content analysis of existing smoking cessation interventions to guide the QuitBot coaching conversations; (3) conducting a needs assessment to determine what an adult seeking help in quitting smoking would need from a cessation chatbot; (4) developing the QuitBot persona, or personality of the chatbot, to shape the user's experience of and bond with the QuitBot chatbot; (5) prototyping QuitBot's basic content and persona; (6) developing the full functionality of the QuitBot; (7) programming the QuitBot; (8) conducting a diary study for user feedback on their interactions with QuitBot and its design and content; (9) conducting a pilot RCT to test QuitBot for smoking cessation; (10) reviewing results of the pilot RCT; and (11) adding a free-form question and answer (QnA) function, based on user feedback from pilot RCT results. The process of adding the QnA function itself involved a three-step process: (1) generating QnA pairs, (2) fine-tuning LLMs on the QnA pairs, and (3) evaluating the LLM model outputs.

Figure 1. Overview of QuitBot's formative research process.



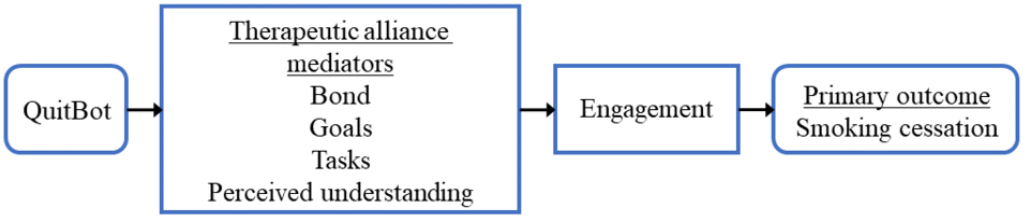
Step 1: Specifying the Conceptual Model Guiding QuitBot for Smoking Cessation

The conceptual model guiding the development of QuitBot for smoking cessation (Figure 2) focuses on impacting user engagement through 4 therapeutic alliance processes. The four processes are as follows: (1) *bond* with QuitBot, (2) agreement on smoking cessation *goal*, (3) agreement on *tasks* for achieving smoking cessation goal, and (4) *perception that QuitBot understands* user's current needs [18].

These working alliance processes have predicted smoking cessation [39] and quit attempts [40] and have mediated the impact of human therapist–delivered smoking cessation interventions [40]. QuitBot uses various strategies to establish a therapeutic alliance, including expressing empathy for the user's struggles [41,42], engaging in social dialogue [43,44], using metarelational communication (ie, discuss the relationship) [45], and expressing happiness while interacting with the user [42]. Language constructs such as inclusive pronouns [41], politeness strategies [46], and the use of greetings and farewells rituals [47] contribute to the creation of this alliance as well. Compared to a technology that did not use these verbal behaviors, a conversational chatbot for physical activity increased these therapeutic alliance processes, which in turn was predictive of higher engagement with the chatbot [48].

Agreement on smoking cessation goal starts by collaboratively setting a quit date (eg, "Have you thought about a specific day you would like to quit? Generally, I recommend about 14 days away."). QuitBot enhances perceived understanding by promptly addressing the user's immediate needs (eg, "You say you are tempted by friends who smoke. Here's a tip that might help..."). In addition, self-disclosure [49] is used to foster perceived understanding, generating various positive outcomes, especially when the listener responds with support and validation [50]. A chatbot that used self-disclosure increased the user's perception that the chatbot understood their needs, which in turn predicted more positive mood [51].

Figure 2. Conceptual model of QuitBot for smoking cessation.



Step 2: Conducting Content Analysis to Guide QuitBot

The content analysis aimed to establish a natural flow of coaching conversations for QuitBot, aligned with US Clinical Practice Guidelines for smoking cessation [52]. In the initial phase of the content analysis, we interviewed a panel of experts, including 3 smoking cessation counselors, a smoking cessation master trainer, and a tobacco cessation scientist from our team. This panel consisted of 4 women and 1 man, with 20% (1/5) from racial and ethnic minority backgrounds. Among them, 40% (2/5) held a PhD in clinical psychology, while 60% (3/5) had master's degrees in counseling or social work. Collectively, they had a wealth of experience ranging from 3 to 20 years, with an average of 8 (SD 4.6) years, in developing and delivering smoking cessation interventions. Deductive coding of these interviews and expert consensus iteratively lead to the formulation of common themes, domain-specific responses, and anticipated user interactions that QuitBot should address. We identified common conversation topics about smoking cessation, including triggers to smoke (ie, physical, emotional, and situational triggers), motivations to quit, and barriers to quitting. Interviews also highlighted the importance of QuitBot's persona to be sensitive and empathetic to the user and to express that their concerns are being heard.

Guided by this expert consensus on conversation topics, the second phase was to extract the content and flow of smoking interventions as they naturally occur in actual interactions between cessation counselors and patients. To achieve this, we conducted semantic analysis of verbatim manually transcribed intervention conversation transcripts obtained from our telephone counseling intervention trial, randomly selected among those who did and did not quit smoking (R01 DA038411) [53]. A total of 159 call transcripts (equating to 63 h and 23 min) from 117 unique participants were randomly selected, constituting a 7.8% (159/2038) sample from each of the 5 sessions (with an average session duration of 22.9 min) of an efficacious behavioral intervention for smoking cessation with a 25% thirty-day point prevalence abstinence (PPA) rate at the 12-month follow-up [53]. These sessions covered various topics, including motivations to quit, triggers to smoke, barriers to quitting, setting a quit date, developing a quit plan, education and proper use of Food and Drug Administration (FDA)–approved medications for quitting smoking, coping skills for dealing with urges, enlisting social support, and strategies for avoiding external cues to smoke. Participants had a mean age of 47.4 (SD 12.7) years, with 43.6% (51/117) male participants and 21.4% (25/117) from racial and ethnic minority backgrounds.

Transcripts underwent deductive coding using a predefined codebook to identify common conversation topics related to smoking cessation, such as triggers to smoke (ie, physical, emotional, and situational triggers), motivations to quit, and barriers to quitting. Using a supervised machine learning approach, these topics formed the basis of QuitBot's entity extraction, wherein elements of the unstructured transcript text were coded into predefined categories. Subsequently, we determined intent classifications, which involved discerning the meaning of the user's text. Finally, we mapped out the natural conversational flow of both the chatbot and the range of verbal responses and comments that users might provide in response to the chatbot. The entity extraction, intent classifications, and conversational mapping were conducted using the LUIS conversational artificial intelligence (AI) program [54].

Step 3: Needs Assessment of Adults Seeking Help in Smoking Cessation

Assessing the needs of adults seeking help in smoking cessation interventions shapes what the user should be able to do with a chatbot. To assess user needs, we first analyzed the results of the content analysis phase. Subsequently, we conducted interviews with 5 adults who had participated in our human-delivered smoking cessation interventions within the past year (including 2 who quit and 3 who did not quit) [55]. Participants had a mean age of 46.1 (SD 10.4) years, with 40% (2/5) female participants and 40% (2/5) from racial and ethnic minority backgrounds. The interviews queried participants about their personal background and smoking history, expectations for a smoking cessation program, experiences with a human cessation coach, perceptions regarding setting, keeping and changing quit dates, coping skills for urges to smoke, and attitudes toward and expectations of what a chatbot could do for helping them quit smoking. Semistructured interviews were conducted in person at the lead author's user experience (UX) Research HABIT laboratory. The deductive thematic analysis organized the user's responses by grouping them into themes,

reviewing the themes, and then interpreting them [56-58]. The themes of the key user needs identified were (1) a coach who can make a personal connection, (2) on-demand help with urges, and (3) skills for preparation to quit and preventing relapse.

Step 4: Developing the QuitBot "Persona"

The user's bond with the chatbot is impacted by its persona [48]. On the basis of interviews with smoking cessation coaches and our master trainer, we created the persona to foster a strong bond with users. Presented to the user as a computer program (eg, "I'm a bot designed to help you live smoke free"), elements of the QuitBot persona included expressions of empathy [41,42], social dialogue [43,44], metarelational communication (ie, discuss the relationship) [45], and expressing happiness to see the user [42]. In addition, specific language constructs, including inclusive pronouns [41], politeness strategies [46], and greetings and farewells rituals, were integrated to enhance the UX and promote a respectful dialogue [47]. Finally, we established 11 core values for the persona, serve as guiding principles for QuitBot's behavior throughout conversations.

Step 5: Prototype Testing of QuitBot's Basic Content and Persona

The prototyping testing of QuitBot's basic content and persona aimed to assess users' initial responses to basic smoking cessation conversations between the user and the persona. Stimuli were built using botmock [59,60] to develop the chat dialogue, which was then integrated into Facebook Messenger (FM; Meta Platforms, Inc) using Chatfuel [61]. Participants had a guided initial chat conversation introducing the chatbot and program goals, querying about triggers for smoking, and setting a quit date. Subsequently, they interacted with QuitBot for a second conversation, focusing on tracking triggers to smoke. For both conversations, a UX researcher frequently paused to prompt participants to think-aloud their experiences with QuitBot. Real-time interactions between the user and QuitBot were facilitated by a UX researcher using the Chatfuel program [61]. To evaluate this process, 75-minute individual interviews were conducted with 8 adults interested in quitting smoking. Four were chosen because they thought a chatbot could be helpful for quitting smoking, while the remaining 4 were selected because they were unsure or skeptical that a chatbot would be helpful for quitting smoking. The mean age of the participants was 42 (SD 11.1) years, with 38% (3/8) male participants, 50% (4/8) female participants, and 12% (1/8) transgender participants. In addition, 38% (3/8) of the participants had high school education or less and 25% (2/8) reported being from racial or ethnic minority backgrounds.

Semistructured Interviews

Semistructured interviews were conducted in person at the lead author's UX Research HABIT laboratory. A deductive thematic analysis method was used to organize user responses into themes, review those themes, and then interpret them [56-58]. Despite initial skepticism from half of participants (4/8, 50%) regarding the usefulness of interacting with a digital coach, the results showed a notable shift in the interest in QuitBot by the end of the interview: 100% (8/8) reported that a chatbot such as QuitBot would be valuable for helping someone quit smoking, with 88% (7/8) expressing willingness to try this chatbot for quitting. In addition, all participants (8/8, 100%) found QuitBot easy to use, noting its conversational tone as "encouraging," "polite," and "reassuring." They deemed the length and speed of onboarding conversations appropriate and felt comfortable providing conversational responses. Participants expressed surprise at the "humanness" of QuitBot's avatar, noting its informal, reassuring, accessible, and easy-to-talk-to demeanor.

When discussing whether the avatar should have a gender or a name, there was consensus among participants in favor of a female persona, with the name "Ellen" deemed appropriate (interestingly, one of the initial participants spontaneously suggested "How about a woman named 'Ellen'?"). Later participants concurred with this choice when asked by the UX researcher.

Participants also expressed a desire for more actionable suggestions and to open and close each conversation with a specific plan of action. In response, we added a plan outlining what to anticipate, letting them know that the avatar would initiate a chat the following day and introduce a new quitting smoking skill in the subsequent conversation. Some participants wanted additional time to decide on a quit date, prompting us to include a dialogue indicating that they postponed setting a quit date until they felt ready. In addition, participants suggested visualizing their progress in quitting smoking, such as through a graph. In response, we added a progress chart displaying the number of cigarettes smoked over time. Overall, participants described feeling "captivated" by the content and expressed eagerness to learn more.

Step 6: Developing Full Functionality

Building upon the prototype as the foundation, we applied insights from the earlier steps to develop a full program consisting of 42 days of 2- to 3-minute focused conversations. These conversations were distributed over several phases of treatment: a prequit phase (14 days of content), quit day (1 day of content), and postquit phase (27 days of content). There are also conversations for those not ready to quit smoking by day 14 (6 days of content) and conversations for those who have relapsed (3 days of content). The content, described in Textboxes 1 and 2, follows US Clinical Practice Guidelines for cessation interventions [62]. The program content was presented as a continuous conversation, built on user input from prior conversations. This ensures a personalized and adaptive approach based on the user's stated motivations to quit, triggers to smoke, and number of cigarettes smoked. QuitBot was proactive and provided daily prompts to start a structured text conversation with Ellen at the user's preferred time, such as "Hi Alex, are you free to chat?" Users also had the flexibility to reach out to Ellen at any time for on-demand help with urges, inspiration, mood, and slips.

Textbox 1. QuitBot and SmokefreeTXT (SFT): phases and corresponding content.

Phase (number of days) and content of both SFT and QuitBot

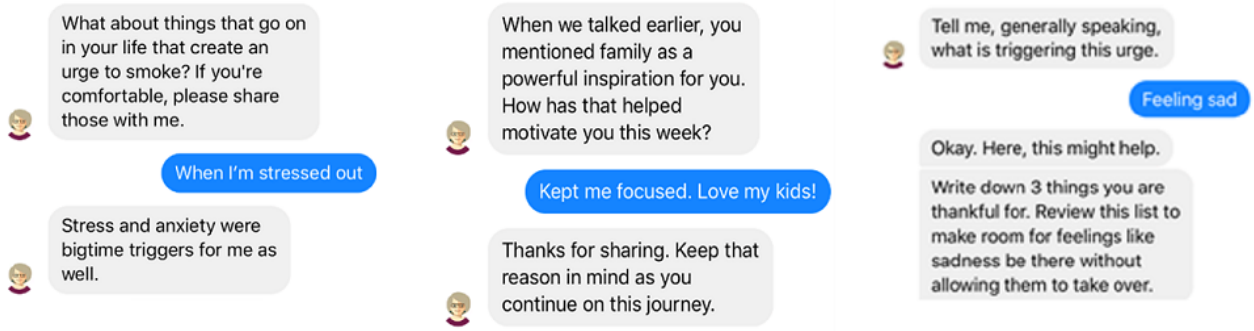
- Prequit day (14 days)
  - Triggers to smoke, motivations for quitting, setting a quit date, Food and Drug Administration–approved medication information, skills to be aware of and cope with urges, and cessation progress tracking
- Quit day (1 day)
  - Encouragement and smoking status check-in
- Postquit (28 days)
  - Withdrawal symptoms education, slips and relapse prevention, managing mood, managing cravings, and cessation progress tracking
- Not ready or quit date >14 days
  - Reviews motivations for quitting and cessation progress tracking
- Anytime help
  - Skills to cope with urges, mood, and slips

Textbox 2. Content communication.

How content is communicated: SmokefreeTXT (SFT) and QuitBot

- SFT: sends texts of the content, answers to daily check-ins (eg, number of cigarettes smoked today), get 1-2 text responses, answers to entering anytime help keywords (eg, “CRAVE”), and get 1 text response
- QuitBot: digital coach sends the user a greeting to start a 2- to 3-minute conversation, presents content in a dialogue with the user via engagement features described in Figure 3 (eg, tailored responses and empathy), and answers to entering anytime help keywords (eg, “CRAVE”) initiate a dialogue

Figure 3. Representative functionalities of QuitBot include (A) determining triggers, (B) maintaining motivation, and (C) providing anytime urge help.



Step 7: Programming QuitBot

We initially sought a development architecture with the flexibility to interact with QuitBot on any major consumer communication channel (eg, as a stand-alone app, FM, and Slack). Such flexibility adapts to current consumer trends in communication technology use, making QuitBot available for use on the channels with current high population-level reach. To determine which communication channel would be used for interacting with QuitBot, we conducted a web-based survey of 100 US adults who smoke, asking them which of these channels they would prefer for a chatbot: stand-alone app, WhatsApp (Meta Platforms, Inc), FM (Meta Platforms, Inc), Skype (Skype, Inc), or Slack (Slack Technologies, LLC). The majority of respondents (74/100, 74%) preferred FM, citing its familiarity, ubiquity, and ease of use. FM is an instant messaging service for online chats. At the time of the study (ie, 2019), there were >133 million FM users in the United States (1.3 billion globally) and FM hosts >300,000 chatbots, with 27% of them for health care (eg, exercise) [63-65]. Following these findings, we hosted QuitBot on FM.

Therefore, we custom built an architecture using the Microsoft Bot Framework that uses Microsoft Azure for the cloud computing and Microsoft Language Understanding (LUIS) platform for the natural language understanding of the QuitBot guide *Ellen*. The preference for natural language understanding over an if-then decision-based conversation flow was made to ensure a more natural and open-ended interaction, allowing a broad range of responses and better conveying that the user is being heard and understood. QuitBot's LUIS allows it to understand common text shorthand. Users can respond freely

or simply select from a menu of responses. If QuitBot does not understand a free response, it will say so and ask the participant to rephrase the response. QuitBot was written in the programming language of Node.js [66].

Step 8: Conducting a Diary Study

We conducted a diary study to obtain ongoing feedback on users' interactions with QuitBot, its design, and content. In user-centered design research, a diary study of 2 weeks with 6 to 12 participants is recommended to obtain this initial feedback [67,68]. Accordingly, we conducted a single-arm 14-day diary study of the program with 9 adults who were smoking at least daily (all smoked ≥30 cigarettes/d), were interested in quitting smoking, and recruited from around the United States via Facebook advertisements. Four were chosen because they were skeptical about chatbots being able to help someone quit smoking, while the remaining 5 were neutral about them. Participant demographics were as follows: mean age 40.4 (SD 13.4) years, 11% (1/9) from racial and ethnic minority backgrounds, 44% (4/9) female, and 67% (6/9) had less than a bachelor's degree.

All 9 participants completed the following: (1) the 60-minute video-based orientation focusing on how to use QuitBot and complete the daily diary entries; (2) 14 evening diary entries (15 min each) about their daily interactions with QuitBot, its design, and content; (3) on day 7, a midpoint 15-minute video call with a member of our user research team to review their impressions to date; and (4) a 60-minute video call exit interview with a member of our user research team. A PhD-level UX researcher with >20 years of experience conducted the interviews. (Example questions from the exit interview are as follows: "Which parts of the app did you find the most helpful? Why?") Semistructured interviews were conducted in person at the lead author's UX Research HABIT laboratory. The deductive thematic analysis organized the user's responses by grouping them into themes, reviewing the themes, and then interpreting them [56-58].

The results showed that, although the focus was on usability, by day 14, three participants quit smoking and the remaining 6 participants reduced to 3 or 4 cigarettes per day. Ratings for usefulness ("Overall, how useful was the QuitBot app for helping you quit smoking?"), satisfaction ("Overall, how satisfied were you with the QuitBot?"), and likelihood of recommending QuitBot ("To what extent would you recommend QuitBot to someone who would like to quit smoking?") were all high: 4.33, 4.67, and 4.88, respectively, on a 0 (not all) to 5 (extremely) scale. All 9 users felt highly supported by Ellen and liked her persona. They liked the skills training for coping with smoking urges and lapses. Their feedback yielded minor content edits and fixes of technical bugs. Representative functionalities of QuitBot are shown in Figure 3.

Diversity and Inclusion in UX Design

The diversity of race, gender, age, and educational characteristics of users who participated in our UX design studies influenced the design in many ways, including Ellen's persona design (eg, men and women both preferred a female persona), Ellen's stories of people who have quit smoking (eg, they were diverse in age, gender, race, and education), use of language (eg, fifth-grade reading level, informal, and respectful), and user interface (eg, larger response buttons and larger font size [69]).

Step 9: Conducting a 3-Arm Pilot RCT

The favorable feedback from the diary study led us to conduct a 3-arm parallel pilot RCT comparing QuitBot (n=200) to the SmokefreeTXT (SFT; n=149) intervention and to a QuitBot delayed access control group (n=55). Following expert recommendations for pilot RCT design [70,71], the feasibility outcomes were the study's primary focus to inform the further development of QuitBot and design of a future full-scale trial of QuitBot. As this pilot RCT was the first time QuitBot was tested and no prior RCTs had been reported on any quit smoking chatbot, estimated effect sizes were unknown. Instead, the sample sizes were based on comparable sample sizes from prior pilot studies we had conducted in our laboratory [72,73]. Participants were recruited nationwide and were randomized to the intervention arm using randomly permuted blocks of size 2, 4, and 6, stratified by biological sex (male vs female), heaviness of smoking index score (≤4 vs >4), and percent confidence in being smoke-free in 12 months (≤70% vs >70%). The study was double-blinded, with both interventions called "QuitBot."

Ethical Considerations

All study procedures were approved by the Fred Hutch Cancer Center Institutional Review Board (8659/RG1001766). The clinical trial protocol was approved by the Fred Hutch Scientific Review Committee (FHIRB008659), and the trial was registered on ClinicalTrials.gov (NCT03585231). There were no deviations to the registered protocol. All study participants provided informed consent, and data were deidentified for privacy and confidentiality.

Eligibility Criteria for the Pilot RCT

The inclusion criteria were as follows: (1) age ≥18 years; (2) having smoked at least 1 cigarette a day for at least the past 12 months; (3) wanting to quit cigarette smoking within the next 14 days; (4) if concurrently using any other nicotine or tobacco products, wanting to quit using them within the next 14 days; (5) being interested in learning skills to quit smoking; (6) being willing to be randomly assigned to either condition; (7) residing in the United States; (8) having daily access to their own smartphone; (9) having both SMS text messaging and FM on their smartphone (criteria 8 and 9 were required to receive each interventions' content); (10) being willing and able to read in English; and (11) not using other smoking cessation interventions. Individuals deemed ineligible to participate were directed to the smokefree.gov website and the 800-QUIT-NOW number for access to their state's quitline resources.

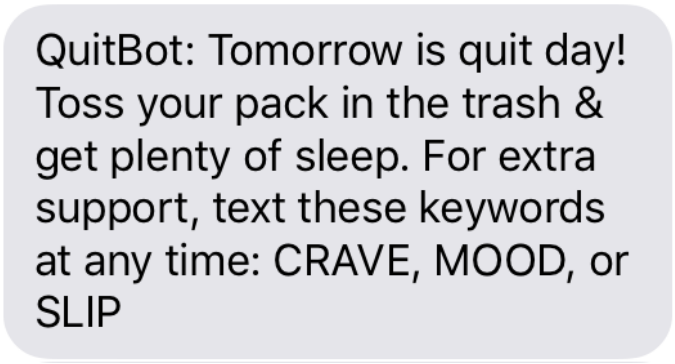
SFT Comparison Condition

For the past 20 years, mobile phone–delivered SMS text messaging interventions have been a prominent technology for delivering smoking cessation interventions [74-78]. Each year, SMS text messaging smoking cessation interventions are reaching >300,000 US adults who smoke and 6 million adults who smoke worldwide [79,80]. SFT's 42-day program was

developed by the National Cancer Institute (NCI). SFT is the most widely accessible SMS text messaging program in the United States. SFT is nonproprietary and free to the public, thereby providing maximal accessibility and replicability. Daily messages are sent about the importance of quitting smoking, setting a quit date, preparing to quit, quitting, and maintaining abstinence. Daily messages check in about quit status. Three keywords can be proactively sent by users to receive help anytime: "CRAVE" (on how to cope with urges), "MOOD" (on how to cope with moods triggering smoking), and "SLIP" (on how to cope with lapses). Participants do not need to respond to or otherwise engage with SFT messages to complete the SFT program. Refer to Figure 4 for sample messages.

NCI's SFT contractor (ICF International [81]) provided us with the full content of SFT so that we could internally host a secured private version for research. In both SFT and QuitBot, participants receive 2 prompts per day (3 on the quit day). Comparisons between QuitBot and SFT are shown in Textboxes 1 and 2.

Figure 4. Sample SmokefreeTXT text message.



QuitBot Delayed Access Comparison Condition

To explore the unique impact of QuitBot on smoking cessation, considering that some participants might quit smoking without intervention, we introduced a delayed access comparison condition. In this condition, 55 participants received delayed access to QuitBot after completing the 3-month follow-up survey. The delayed access comparison condition served the ethical purpose of providing participants access to a treatment (as opposed to no treatment at all).

Outcome Measures

Outcome data were collected through an encrypted web-based survey. Participants not completing the web-based survey were sequentially offered the survey via phone, mailed survey, and postcard. The primary feasibility outcomes were (1) sufficient accrual of the planned number of study participants, (2) balanced demographic and smoking characteristics at baseline between study arms, and (3) retention of the primary 30-day PPA smoking outcome at the 3-month follow-up. Intervention engagement was assessed based on comparing the active treatment study arms on the number of times and number of days participants interacted with their assigned intervention. All interactions with the participants' assigned interventions were objectively logged using an internally hosted secure server. The primary smoking cessation outcome was 30-day PPA, based on compete-case analysis, and 7-day complete-case PPA was secondary.

Statistical Analysis for the Pilot RCT

The feasibility of the pilot RCT was assessed based on sufficient accrual, balanced randomization, and adequate follow-up data retention rates that did not differ between arms. Baseline characteristics were compared between the 3 study arms using ANOVA for continuous variables and Fisher exact tests for categorical variables and were summarized with the "arsenal" package in R (version 4.2.3; R Foundation for Statistical Computing) [82,83]. We used generalized linear models to assess differences between study arms in the number of days participants used their intervention.

We used negative binomial models, implemented with the R package "MASS" [84], to compare treatment arms on total number interactions because the data were heavily right-skewed. Logistic regression models were used to test the effect of the treatment arm on binary smoking cessation outcomes. On the basis of evidence from meta-analyses of SMS text messaging trials [85], all outcome models were adjusted for the 3 factors used in stratified randomization: biological sex (male vs female), heaviness of smoking index score (≤4 vs >4), and percent confidence in being smoke-free in 12 months (≤70% vs >70%). Wald tests for pairwise comparisons of each outcome between study arms were adjusted for multiple comparisons with the Holm procedure [86]. Statistical tests were considered significant at $\alpha<.05$. Deductive thematic analysis organized participants' comments about QuitBot by grouping them into themes, reviewing the themes, and then interpreting them [56-58].

Results

Step 10: Main Results of the Pilot RCT

Recruitment Was Successful

On the basis of our successful methods for national recruitment [87], we developed and tailored Facebook advertisements with ongoing monitoring and adjustment of recruitment yield. These efforts resulted in screening 2954 participants, with 1380 eligible, 583 consenting, and 418 randomized between September 2018 and June 2019. After the completion of study participation, 14 participants were found to be cases of fraud, duplicate participants, or in the same household as another

participant, leading to a total of 404 participants included in analyses.

Randomization

The 3 stratification conditions were balanced at baseline on all measured characteristics (all *P* values >.05). As shown in Table 1, participants were on average 36 years old, 70% (283/404) were women, 28.9% (116/401) reported being from racial or ethnic minority backgrounds, 52.7% (213/404) were unemployed, 83.9% (339/404) had no college degree, 71.5% (289/404) smoked more than one-half pack daily, and 59.9% (242/404) had high cigarette dependence (Fagerström Test for Cigarette Dependence scores of ≥6). The characteristics of this FM sample are very similar to those of other digital health intervention trials [85,88,90].

Table 1. Baseline participant characteristics by study arm.

Characteristic	Total (n=404)	SmokefreeTXT (n=149)	Delayed (n=55)	QuitBot (n=200)	*P* value
Baseline characteristic					
Age (y), mean (SD)	36.0 (10.4)	36.2 (11.2)	35.6 (9.6)	35.9 (9.9)	.92
Gender, n (%)					
Woman	283 (70)	103 (69.1)	39 (70.9)	141 (70.5)	.95
Man	121 (30)	46 (30.1)	16 (29.1)	59 (29.5)	
Race, n (%)					.52
Asian	2 (0.5)	0 (0)	0 (0.0)	2 (1)	
Black or African American	51 (12.6)	21 (14.1)	9 (16.4)	21 (10.5)	
Native American or Alaska Native	12 (3)	4 (2.7)	0 (0)	8 (4)	
Native Hawaiian or Pacific Islander	1 (0.2)	0 (0)	0 (0)	1 (0.5)	
White	296 (73.3)	110 (73.8)	40 (72.7)	146 (73)	
Multiple races	31 (7.7)	13 (8.7)	4 (7.3)	14 (7)	
Unknown race	11 (2.7)	1 (0.7)	2 (3.6)	8 (4)	
Hispanic ethnicity, n (%)	28 (6.9)	7 (4.7)	6 (10.9)	15 (7.5)	.27
Minority race or ethnicity (n=401), n (%)	116 (28.9)	42 (28.2)	17 (30.9)	57 (28.9)	.93
Married, n (%)	104 (25.7)	32 (21.5)	16 (29.1)	56 (28)	.32
Employed, n (%)	191 (47.3)	80 (53.7)	24 (43.6)	87 (43.5)	.14
No college degree, n (%)	339 (83.9)	126 (84.6)	47 (85.5)	166 (83)	.87
Heavy alcohol use (n=395), n (%)	47 (11.9)	18 (12.5)	6 (11.3)	23 (11.6)	.96
Positive depression screening results (n=402), n (%)	223 (55.5)	91 (61.5)	28 (50.9)	104 (52.3)	.17
Smoking behavior					
FTCD[a] score, mean (SD)	5.7 (2.0)	5.5 (2.0)	6.1 (2.2)	5.7 (2.0)	.17
High nicotine dependence, n (%)	242 (59.9)	88 (59.1)	36 (65.5)	118 (59)	.66
Smokes more than one-half pack per day, n (%)	289 (71.5)	98 (65.8)	42 (76.4)	149 (74.5)	.14
Smokes >1 pack per day, n (%)	66 (16.3)	20 (13.4)	14 (25.5)	32 (16)	.11
First cigarette within 5 minutes of waking, n (%)	205 (50.7)	75 (50.3)	34 (61.8)	96 (48)	.19
Smoked for ≥10 years, n (%)	317 (78.5)	112 (75.2)	44 (80)	161 (80.5)	.46
Used e-cigarettes at least once in the past month, n (%)	122 (30.2)	42 (28.2)	16 (29.1)	64 (32)	.73
Quit attempts in the past 12 months (n=377), mean (SD)	1.6 (4.7)	1.6 (3.3)	1.1 (3.2)	1.7 (5.8)	.68
At least 1 quit attempt in the past 12 months (n=377), n (%)	145 (38.5)	51 (37.8)	16 (30.2)	78 (41.3)	.33
Confidence to quit smoking, mean (SD)	64.1 (27.0)	62.6 (27.0)	72.2 (27.3)	62.9 (26.8)	.05
Friend and partner smoking					
Close friends who smoke, mean (SD)	2.8 (1.7)	2.8 (1.7)	2.7 (1.6)	2.8 (1.8)	.97
Number of adults in home who smoke, mean (SD)	1.5 (0.9)	1.4 (0.9)	1.7 (1.1)	1.5 (0.8)	.19
Living with partner who smokes, n (%)	145 (35.9)	51 (34.2)	24 (43.6)	70 (35)	.43

[a]FTCD: Fagerström Test for Cigarette Dependence.

The 3-Month Follow-Up Rates Were High

To maximize outcome data completion, we followed our team's successful protocol [87]: 4 sequential survey modalities (first web, followed by phone, mail, and postcard). As agreed in the informed consent, participants received US $25 for submitting their responses and received an additional US $10 bonus for completing the web survey within 24 hours. The achieved *outcome survey completion rate of 96%* provided confidence in the follow-up survey methods. The data retention did not

differ between study arms (*P*=.54). Given the limitations of the pilot budget, cessation data were self-reported.

Engagement and Cessation Results Were Promising for QuitBot

The number of times participants interacted with their assigned intervention was 1.3 times greater in QuitBot as compared to SFT (incidence rate ratio 1.33, 95% CI 1.04-1.70; *P*=.02; Table 2). Participants used their assigned intervention 11 days longer in the QuitBot arm than in the SFT arm (point estimate 11.5, 95% CI 4.9-18.1; *P*=.001). QuitBot's intervention completion results are substantial when considering that each day's content involved a 2- to 3-minute conversation. (By contrast, SFT participants did not need to respond to or otherwise engage at all with their messages to complete their program; daily SFT text messages were sent automatically.) Participant engagement was limited by QuitBot's inability to answer participants' open-ended questions (see the *Representative QuitBot Comments* section). Therefore, cessation results are reported for all participants and for participants who completed their assigned intervention.

For all participants, the 30-day PPA rates at 3-month follow-up were 31.1% (59/190) for QuitBot versus 34.7% (50/144) for SFT (QuitBot vs SFT: odds ratio [OR] 0.81, 95% CI 0.50-1.29; *P*=.36; Table 3) versus 7% (4/54) for delayed treatment (QuitBot vs delayed: OR 5.97, 95% CI 2.04-17.45; *P*=.002). For those who completed their assigned intervention (ie, viewed all 42 days of planned content), the 30-day, complete-case, PPA rates at 3-month follow-up were 63% (39/62) for QuitBot versus 38.5% (45/117) for SFT (QuitBot vs SFT: OR 2.58, 95% CI 1.34-4.99; *P*=.005). The pattern of results was highly similar for the outcome of 7-day, complete-case, PPA rates at 3-month follow-up, albeit with higher abstinence rates in each study arm.

Table 2. Comparison of QuitBot and SmokefreeTXT (SFT) interventions on 3-month engagement outcomes.

Study engagement outcome	SFT (n=149), mean (SD; median)	QuitBot (n=200), mean (SD; median)	QuitBot vs SFT			
			IRR[a] (95% CI)	*P* value	PE[b] (95% CI)	*P* value
Number of times interacted (n=266)	24.2 (25.8; 15)	32.9 (29.0; 25)	1.33 (1.04-1.70)	.02	—[c]	—
Days from randomization to last input	44.1 (22.7; 54)	55.7 (36.0; 70)	—	—	11.5 (4.9-18.1)	<.001

Representative QuitBot Comments

Comments from QuitBot arm trial participants reflected a strong overall bond with the chatbot's persona:

> *I loved Ellen. She was always there when I needed her.*
>
> *Ellen was always there for me when I had a craving.*
>
> *I love how engaged she was, I could really quit with her there to talk to.*
>
> *She made me feel like I was not alone.*
>
> *She was there without making me feel ashamed.*
>
> *She was kind, nonjudgmental.*
>
> *She held me accountable.*
>
> *Felt like a friend encouraging me.*

Conversely, participants were frustrated by QuitBot's inability to respond to their specific questions about quitting smoking:

> *I could not ask questions and get real answers back.*

I could not ask it real live questions.

I wanted to write my own questions.

Can't ask any question.

Not being able to respond to my questions.

I wish you could talk to her...without it being a constant couple of options.

I didn't like how it selected responses.

The fact that you cannot ask a question and [it] has no idea what you are saying unless you select one of the options.

Main Conclusions From the Pilot RCT

Our main conclusions were as follows: (1) the intervention demonstrated potential for rigorous testing based on sufficient accrual, balanced randomization, and high retention rates; (2) overall, there was a strong engagement with QuitBot; and (3) promising quit rates were observed, particularly among participants who completed the content of their assigned intervention. The effectiveness of QuitBot was evident, as quit rates in the delayed condition group were significantly lower (59/190, 31.1% vs 4/54, 7%; *P*=.002), indicating a net percentage point increase in smoking cessation of 24%. Therefore, it is highly unlikely that effects of QuitBot were merely due to the passage of time or baseline motivation to quit smoking (ie, few participants quit without offering intervention).

Challenges were also identified, potentially impacting participant engagement and quit rates. Specifically, QuitBot's inability to respond to participants' own questions about quitting smoking led to a significant level of frustration. While the participant can answer questions asked by the QuitBot (eg, "Tell me what is triggering your urge."), the reverse was not possible: participants could not ask QuitBot their own questions. A QuitBot feature that allows participants to ask free-form questions would be needed to address this limitation.

Technical Limitations of the FM Platform

While FM was the preferred communication platform from our survey results, Facebook introduced changes that would limit participants' engagement with QuitBot as well as our own access to user data: (1) Facebook made policy changes that revoked access permissions to proactively outreach (eg, to invite participant to check in or start a conversation), effectively removing our ability to proactively contact users (restricting that ability to news-related apps only); and (2) Facebook made platform changes that restricted our ability to access demographic information of users, inhibiting data collection. Facebook's changes raised concerns about the feasibility of QuitBot's conversational functionality and data collection. This critical limitation could be addressed by transitioning to a stand-alone smartphone app communication platform, enhancing accessibility and control for both participants and the development and research teams.

Step 11: Building a Main Function Enabling Users to Pose Free-Form Questions About Smoking

Overview

The goal of this specific QuitBot refinement was to build a main function of QuitBot that would enable users to pose free-form questions about quitting cigarette smoking and for the QuitBot to respond with accurate, concise, professional, and nonrepetitive answers. This was an iterative 3-step process, which is detailed in Table 4.

Table 4. Steps, sources, and results of QuitBot's question and answer (QnA) iterative development process.

Step	Source (year)	Results
1. Generate QnA pairs	• Alexander Street therapy transcripts (2020) • National Cancer Institute call center transcripts (2020) • HABIT laboratory cessation counseling intervention transcripts (2020) • HABIT laboratory digital intervention content (2020) • HABIT laboratory clinical team generates QnA (2020-2021) • Prolific survey of adults who Smoke (2021)	• 11,000 smoking QnA pairs • 8223 chitchat QnA pairs
2. Training LLM[a] models on QnA pairs	• Azure application programming interface (2020-2023) • DialoGPT (2021) • ParlAI (2021) • Davinci GPT-3 (2021) • Curie GPT-3 (2021) • Ada GPT-3 (2021) • Contextualized GPT-3.5 (2022) • GPT-4.0 (2023)	• Models with higher self-scored confidence about answers provided: processed by Azure application programming interface • Models with lower self-scored confidence about answers provided: handled by Curie GPT-3 (2021) and replaced by contextualized GPT-3.5 (2022)
3. Evaluating LLM outputs	• Automated evaluation: pertinence and grammaticalness (2020-2023) • Manual evaluation: accuracy and tone (2021-2023) • 14-day user resting (2021)	• Identified the answers that were repetitive, incorrect, or had impersonal or nonprofessional tone

[a]LLM: large language model.

Step 11.1. Generating QnA Pairs

The first step was to develop a knowledge base of QnA pairs focused on the topics of quitting cigarette smoking. Smoking cessation clinical data sources included the Alexander Street data sets of counseling transcripts [90], NCI call center transcripts of smoking cessation coaching conversations [91], and transcripts of counseling sessions from our Fred Hutch Cancer Center research laboratory's prior smoking cessation intervention trials [53]. The categories of smoking cessation questions spanned a wide range, including medications to aid smoking cessation, the role of vaping e-cigarettes in quitting smoking, health consequences of smoking on self and others, staying motivated to quit smoking, triggers to smoke, barriers to quitting smoking, tips for managing cravings and withdrawal, and relapse prevention and recovery.

For generating a diversity of QnA sources, the knowledge base was broad, drawn from Alexander Street transcripts of therapy sessions [90], NCI call center transcripts of web-based Live Chats [91], Fred Hutch Cancer Center's HABIT laboratory cessation counseling intervention transcripts [53], written clinical content from HABIT laboratory digital smoking cessation interventions [92,93], and manual generation of questions and answers by HABIT laboratory clinical team members. We created a sequence-to-sequence (seq2seq) training model and processed cleaned transcripts, generating >8000 QnA pairs specifically focused on the topic of quitting cigarette smoking. As detailed in step 3, our evaluations led us to revisit step 1. In this iteration, we generated 2000 new questions posed by 32 adults interested in quitting cigarette smoking in a Prolific web-based survey. Then, our HABIT laboratory clinical team members generated answers to those questions. We also generated 1000 additional new questions from NCI call transcripts and transcripts related to our laboratory's intervention research. This iterative process yielded >11,000 QnA pairs.

Step 11.2. Training LLMs on QnA Pairs

The second step was to use these QnA pairs to train a series of LLMs. The first LLM deployed was an Azure application programming interface customized for the chatbot's 6-level chat architecture:

1. Motivations to quit smoking, triggers to smoke, and frequency of smoking
2. Dispatcher dialogue flow, to interpret and route utterances to the correct target, either Azure's 8000 QnA library or a custom AI model
3. QnA-maker-based "caring" personality chitchat to express empathy and provide supportive interactions with the user
4. QnA-based custom "help" to respond to trigger words such as suicide
5. Custom transformer-based model to handle chitchat QnA scenarios in dialogues that do not align with any specific intent
6. Custom transformer-based model designed to address smoking-related QnA scenarios in dialogues that do not align with any specific intent

In 2021, we tested 4 neural network models: a preexisting DialoGPT "Chitchat" model, 2 smoking content–trained DialoGPT models (1 trained on our 8000 QnA pairs and 1 on NCI chatlogs), and 1 smoking content–trained ParlAI model. We then accessed OpenAI's GPT-3 and conducted a comparative analysis of its model performance against our then best-performing model DialoGPT. GPT-3 outperformed the specially trained DialoGPT. Subsequently, to further improve GPT-3 performance, we compared the following model options: (1) Davinci, (2) Curie, and (3) fine-tuned Curie, concluding that the fine-tuned Curie model provided the best performance. Upon the release of GPT-3.5 (March 2022), we compared its performance with the fine-tuned GPT-3 Curie model [94]. This evaluation involved batch testing of questions that were not present in the QnA library, followed by a ranked review of answers (Textbox 3). GPT-3.5 provided better or comparable answer quality but required additional contextualizing parameters to match fine-tuned performance tailored for smoking-specific content.

Therefore, we used GPT-3.5 to expand the Azure QnA library by generating variations of existing questions and answers. This procedure expanded the Azure QnA library's capacity to accommodate a wider range of user question formulations, providing QuitBot with greater control over the quality of answers delivered to users.

Textbox 3. Comparisons of large language model answers to 3 sample questions on quitting smoking.

Sample question 1: "What is the quickest way to stop smoking?"

- Davinci: "The quickest way to stop smoking is to not start!"
- Curie: "Tapering down is the best way to stop smoking. Quitting smoking is a process. Make a quit plan and notice what triggers you to smoke."
- Fine-tuned Curie: "Our program was created to give you a plan that will work for you. We start by making a quit plan. Write down what inspires you to quit smoking. Choose a quit date and start cutting back on cigarettes."
- GPT-3.5: "The quickest way to stop smoking is to quit cold turkey, which means stopping smoking abruptly and without any aids such as nicotine replacement therapy or medication. However, quitting cold turkey can be difficult and the withdrawal symptoms can be challenging. We found that it works best to follow the program steps: make a quit plan and notice what triggers you to smoke. Then use quit smoking medication to help with withdrawal and use our tools to help urges pass as you quit gradually. Either way, it's important to find a method that works for you and stick with it."

Sample question 2: "I smoke when I am lonely. What should I do?"

- Davinci: "You are addicted to the nicotine in cigarettes. The only way to truly stop smoking is through nicotine replacements or prescription medications."
- Curie: "It's hard to feel lonely. Notice what thoughts and feelings are there and try not smoking them away."
- Fine-tuned Curie: "The first step is to make a quit plan. Write down what inspires you to quit smoking. Choose a quit date and start cutting back on cigarettes. Be aware of what triggers you to smoke."
- GPT-3.5: "It's hard to feel lonely. Notice what thoughts and feelings are there and try not smoking them away. Trying to be a friend to yourself in that moment and do something that would be nourishing to you."

Sample question 3: "Aren't e-cigarettes like the nicotine inhaler?"

- Davinci: "No, because unlike nicotine inhalers, e-cigarettes are used as simultaneous consumption of nicotine and air."
- Curie: "No. While e-cigarettes/vaping don't have the harmful contaminants of tobacco smoke they are not safe."
- Fine-tuned Curie: "They appear similar but are actually very different. The content of the nicotine inhaler is regulated by the FDA and when used stays mostly in throat and mouth. E-cigarettes are less harmful than regular cigarettes however, they are still addictive and contain noxious chemicals which can damage the heart and blood vessels."
- GPT-3.5: "Although they may look similar, the content of nicotine inhalers and e-cigarettes are actually different. The nicotine inhalers are regulated by the FDA and the nicotine content stays mostly in the throat and mouth. The e-cigarettes are not regulated, and the nicotine content can vary greatly, sometimes having more nicotine than a cigarette. They can also have other harmful substances besides nicotine. Because it is heated into a mist, the vapor goes into the lungs."

Step 11.3. Evaluating LLM Outputs

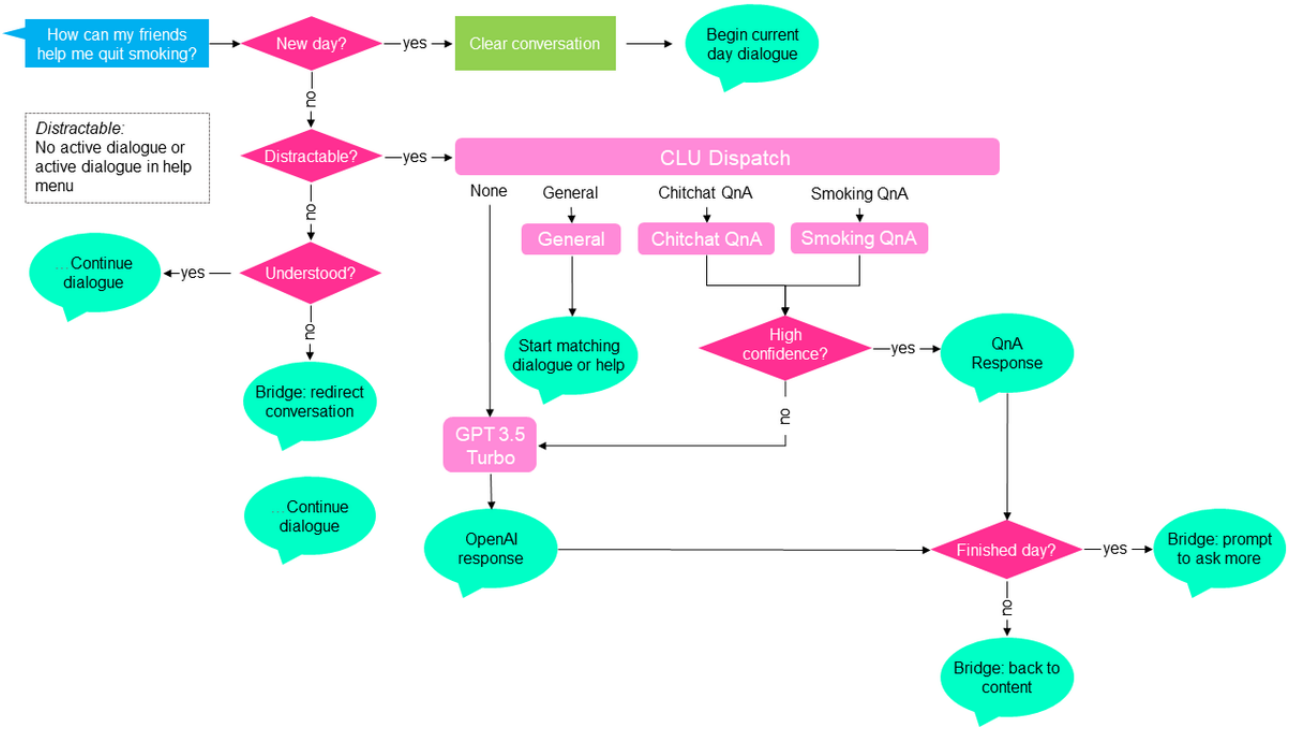
The third step in the development of the QuitBot's QnA feature involved evaluating the results of the LLMs using both automated and manual evaluation methods as well as user testing from adults who wanted to quit smoking. The automated evaluation used a scoring system of entropy (pertinence) and perplexity (grammaticalness) scores to rate the quality of answers generated by the LLMs. In addition, we implemented a filtering and scoring system to enhance the QuitBot's ability to communicate when it fails to comprehend a question. In such cases, the QuitBot asks users to be more specific if the confidence score for an answer falls below a certain threshold. The manual evaluation was conducted by trained raters in our HABIT laboratory, who hand scored the results of the models on measures of answer *accuracy* (yes or no), *repetitiveness* (yes or no), and *tone* (acceptable or needs improvement). Answers requiring improvement underwent manual revisions and were included into future iterations of model testing.

After retraining the model, in 2022, adults who smoke (n=14) were recruited from nationally placed Facebook advertisements to provide feedback on QuitBot prototype over a period of 14 days. Participant demographics were as follows: mean age 44.6 (SD 9.9) years, 43% (6/14) from minority race and ethnicity backgrounds, 64% (9/14) female, and 50% (7/14) had less than a bachelor's degree. A PhD-level UX researcher with 20 years of experience conducted the interviews. Deductive thematic analysis organized the user's responses by grouping them into themes, reviewing the themes, and then interpreting them [56-58].

Participants were highly receptive to the structured clinical conversations and noted that the free-form chats required additional fine-tuning to enhance comprehension of the users' questions. On the basis of this feedback, we determined the final organization of the chatbot architecture, combining 2 different models (Figure 5):

1. Microsoft's Azure QnA maker to handle questions matching our library of 11,000 QnA pairs that are based on scientific and clinical expertise. QnA maker uses Microsoft Language Understanding framework (LUIS) to leverage transformer models for responding to structured questions, with vetted answers stated in a professional manner.
2. Fine-tuned GPT-3.5 Turbo model to respond to questions that are not within our library of QnA pairs. Answers accurately with human-like variability, with different wording variations each time. GPT-3.5 is a backup to our QnA library.

Figure 5. QuitBot's architecture for handling free-form questions about quitting smoking. CLU: conversational language understanding; QnA: question and answer.



From the perspective of computer science, the QuitBot's chatbot's program runs on a *finite state machine* [95], which is a model of a system that runs on a limited set of modes. Depending on which mode the program is in, the QuitBot will behave in one manner or another. Ellen's state machine tracks what it is currently doing and combines interactions with the user to determine the next state. As the user can say anything, a hierarchy of possible intentions ranked by importance to the current state is used to decide the response to the user and the next state of the conversation.

A daily welcome exchange is an example. In this example, it is the start of the day and Ellen is in the "welcome" state. The user opens the app and says, "Hi!" To handle this prompt, the user's text goes through several steps in the finite state machine, illustrated in Figure 5: (1) categorize the user's intent; (2) determine if the intent is relevant to the current state of the conversation; (3) accordingly, move the current state of the conversation; and (4) formulate a response. In this case, "Hi!" is interpreted as a greeting intent, which is relevant to the current conversation. Ellen moves the state of conversation to "daily check-in" and responds with a greeting of her own, "Good morning. Thanks for checking in." When formulating a response, the user's intent determines which AI model will be used. General banter goes to a "chitchat" model powered by our Azure QnA library, smoking questions go to the Azure QnA model specifically trained on smoking questions, and unknown or low confidence intents go to GPT-3.5 Turbo. Finally, prewritten responses from our Azure QnA library that fit into the current conversation are used for specific scenarios.

Final Version of QuitBot

The final version of QuitBot is a stand-alone app that features (1) a personal coach (named "Ellen") who supports the user; (2) a series of 42 days of 2- to 3-minute structured clinical conversations with Ellen, guiding the user through distinct stages of quitting smoking; and (3) the ability for users to pose any free-form question related to quitting smoking. The structured conversations provide the valuable function of a clear step-by-step program for staying motivated, learning about one's triggers to smoke, setting a quit date, and staying smoke-free. Complementing the structured conversations, the free-form question feature provides users the freedom to ask their own questions, the option to address unique clinical needs, and the opportunity to follow-up on the content provided in the structured conversations. The combination of both structured and free-form conversation features is intended to balance their main strengths and limitations: the structured clinical format offers a guided program on quitting smoking, albeit with limited user question flexibility, while the open-ended format provides freedom but may encounter instances of not fully understanding the user's questions to give them clear guidance, despite the positive performance of the QnA feature thus far. Representative screenshots of QuitBot are provided in Multimedia Appendix 1.

Discussion

Principal Findings

This paper described the research group's 4-year process of developing a conversational chatbot for cigarette smoking cessation ("QuitBot"). The user-centered development process yielded a comprehensive quit smoking program that follows a series of 42 days of 2- to 3-minute structured clinical conversations. The program content covers topics ranging from motivations to quit, setting a quit date, choosing FDA-approved medications, identifying and coping with a wide range of triggers to smoke, and recovering from lapses or relapses. The program content, which follows the US Clinical Practice

Guidelines for smoking cessation, is presented as a continuous conversation, built on user input from prior conversations. QuitBot is available for both proactive and on-demand assistance at any time. Users can continue to interact with QuitBot after completing the 42 days of conversations.

Pilot RCT testing of QuitBot showed that the intervention had high user engagement and promising cessation rates, especially among participants who completed their assigned intervention. However, Facebook made policy changes that revoked access permissions to proactively outreach (eg, to invite participant to check in or start a conversation), effectively removing our ability to proactively contact users (restricting that ability to news-related apps only). This limitation was addressed by changing the FM communication platform to a stand-alone smartphone app that is fully accessible and controllable by the development and research teams.

The primary feedback from users was their frustration that the QuitBot could not respond to their own questions about quitting smoking. Therefore, we created the core conversational feature that would allow users to ask free-form and open-ended questions about quitting cigarette smoking and for the QuitBot to respond with accurate, concise, professional, and nonrepetitive answers. We developed a library of 11,000 QnA pairs on the topic of quitting cigarette smoking. The results of our model testing showed that Microsoft's Azure-based QnA maker could handle any question that matched our library of 11,000 QnA pairs. In contrast, a fine-tuned, contextualized GPT-3.5 could answer new questions that were not within our library of QnA pairs.

QuitBot has several key limitations that might present a challenge for users who expect fast responses to their questions. QuitBot was designed for users to wait until the end of the 2- to 3-minute structured clinical conversations before they can ask free-form questions. This design element was necessary to prevent breaking the logic of each of the structured conversations and thereby going off on tangents without an ability to return to the structured conversation. We address this design element by asking the user to hold onto their questions until the end of the structured conversation at various times throughout the program. To date, this message appears to have been effective at training the user to wait until the end of the structured conversation to ask free-form questions. The second major limitation is the response time latency for free-form questions when the GPT servers are running at capacity. While usually the response latency is only a few seconds, we have observed some instances where it can take up to 30 seconds. To address this potential delay, we inform users that it may take a moment to answer their questions and appreciate their patience.

By contrast, this study has numerous strengths that have the potential to advance clinical intervention development research and practice to aid smoking cessation. Most importantly, this study illustrates the value of following a methodical, user-centered design framework in the development of technology interventions. The framework has yielded a chatbot with a comprehensive step-by-step clinical program for quitting smoking and possesses a broad knowledge base on the topic of quitting smoking. QuitBot allows users to ask free-form and open-ended questions about quitting smoking, with answers informed by a broad set of clinical experience and scientific research. This technical capability has been afforded by the LLMs that underlie the state-of-the-art versions of Azure QnA Maker and GPT. The result is that users can obtain accurate and informative answers to their questions, which would otherwise be difficult to glean and evaluate from other accessible digital resources such as internet searches.

By contrast, prior reports of chatbots only address certain aspects of the quit smoking process, such as providing reflections on the pros and cons of smoking or helping ambivalent adults who smoke in contemplating a quit attempt. Only 8% of participants rated such chatbots as helpful [36]. Similarly, early iterations of QuitBot, which relied on a forced-choice answer format, left participants wishing responses tailored to their individual needs [96]. Likewise, a study of 6 users of a tablet-based chatbot, aimed at encouraging them to contemplate quitting and set a quit date, was limited by a forced-choice answer format [97]. In the only prior RCT of a smoking cessation chatbot, responses were confined to preset scripts and had an outcome data retention rate of only 45% [98].

Although users are informed that QuitBot is only a computer program, the supportive and conversational tone of the messages has the potential to lead to a long-term social-emotional connection. Indeed, the interim trial result of a mean of 72 days from first to last use is longer than we have observed in rule-based SMS text messaging interventions for smoking cessation (which typically last about 7 days) [85,99,100] and longer than typical human clinician–delivered interventions, such as telephone quit coaching (which typically last about 7 days) [101,102]. The length of intervention engagement is a strong predictor of treatment success [103,104], so these initial results on QuitBot's engagement certainly appear promising.

While we developed and tested QuitBot in the United States for an English-speaking audience, the program could be tailored to other nationalities and languages across the world. As a health behavioral change platform, QuitBot has the potential to be adapted to other behavior changes, including alcohol and drug use, dietary change, and physical activity.

Lessons Learned

QuitBot was developed in the midst of rapid changes in LLM technology, during what is arguably one of the most rapidly transformative periods of AI history (2020 to 2023) [105,106]. Thus, the most important lesson we learned was the value of investing the time in continuing to iterate and improve on our free-form QnA feature as new LLMs were continuously being released. Indeed, when we started to develop the free-form QnA feature in 2020, LLM capabilities were primitive by the current (January 2024) standards. Despite being based on 345 *million* parameters, we learned that DialoGPT was limited in its ability to determine the intent of our questions. By the time GPT-3.5 was released (based on 175 *billion* parameters), the performance of the free-form QnA feature was far superior, which in turn allowed us to improve the quality of answers provided by Azure QnA.

The second most important lesson we learned is the challenge of training an LLM model for a specific clinical domain. The popular press has provided ample examples of LLMs such as GPT providing very detailed answers to questions in a wide variety of topics [105,107,108]. While much has been written about the tendency for LLMs to "hallucinate" (ie, providing confident-sounding answers that are factually wrong or fabricated) [109], the more common problem we encountered in our development process was providing an extensive knowledge base to address highly specific questions within a clinical domain. In our experience, off-the-shelf LLMs are like dilettantes: they possess broad knowledge but lack depth in a particular subject. From this project, we glean that this characteristic holds particularly true when the subject matter requires clinical expertise and familiarity with scientific literature within a specific clinical domain. Overcoming this challenge required multiple iterations to build a knowledge base grounded in empirically supported best practices for smoking cessation. The responses needed to be accurate and clinically sensitive, suggesting that a similar knowledge-building process will be essential for developing chatbots in any other clinical domain.

Conclusions

The development process yielded a comprehensive, fully developed, quit smoking program delivered through a conversational chatbot. Iterative testing led to improvements in the delivery platform, and a core LLM–supported conversational feature was integrated, enabling users to pose open-ended questions about quitting cigarette smoking. Our next step is testing QuitBot's efficacy for smoking cessation in a full-scale RCT.

Acknowledgments

The authors gratefully acknowledge the National Cancer Institute for providing their call center transcripts; James Jacoby and Tara Ward at Moby Inc for providing QuitBot development expertise and technical project management; Jessica Harris, Sarah Hwang, Julie Packard, Victoria Sanborn, and Christeine Terry at the Fred Hutch HABIT laboratory for supporting the QnA development; Daniella Kim at Halibut Flats for leading the user testing; Andrew Pham and Adam Rhine for their design and programming expertise in the early phase of developing QuitBot; the research staff at OpenAI for providing access to and technical support for fine-tuning GPT; and the research staff, including Anusua Trivedi, Marci Strong, and Thomas Roca, at Microsoft's AI for Good for providing technical expertise in large language models. An interview about QuitBot with the lead author and Trevor Noah is available on YouTube [110].

Abstract

Background: Despite the growing availability of smoking cessation apps, low engagement and cessation rates have remained a significant challenge. To address this issue, we used a user-centered design to iteratively develop a mobile app (MO) to provide comprehensive, tailored, and evidence-based content to support smokers in their quitting journey.

Objective: This study examined the acceptability, use, and preliminary efficacy of the MO app for smoking cessation. Specifically, we sought to understand smokers' preferred features, engagement, and satisfaction with MO; identify concerns in using the app and ways to improve the app; and evaluate its smoking cessation outcomes.

Methods: Through 3 cohorts, we recruited 10, 12, and 85 adult smokers who attempted to quit smoking to pilot-test the MO app between December 2019 and July 2022. Participants were instructed to complete a baseline survey, interact with the app for 6 weeks, and fill in a postsurvey at week 6. Participants in cohort 3 completed an additional postsurvey at week 12. Participants' app use was tracked and analyzed. The primary outcome measures were participants' 7-day point prevalence abstinence at 6 and 12 weeks.

Results: Participants reported high levels of satisfaction with the MO app across all 3 cohorts, rating it between 4.40 and 4.76 on a scale of 5 for acceptability. Users engaged with app activities for an average of 89 to 159 times over 35 days. The most liked features of the app included "quit plan," "tracking," "reminders and notifications," "MOtalks," and "motivational quotes." The 7-day point prevalence abstinence rate of the modified intention to treat population in cohort 3 was 58% at 6 weeks and 52% at 12 weeks. Those who interacted more frequently with app features and engaged with more diverse activities were more likely to maintain abstinence at weeks 6 and 12. For each additional time logged into the app, the odds of staying abstinent at week 12 increased by 5% (odds ratio [OR] 1.05, 95% CI 1.01-1.08). Participants who earned >5000 points during app use also had higher odds of quitting at both 6 weeks (OR 3.12, 95% CI 1.25-7.75) and 12 weeks (OR 4.65, 95% CI 1.83-11.76), compared with those who earned <5000 points.

Conclusions: Our study demonstrated that MO is a feasible mobile phone app with high acceptability and usability and can effectively deliver smoking cessation support to individuals who want to quit. Implications for developing and evaluating mobile phone apps for smoking cessation are discussed.

Introduction

Background

Tobacco use remains the leading cause of preventable death in the United States and globally, with nearly half a million people dying each year in the United States alone due to tobacco-related diseases. Over a billion people worldwide still smoke [1], which highlights the enormous global burden of tobacco use. Recent evidence indicates that quitting before the age of 40 years can reduce the risk of premature death by 90%. This underscores the importance of effective tobacco cessation interventions. Cessation at any age can provide major disease risk reduction benefits. Despite the increasing awareness of the adverse health effects of smoking and the clear benefits of quitting, cessation rates remain low, particularly among highly nicotine-dependent individuals who face a high risk of relapse [2]. Nicotine is one of the most addictive substances known in medicine, which explains the major challenges of successful quitting and contributes to the persistently low cessation rates. Thus, there is a critical need for accessible and clinically validated smoking cessation interventions that can effectively address the barriers and challenges associated with nicotine addiction.

Compared with spontaneous unmedicated cessation rates (about 2%/year), nicotine cessation therapies have documented success rates of approximately 20% at 1 year. Motivated smokers who receive professional counseling and evidence–based cessation medications can have a success rate as high as 35% at 1 year [2,3]. However, traditional counseling interventions have limited reach, and the multiple available medications for cessation can be confusing for people seeking help. Patients face various barriers to accessing face-to-face tobacco cessation services, including financial challenges, language issues, traveling difficulties, and low-time commitment for in-person counseling [4,5]. The social stigma for free telephone-based counseling [6], lower-income patients' distrust of health care systems [7], and low awareness of the health risks of smoking further exacerbate these challenges for smokers with low socioeconomic status (SES). Hence, there is an urgent need to disseminate high-quality cessation treatments to the widest possible target audiences, including those in remote locations, those without health insurance, and those who cannot or will not receive counseling in person. Innovative strategies that deliver evidence–based cessation interventions to smokers attempting to quit could further enhance the success rate of quitting and prevent tobacco-related diseases while improving both physical and psychological well-being. Therefore, exploring novel approaches to promote smoking cessation is a critical public health priority.

Mobile Apps for Smoking Cessation

The ubiquity and widespread availability of smartphones provide an opportunity to extend the reach of smoking cessation professional counseling and evidence-based treatment beyond clinics. As of 2021, 85% of the adults in the United States own a smartphone, which covers low-income populations who are known to have higher smoking rates. In 2017, mobile health (mHealth) apps were downloaded 3.7 billion times worldwide [8], and this number increased dramatically during and after the COVID-19 pandemic. The high demand for mHealth apps represents a promising opportunity to leverage mobile technologies to facilitate smoking cessation and reduce health disparities in quitting.

Increasing evidence has shown the positive outcomes of mobile phone apps for smoking cessation [9-15]. According to a review, the cessation rate of people using mobile apps ranges from 13% to 24%, higher than the average cessation rate of using SMS text messaging alone (10%) [16]. Combining smartphone-based interventions with pharmacotherapy yields greater smoking abstinence rates than using pharmacotherapy alone [17]. However, limited and mixed evidence exists for the long-term effectiveness and retention rates of mobile phone apps. Very few of the popular smoking cessation apps (4% of the top 50 apps) are evidence based and adhere to the US Public Health Service's Clinical Practice Guidelines for Treating Tobacco Use and Dependence [18-21]. Currently, available apps lack tailored features and integration of multiple evidence–based approaches into the app design, such as a comprehensive review of medication options. In addition, existing apps have limited support throughout the different phases of smoking cessation, including preparation to quit, maintenance of cessation, and relapse prevention and support.

We developed a comprehensive and integrative smoking cessation mobile phone app called "MO"—an abbreviation for "mobile" and "motivation"—to address these limitations. The aim of MO is to provide user-centered, tailored cessation support using evidence-based approaches, integrating cognitive-behavioral therapy, peer support, and medication information. MO provides learning materials regarding how to quit smoking in different formats (eg, texts, audios, videos, and quizzes) and explains in easy-to-understand language the intensely addictive nature of nicotine. The app offers cessation and relapse support throughout the "prequit and planning," "quit and maintenance," and "relapse prevention" phases of smoking cessation and helps the user remain motivated toward quitting. Existing smoking cessation apps often have low user engagement and retention rates. MO seeks to address this by consistently motivating users to quit and encouraging long-term engagement to increase the efficacy of quitting.

Development of MO Smoking Cessation App

The MO app was developed with guidance from the US Public Health Service's Clinical Practice Guidelines for Treating Tobacco Use and Dependence, using the 5 *A*'s model (ask, advise, assess, assist, and arrange) and more than 80

evidence–based behavioral modification and motivation techniques. The app was designed to guide users step-by-step throughout their quitting process.

In the prequit or planning phase, there are 3 main functions: creating an individualized profile, tracking smoking behaviors, and advising on tasks and activities to prepare for quitting. The app's first function (setting up profile) assesses factors, such as level of nicotine addiction, health conditions, use of medications, quit date, motivations, and reasons for quitting, gathered from user profile information to make tailored recommendations based on proprietary algorithms and using tenets of motivational interviewing. The second function (tracking behaviors) is to help users track smoking behaviors (eg, concurrent activities, locations of smoking, time of the day, and the number of cigarettes smoked), identify triggers, and guide them through the process of choosing substitutive activities or distractions to replace smoking. The third function (task advising and learning) is to prepare users to stop smoking through education and specific activities, such as obtaining medications, modifying their environment, and informing family and friends to support their quit effort. General advice and strategies on how to stop smoking are available in text, audio, and video formats for users to learn at their own pace. Each day before the quit day, users can use this function to go through a specific theme preparing them to quit smoking. Cessation medications are described in detail and consistent with existing guidelines, yet none are specifically recommended, and the user is encouraged to make the decision about medication use with a health care provider.

In the quit or maintenance phase, the app also has 3 main functions. The first is the daily check-in, which prompts the users to track their moods, urges, smoking behavior, use of medications, and interactions with their social network. The second function is the "urge" button, which provides immediate support and strategies for managing urges to smoke. The third function delivers educational content through video clips and quizzes based on user motivations and data gathered in the prequit phase. The smoker will guide themselves through content that matches their highest interest and view new modules or review old modules to reinforce knowledge about smoking cessation.

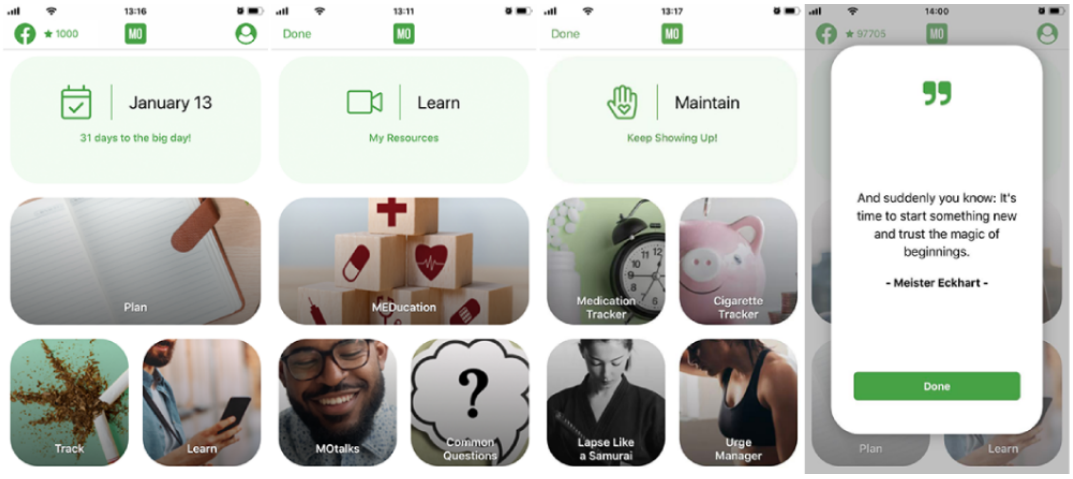
The app also includes functions to manage lapses (a momentary slip), relapses (return to smoking that may last for several days before resuming the cessation program), and collapses (a major reduction in motivation and return to smoking), which are often neglected by smoking cessation apps. The MO app anticipates these events, supports users through these inevitably difficult moments, and keeps users engaged and motivated. Specific functions for this phase include educational videos and audio segments helping users determine what happened, reestablish motivations, and how to prevent it the next time.

The app incorporates several features to encourage long-term user engagement. Every time a user opens the app, an uplifting quote will pop up to boost smokers' motivation to quit. Gamification features, including a point system and badges, help users celebrate their success in the quitting process. This feature visualizes users' progress and motivates them to stay abstinent. As each user completes a module, they will receive certain points (250, 500, or 1000) for the activity they engaged in. These points are designed to recognize the actions users take toward the quitting goal. Modules that are reviewed can be repeated to accumulate additional points. This "nudge" feature assigns more points to activities that have scientific evidence suggesting a positive role in cessation. Points are shown on the home screen, which may help users feel invested in their progress and remind them of their previous efforts if a lapse or relapse occurs after the quit date. Existing evidence has consistently suggested that financial incentives can improve smoking cessation outcomes [22]. As a potential reward, users who obtained >10,000 points will enter a lottery for a US $50 gift card in addition to the study compensation.

Informed by text-to-quit data suggesting social group aggregation may improve outcomes [23], the MO app has an internal chat feature that allows daily posting to the quitter's support network. This is a secure, customizable platform uniquely created for the app. The chat function allows for secure data management and professional moderation, with the goal to provide a supportive, understanding community breaking the negative effects of isolation and motivating users through positive social contagion. In addition, the story booth feature allows users to record and share brief video clips about their cessation journey and to view other people's stories.

The main features of the MO app are illustrated in Figure 1. The development of MO involved a web-based asynchronous focus group with end users to evaluate and provide suggestions for the initial prototypes of the app. Participants were asked to post comments to a web-based discussion board as to the viability, content usability, and attractiveness of each app element and the ability for each to engage the intended audience. We incorporated participants' comments and developed the beta version of the MO smoking cessation app.

Figure 1. Interface and main features of the MO smoking cessation app.



Research Questions and Hypotheses

This study used an iterative process to evaluate and improve the feasibility and usability of the beta version of the app. A series of studies were conducted to address the following research questions (RQs) and hypotheses related to the app's acceptability, user engagement, and preliminary effectiveness on smoking cessation.

- RQ1: Are participants satisfied with using MO for smoking cessation?
- RQ2: What are the most liked features of the app?
- RQ3: What are the least liked features of the app?
- RQ4: What are the suggestions for improving the app?
- RQ5: What are the 7-day point prevalence abstinence rates at 6 and 12 weeks after using the MO app?
- Hypothesis 1: Participants who engage with a greater number of app activities are more likely to self-report quitting at the 6 and 12-week follow-ups.
- Hypothesis 2: Participants who earned more points are more likely to self-report quitting at the 6 and 12-week follow-ups.

Methods

Overview of the Study Design

Studies were conducted in 3 participant cohorts to examine the RQs and hypotheses mentioned earlier. In cohorts 1 and 2, we examined acceptability and usability of the app among a group of end users to ensure the various features work as intended, are perceived acceptable by the intended users, and can be easily used. Features and interfaces of the app will be refined based on participants' use experience and feedback. In cohort 3, we additionally assessed the preliminary effectiveness of the MO app on smoking cessation outcomes.

Participant Recruitment

We intended to recruit 10, 10, and 80 participants into cohorts 1, 2, and 3, respectively, during the following 3 periods: December 19, 2019, to March 19, 2020; August 10 to December 10, 2020; and April 7 to July 26, 2022. Eligible participants included (1) persons aged between 18 and 59 years; (2) who were current smokers consuming at least 5 cigarettes daily for at least the past 12 months, as consistent with cessation trials [24]; (3) self-reported a relatively high level of commitment to quit smoking of at least 7 on a scale of 0 to 10; (4) who were interested in learning skills to quit smoking; (5) resided in the United States; (6) had at least daily access to their own iPhone with internet access; (7) were able to read English; and (8) were not using other smoking cessation interventions (including apps, medications, or other intervention studies). We excluded participants who were younger than 18 years or older than 59 years as they may have had different cessation motivations; who had health contraindications to nicotine patch use; who were actively taking medication for depression, anxiety, or quitting smoking; who used illicit drugs or marijuana; or who failed to provide contact information.

Participants were recruited using web-based advertising through Craigslist (Craig Newmark) posts, Facebook (Meta), and Google (Google LLC) advertisements, and a university listserv for research participant recruitment. People who saw the advertisements could also refer the study information to their smoking relatives or friends. Interested participants clicked the enrollment link in the advertisements, which directed them to a short screening survey. Once eligibility was established, participants were shown a short video containing the informed consent materials.

Eligible participants who consented to participate were enrolled in the study. They were asked to complete a baseline survey to document their smoking history, use of nicotine replacement, and other health behaviors. We documented factors known to correlate with smoking cessation, such as social support, attitudes and norms related to smoking, and intentions to quit.

Participants were instructed to download MO and interact with the app and its various features for 6 weeks. A 10-minute walkthrough video was sent to every participant to introduce the main features of the app. The walkthrough video is available in Multimedia Appendix 1. A postsurvey was developed to examine app acceptability and usability and was sent to participants at 6 weeks (day 42) and at 12 weeks (day 84, only for cohort 3). Participants that returned the 6-week and 12-week questionnaires were part of a completer's analysis of efficacy. Participants not returning the questionnaire were imputed as nonresponders and having returned to smoking.

Measures

Acceptability

Acceptability refers to the degree to which an intervention is deemed acceptable by its intended users. In cohorts 1 and 2, we measured users' acceptability of MO using 3 items: "I enjoyed using the MO smoking cessation app," "The MO smoking cessation app was useful to me," and "The MO smoking cessation app was easy to navigate" on a 5-point Likert scale (1=strongly disagree and 5=strongly agree). In cohort 3, we additionally asked 6 questions adapted from previous studies on app-based smoking cessation interventions [25] to have a more comprehensive evaluation of users' satisfaction with and perceived usefulness of the MO app for smoking cessation.

App Engagement

We tracked participants' interaction with and navigation through the MO app through Firebase Performance Monitoring (Google LLC) for 12 weeks. Specifically, we recorded the type of activities users engaged in within the app, whether they completed each module or task, and the frequency of engagement. We also asked users to identify their most liked and disliked app features, explain why they liked or disliked certain features, and provide suggestions for improving the app through open-ended survey questions.

Effectiveness

In cohort 3, smoking cessation outcomes were additionally examined. Participants were asked to self-report their smoking status at 6 and 12 weeks through 2 postenrollment surveys, including the 7-day point prevalence abstinence rate as the primary outcome variable, number of cigarettes smoked, and frequency of smoking in the past month. Self-report 7-day point prevalence abstinence, which is one of the commonly used measures for evaluating users' smoking cessation outcome [26], asks whether participants maintain smoke-free in the past 7 days.

Analytic Approach

The intent-to-treat (ITT) group typically includes all participants enrolled in the study who were assigned to receive a treatment. The modified ITT (mITT) is a subset of the ITT sample that removed participants who did not receive or start the treatment. In our study, participants who completed the screening test and successfully enrolled were considered the ITT group, and those who downloaded and used the MO app were considered the mITT group. The mITT group is more appropriate for the app engagement and preliminary efficacy analyses because they are the true participants who became exposed to and received the smoking cessation treatment, removing participants who did not download, open, or interact with the MO app at all. Because acceptability is a subjective evaluation of participants' satisfaction with the app, we were only able to analyze data input by participants who completed the postsurvey. Those who dropped out of the study were not included in the acceptability analysis.

To examine acceptability (RQ1), we calculated participants' average level of satisfaction with the MO smoking cessation app. We anticipated that at least 80% of the users will be "satisfied" or "very satisfied" with the app. To address RQs on usability (RQs 2-4), we qualitatively analyzed participants' responses to open-ended questions—to identify themes around (1) difficulties in using or navigating the app, (2) liked features, (3) disliked features, and (4) suggestions for improving the app. We also evaluated engagement by calculating multiple aspects of user experience with the app, including the number of times the app was opened and the frequency and types of features used.

To explore RQ 5, we assessed the percentage of participants remaining abstinent from cigarette smoking and use of other nicotine or tobacco products in the previous 7 days at 6 and 12 weeks after using the app. All participants who completed the baseline survey, downloaded the app, and answered the questionnaire were included in this completer analysis. Participants that were lost to follow-up at the 6th and 12th weeks were imputed to be smoking.

We also examined the dose response relationship between quit status and greater use of the app in general (hypothesis 1) and more points earned (hypothesis 2) using logistic regressions to test the proposed hypotheses. We conducted exploratory analyses to assess the relationship between use of specific features of the app and the participant's quit status.

Ethical Considerations

The study was reviewed and approved by the Colorado Multiple Institutional Review Board (protocol number 14-2225). Participants were asked to view the informed consent video. Contact information for research staff was included in the video in case participants had any questions during the consent process. The material covered in the video was made available in a printable document so the participant could download and print it if desired. Participation in this study was completely voluntary. Participants may decline to participate or withdraw from the study at any time without penalty. Participants in cohorts 1 and 2 received a US $20 gift card incentive for participation. For cohort 3, participants received a US $40 gift card incentive for participation, as 2 follow-up surveys (at 6 and 12 weeks) were collected. All information was kept confidential, and the data were deidentified. Study procedures were in accordance with institutional ethical standards for conducting human subjects research and with the Helsinki Declaration.

Results

Participant Recruitment and Demographics

We enrolled 15, 19, and 132 eligible participants (the ITT groups) into the 3 cohorts. Among them, 9 (60%), 12 (63%), and 85 (64.4%) participants (the mITT group) downloaded and used the MO app. All statistics were calculated based on this mITT sample. The retention rates at 6-week follow-up were 90%, 83%, and 66%, respectively. For cohort 3, the retention rate at 12 weeks was 55%. Participants' basic demographic characteristics, smoking history, level of commitment to quit smoking, and sources of recruitment were summarized in Table 1.

Table 1. Demographics of participants across the 3 cohorts.

[b]These questions were only asked among participants who indicated previous use of nicotine replacement.

Acceptability

Overall, participants had high levels of satisfaction with using the MO app. At 6 weeks, participants from the 3 cohorts reported 4.67, 4.40, and 4.76 out of 5 for app satisfaction. Table 2 shows details regarding participants' acceptability of the app.

Table 2. Acceptability of the MO app across the 3 cohorts.

Statements	Cohort 1: 6 weeks, mean (SD)	Cohort 2: 6 weeks, mean (SD)	Cohort 3: 6 weeks, mean (SD)	Cohort 3: 12 weeks, mean (SD)
Satisfaction				
I enjoyed using the MO smoking cessation app	4.63 (0.70)	4.60 (0.66)	4.86 (0.35)	4.87 (0.34)
The MO smoking cessation app was useful to me	4.75 (0.43)	4.30 (0.64)	4.71 (0.49)	4.62 (0.80)
The MO smoking cessation app was easy to navigate	4.63 (0.48)	4.30 (0.64)	4.70 (0.66)	4.62 (0.71)
Satisfaction with the app for cessation treatment				
I can rely on the app to provide guidance that will help me to quit smoking and stay quit.	—[a]	—	4.59 (0.53)	4.70 (0.55)
I feel that the app provides smoking cessation treatment that is personalized to my specific needs.	—	—	4.46 (0.71)	4.57 (0.58)
I believe that the app will help me to quit smoking and stay quit.	—	—	4.54 (0.66)	4.55 (0.72)
The app knows how to help me to quit smoking.	—	—	4.61 (0.53)	4.70 (0.47)
I believe I can depend on the app.	—	—	4.46 (0.60)	4.47 (0.88)
I find the app to be annoying.	—	—	1.31 (0.57)	1.48 (0.91)

App Engagement

On the basis of the tracked data, Table 3 summarizes participants' general use of the app and engagement with specific features. Due to technical issues, we were not able to track 3 participants' app use in cohort 3. Therefore, data analysis on app engagement in cohort 3 was based on 82 (96%) of 85 participants. In general, participants perceived almost all the features to be useful. The top 5 most liked features of the app included "quit plan," "tracking," "reminders and notifications," "MOtalks," and "motivational quotes." MOtalks are short video or audio lectures of a specific theme related to smoking cessation. Participants explained that the "quit plan" feature "helped with learning about the habit and situations that trigger me to smoke and how to make a plan to deal with it," and the "tracking" feature "showed me some patterns I wasn't aware of." Participants liked the "reminders and notifications" because "the daily reminders came as pop-up notifications to enter your smoking status for the day. With that it makes you feel responsible and like you are making progress." Participants also enjoyed the "quotes" because they were "uplifting" and "motivational." These findings were consistent with users' actual engagement with various features, with "login" as the most frequently used function, followed by "quit plan" and "medication tracker." The least liked feature of the app was the "comments." Because this feature was not frequently used, participants mentioned that "I could not see any comments or messages there."

Table 3. Use of the MO app.

	Cohort 1	Cohort 2	Cohort 3
General use of the app, mean (SD)			
Duration of app use (days)	37.56 (29.79)	35.33 (36.56)	46.31 (41.52)
Total activities engaged (times)	89.22 (76.62)	159.60 (213.97)	158.89 (236.71)
Unique activities engaged (types)	37.11 (23.85)	79.42 (76.45)	67.66 (80.83)
Log-in times	17.56 (21.38)	13.75 (28.57)	9.98 (15.79)
Points earned	20,430 (25916.20)	26,933.75 (33859.66)	28,764.48 (40,157.13)
Engagement with specific app features (most frequently engaged features), mean score			
Quit plan	8.00	6.46	12.47
Medication tracker	4.89	3.00	3.56
MOtalks: meet your hosts	0.89	4.5	2.25
Why quit	1.11	0.83	2.20
MOtalks: denial stories	0.22	2.33	2.12
MOtalks: triggers	0.33	1.00	1.85
Quit date setting	1.11	2.75	1.74

Suggestions for Improvement

The following themes emerged from thematic analysis of participants' responses to open-ended questions regarding things to be improved for the app. The first identified theme was "availability." Participants recommended "enabling it in all devices—that is, iOS and Android." The second theme was "staying logged in." Participants mentioned that "there should be an option to always stay logged in since no one else uses my phone but me. The ability to stay logged in after closing the app for a while will save me the time of having to log in with my details again or entering my phone passcode since my phone is virtually always on me." "Stability" was the third theme, as participants suggested to "make the app more stable and working perfectly to avoid it crashing." The last theme was "removing visual smoking triggers." As participants put it, "the app is perfect as it is, but taking out pictures of cigarettes and someone smoking would help a lot." In addition to the general themes, participants also pointed out that certain features could be improved. For example, for the tracking function, participants could not see all the days they smoked even within that month. Participants also think the "common questions" feature "needs more development and more options to pick from."

Preliminary Effectiveness

We performed a series of logistic regression analyses to examine whether participants with greater app engagement are more likely to self-report quitting at the 6 and 12-week follow-ups (hypothesis 1). Results showed a significant effect of total activities engaged on both 6-week cessation status (Wald χ^2_1=4.41; *P*=.04) and 12-week cessation status (Wald χ^2_1=7.93; *P*=.005). The odds of staying abstinent at week 6 and week 12 increased by 0.3% (odds ratio [OR] 1.003, 95% CI 1.00-1.01) and 0.4% (OR 1.004, 95% CI 1.001-1.01), respectively, for every additional app activity engaged.

The types of activities participants engaged in also significantly predicted the odds of quitting at 6 weeks (Wald χ^2_1=4.19; *P*=.04) and 12 weeks (Wald χ^2_1=7.97; *P*=.005). The odds of staying abstinent at week 6 and week 12 increased by 0.6% (OR 1.006, 95% CI 1.00-1.01) and 0.9% (OR 1.009, 95% CI 1.003-1.02), respectively, for every additional type of activity engaged.

Use frequency, indicated by "login times," did not significantly influence smoking cessation rate at 6 weeks (Wald χ^2_1=1.85; *P*=.17, OR 1.02, 95% CI 0.99 to 1.06) but predicted the odds of quitting at 12 weeks (Wald χ^2_1=5.25; *P*=.02). The odds of maintaining abstinence from smoking at week 12 increased 1.05 times for each additional log-in (OR 1.05, 95% CI 1.01-1.08).

To examine whether earning more points is associated with a higher likelihood of self-reported quitting (hypothesis 2), we recoded participants' points earned into 4 dummy coded categories: >5000 points, >10,000 points, >50,000 points, and >100,000 points. Among them, only ">5000 points" significantly predicted the odds of quitting at 6 weeks (Wald χ^2_1=5.96; *P*=.02) and 12 weeks (Wald χ^2_1=10.41; *P*=.001). Participants who earned >5000 points had higher odds of quitting at 6 weeks (OR 3.12, 95% CI 1.25-7.75) and 12 weeks (OR 4.65, 95% CI 1.83-11.76). Changes in other smoking-related outcomes from baseline, 6 weeks, to 12 weeks in cohort 3 were summarized in Table 4.

Table 4. Smoking-related outcomes in cohort 3 (N=85).

Characteristic	Baseline upon installation, n (%)	6 weeks, n (%)	12 weeks, n (%)
Number of participants completed the survey			
Completed	85 (100)	56 (66)	47 (55)
Missed	0 (0)	29 (34)	38 (45)
Smoking status			
Active smoker	85 (100)	8 (9)	5 (6)

Very high (8-10)	8 (9)	0 (0)	0 (0)

[a]Not available.

[b]FTND: Fagerstrom Test for Nicotine Dependence. This score was only assessed and analyzed among active smokers.

We also performed a series of post hoc analyses to explore the effects of specific app features on cessation outcomes. In the prequit and planning phase, engaging with "why track," "what influences are around me," "quit story," "meducation vaping," or "meducation nicotine addiction" predicted a greater likelihood of quitting at both week 6 and week 12. Completing reasons for "why quit" and "MOtalks triggers" did not affect the 6-week cessation status but was significantly associated with

participants' 12-week cessation status. Completing "about me" was not linked with cessation status at either time point. Detailed results are reported in Table 5.

Table 5. Effects of engaging with specific app features on cessation outcomes.

	Wald chi-square	*P* value	OR[a] (95% CI)
Quit at week 6			
About me	0.19	.67	1.31 (0.39-4.94)
Why quit	2.39	.12	2.05 (0.83-5.07)
Why track	4.35	.04	2.75 (1.06-7.12)
Quit story	4.53	.03	2.71 (1.08-6.76)
What influences are around me	5.05	.03	3.19 (1.16-8.75)
MOtalks triggers	3.39	.07	3.15 (0.93-10.69)
Meducation vaping	3.94	.05	2.93 (1.01-8.47)
Meducation nicotine addiction	5.12	.02	3.63 (1.19-11.12)
Medication tracker	3.57	.06	2.66 (0.96-7.36)
MOtalks medication	0.82	.37	1.72 (0.53-5.58)
MOtalks breathing	2.61	.11	2.42 (0.83-7.07)
MOtalks urges	0.64	.42	1.57 (0.52-4.76)
MOtalks stress	4.09	.04	3.50 (1.04-11.79)
MOtalks tools	0.82	.37	1.72 (0.53-5.58)
Quit at week 12			
About me	3.05	.08	3.10 (0.87-11.06)
Why quit	5.79	.02	3.22 (1.24-8.36)
Why track	6.39	.01	3.33 (1.31-8.48)
Quit story	7.67	.006	3.66 (1.46-9.16)
What influences are around me	6.40	.01	3.50 (1.33-9.24)
MOtalks triggers	6.94	.008	5.20 (1.52-17.74)
Meducation vaping	4.41	.04	2.94 (1.07-8.02)
Meducation nicotine addiction	5.47	.02	3.45 (1.22-9.73)
Medication tracker	8.83	.003	4.76 (1.70-13.31)
MOtalks medication	2.91	.09	2.79 (0.86-9.05)
MOtalks breathing	6.64	.01	4.13 (1.40-12.15)
MOtalks urges	2.80	.09	2.58 (0.85-7.83)
MOtalks stress	8.01	.005	5.83 (1.72-19.78)
MOtalks tools	2.91	.09	2.79 (0.86-9.05)

[a]OR: odds ratio.

In the quit and maintenance phase, we found a marginally significant effect of using the medication tracking feature on the 6-week cessation status (Wald χ^2_1=3.57; *P*=.06; OR 2.66, 95% CI 0.96-7.36), and a significant effect on the 12-week cessation status (Wald χ^2_1=8.83; *P*=.003; OR 4.76, 95% CI 1.70-13.31). Similarly, participants who completed "MOtalks breathing" had a greater chance of quitting at the 12 weeks than those who did not. Engaging "MOtalks medication" was not associated with cessation outcomes.

In the relapse prevention phase, learning from "MOtalks stress" was significantly linked with a higher likelihood of quitting at 6 and 12 weeks. However, engaging with "MOtalks urges" or "MOtalks tools" did not predict cessation status.

Discussion

Overview

In this study, we used a systematic approach to develop and pilot-test the MO mobile phone app for smoking cessation. This process involved iterative engagement with users, incorporating

their feedback to make improvements and updates to the app. We used a combination of qualitative and quantitative methods, including closed and open-ended questions and app use tracking, to gather user feedback and refine the app's features.

In cohort 1, we identified and fixed the issue of frequent crashes and enhanced the point reward system by adding badges. We also tailored the progress reports and reminders based on users' stages of quitting. On the basis of user data analysis in cohort 2, we further refined the MO app by introducing a new "chat" feature, which served as an internal support group to replace a prior support group feature that required participants to exit the app to engage it. Discussions in this chat were moderated by a researcher on an intermittent basis. In addition, we implemented a new reward mechanism where users achieving the intermediate stage (5 stages in total: beginner, fast starter, intermediate, master, and expert) of 20,000 points were entered into a lottery for a US $50 gift card. These updated features aimed to promote engagement and motivation among participants to quit smoking. The performance of the app steadily increased from cohort 1 to 3, with cohort 3 reporting the highest level of acceptability and engagement, as indicated by the duration of active app use and total points earned. The "quit plan" feature was the most frequently used among cohort 3 participants. Participants also frequently interacted with and positively rated the MO talks. The most popular topics of MO talks were "meet your host," "denial stories," and "breathing."

Principal Findings

Results demonstrated that the MO app was promising in assisting smokers to quit. The 7-day point prevalence abstinence rates of the mITT population were 58% (49/85) at week 6 and 52% (44/85) at week 12, while the 30-day point prevalence abstinence rates were 29% (25/85) at week 6 and 36% (31/85) at week 12. These cessation rates were higher than the 7-day point prevalence abstinence rates reported for other smoking cessation apps, which typically ranged from 13% to 35% at the 12-week follow-up [9,16,24]. We also found that participants who engaged more frequently with the app's features, interacted with a greater variety of features, and earned more points were more likely to maintain abstinence from smoking. Participants that did not complete the study questionnaire were imputed to return to smoking. This conservative approach may not capture any benefits, such as decreased cigarette use for a period. Furthermore, no adverse events or safety and privacy concerns were reported during the study period. Despite minor technical issues, such as unexpected crashes, all features of the app functioned as intended, indicating its feasibility for everyday use by smokers.

The significant association between app engagement and cessation outcome found in this pilot study underscores the critical role of an engaging system in driving and sustaining abstinence. Previous research has also shown that improved abstinence rates were linked with increased app engagement, indicated by a greater number of app openings and adherence to app features (ie, completing required tasks) [16,27,28]. In a pilot randomized clinical trial, the number of interactions with app features completely mediated cessation outcomes [29]. Our study contributes to existing literature by identifying the types of activities users engaged in and the points earned through interactions with app features as additional forms of engagement that significantly predict smoking cessation outcomes. We found that users who received >5000 points were more likely to remain abstinence at weeks 6 and 12. However, users who accumulated >10,000 points did not show significantly different cessation outcomes compared with those with fewer points. This suggests that earning 5000 points represents a critical threshold for the app's effectiveness. The finding that additional points beyond this threshold did not enhance cessation outcomes does not necessarily indicate a ceiling effect but rather reflects the complex and recursive nature of smoking cessation. Users who found quitting relatively easy may not need to earn many points and can quit at an early stage. In contrast, users who accumulated >10,000 points might indicate 2 possibilities: on one hand, they were highly motivated to quit and thus engaged more with the app; and by contrast, they faced greater challenges in quitting, requiring prolonged app engagement. While both scenarios result in greater points earned, the former is associated with more favorable quitting outcomes, whereas the latter is linked to continued smoking or an extended period required to quit.

Our data shed light on several strategies for designing engaging health apps. First, smoking cessation apps should provide users with the flexibility to create their own quitting plans, including setting quit dates, identifying reasons to quit, establishing quitting goals, and learning about medication options. These features were the most frequently used in the MO app. Second, the app should enhance users' efficacy in quitting smoking and equip them with skills to cope with relapses. Features that facilitated the tracking of smoking habits, sent reminders, and provided educational materials on strategies for managing urges were rated as the most liked features by participants. These design considerations align with the self-determination theory [30,31], which suggests that behaviors are driven by the internal needs of autonomy (ie, taking control of the quitting process), competence (ie, having necessary skills to achieve the cessation goal), and relatedness (ie, social connections and sense of belonging). Features related to "autonomy" and "competence" were well received by MO users. While MO also addressed the "relatedness" need by establishing a secure peer-support community within the app through chat and story sharing functions, these features were not completely used by participants. This finding is consistent with previous research that showed low levels of engagement and perceived usefulness for smoking cessation apps that relied on social network members [32]. One potential reason for such limited engagement is the challenge participants faced in building trust with other users within a relatively short period. However, the chat and story booth features may play a more important role for users in the later stage of smoking cessation, especially when they experience relapses. In addition to sharing experiences with smoking cessation peers, individuals may also need support and encouragement from family members or close friends. While receiving social support has been positively associated with changes in smoking cessation stages [33], meta-analyses yielded mixed results regarding the effects of interventions that enhance partner and family support on cessation rates [34,35]. Therefore, stronger empirical evidence is needed to determine the

effectiveness of integrating family-based support into the design of smoking cessation apps.

In response to open-ended questions soliciting suggestions for increasing app engagement, participants emphasized the importance of reducing barriers to app use and making it as accessible as possible. Recommendations included streamlining the log-in process and ensuring compatibility with both iPhone and Android devices. Enabling logins with biometrics, such as using fingerprints or facial recognition, would further enhance the convenience and security of the log-in process. Participants were also inspired by the motivational talks and uplifting quotes provided by the app, as these elements helped build confidence and foster positive beliefs about quitting smoking. On the basis of this finding, it might be helpful to further refine the "story booth" function, including providing prompts, instructions, or incentives to encourage former successful quitters who used the app to record their experience, allowing different forms of story sharing (eg, textual, audio, or video stories), and helping current users find quitters sharing similar backgrounds with them so that they are more likely to learn from and become motivated by peers' quitting journey. Furthermore, the point system and financial incentives were found to be useful in increasing participants' motivation to remain engaged with the MO app. The financial incentives may be particularly attractive to and useful in assisting low-SES smokers in quitting. These reward mechanisms could be reinforced in future iterations and adapted to nonstudy users. For example, the point system could be used to unlock advanced features (eg, personalized motivational quotes, an artificial intelligence-powered smoking cessation chatbot). In addition, enabling users to share their achievements on social media or with significant others could further enhance engagement and motivation. While it may not be feasible to provide large-scale monetary rewards to public users, alternative financial incentives could be offered in the form of free web-based consultation with professionals, free nicotine cessation medications, or coupons for healthy products.

Given the proliferation of numerous cessation apps with varying quality, clinical research data are essential to help smokers make informed choices and enhance their chances of success. Although there has been an increase in clinical research on mobile phone-based smoking cessation interventions in recent years, we are still in the early stages of accumulating rigorous clinical research evidence to establish best practices for smoking cessation apps. Health care professionals require credible data to confidently recommend mHealth platforms to their patients. Our findings were based on user experience and cessation outcomes of a good mix of males and females as well as smokers of different ethnicities and races, representing a diverse smoking population. By identifying users' level of app engagement (eg, 5000 points) associated with cessation, the app platform can serve as a tool for health care professionals to encourage patients to reach and surpass this activity level. Moreover, this mobile-based system can be easily integrated into clinical practices, such as short advice or counseling sessions, complementing clinical support for smoking cessation and assisting in tracking patients' adherence to cessation treatment.

Limitations

The study had several limitations. First, being a pilot evaluation study, the sample size was small, and the representativeness of the sample cannot be guaranteed. Therefore, the findings may not be generalizable to the entire population of smokers intending to quit. Although recruitment through web-based advertisements proved to be feasible and efficient in recruiting eligible participants, it is important to note that the participants in our study exhibited high levels of technology literacy and motivation to quit smoking. Participants who joined this research were young, with more than 85.8% (91/106) of participants aged younger than 40 years, and most of them had a smoking history between 1 and 10 years. We also set an eligibility criterion requiring participants to have a high intention to quit (ie, scored at least a 7 on a scale of 0-10 on a self-assessed commitment scale). The unique characteristics of the sample, including the younger age, relatively short smoking history, and strong motivation to quit, could be reasons for the high smoking cessation rate of using the MO app. In addition, the study was conducted during the COVID-19 pandemic, which presented a unique opportunity for smokers to quit due to social distancing and quarantine policies that significantly reduced social and environmental smoking triggers. This health crisis also made staying healthy a more salient goal in people's minds, and therefore, participants may have been more motivated to quit smoking. By contrast, social isolation, anxiety, and depression increased during the pandemic, and self-reported cessation attempts and cessation-related medications declined at the beginning of the pandemic [36]. The unique characteristics of participants, social contexts, and the special period should be considered when interpreting this study's findings.

Second, the follow-up period in this study was relatively short (6 and 12 weeks) for testing the app's engagement and effectiveness. Smoking cessation is a long-term process involving potential setbacks and relapses. In future studies, we plan to follow-up with app users for 6 months and 1 year to examine the apps' long-term cessation effects and the dynamic relationship between app engagement and cessation outcomes at different stages of quitting.

Third, this study assessed cessation outcomes through self-reported data from web-based surveys, without biochemical verification of cotinine levels or exhaled carbon monoxide monitoring. Obtaining biochemically verified cessation status was not feasible during the pandemic period, and the Society for Research on Nicotine and Tobacco Subcommittee on Biochemical Verification has suggested that biochemical confirmation may not be necessary in certain studies [37]. Considering cost and other constraints, self-reporting can be considered an acceptable standard method in cessation trials and clinical practice [38]. However, future studies incorporating biochemically verified data would be valuable to check whether the high cessation rate after using the MO app can be replicated.

Finally, this study did not have time-stamped historical logs of user engagement with each app feature, so we were unable to demonstrate users' dynamic engagement with specific activities over time. To improve the user-centered design and usability of the app, it is critical to understand how users interact with

the app initially, whether they can quickly learn and explore the various functions, and how users' initial, instant responses to the app differ from adaptive responses several weeks later. It is useful for future studies to track users' first-week use and compare it with use at 1 month.

One advantage of the MO app is that it incorporates the medication tracking function to facilitate smokers with medication use and compliance of cessation medications in everyday settings. Due to the small sample size, we were only able to analyze the effect of using the medication tracking function on cessation outcomes and were underpowered to have more detailed descriptions about how they used this function, what kinds of medications they used, and the corresponding effects. Further research should fill this gap by providing empirical evidence on how using different cessation medications and adherence rates, facilitated by smoking cessation apps, are associated with cessation outcomes.

Our next step is to conduct a larger-scale randomized clinical trial that compares MO with other standard smoking cessation apps to further explore its effectiveness on short-term and long-term quitting outcomes. It is also worth investigating whether the app is accessible to and acceptable to low-SES smokers, which is critical to help reduce disparities in smoking cessation. While mHealth apps have enhanced the accessibility of health interventions to the public, it is unclear whether disparities exist in the use of mobile technologies for smoking cessation. Considering that the low-SES population comprises most current smokers, understanding the effects of MO on facilitating smoking cessation among this group is necessary.

Conclusions

MO is a feasible mobile phone app that effectively provides smoking cessation support to individuals who desire to quit. The study demonstrated high acceptability, usability, and potential efficacy of the app in enhancing cessation outcomes. Further research, including a randomized controlled trial, is needed to rigorously evaluate long-term app engagement and effects on smoking cessation.

Acknowledgments

The authors want to thank Dawn Repola for her invaluable contributions and support throughout the app development and research process. We'd also like to acknowledge the insightful comments and contributions of Lisa Kroon, PharmD and Suzanne Harris, RN in the early development phase of the platform.

Conflicts of Interest

Abstract

Background: Obsessive-compulsive disorder (OCD) is the third most prevalent mental health disorder in Singapore, with a high degree of burden and large treatment gaps. Self-guided programs on mobile apps are accessible and affordable interventions, with the potential to address subclinical OCD before symptoms escalate.

Objective: This randomized controlled trial aimed to examine the efficacy of a self-guided OCD program on the mobile health (mHealth) app Intellect in improving subclinical OCD and maladaptive perfectionism (MP) as a potential moderator of this predicted relationship.

Methods: University students (N=225) were randomly assigned to an 8-day, self-guided app program on OCD (intervention group) or cooperation (active control). Self-reported measures were obtained at baseline, after the program, and at a 4-week follow-up. The primary outcome measure was OCD symptom severity (Obsessive Compulsive Inventory–Revised [OCI-R]). Baseline MP was assessed as a potential moderator. Depression, anxiety, and stress (Depression Anxiety and Stress Scales-21) were controlled for during statistical analyses.

Results: The final sample included 192 participants. The intervention group reported significantly lower OCI-R scores compared with the active control group after the intervention (partial eta-squared [η_p^2]=0.031; *P*=.02) and at 4-week follow-up (η_p^2=0.021; *P*=.044). A significant, weak positive correlation was found between MP and OCI-R levels at baseline (*r*=0.28; *P*<.001). MP was not found to moderate the relationship between condition and OCI-R scores at postintervention (*P*=.70) and at 4-week follow-up (*P*=.88).

Conclusions: This study provides evidence that the self-guided OCD program on the Intellect app is effective in reducing subclinical OCD among university students in Singapore. Future studies should include longer follow-up durations and study MP as a moderator in a broader spectrum of OCD symptom severity.

Introduction

Background

Obsessive-compulsive disorder (OCD) is one of the most common mental health disorders, with an estimated lifetime prevalence of 3.6% in Singapore [1] and from 2% to 3% globally [2]. OCD is characterized by the presence of recurrent unwanted thoughts, urges, or images (obsessions, compulsions, or both). Common contents of obsessions include preventing harm from mistakes or contamination; concern over order and incompleteness; and intrusive violent, religious, or sexual thoughts [3]. Typically, obsessions are ego-dystonic and inconsistent with one's fundamental beliefs and personality. Hence, obsessions evoke significant anxiety or distress, which may drive the individual to carry out repetitive and excessive behaviors or mental acts (compulsions) that aim to neutralize the discomfort or avert the threat of a feared event.

OCD is associated with serious disability and decreased quality of life [4], leading to significant impairment in areas of family relations, social interactions, education, and work [5]. However, OCD-related impairment is not restricted to individuals who meet the full diagnostic criteria. OCD symptoms exist on a spectrum that varies in frequency and intensity across clinical and nonclinical populations [6]. Compared with the general population, individuals with subclinical OCD symptoms reported significantly lower life satisfaction and quality of life, and greater health care use [7]. In nonclinical populations, prevalence rates of intrusive thoughts have ranged from 74% to 99.4%, with individuals also found to carry out compulsive behaviors, such as checking, washing, or thought suppression [8,9]. Hence, recent research has emphasized early detection and intervention for individuals at risk of developing OCD [10].

The cognitive-behavioral model of OCD posits that obsessional distress stems from an individual's appraisal of normal intrusive thoughts, images, and urges as extremely significant or threatening. Additionally, the individual appraises that the occurrence of the intrusion indicates their potential responsibility for causing harm [11]. These appraisals trigger distress and anxiety, which culminate in the decision to perform compulsions. Consequently, the short-term relief following compulsions negatively reinforces the behavior, leading to an increased behavioral tendency for compulsions over time [12]. As clinical obsessions develop from intrusive thoughts that most people experience [13], OCD symptoms in nonclinical samples are often investigated to uncover findings that can be extended to clinical populations.

The first-line psychotherapeutic treatment for OCD is cognitive behavioral therapy (CBT) with exposure and response prevention (ERP) [14]. ERP involves gradually confronting obsessions while refraining from compulsions, breaking the cycle of compulsions by teaching individuals to tolerate distress without engaging in counterproductive behaviors. ERP facilitates inhibitory learning, helping individuals form nonthreat associations that inhibit threat responses [15]. Extensive research has supported the superior efficacy of CBT in reducing OCD symptoms compared with placebo, relaxation therapy, and anxiety management [16,17]. The efficacy of CBT has been similarly demonstrated across countries, OCD severity, and treatment settings [18]. However, up to 50% of individuals drop out of treatment prematurely and approximately 25% refuse treatment [19]. Barriers to CBT include cost, limited availability of qualified practitioners, societal stigma, and difficulties attending sessions [20,21]. Hence, only a minority of individuals with OCD access evidence-based treatment [22].

Computerized internet-based CBT (ICBT) can reduce these barriers and overcome the limitations of face-to-face psychological interventions. Digital interventions are accessible from any location with an internet connection, offer a broad reach, are cost-effective, and are available 24/7 [23]. ICBT has demonstrated comparable effectiveness to face-to-face CBT for OCD [24], and self-guided ICBT has been suggested as an alternative to remote clinical support [25]. Self-guided ICBT has proven superior in reducing OCD symptom severity levels compared with waitlist and active control conditions [23,26]. Thus, self-guided digital interventions present a promising option for addressing the treatment gap and facilitating the delivery of evidence-based care.

While mobile health (mHealth) apps have gained traction in mental interventions for anxiety, stress, and depression [27], few studies are available on the efficacy of self-guided, mHealth app–based OCD programs that use CBT with ERP. Two randomized controlled trials (RCTs) examined the effectiveness of GG Relationships, Doubt, and Obsessions. However, as GG Relationships, Doubt, and Obsessions was designed to target symptoms of relationship OCD, the study samples were more selective, requiring all participants to have romantic relationship experience [28,29]. An RCT and an open pilot trial investigated the effectiveness of the apps OCfree and nOCD for OCD symptoms and found statistically significant reductions in OCD symptom severity at postintervention [30,31]. However, these apps were used alongside in-person therapy. Hence, it remains unclear whether self-guided mHealth apps for OCD are effective without therapist support. Moreover, previous studies focused on clinical OCD samples, potentially limiting generalizability to those with mild or subclinical symptoms who might benefit from low-intensity, self-guided treatments [32]. The authors also highlighted limitations, such as small sample sizes (N≤50), the lack of a control group not undergoing CBT, and the necessity for replication in future RCTs. Other limitations include the absence of follow-up assessments in 2 out of 4 studies and only 1 Asian sample being studied [29,31]. Notable gaps remain regarding the effectiveness of self-guided mHealth interventions for subclinical OCD populations.

Moreover, variables affecting the efficacy of self-guided mHealth app programs for OCD are underexplored. Only Gamoran and Doron [33] examined moderators in a sample of 46,955 users of OCD.app. Initial OCD severity, age, gender, trait mood, and app use data were identified as predictors of change. However, no psychological variables were analyzed as potential outcome moderators, leaving a gap in OCD treatment research [34]. A potential moderator of OCD outcomes from mHealth app programs is maladaptive perfectionism (MP). Perfectionism refers to one's tendency to demand and pursue unrealistically high standards of performance, accompanied by excessively critical self-evaluations [35]. Frost et al [36]

proposed a 6D measure of perfectionism, which involves being overly concerned about making mistakes (CM), setting and pursuing high personal standards, perceiving high parental expectations (PE) and parental criticism (PC), doubting the quality of one's actions (DA), and preferring order and organization. As a multidimensional construct, perfectionism comprises adaptive and maladaptive aspects. While perfectionistic individuals seek excellence which may promote well-being [37], they may experience dysfunction when excessively fixating on mistakes and meeting external standards. MP is commonly observed in individuals with OCD [38]. It is a risk factor for OCD development and has been viewed as an essential predisposing trait [39]. Additionally, MP has been shown to impede OCD treatment [40]. As moderators can help to identify individuals who may face a poor prognosis and assist in matching individuals with appropriate treatments, it would be useful to examine how baseline MP levels can affect intervention outcomes for self-guided CBT-based mHealth app programs for OCD.

This Study

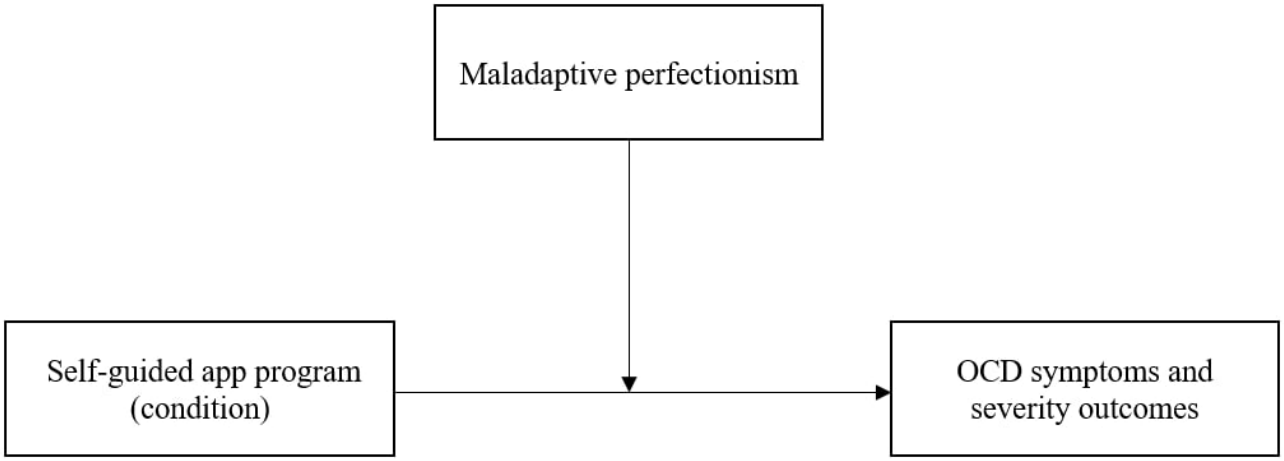
Using an RCT design, we evaluated the efficacy of a self-guided program on an mHealth app in reducing subclinical OCD symptoms and severity among university students from Singapore. Additionally, we examined the association between MP and OCD symptom severity and investigated MP as a moderator of intervention outcomes. Although the mean age of onset for OCD is around 20 years, intervening in university students with subclinical symptoms can still prevent further progression. Early intervention, even at this stage, is crucial for reducing the risk of symptom escalation and long-term impairment.

Given that OCD ranks among the top 3 most prevalent mental health conditions in Singapore, with a lifetime prevalence that is approximately 0.4% to 1.6% higher than the global average, it is crucial to identify accessible and effective OCD interventions. In particular, Singaporeans aged 18 to 34 years have the highest lifetime prevalence rates of OCD, at 6.7% [1]. Yet, OCD remains poorly recognized and has the second-largest treatment gap out of at least 7 mental disorders studied in Singapore [41]. Given the typical onset of OCD in adolescence and early adulthood and its likely chronic course without appropriate intervention [42], it is critical for this population to access evidence-based interventions before symptoms escalate [1]. Young adults have responded positively to mHealth apps, citing their appeal due to flexibility, interactivity, and accessibility [43]. Furthermore, as a population with high smartphone use and common obstacles to accessing traditional mental health services, mHealth apps offer considerable promise to engage Singapore's young adults [44,45].

Given Singapore's cultural context, MP is also a relevant variable to examine. Extensive research has indicated that Asian populations generally exhibit significantly higher levels of perfectionism compared with African and White populations [46,47], which may be due to cross-cultural differences in parenting. Asian parents were found to set higher expectations for their children than European American parents [48] and provide conditional love based on their children's achievements [49]. Additionally, Asian parents typically adopt more controlling and directive parenting styles compared with European parents [50], which is associated with the development of MP [51]. Thus, individuals who grew up in such demanding environments may develop perfectionism as they internalize these standards [52]. In a sample of 302 Singaporean children, a large proportion was found to exhibit high levels of MP [53]. This finding may be attributed to parental intrusiveness and the general emphasis on academic achievement in Singapore, which have been identified as factors that predict increased perfectionistic strivings and concerns [54,55]. Hence, as findings on OCD and MP may be culturally influenced, these variables are pertinent to study in Singapore for the development of effective interventions.

The hypotheses of the study are in 3 parts. First, we expected participants in the OCD program to report significant reductions in OCD outcomes compared with the active control group at postintervention and 4-week follow-up. Second, we hypothesized that baseline OCD symptom severity and MP will be positively correlated. Third, we predicted that participants with the lowest levels of MP would experience the greatest reduction in OCD symptoms and severity at postintervention and 4-week follow-up (Figure 1).

Figure 1. Predicted relationship with maladaptive perfectionism as a moderator of the direct effect of the self-guided app program on OCD symptom and severity outcomes. OCD: obsessive-compulsive disorder.



Methods

Design

This RCT used a 2×3 mixed factorial design with condition (intervention vs active control) as the between-subjects factor and time of assessment (baseline vs postintervention vs 4-week follow-up) as the within-subjects factor. The intervention group participated in an 8-day, self-guided OCD program, and the active control group participated in an 8-day, self-guided cooperation program. The dependent variable measured was OCD symptom severity. Additionally, general psychological distress was measured to be controlled for during analyses, and MP was measured for correlation and moderation analyses.

Ethical Considerations

The study's ethics was approved by the National University of Singapore's (NUS) Institutional Review Board (NUS-IRB-2023-444). The study was also preregistered with ClinicalTrials.gov (registration NCT06202677). All study procedures adhered to the ethical standards outlined by the Declaration of Helsinki (as revised in 2000). Participants were provided with a detailed Participant Information Sheet, which explained the study's objectives, procedures, potential risks, and benefits. Written informed consent was obtained from all participants prior to their enrollment in the study, and they were explicitly informed of their right to withdraw at any point without penalty.

Power Calculation

A meta-analysis examining low-intensity, technology-delivered CBT programs for OCD found small effect size reductions in OCD symptoms posttreatment [56]. Using Cohen *f*=0.10, α=0.05, and power=0.80, G*Power 3.1 revealed a minimum number of 164 participants. Attrition rates in similar mHealth app–based studies conducted among NUS students have ranged from 1% to 44.9% [57-59]. Additionally, accounting for 10% of invalid data typically encountered in web-based research studies [60], this study aimed to recruit a minimum of 206 participants.

Recruitment and Study Participants

The sample of 225 participants had a mean age of 21.68 (SD 1.71) years and consisted of 171 female individuals, 52 male individuals, 1 nonbinary individual, and 1 individual of other gender. Recruitment was carried out by word of mouth and on the university recruitment platforms. Participants were reimbursed with either course credits or monetary cash (see the *Procedure* section below). The inclusion criteria required participants to be a Singapore citizen or permanent resident, be able to read and understand English, be a student from the NUS between the ages of 18 and 30 years, present with mild or subclinical OCD symptoms, and own a mobile phone to download the Intellect app for use in the study. Participants were also required to refrain from using external mental health services during their participation in the study. Individuals with moderate to high OCD symptom severity, as determined by their OCI-R (Obsessive Compulsive Inventory–Revised) scores, were excluded and directed to appropriate resources for the necessary treatment

Materials

Intellect is an mHealth app that can be downloaded from the Apple App Store and the Google Play Store. It hosts numerous self-guided programs that have been reviewed by clinical psychologists and cognitive behavioral therapists. The app adheres to the highest standards of data security and privacy, using zero-knowledge encryption to ensure user data confidentiality. Various self-guided programs on the app have been validated in previous RCTs using samples of Singaporean university students: "Stress," "Improving your Body Image," and "Anxiety & Worry" [57-59]. In this study, participants used Intellect to access either the "Obsessive Compulsive Disorder" or "Cooperation" learning program, depending on their assigned condition.

Learning Programs

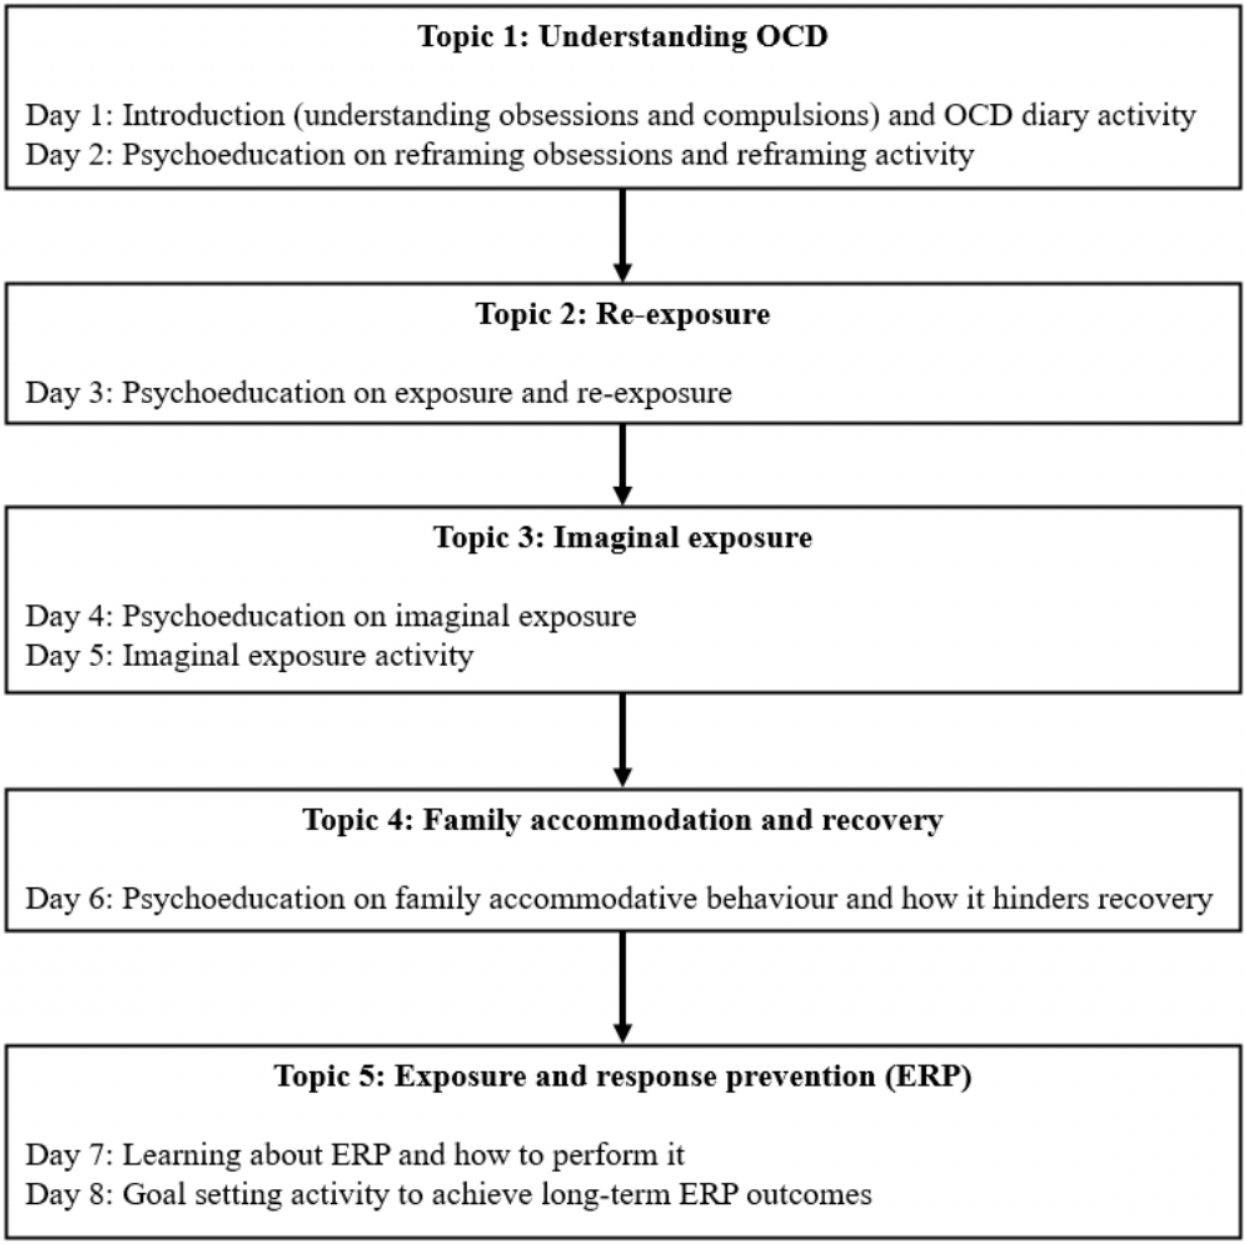
OCD Program (Intervention Condition)

This 8-day program used principles of CBT with ERP for OCD. Each daily session took approximately 5 minutes to complete. The program commenced with psychoeducation on obsessions and compulsions, and how to identify them. Subsequently, through a series of content learning and daily exercises that increase in difficulty, participants were guided to conduct exposure exercises while tolerating distress and refraining from compulsions. For example, in Topic 2 (Re-exposure), participants were asked to face their feared stimuli (eg, touching a "contaminated" surface) and refrain from performing compulsive behaviors (eg, excessive hand-washing) while observing and tolerating the discomfort that arose. This program structure aimed to enable participants to actively practice using the skills that were taught, while not overwhelming them. During the final program session, participants were guided to set goals for continual progress. Due to the challenging nature of ERP, the program also provided advice on concerns that are frequently encountered during ERP. An overview and timeline of the program are presented in Table 1 and Figure 2.

Table 1. Overview of obsessive-compulsive disorder (OCD) program.

Topics	Content
Topic 1: Understanding OCD	• Identify personal obsessions and compulsions • Identify when/where obsessions and compulsions arise • Understand how the importance placed on obsessions causes distress • Understand that obsessions are not based on reality • Develop skills to reframe obsessions
Topic 2: Re-exposure	• Introduce the concept of re-exposure • Understand the function of exposure and re-exposure exercises • Develop skills to carry out re-exposure • Develop skills to tolerate obsessional distress
Topic 3: Imaginal exposure	• Introduce the concept of imaginal exposure • Develop skills to carry out imaginal exposure
Topic 4: Family accommodation and recovery	• Introduce the concept of family accommodation • Understand how family accommodative behaviors can hinder recovery • Develop skills to identify family accommodative behaviors
Topic 5: Exposure and response prevention (ERP)	• Introduce the concept of ERP • Understand the importance of prioritizing long-term OCD reduction goals over short-term discomfort • Develop skills to confront obsessions and resist compulsions • Develop goal-setting skills for long-term ERP progress

Figure 2. Timeline of OCD program. ERP: exposure and response prevention; OCD: obsessive-compulsive disorder.



Cooperation Program (Active Control Condition)

Participants in the active control group were allocated to an 8-day, self-guided program on cooperation, which was housed within the same Intellect app but offered a different module unrelated to OCD content. Having an active control group ensured that participants in both groups shared as many experiences as possible. This controlled for nonspecific factors and attentional effects, which could impact the study's results [61]. The program aimed to improve participants' collaborative skills and interpersonal wellness through a series of content learning and practice exercises, including activities reflective exercises on communication skills. To ensure that participants in both conditions spent a comparable amount of time and effort, the approximate duration for completing each daily session was matched to be 5 minutes.

Procedure

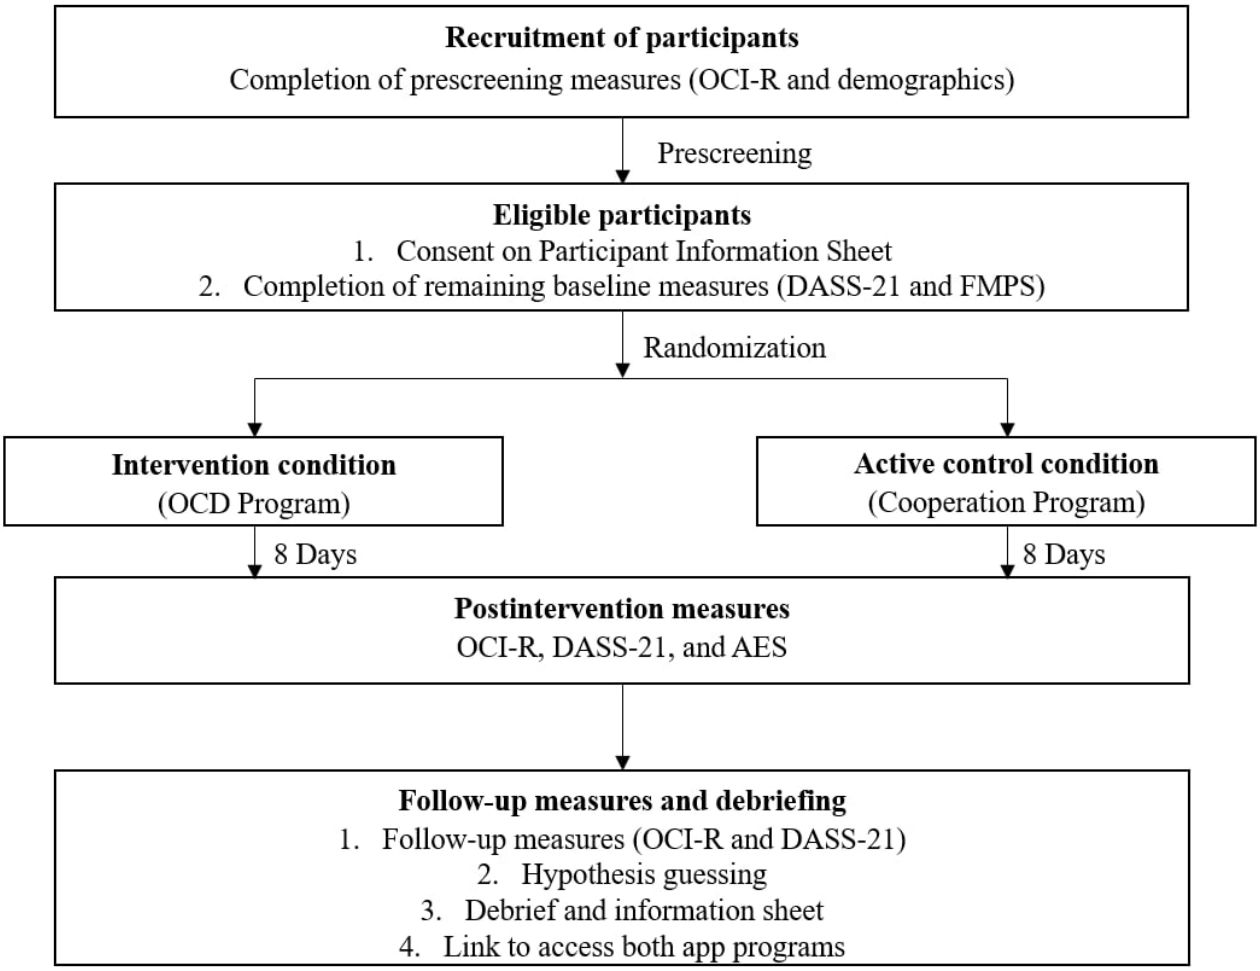
Interested individuals signed up for the study by responding to the web-based advertisement via a link to the web-based survey hosted on Qualtrics. First, they completed a prescreening test comprising measures on OCD and demographics and were screened for eligibility according to the inclusion criteria. Eligible participants read the Participation Information Sheet, and after providing informed consent, completed measures on psychological distress, and perfectionism.

Thereafter, participants were randomly allocated to the intervention or active control condition, using computer-generated random numbers in a 1:1 ratio. To minimize potential confounding effects, participants were instructed not to use any other mHealth apps for the study duration. Additionally, to reduce demand characteristics, participants were not informed of the conditions' functions or the study's objective to evaluate the efficacy of the OCD program. Instead,

participants were informed that the study examined well-being and the learning effectiveness of mental health–related topics using a smartphone app. Participants were then instructed to download the Intellect app, create an account, and access the program of their allocated condition. Participants in the intervention group underwent 8 days of the OCD program, while participants in the active control group underwent 8 days of the cooperation program. Participation in each program took approximately 5 minutes per day. To encourage study adherence, participants were sent a daily reminder to complete app activities via WhatsApp Messenger or Telegram Messenger. To verify program completion, participants sent a screenshot of their learning logs to the investigator.

After verification, participants were sent a postintervention survey link to complete the measures on OCD, psychological distress, and the App Engagement Scale (AES). Four weeks after program completion, participants were sent a follow-up survey link to complete measures on OCD and psychological distress. To further control for demand effects and confounders, participants were asked to guess the study's hypothesis and indicate whether they had undergone mental health treatment during the past 4 weeks. Thereafter, they were debriefed on the study's objectives and hypotheses. Participants who participated in the cooperation program were given access to the OCD program and vice versa. Participants were reimbursed with either SGD 10 (US $7.43) or 2 course credits after completion of the postintervention survey, and an additional SGD 2.50 (US $1.90) or 0.5 course credits after the follow-up survey. Figure 3 presents the study procedure.

Figure 3. Study flowchart. AES: App Engagement Scale; DASS-21: Depression Anxiety Stress Scale-21; FMPS: Frost Multidimensional Perfectionism Scale; OCD: obsessive-compulsive disorder; OCI-R: Obsessive Compulsive Inventory–Revised.



Measures

OCI-R Questionnaire

OCI-R [62] is an 18-item questionnaire that assesses OCD symptoms across 6 subscales: washing, checking, neutralizing, obsessing, ordering, and hoarding. Items are rated on a 5-point Likert scale (0=not at all; 4=extremely). OCD symptom severity can be derived by summing all the items to obtain a total score. Total OCI-R scores correspond to mild (OCI-R=0-15), moderate (OCI-R=16-27), and severe (OCI-R=28-72) OCD symptom severity [63]. In this study, the OCI-R was used as a measure of OCD symptom severity at baseline, postintervention, and 4-week follow-up. Participants with scores of 21 and above were screened out due to a likely presence of clinically significant OCD [62]. Subclinical OCD refers to above-average levels of symptoms that do not meet the clinical threshold but can still cause distress and functional impairment. Reducing even these subclinical symptoms is important to prevent potential escalation to more severe forms of OCD. The OCI-R

showed acceptable internal consistency, with Cronbach α of 0.68.

Frost Multidimensional Perfectionism Scale

The Frost Multidimensional Perfectionism Scale (FMPS) [36] is a 35-item scale that assesses perfectionism across 6 subscales: CM, personal standards, PE, PC, DA, and preferring order and organization. Items are rated on a 5-point Likert scale (1=Strongly disagree; 5=Strongly agree). The FMPS has demonstrated good internal consistency and convergent validity with other measures of perfectionism within nonclinical and clinical samples [36]. In this study, the MP dimension (FMPS–Maladaptive Perfectionism [FMPS-MP]) was obtained by summing scores on the subscales of CM, DA, PE, and PC [64]. Perfectionism was assessed as a moderator of OCD symptom outcomes but was not directly addressed in the intervention content. The FMPS and FMPS-MP showed excellent internal consistency with Cronbach α of 0.91 and 0.92, respectively.

Depression Anxiety Stress Scale-21

The Depression Anxiety Stress Scale-21 (DASS-21) [65] is a set of 3 scales assessing depression, anxiety, and stress, and it is commonly used in student samples [66]. Each subscale contains 7 items, which are rated on a 4-point Likert scale (0=Did not apply to me at all; 3=Applied to me very much or most of the time). In this study, the DASS-21 total score was computed by summing the scores of all items and used as a measure of general psychological distress [65]. Additionally, as depression, stress, and anxiety have been identified in the pathogenesis and maintenance of OCD [67-69], baseline total DASS-21 scores were controlled for during analyses to disentangle the effect of the intervention on OCD symptoms from depression, stress, and anxiety. Internal consistency of the DASS-21 was excellent, with Cronbach α of 0.91.

AES Instrument

The AES [70] is a 7-item scale that assesses app engagement. Each item is rated on a 5-point Likert scale (1=definitely disagree; 5=definitely agree). The total score is derived by summing all the items. Internal consistency of the AES is good, with Cronbach α of 0.88.

Analytic Approach

Incomplete responses and participants who indicated that they received psychotherapy during the study's duration were excluded. Invalid data due to careless or insufficient effort responding were then sequentially identified in 2 steps and removed using a multiple hurdles approach [60]. First, response times of less than 500 seconds on the baseline survey, less than 215 seconds on the postintervention survey, and less than 180 seconds on the follow-up survey suggested that participants may have rushed through the questionnaires and app activities. Long string analysis and attention checks were carried out to confirm if these participants' responses were invalid. Responses were identified and removed if the same option was selected across the entire scale of any measure or responses to attention-check items were incorrect. A total of 32 participants were excluded for failing these data quality checks, including response times indicating rushed responses, long string analysis, and attention check failures, as their data were deemed unreliable for analysis.

Finally, data were screened for univariate outliers that fell beyond 3 SDs from the mean. Winsorization was conducted to address these outliers by substituting them with the closest nonoutlying value [71]. Subsequently, all analyses were conducted with and without the outliers. As the results were consistent across both datasets, only results from the initial dataset were reported.

SPSS (version 26.0, IBM Corp) was used for all statistical analyses. Independent 2-tailed *t* tests, Mann-Whitney *U* tests, and chi-square tests were conducted to analyze differences between the intervention and active control groups on the baseline and demographic variables. While the initial intention-to-treat (ITT) analysis was conducted on the full dataset of 115 and 109 participants, 32 participants were excluded after failing data quality checks. Thus, the final numbers analyzed were 94 and 98, reflecting a modified per-protocol analysis after quality checks.

Missing data were assessed for attrition biases using independent 2-tailed *t* tests, chi-square tests, and Mann-Whitney *U* tests to ensure there were no significant differences between participants who completed all assessments and those who did not. As all missing data were verified to be missing at random, they were addressed using ITT analyses [72], whereby missing data on the postintervention and follow-up assessment were substituted with data from the last completed questionnaire. Missing AES data were replaced using the mean score.

Preliminary Analyses

Main Analyses

Analysis of covariance (ANCOVA) examined if changes in OCD symptom severity at postintervention and follow-up were significantly different between the intervention and active control groups. ANCOVA is recommended for inferential testing intervention effects [73], as controlling for baseline scores ensures that results at postintervention and follow-up are attributable to the intervention [74]. ANCOVA was conducted on postintervention and follow-up OCI-R scores, with baseline OCI-R and DASS-21 scores as the covariates. The α level was set at $P<.05$. Cohen [75] guidelines for eta square were used to interpret effect sizes (η_p^2), whereby 0.01 to 0.05 indicates a small effect, 0.06 to 0.13 indicates a moderate effect, and 0.14 and above indicates a large effect.

Correlation and Moderation Analyses

Pearson correlation was conducted to test if baseline OCI-R scores were correlated with FMPS-MP scores. Due to nonnormality of baseline OCI-R scores, the bias-corrected and accelerated method (BCa) with 1000 bootstrap iterations was used to generate 95% CIs for Pearson correlation coefficients [76]. Pearson correlation analysis with BCa is robust to nonnormality and retains type I error control by generating more accurate CIs [77,78].

Subsequently, Hayes PROCESS (version 4.2, IBM Corp, macro model 1) was used for moderation analyses. A total of 2 models

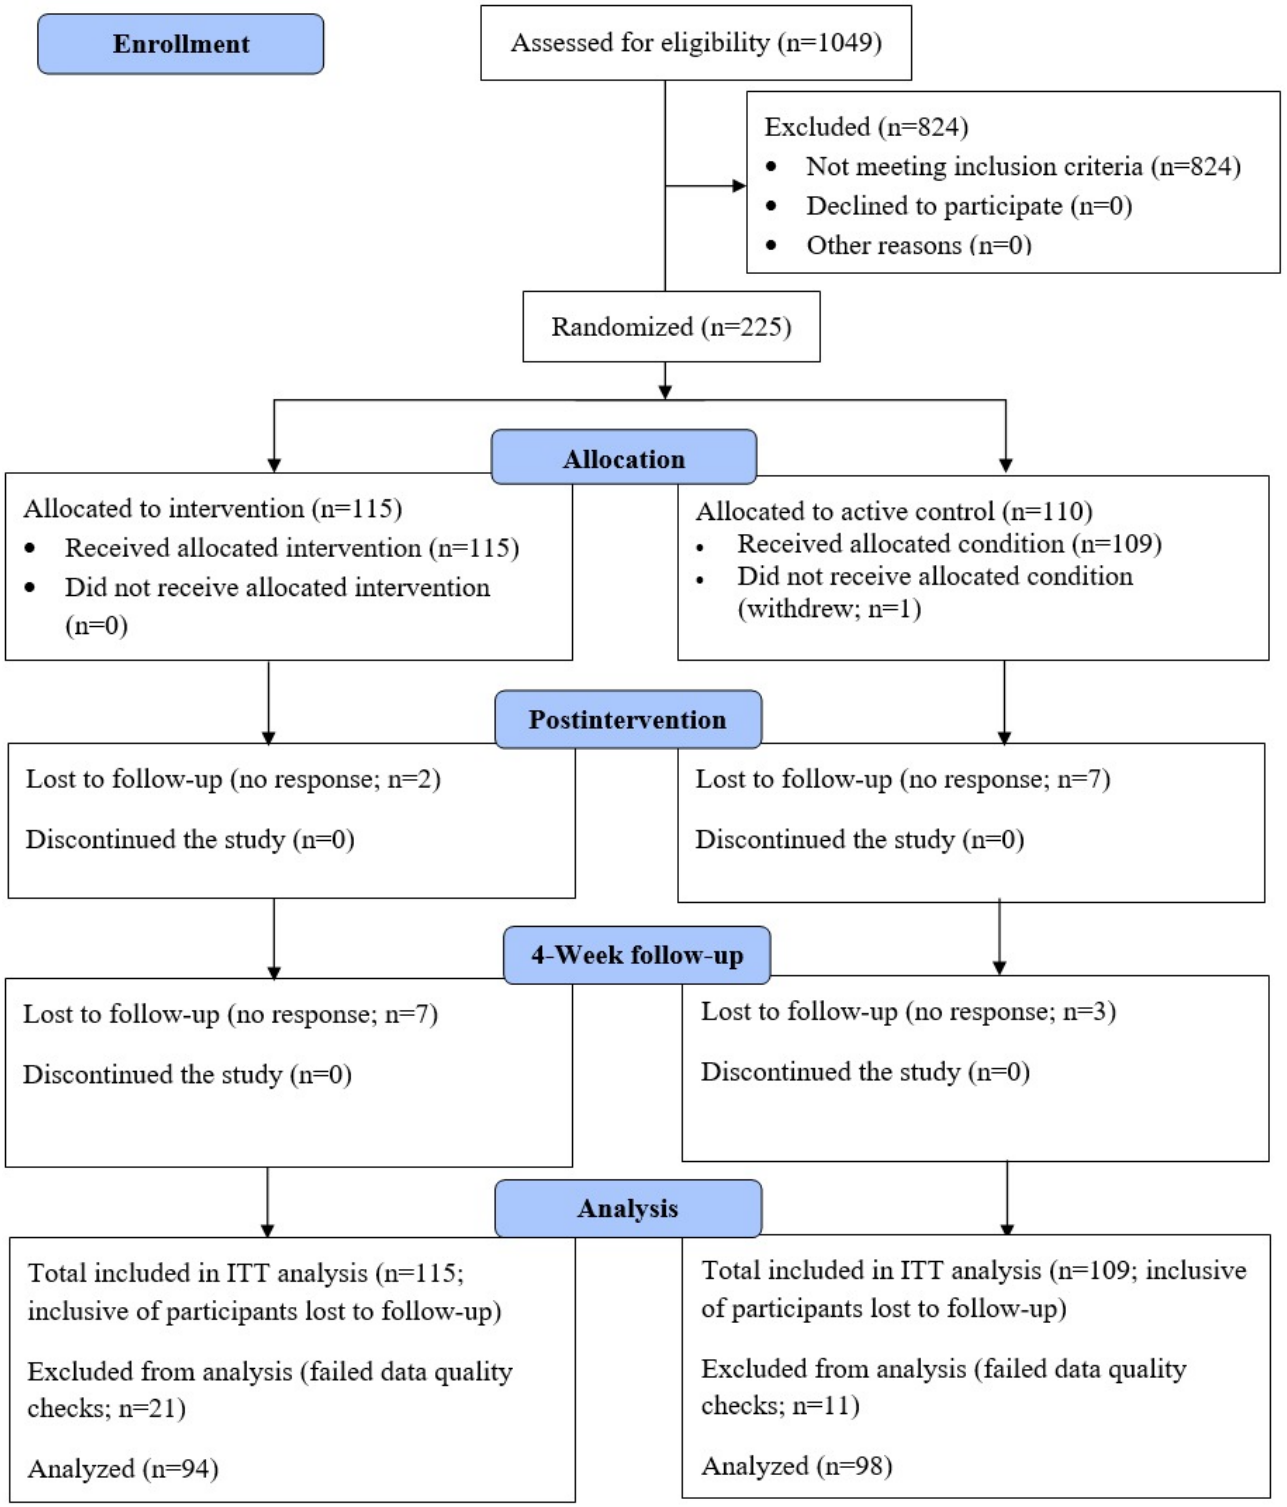
were analyzed. Postintervention and follow-up OCI-R scores were used as the dependent variables in the first and second models, respectively. Each model ran a simple moderation analysis to investigate the moderating effects of MP on the relationship between condition and OCI-R scores at postintervention or follow-up. Baseline OCI-R and DASS-21 scores were entered as the covariate for all analyses. The 95% CIs were used, with 5000 bootstrap iterations. The interaction term between condition and FMPS-MP was interpreted, whereby $P<.05$ indicates that MP moderates OCI-R scores at postintervention or follow-up.

Results

Participant Characteristics

A total of 1049 responses were screened for eligibility. Of these, 225 participants met the inclusion criteria, completed the baseline survey, and were randomly assigned to either the intervention or active control condition. One participant withdrew from the study before completing the postintervention assessment, resulting in 224 participants who completed the intervention. Among these, 215 (95.56%) participants completed the postintervention assessment, and 204 (90.67%) participants completed the follow-up assessment. Additionally, 32 participants were excluded from the analyses after failing data quality checks, leading to a final sample of 192 participants included in the statistical analyses (Figure 4).

Figure 4. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. ITT: Intention to treat.



At baseline, 111 participants exhibited mild OCD symptom levels, and 81 participants exhibited moderate OCD symptom levels. Psychological distress was measured using the DASS-21, with average scores at baseline (mean 11.45, SD 8.66), postintervention (mean 9.93, SD 8.37), and follow-up (mean 11.59, SD 9.46), indicating that the participants were generally experiencing mild distress throughout the study.

Preliminary Analyses

The intervention and active control groups did not differ significantly on baseline demographic and outcome variables (Tables 2 and 3).

Table 2. Descriptive statistics for demographic variable of gender by condition.

Demographic variable	Full sample (n=192), n (%)	Intervention condition (n=94), n (%)	Active control condition (n=98), n (%)	*P* value
Gender				.47
Women	147 (76.6)	74 (78.7)	73 (74.5)	
Men	43 (22.4)	19 (20.2)	24 (24.5)	
Nonbinary	1 (0.5)	1 (1.1)	0 (0.0)	
Other	1 (0.5)	0 (0.0)	1 (1.0)	

Table 3. Descriptive statistics for baseline demographic and outcome variables by condition (n=192).

Variable	Intervention condition (n=94), mean (SD)	Active control condition (n=98), mean (SD)	*P* value
FMPS-MP[a]	61.21 (14.56)	57.93 (12.60)	.10
Age (years)	21.69 (1.46)	21.74 (1.82)	.82
OCI-R[b]	12.83 (5.41)	13.01 (5.18)	.86
DASS-21[c]	11.83 (9.32)	11.09 (8.00)	.79

[b]OCI-R: Obsessive Compulsive Inventory–Revised.

[c]DASS-21: Depression Anxiety Stress Scale-21.

For participants lost to postintervention and follow-up, Mann-Whitney *U* tests, chi-square tests, and independent 2-tailed *t* tests revealed no attrition-related biases across demographic and outcome variables. ITT analysis was conducted to address participants' missing data by bringing forward scores from their last completed survey. Mean substitution was conducted to address missing AES scores.

Independent 2-tailed *t* tests indicated that participants in both conditions enjoyed using the app, with no significant differences (*P*=.81) found between the intervention group (mean 25.33, SD 3.90) and the active control group (mean 25.47, SD 4.01) on the AES.

Participants were directly asked after the study if they believed they could guess the hypothesis. Mann-Whitney *U* tests indicated that participants who correctly guessed the study's hypothesis did not differ significantly from participants who incorrectly guessed the hypothesis on all measures at postintervention and follow-up.

Main Analyses

The assumptions for ANCOVA were met, except for the assumption for normality. However, due to the robustness of ANCOVA against deviations from normality when sample sizes are larger than 100 [77,78], analysis using ANCOVA proceeded. At both postintervention and follow-up, the intervention group reported significantly lower OCI-R scores compared with the active control group, with a small effect size (Table 4).

Table 4. Means, SDs, univariate *F* values, and effect sizes for OCI-R[a] scores at postintervention and 4-week follow-up.

	Intervention, mean (SD)	Control, mean (SD)	*F* test (*df*)	*P* value	ES[b]
Baseline	12.83 (5.41)	13.01 (5.18)	—[c]	—	—
Postintervention	11.03 (7.40)	13.04 (6.53)	5.79[d] (1)	.02[e]	.030
Follow-up	10.53 (7.36)	12.37 (7.46)	4.11[d] (1)	—	—

[b]Effect size of 0.01=small, 0.06=moderate, 0.14=large [75].

[c]Not applicable.

[d]*P*<.05.

[e]Significant *P* value at .05.

Correlation and Moderation Analyses

Results from Pearson correlation analysis revealed that OCI-R and FMPS-MP were significantly correlated (*P*<.001) with a weak positive correlation (*r*=.28), and the BCa bootstrap (95% CI 0.14-0.41) did not include zero.

Moderation analyses indicated a significant effect in the overall moderation model with OCI-R scores as the dependent variable

and FMPS-MP as the moderator. At postintervention, the model showed R^2=0.38, $F_{5,186}$=22.57, and P<.001, and at follow-up, it showed R^2=0.29, $F_{5,186}$=15.23, and P<.001. However, the interaction term between the condition and FMPS-MP was not statistically significant at postintervention and follow-up. Results are displayed in Table 5.

Table 5. Standardized coefficients, SEs, t values, *P* values, and 95% CIs for moderation analyses.

Discussion

Principal Findings

This study evaluated the efficacy of an 8-day, self-guided OCD program on an mHealth app compared with active control in reducing subclinical OCD symptoms and severity in a sample of Asian university students. The study further investigated the correlation between MP and OCD symptomatology, and MP as a factor that might help identify individuals who will benefit most from the self-guided program. The study addresses important gaps in the literature regarding the dearth of RCTs studying evidence-based mHealth app programs for OCD and the factors that influence the efficacy of such programs.

Our hypotheses regarding the efficacy of the app-based OCD program were supported. The intervention group reported significant reductions in OCD symptom severity compared with the active control group at both postintervention and follow-up. Consistent with past studies on longer ICBT or in-person interventions, our findings revealed that an 8-day, self-guided program using principles of CBT with ERP can reduce OCD symptoms and severity [16,23,79]. The small effect size reductions for OCD symptom severity in our OCD program are also comparable with a 12-week self-guided ICBT program for OCD at postintervention [80]. Taken together, these findings suggest that OCD gains can be obtained in a shorter duration through self-guided mHealth app programs. However, as there is limited research regarding the optimal duration of self-guided interventions, future research should examine how the efficacy of self-guided, low-intensity interventions for OCD might vary with program duration. While longer interventions may offer more comprehensive content and exercises, shorter interventions may offer increased convenience and improve program completion rates.

Our study also extended the findings from guided, 6-week-long, app-based program by Hwang et al [31], demonstrating that even without therapist support, app-based CBT can be beneficial for individuals with OCD symptoms. However, compared with the study by Hwang et al [31], which used a sample with clinical OCD, our study's subclinical sample did not yield large effect

size reductions for OCD. Despite our study's overall small effect sizes, this result is larger or comparable to effect sizes found after using the self-guided OCD.app for approximately 8.52 days. Specifically, Gamoran and Doron [33] found null effect sizes for participants with mild OCD symptom levels, and small effect sizes for participants with moderate OCD symptom levels. Research from previous RCTs has suggested that mHealth app use leads to greater decreases in symptoms for participants with moderate to severe OCD symptom levels [81], compared with those with less severe OCD symptom levels [29]. As such, because our study's sample comprised participants with both mild and moderate OCD symptom severity, it is possible that analyzing their data collectively diluted the effect size. Moreover, participants with OCI-R scores near zero were included in our study. Such participants would expectedly have a limited reduction in OCD symptom severity after the intervention. As participants in both groups generally reported low OCI-R scores at baseline, it is possible that a floor effect limited intervention effects. Hence, it would be fruitful for future RCTs to investigate how effect sizes may vary across different levels of OCD symptom severity after using self-guided app-based OCD programs. Additionally, the efficacy of such programs should be tested in samples with clinically significant levels of OCD symptom severity to better understand their clinical utility.

Overall, these findings provide preliminary support for the use of CBT with ERP on mHealth apps to reduce OCD symptom severity in Asian university students. As such, our findings align with the National Institute for Health and Care Excellence [32] stepped-care approach for managing OCD-related symptoms using low-intensity treatments. Additionally, the 4-week follow-up effects were encouraging as they suggest that the app-based OCD program can produce sustained effects, addressing the lack of follow-up data in mHealth app research [82]. As ICBT for OCD has been found to produce treatment effects maintained after 2 years [83], future mHealth app studies for OCD may seek to administer longer follow-up assessments to evaluate the long-term maintenance of treatment gains.

Our hypothesis that MP predicts OCD symptom severity was also supported. This finding corroborated with prior research that MP is highly prevalent in individuals with OCD [38]. Based on the cognitive-behavioral model of OCD, exhibiting higher levels of MP increases the risk of OCD as individuals are prone to beliefs that there is a perfect method to performing any task (eg, "I must order my books perfectly parallel to each other"). Additionally, individuals with high MP often have an inflated sense of responsibility over obsessions, anticipating that small mistakes and failures will have catastrophic consequences which they are responsible for preventing [84]. Consequently, obsessive distress and anxiety drive the individual to perform compulsions to dispel the threat of their obsessions [85]. However, the strength of the correlation found between MP and OCD symptoms in our study was weaker than that of prior research [86]. This may be due to a range restriction of OCI-R scores. Given that participants with clinically significant levels of OCD were excluded from our sample, our study's participants represent a narrower segment of the OCD severity spectrum than the general, broader OCD population. By limiting the variability in OCD symptom severity, the true strength of the correlation between MP and OCD symptom severity may have been obscured [87].

Furthermore, our hypothesis that MP would moderate the decrease of OCD symptoms at postintervention and follow-up was not supported. This result was unexpected, given that MP has been found to impede OCD treatment [40,88]. The weak correlation between MP and OCD symptom severity may have consequently led to and explained the lack of moderation effect of MP on the decrease of OCD symptoms at postintervention and follow-up. Another possible explanation for the lack of significant moderation effect could be due to the sample's high mean MP and small spread (mean 59.46, SD 13.72) [86,89]. As such, there might have been insufficient variability in MP scores needed to detect a moderating effect. Future studies may consider further examining MP as a moderator in samples with a wider range of OCD symptom severity.

Strengths and Limitations

The RCT design enabled the establishment of causal conclusions from the study's intervention and results [90]. Additionally, using an active control group controlled for attentional influences and nonspecific variables. Our study also had an attrition rate of 9.33%, which is much lower than participant dropout rates of up to 44.44% in similar studies on app-based OCD programs [81]. Furthermore, no attrition-related biases were detected in participants who discontinued the study. Altogether, these factors strengthened the overall validity of our results.

However, our study had several limitations. First, the low attrition and relatively high compliance observed may be partially attributable to the daily messaging by the study team, which is unlikely to be replicable in real-world settings. Next, data regarding how long participants spent applying skills from the programs in their daily lives were not collected. CBT research has found that greater application of CBT skills improves treatment outcomes [91], hence it is probable that participants who practiced the skills taught in our programs more frequently would have made increased gains. Moreover, there was no objective assessment of participant engagement and effort expended on the intervention programs as the time participants spent using the app was not tracked or controlled for. However, as poor engagement with mHealth apps has been associated with reduced gains [92], measures were taken to encourage adherence and ensure that app activities were fully completed. Participants received daily reminders to complete the app activities, and the app was programmed such that participants could only proceed to the next session if all preceding sessions were completed. Crucially, all participants were verified to have completed their assigned program. Given that no significant differences were found on the AES, both groups likely shared similar levels of engagement and time spent on the programs. Regardless, future studies should control for the duration of mHealth app use and investigate how the duration of app engagement may impact treatment outcomes.

Next, self-report measures are susceptible to individual biases, which could have contributed to the study's results. Social desirability bias is a concern because participant blinding was

not fully feasible, given that the study's hypothesis might be guessed based on the content of the allocated program. However, participants who correctly guessed the study's hypothesis did not report significantly different results on OCD outcomes compared with incorrect participants, which gives us some confidence that the effect of social desirability bias was limited. Nonetheless, our results should be interpreted with caution. Retrospective recall biases may also be present as the OCI-R required participants to report their experiences in the past month. To strengthen the accuracy of participants' self-reports on treatment outcomes, future studies may use daily journaling methods which can minimize memory distortion from prolonged recall periods [93].

Finally, as participants were recruited from one university and comprised mostly of female students, the external validity of our study may be limited. Future studies may replicate our findings with a more diverse sample of young adults.

In sum, the Intellect app offers a valuable solution for early intervention in subclinical OCD, helping prevent the escalation of symptoms into more severe forms. Its self-guided, CBT-based structure provides accessible support without the need for therapist involvement, addressing gaps in traditional mental health services. By offering a scalable and cost-effective option, the app enables individuals to manage their mental health more effectively, improving quality of life and reducing the risk of future clinical impairment.

Conclusion

Overall, our study provides preliminary support for the efficacy of a self-guided mHealth app program using principles of CBT with ERP in improving OCD symptom severity in young adults, producing gains maintained after 4 weeks. While MP was found to predict OCD symptom severity, MP did not moderate treatment outcomes. Identifying moderators can optimize outcome and treatment delivery on OCD-related mHealth apps. Hence, the impact of MP on treatment outcomes should be further studied in a broader spectrum of OCD symptom severity. Given the potential for cost-effective and accessible mHealth app programs to reach young adults and overcome traditional treatment barriers, future studies should aim to improve the efficacy of these programs.

Conflicts of Interest

The study was partly funded by Intellect Pte Ltd. OS holds the position of Vice President of Clinical at Intellect Pte Ltd; he also holds equity in Intellect.

Abstract

Background: Contact tracing technology has been adopted in many countries to aid in identifying, evaluating, and handling individuals who have had contact with those infected with COVID-19. Singapore was among the countries that actively implemented the government-led contact tracing program known as TraceTogether. Despite the benefits the contact tracing program could provide to individuals and the community, privacy issues were a significant barrier to individuals' acceptance of the program.

Objective: Building on the privacy calculus model, this study investigates how the perceptions of the 2 key groups (ie, government and community members) involved in the digital contact tracing factor into individuals' privacy calculus of digital contact tracing.

Methods: Using a mixed method approach, we conducted (1) a 2-wave survey (n=674) and (2) in-depth interviews (n=12) with TraceTogether users in Singapore. Using structural equation modeling, this study investigated how trust in the government and the sense of community exhibited by individuals during the early stage of implementation (time 1) predicted privacy concerns, perceived benefits, and future use intentions, measured after the program was fully implemented (time 2). Expanding on the survey results, this study conducted one-on-one interviews to gain in-depth insights into the privacy considerations involved in digital contact tracing.

Results: The results from the survey showed that trust in the government increased perceived benefits while decreasing privacy concerns regarding the use of TraceTogether. Furthermore, individuals who felt a connection to community members by participating in the program (ie, the sense of community) were more inclined to believe in its benefits. The sense of community also played a moderating role in the influence of government trust on perceived benefits. Follow-up in-depth interviews highlighted that having a sense of control over information and transparency in the government's data management were crucial factors in privacy considerations. The interviews also highlighted surveillance as the most prevalent aspect of privacy concerns regarding TraceTogether use. In addition, our findings revealed that trust in the government, particularly the perceived transparency of government actions, was most strongly associated with concerns regarding the secondary use of data.

Conclusions: Using a mixed method approach involving a 2-wave survey and in-depth interview data, we expanded our understanding of privacy decisions and the privacy calculus in the context of digital contact tracing. The opposite influences of privacy concerns and perceived benefit on use intention suggest that the privacy calculus in TraceTogether might be viewed as a rational process of weighing between privacy risks and use benefits to make an uptake decision. However, our study demonstrated that existing perceptions toward the provider and the government in the contact tracing context, as well as the perception of the community triggered by TraceTogether use, may bias user appraisals of privacy risks and the benefits of contact tracing.

Introduction

Background

Contact tracing technology has been implemented in many countries to help identify, assess, and manage individuals exposed to persons infected with COVID-19 [1]. The main aims of a digital contact tracing system are not only to notify those who may have contracted the virus unknowingly but also to provide corresponding information and instructions from public health officials. Hence, some of contact tracing applications are designed to track the geolocations and mobility patterns of individuals using GPS and location-based solutions [2,3]. Digital contact tracing identifies individuals' close contacts with people confirmed or suspected of having COVID-19 through Bluetooth technology [4] or even allows authorities to make decisions as to whether certain individuals are certified as healthy enough to enter public spaces [5]. The use and implementation of contact tracing apps during COVID-19 brings concerns of privacy intrusion and surveillance to the forefront, as the attempt to digitally map and trace the spread of the virus is conducted through apps that collect some of the most personal and sensitive data. Thus, privacy concerns were identified as a significant barrier to adopting the contact tracing system, significantly influencing the intention to participate in the program [6,7].

Applying the privacy calculus model, that is, the extent to which individuals are willing to disclose personal information after weighing the risks and benefits, this study examines how individuals' perceptions of two important key entities—government and community members—involved in digital contact tracing play roles in their privacy calculus for adopting contact tracing. First, most contact tracing systems, including those in Singapore, Ireland, and France, were introduced and managed by the national government [6]. Derived from the social exchange concept, prior research on privacy suggests that trust in a service provider is a significant determinant of privacy calculus on the web [8,9]. Considering the managerial roles played by the government for contact tracing measures and the extensive personal information collected and analyzed for this effort, we postulated that individuals' trust in the government would be the key influencer of their privacy calculus in digital contact tracing.

Community members are another key entity involved in the privacy calculus in digital contact tracing. The active participation of community members in the contact tracing program is crucial for the success of preventive efforts. However, digital contact tracing implies that the participants are connected through a web-based system for tracking, which may trigger privacy risks among users. Therefore, the sense of community triggered by the contact tracing measure may influence the relationship between privacy concerns and benefits, shaping one's intention to participate in contact tracing efforts.

This study focuses on understanding privacy calculus in the context of using TraceTogether, a nationwide contact tracing program implemented in Singapore during the COVID-19 pandemic. The Government Technology Agency of Singapore, also known as GovTech, launched TraceTogether on March 20, 2020, followed by the launch of a token on June 28 to increase accessibility for those without a smartphone. In late December 2020, it became mandatory to check using TraceTogether before entering various places, including restaurants, workplaces, schools, places of worship, and shopping malls. As COVID-19 prevention measures eased, TraceTogether check-ins were no longer required in most settings from April 26, 2022.

Objective

This study investigates how trust in government and the sense of community during the early stage of contact tracing influence privacy calculus and intention to use the technology during the later stage when contact tracing becomes compulsory. To this end, a 2-wave survey and a follow-up in-depth interview with those who participated in the contact tracing program in Singapore were conducted. Building on the survey results, in-depth interviews were conducted to gain insights into privacy calculus in digital contact tracings, as well as the ways and reasons why trust in government and sense of community impact privacy calculus in contact tracing for COVID-19 prevention.

Literature Review

Theoretical Framework: Privacy Calculus Theory

Overview

Privacy concerns about contact tracing programs during the COVID-19 pandemic have been raised because of the potential risks of extensive data collection, surveillance, and the possibility of unauthorized access [6,7], necessitating a careful balance between public health benefits and safeguarding individuals' private information. Thus, privacy calculus theory has been used as one of the most robust theories within the field of communication [10] to unpack the underlying theoretical mechanisms in explaining the use of contact tracing apps through the lens of privacy. Having its theoretical roots and origins in economics and social exchange theory, individuals are assumed to be rational in making decisions and weighing trade-offs, and these decisions can be mathematically modeled as a function of the interaction between the benefits and risks of adopting a behavior [11]. For these reasons, privacy calculus theory offers a useful framework for investigating the influence of competing positive and negative beliefs on individuals' willingness to engage with technologies by capturing the extent of trade-offs individuals are willing to make in relation to privacy [12]. For instance, despite knowing that companies such as Google or Waze could identify individuals' precise geocoordinates, individuals who commute by driving may be willing to disclose this otherwise sensitive information (where they are and their mobility patterns) in exchange for the benefit of getting to their desired locations.

Privacy Concerns About Digital Contact Tracing

At the heart of privacy calculus theory is the act of self-disclosure of personal data, which is a product of two opposing forces: privacy concerns and the perceived benefits of information disclosure. *Privacy concerns* can be defined as individuals' fears and apprehensions over the possible loss of privacy, as well as how their personal data could be used or abused [13,14]. Privacy concerns are multidimensional by nature, for example, [15,16]. Privacy concerns encompass 3 dimensions: *perceived surveillance*, *perceived intrusion*, and *secondary use of information* [16]. At a fundamental level, privacy concerns are the worries that people are being watched. *Perceived surveillance* encapsulates this notion and refers to individuals' perceptions of the act of data collection pertaining to their lives—whether legitimate or illegal [17]. In the digital age, this could take the form of devices and technological platforms that capture individuals' personal activities by recording their behaviors [18]. For instance, people living in Florida expressed concerns over the Florida Department of Health's Healthy Together contact tracing app in collecting data such as contact lists, phone numbers, and medical conditions [19]. Relatedly, *perceived intrusion* is another dimension of privacy concerns and refers to the extent to which others are able to make independent decisions about possessing or soliciting information. For instance, in China, the government implemented a QR code system for contact tracing and assigned colors, such as green, yellow, or red, depending on the health status of individuals and the risk of exposure by triangulating data from public transport and health care systems [20], which determined whether they had access to public places [21]. The third dimension of privacy concerns is the secondary use of information, defined as the use of personal data collected from individuals for purposes other than what it was intended for [22]. As a large volume of data were collected by contact tracing apps, there were fears over how the government would use (or abuse) potentially sensitive data [20,21].

In the context of contact tracing app use, a recent study showed that when people are concerned about the extent of surveillance and intrusion of the implementation of contact tracing apps, this may negatively influence their intention to use, as fears of public health surveillance could be transformed into routine monitoring of populations extending beyond the purpose of infectious disease management [23]. This is consistent with prior evidence of privacy concerns and different facets of technology use or behaviors to engage in privacy protection behaviors [13,24]. In Singapore, after the government announced that police would have access to TraceTogether data for criminal investigations and after correcting perceptions that the data were only collected for contact tracing and no other purpose, some members of the public expressed concerns and disappointment and indicated their intention to use it less [25].

Perceived Benefits

In this study, perceived benefits were conceptualized as the health benefits that individuals would receive by using contact tracing apps, such as protecting them from COVID-19, making them more informed, or improving the overall public health capacity in managing and keeping infections low [12]. Hence, the use of contact tracing during the COVID-19 pandemic addresses a common problem by providing a crucial tool for communal health management, where the benefits extend beyond individual interests.

Although the loss of personal privacy is a major concern for different populations during the use of COVID-19 contact tracing apps, some have recognized the potential benefits of digital surveillance. First, advocates of "big data systems" would argue that tracking and mapping the spread of infectious diseases through digital means (eg, electronic health records) is more efficient than the traditional means of calling and asking people to remember their close contacts during the day and would reduce the burden on health care workers [26]. The data collected could enable public health agencies to quickly map potential hotspots in real time [27] and take decisive actions to curb the spread of COVID-19. Second, the use of contact tracing technology may help users feel empowered. Research has shown that individuals may gain psychological relief and peace of mind by using contact tracing apps as they provide a sense of empowerment and certainty—having data and knowledge about whether they were in close proximity with the infected, as they coped with the ambiguity of the pandemic by monitoring and interacting with their own health data [19]. A study conducted in Sweden [7] found that the benefits of contact tracing apps were positively associated with willingness to use them. They found that the perceived prosocial usefulness of contact tracing apps was positively associated with willingness to use contact tracing apps. Research has also underscored the prevalence of the privacy paradox that, despite concerns over privacy loss, people are willing to accept and use apps as long as they are perceived to be beneficial in lowering infection rates [7].

Trust in Government and Sense of Community as Antecedents of Privacy Calculus in TraceTogether

Overview

Communication privacy management theory, built upon the privacy calculus model, uses the metaphor of "boundaries" to explain the motivation to reveal or withhold information [28]. According to this theory, boundary openness or closure for information flow is largely dependent on how individuals perceive institutional privacy assurances. In other words, the cognitive processes of risk control assessment and privacy concerns are context specific. Thus, privacy-relevant beliefs are "better related to individuals' own information experiences and social contexts rather than regarded as a global consequence of technology use per se" [16]. This approach aligns with the notion that privacy is a dynamic process [29,30]. This study also investigated the antecedents that shape privacy calculus in the context of digital contact tracing.

Specifically, we posit that the service provider (ie, government) of the tracing system and other community members who use the device to collectively fight against COVID-19 would be the key entities that would influence individual users' intentions to use a contact tracing device. This study examines how (1) trust in government and (2) the sense of community triggered by the use of contact tracing technology are associated with one's privacy calculus regarding digital contact tracing, thereby shaping one's intention to adopt digital tracing technology.

Trust in Government

Social exchange theory suggests that users disclose personal information to gain intangible benefits from a relationship, given that these perceived benefits outweigh the perceived risks [31]. The benefits of a social exchange might differ from an economic exchange in that the former may rely on existing social ties and involve intangible values, including emotions and social power [31]. Similar to other contact tracing programs, TraceTogether is government-initiated. Therefore, user acceptance and adoption are deeply linked to Singaporeans' trust and confidence in their government [26].

Trust is established when individuals or groups harboring positive perceptions of one another enable the relationship to achieve anticipated results [32]. When an individual places trust in another person, group, or organization, they find themselves liberated from the burden of anxiety and obligation to constantly monitor the actions of the other party [33]. Thus, it can be expected that people who use the contact tracing system will perceive social exchange as more reliable if they trust the government. Supporting this notion, prior studies on web-based privacy have demonstrated that trust in web-based service providers or vendors significantly influences privacy management decisions by decreasing privacy concerns [8,9]. A study in Singapore [34] found that political trust could mediate Singaporeans' privacy concerns, and those who exhibited trust in their government tended to have more positive attitudes toward digital contact tracing technology. This finding is echoed in multiple studies on contact tracing apps in countries including France [35], Japan [36], Germany [37], and the United Kingdom [38].

Trust in service providers can also be critical to increasing users' perceived disclosure benefits [39]. Building on the concept of privacy calculus [40], one study [41] argues that gaining users' willingness to disclose personal information requires the exchange to be based on a fair social contract. In other words, users find the benefits more attractive when they perceive the provider as trustworthy, leading to a positive bias in their privacy calculus. Taken together, we hypothesized that the effects of trust in the government on privacy calculus in TraceTogether would be as follows:

> *H1: Trust in government increases the perceived benefit of using contact tracing apps.*
>
> *H2: Trust in government will decrease privacy concerns when using contact tracing apps.*

Sense of Community Triggered by Contact Tracing

The effectiveness of the contact tracing program for infectious disease prevention largely depends on the participation rate of individuals in the community. Moreover, recognizing the collective action nature of contact tracing underscores its significance in navigating the social dilemma posed by the virus, emphasizing the shared responsibility in curbing the spread for the greater well-being of the community. To enhance the uptake rate of TraceTogether, one way in which the government has promoted the application to Singaporeans is by framing digital contact tracing as a community effort and responsibility. The TraceTogether interface included various elements designed to encourage feelings of closeness and connectedness with other users. For example, the TraceTogether app indicates the number of activated devices nearby and shows how many Bluetooth signals are exchanged among them. The language used in an official promotional video for TraceTogether also reinforced this, depicting the tool as being for "'community-driven' contact tracing suggesting that this is a 'grassroots' mechanism of fighting the virus" [42]. Therefore, group membership and collective benefit have been leveraged to encourage user adoption and acceptance of TraceTogether.

However, the contact tracing program connects those in the vicinity via Bluetooth technology to estimate the proximity and duration of encounters, which may also trigger privacy concerns. Communication privacy management theory [28] suggests that privacy management is not just about deciding to disclose or withdraw personal information with others (personal boundaries). When one's personal information is shared, those who can access it become co-owners of the information, suggesting that privacy management also involves comanaging collective boundaries. Thus, the disruption of the synchronized management of collective privacy boundaries among co-owners is a significant source of privacy risk perception. Although individual participants in the contact tracing program cannot access others' information directly, contact tracing implies that people encountered may be notified of one's infection. Moreover, signaling connectivity with others through interface cues may trigger privacy risk heuristics, heightening privacy concerns among users [43].

Collectively, we expect that the perception of "the greater good" for the improved safety of loved ones and the community is a significant factor influencing the privacy calculus of being part of the contact tracing program [44,45]. This study hypothesizes a paradoxical function of the sense of community such that the sense of community triggered by digital contact tracing will enhance perceived benefits while simultaneously presenting privacy concerns at the same time:

> *H3: The sense of community triggered by contact tracing apps increases the perceived benefits of contact tracing apps.*
>
> *H4: The sense of community triggered by contact tracing apps will increase the privacy concerns of contact tracing apps.*

This study also examined the interplay between one's perception of the government and the community on privacy calculus in digital contact tracing. Although trust in government has developed over time, a sense of community can be promoted through various design and marketing elements of digital contact tracing. As discussed above, TraceTogether was promoted to Singaporeans by framing contact tracing as a community effort and responsibility [46]. The user interface of the application was also designed to imbue users with a sense of community through various design elements. Thus, the study attempts to test whether one's trust in government factors in the privacy calculus in contact tracing would vary as a function of the larger community that they perceive through participation in the collective contact tracing effort. However, given the absence of literature documenting the moderating role of sense of

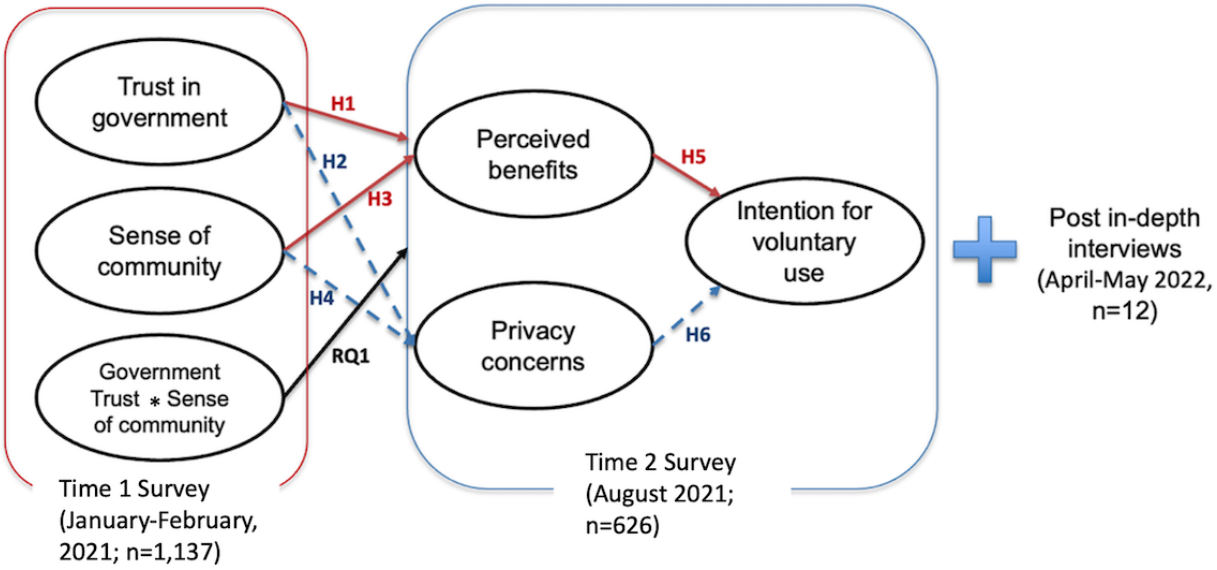
community in the relationship between trust in government and privacy calculus, this study investigates the interplay between sense of community and trust in government, proposing the following research question:

> *RQ1. Will the sense of community generated by contact tracing apps moderate the influence of trust in government on privacy concerns and perceived benefits of using contact tracing apps?*

Finally, based on the basic tenet of privacy calculus theory discussed earlier, we also hypothesize that privacy concerns and perceived benefits will have opposite associations with the intention to use TraceTogether. Given that the use of a contact tracing system itself implies the disclosure of personal information, we tested the intention to use TraceTogether as the outcome of the privacy calculus. Checking through TraceTogether was mandatory to enter most venues, including shopping malls, offices, workplaces, and schools, at the time of the second wave of data collection when use intention had been measured. Therefore, the measurement was designed to assess their intention to use TraceTogether voluntarily until the pandemic ended, rather than merely assessing their intention to use the device for a certain duration. The study model and methodology are illustrated in Figure 1.

> *H5: Perceived benefits are positively associated with the intention to actively participate in contact tracing programs.*
>
> *H6: Privacy concerns are negatively associated with the intention to actively participate in the contact tracing programs.*

Figure 1. Summary of the study model and methodology. H: hypothesis; RQ: research question.



Study 1: Two–Wave Longitudinal Survey

Methods

Recruitment

To test our hypotheses and research questions, we used a mixed method approach involving a 2-wave survey and in-depth interviews. The first survey was conducted from January to February 2021 with panel members provided by a local research company. English-speaking Singaporean citizens or permanent residents aged 21 years or above participated in the survey (N=1198). The quota sampling procedure was employed to ensure that the study sample represented the proportion of the ethnic structure of the national population [47]. The first study was conducted in an omnibus survey format to understand the various perceptions and behaviors related to COVID-19 and contact tracing practices. Among all participants who completed the survey, 94.91% (n=1137) responded that they had downloaded the TraceTogether mobile app or collected the token.

A follow-up second-wave survey was carried out in August 2021, approximately 6 months after the first survey. This survey assessed privacy calculus factors: privacy concerns, perceived benefits, and adoption intention. A second-wave survey invitation was sent to those who completed the first survey. In total, 674 participants completed the second-wave survey (response rate: 59.3%). Data from those who either downloaded the TraceTogether mobile app or received the token and who completed both studies at the point of the first wave of data collection were included in the study sample (n=626; see Table 1 for the descriptive statistics of the study sample). Our sample comprised 88.7% (n=555) Chinese, 4.3% (n=27) Malay, and 7% (n=44) Indian individuals. In comparison to the ethnic structure of the national population in Singapore, where Chinese people constitute 74%, Malay people 13%, and Indian people 9% [48], our sample overrepresented the Chinese group and underrepresented the Malay group. Moreover, the sample included only a small portion of participants aged older than 65 years (n=25; 4%), thereby underrepresenting the older population. During the first wave of data collection (January-February 2021), the TraceTogether app or token could be used for checking at selected venues where people were likely to be in close contact for prolonged periods or where high human traffic is expected. These venues included schools, educational institutes, shopping malls, restaurants, and workplaces. People can still choose to scan the QR code

displayed at the entrance instead of using TraceTogether. From June 2021, the use of TraceTogether became mandatory when entering these venues.

Table 1. Descriptive statistics.

Variables	Values (N=626)
Gender, n (%)	
Male	332 (53)
Female	294 (47)
Age group (y), n (%)	
21-34	130 (20.8)
35-49	281 (44.9)
50-64	190 (30.3)
65 or older	25 (4)
Mean age (y), mean (SD)	44.9 (11)
Ethnicity, n (%)	
Chinese	555 (88.7)
Malay	27 (4.3)
Indian	44 (7)
Education level, n (%)	
Secondary and below	13 (2)
Preuniversity	270 (43.1)
University degree or above	343 (54.8)
Yearly household income (Singaporean $[a]), n (%)	
<2000	37 (5.9)
2000-6000	185 (29.6)
6000-10,000	241 (38.5)
≥10,000	163 (26)
Self-assessed health status, n (%)	
Poor	18 (3)
Fair	163 (26)
Good	293 (46.8)
Very good	126 (20.1)
Excellent	26 (4)
TraceTogether adoption	
Have downloaded TraceTogether app (Yes)	Wave 1: 494 (78.9); wave 2: 586 (93.6)
Have collected TraceTogether token (Yes)	Wave 1: 452 (72.2); wave 2: 549 (87.7)

[a]Singaporean $1=US $0.75.

Measurement

The two exogenous variables (government trust, sense of community) and control variables (demographic information and TraceTogether use) were measured in the first-wave survey. Privacy calculus factors—privacy concerns and perceived benefits—and TraceTogether use intention were measured in the second-wave survey.

Trust in government was measured using 3 items adapted from Wu et al [49]. The *sense of community* was measured using 5 items adapted from 2 studies [50,51]. The sense of community captured the extent to which users felt a sense of belonging and emotional ties with other TraceTogether users. *Privacy concerns* were assessed using 10-item measures which captured 3 aspects of privacy concerns, namely perceived surveillance, perceived intrusion, and secondary use of personal information [16]. The *perceived benefits* of using TraceTogether were measured with 5 items that assessed the extent to which the participant perceived the health and information benefits they received from using TraceTogether [52]. Finally, *use intention* was

measured using three items. Checking TraceTogether was mandatory to enter most public venues. Therefore, the measurement assessed their intention to use TraceTogether voluntarily until the pandemic ended, rather than asking about their intention to use the device within a certain period. All items used a 7-point Likert scale (1=strongly disagree to 7=strongly agree) unless otherwise indicated. Table 2 lists the measurement items and their factor loadings.

Table 2. Measurement items and factor loadings.

Variable and items	Values, mean (SD)	Factor loading, β
Trust in government	4.80 (1.53)	
Even if not monitored, I would trust the government to do the right thing.		.91
I trust the government to protect my personal information.		.96
I believe that the government is trustworthy.		.95
Sense of community (sentences complete the phrase "When I use TraceTogether..."	4.51 (1.62)	
It makes me feel like I am part of a community.		.89
I feel a high sense of attachment with other users.		.94
I feel an emotional connection with other users.		.93
It reminds me of the people around me.		.90
It makes me feel a sense of belonging.		.94
Privacy concerns	4.71 (1.50)	
I believe that my location is being monitored in real time when using TraceTogether.		.83
I am concerned that TraceTogether is collecting too much information about me.		.88
I am concerned that TraceTogether may monitor my activities.		.91
I am concerned that my activities are being monitored.		.91
I feel that as a result of using TraceTogether, others know more about me than I am comfortable with.		.88
I believe that as a result of using TraceTogether, information about me that I consider private is now more readily available to others than I prefer.		.90
I feel that as a result of using TraceTogether, information about me is out there that, if used, will invade my privacy.		.90
I am concerned that TraceTogether may use my personal information for other purposes without notifying me or getting my authorization.		.90
I am concerned that TraceTogether may use my information for other purposes.		.87
I am concerned that TraceTogether may share my personal information with other entities without getting my authorization.		.87
Perceived benefits	5 (1.39)	
Using TraceTogether would improve my access to my health information related to COVID-19.		.86
Using TraceTogether would improve my access to my health information related to COVID-19.		.87
Using TraceTogether would improve my ability to manage my health.		.93
Using the COVID app would improve the quality of health care.		.91
I would manage my health more effectively using TraceTogether.		.90
TraceTogether use intention	5.23 (1.40)	
I will use TraceTogether even if TraceTogether becomes optional when entering public venues.		.86
I am willing to use TraceTogether until the COVID pandemic ends.		.74
I plan to use TraceTogether even if I am not monitored.		.86

Ethical Considerations

The study procedure and questionnaire were reviewed and approved by Nanyang Technological University Institutional Review Board (IRB-2022-213). A consent form was displayed on the first page of the survey, and the participants were required to provide their consent to complete the study.

Results

Measurement Model

Confirmatory factor analysis was conducted using Mplus (version 8.8; Muthen & Muthen) statistical software with a maximum likelihood estimation method. The confirmatory factor analysis results indicated a reasonable fit to data: χ^2_{286}=937.9 (*P*<.001), root mean square error of approximation=0.06 (90% CI 0.056-0.065), comparative fit index=0.97, and Tucker-Lewis index=0.96). The indicators reflected their respective latent variables, as evidenced by the high factor loadings. The magnitude of all factor loadings and Cronbach α were equal to or greater than 0.74 and 0.86, respectively. The measurement model showed robust convergent and discriminant validity: composite reliability and average variance extracted (AVE) were greater than 0.70 and 0.50, respectively. The square roots of the AVEs of all observed variables were greater than the intercorrelations between variables. All factors were significantly correlated with each other. See Table 3 for composite reliability, AVE, and Cronbach α, and see Table 4 for the correlation matrix.

Table 3. Validity and reliability.

	CR[a]	AVE[b]	Cronbach α
Government trust	0.958	0.885	0.958
Sense of community	0.964	0.844	0.964
Privacy concerns	0.973	0.783	0.974
Perceived benefits	0.952	0.798	0.952
Behavior intention	0.862	0.676	0.859

[a]CR: composite reliability.

[b]AVE: average variance extracted.

Table 4. Correlation matrix (Pearson r).

	Government trust	Sense of community	Privacy concerns	Perceived benefits
Sense of community				
r	0.63	—[a]	—	—
P value	<.001	—	—	—
Privacy concerns				
r	−0.27	−0.17	—	—
P value	<.001	<.001	—	—
Perceived benefits				
r	0.48	0.54	−0.17	—
P value	<.001	<.001	<.001	—
Behavior intention				
r	0.44	0.47	−0.21	0.63
P value	<.001	<.001	<.001	<.001

[a]Not applicable.

Model Testing

The structural equation modeling (SEM) result without the interaction term in the model revealed a good fit: χ^2_{562}= 1382.9 (*P*<.001), root mean square error of approximation=0.048 (90% CI 0.045-0.052), comparative fit index=0.957, and Tucker-Lewis index=0.952. As these model fit indices have not been developed for the SEM models assessing latent interaction effects, we used a log-likelihood (−2 LL) ratio test to compare the SEM model where the interaction was not estimated (parsimonious model) with the model where the interaction was estimated (more complex model) [53]. The test was statistically significant, meaning that the model without the interaction term represented a significant loss of fit relative to the more complex model. Thus, we conclude that the model with the interaction term is well-fitted. In addition, the model with the interaction term had lower values of the 2 fit indices, Akaike information criteria and Bayesian information criteria, in comparison to the model without the interaction term.

Our analysis revealed that trust in the government significantly reduced privacy concerns of TraceTogether (β=−.39; *P*<.001), whereas sense of community did not have a significant impact on privacy concerns (β=.02; *P*=.86). However, both government trust and sense of community significantly increased the perceived benefits of using TraceTogether (government trust: β=0.28; *P*<.001; sense of community: β=.54; *P*<.001). H1, H2

and H3 were supported, while H 4 was not supported. Regarding RQ1, the results indicated that trust in the government and sense of community interacted only with perceived benefits (β=−.14; *P*=.004). The results are summarized in Figure 2. The interaction pattern (Figure 3) shows that the triggering sense of community has a larger impact on those who display lower trust in the government than on those with high trust. This finding suggests that triggering a sense of community can buffer the negative impact of skepticism in the government on their perceptions of the benefits they can obtain using TraceTogether.

Figure 2. Summary of structural equation model results. *P<.05, **P<.01, ***P<.001. Age, gender, ethnicity, education, income, and use frequency of TraceTogether use measured at time 1 were controlled.

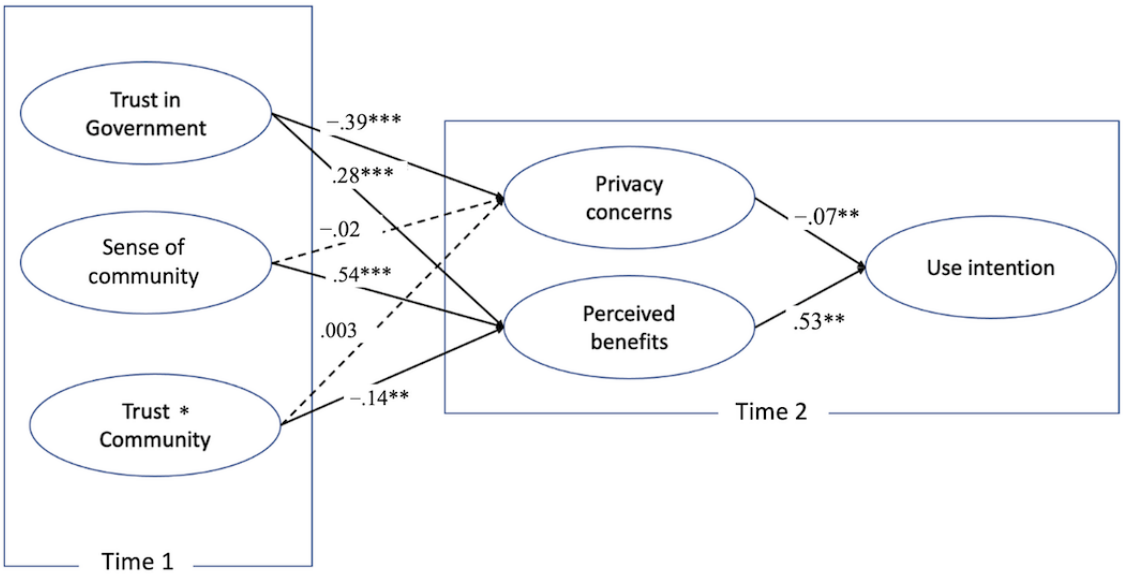


Figure 3. Interaction between the trust in government and sense of community on perceived benefits.

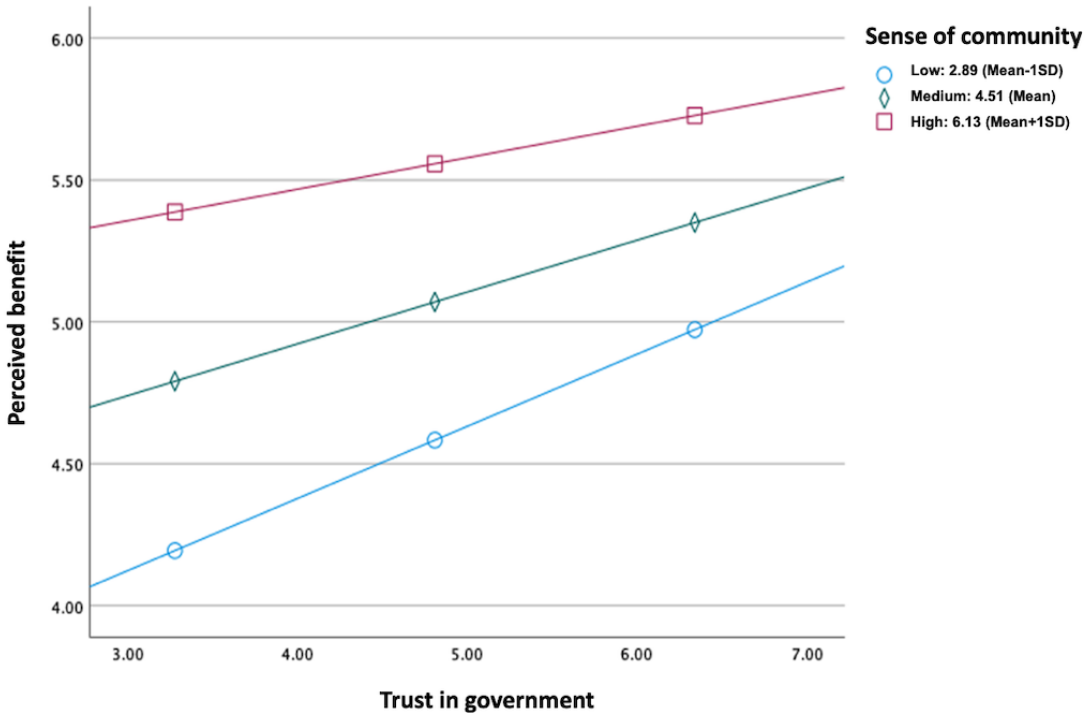

Finally, supporting the privacy calculus hypothesis, privacy concerns decreased TraceTogether use intention (β=−.07; *P*=.04) whereas perceived benefit increased use intention (β=.53; *P*<.001). Hence, H5 and H6 were supported.

Study 2: After In-Depth Interviews

Overview

The survey results illustrated the effects of trust in the government and a sense of community on TraceTogether privacy calculus and, ultimately, TraceTogether users' intentions. However, with the survey data, we could not identify which aspects of privacy concerns were factored in the privacy

calculus, influencing their intention to use TraceTogether. In addition, given the significant roles of trust in government and sense of community in TraceTogether and privacy calculus identified by the survey results, we conducted in-depth interviews to further understand the underlying reasons for these effects. The purpose of this study was two-fold: 1) to understand the reasons underlying the effects of government and sense of community on the privacy calculus of TraceTogether use, and 2) to obtain a deeper understanding of different aspects of privacy concerns among TraceTogether users and the implications for their privacy calculus.

Methods

Participants and Procedure

To obtain additional insights into the privacy calculus of TraceTogether, we conducted in-depth interviews with 12 Singaporeans between April 13 and May 11, 2022. We recruited Singaporeans (mean age 38, SD 13.28; 7 female participants, 5 male participants; see Table 5) who used TraceTogether during the COVID-19 pandemic. Among them, 7 were Chinese, 3 Malay, and 2 Indian. A trained research assistant conducted the interviews using a web-based conference program (ie, Zoom) in English. Participants were given a link to the consent form before starting the interview, which began once their consent was received. Each interview followed a preconstructed list of questions to understand their perceptions and use of TraceTogether. After completing the 4 interviews, the TraceTogether check-in was no longer used, starting from April 26. Subsequently, for the remaining 8 interviews, the participants were asked to answer questions reflecting their prior experiences with TraceTogether. Interview recruitment was stopped when we reached a state of theoretical saturation [54].

Table 5. Demographics of in-depth interview participants.

ID	Gender	Ethnicity	Age (y)	Occupation
1	Male	Indian	24	Student
2	Male	Chinese	23	Student
3	Female	Chinese	23	Student
4	Female	Chinese	49	Manager
5	Male	Chinese	56	Teacher
6	Female	Chinese	49	Teacher
7	Female	Malay	50	Teacher
8	Female	Malay	31	Teacher
9	Male	Malay	31	Clinician
10	Male	Chinese	51	Worker in the Singapore armed forces
11	Female	Chinese	49	Administrator
12	Female	Indian	24	Social media and project manager

Data Analysis

We used the 3-step protocol [55], which provides a structured framework for qualitative researchers to systematically analyze and derive meaningful interpretations from their data, involving 3 stages of data analysis: open-coding, axial and hierarchical coding, and theoretical interpretation, outlined as follows: First, 2 research assistants, including the interviewer, reviewed and coded the transcribed interviews independently. They read the transcribed interviews line by line and assigned the initial codes according to the themes of the original conversations (eg, concerns about using TraceTogether and adoption barriers). The second step was the axial and hierarchical coding stage; 2 researchers identified the second-level interpretive themes based on the theoretical framework and hypotheses (eg, surveillance, intrusion, and secondary use of data) by analyzing and grouping the initial coding performed by the 2 research assistants. Prior literature on web-based privacy calculus and privacy issues of digital contact tracing guided this coding stage. Finally, the researchers discussed how to interpret the themes that surfaced in the second stage in order to answer the research questions.

Ethical Considerations

Participants were given a link to the consent form before starting the interview, which began once their consent was received. The consent form, interview questions, and protocols were reviewed and approved by the primary investigator's institute (IRB-2022-213).

Results

Overview

In a scenario where policies on and implementation of a contact tracing system were rolled out urgently and comprehensively, privacy became a significant barrier to adopting the program. Our study revealed that trust in the government serves as a social lubricant, effectively mitigating privacy concerns arising from the inherent risks associated with the tracing program, thereby facilitating smoother implementation of the program. Our interview results indicated that trust in the government translated into the belief that the government would possess adequate security measures to safeguard citizens' privacy and prevent the misuse of their information. However, considering other community members while participating in the contact tracing program does not necessarily alleviate privacy concerns. The

interviews also highlighted surveillance as the most prevalent aspect of privacy concerns regarding TraceTogether use. In addition, our findings revealed that trust in the government, particularly the perceived transparency of government actions, was most related to concerns regarding the secondary use of data. The detailed results, accompanied by key supporting quotes, are outlined in the following sections.

The Role of Trust in Government in TraceTogether Privacy Calculus

The interview responses also suggested a significant influence of trust in the government on both perceived benefits and privacy concerns. Consistent with the findings of our web-based survey, the results indicated that individuals who trust the government were more likely to perceive TraceTogether as beneficial while exhibiting lower privacy concerns. For example, participant 7 (female, age 50 y) did not understand why the app should track user locations; therefore, she felt that she did not want to use it. However, she explained that she downloaded the app because she trusted the government, stating, “I trust that my government knows what they’re doing to the people. I trust that it is for the good of us.” Conversely, participant 12 (female, age 24 y), who indicated distrust in the government, did not perceive any additional benefits of using TraceTogether beyond using QR codes for checking-in, stating, “I feel like using the QR code would still work.” Furthermore, she voiced several privacy concerns, remarking, “What if this thing is tracking me 24/7? What if I am at home has my constant location at home, and my address is being transmitted?” She also referenced the public backlash at the start of 2021, when Foreign Minister Vivian Balakrishnan revealed that the police could access TraceTogether data for criminal investigations. This announcement contradicted his statement in June of the previous year that TraceTogether data would only be used for contact tracing [56]. She mentioned that she felt betrayed by government. Regarding the same incident, however, participant 5 (male, age 56 y) felt indifferent, stating: “There’s nothing to hide, so I am not concerned. Those who are criminals, they should be afraid. Good for them. They are better afraid.” His indifference was his strong trust in the government. He added, “I think the government is smart enough not to use it against themselves, because if it blows out of proportion, I tell you, the government will pay a high price. I don’t think they try to do that.”

The Role of Sense of Community in TraceTogether Privacy Calculus

Our survey data revealed that a sense of community when using TraceTogether significantly increased the perceived benefit but did not influence their privacy concerns. The interview respondents also understood that collective efforts were required to make the digital contact tracing system successful. For example, participant 1 (male, age 24 y) mentioned, “If enough people download it and contact tracing becomes easier, then we can, in a sense, fight this disease and end it earlier instead of letting it prolong.” The responses suggest that protecting the community is a strong motivation for adopting a digital contact tracing system. However, consistent with the survey results, the interview responses indicated that a sense of community did not necessarily alleviate concerns about privacy invasion through the contact tracing system. Participant 5 (male, age 56 y) stated, “It’s for the greater good. If it’s going to protect the country from this virus, it would be good. It won’t last forever. These two years, you have had your privacy invaded, but subsequently, you are fine.”

Dissecting the Multiple Aspects of Privacy Concerns in TraceTogether

As discussed earlier, privacy concerns are not a single-faceted concept, but encompass multiple aspects, including perceived surveillance, perceived intrusion, and secondary use of data [16]. Through the postinterviews, we attempted to understand the different aspects of privacy concerns among TraceTogether users.

Surveillance stood out as the most prominent privacy concern, as mentioned by 7 of 12 respondents. Respondents explained that lack of control contributes to their fear and anxiety about being watched, even if they feel that they have nothing to hide. Some respondents preferred using a TraceTogether token to the mobile app to reclaim a sense of control over where and when their locations were traced. For example, participant 7 (female, age 50 y) mentioned, “I am not afraid because I don’t have anything to hide and that I am doing anything wrong or I am a criminal... It’s just that... I don’t like to know that my personal particulars are being shared.” Participant 4 (female, age 49 y) also shared, “I can put it [token] at home...They cannot even trace me to home. They can trace the data on my phone.” These deliberate choices can be understood as small acts of resistance to mandated surveillance.

The respondents also shared that the digital contact tracing system, in fact, collected more information beyond what was necessary, such as how participant 4 (female, age 49 y) expressed her concerns. “Government is going to trace me where I go, what I do, who I meet. I feel very invaded by my privacy.” From the responses, we discovered that perceived intrusion becomes prominent because they do not know what information is to be tracked and used and the purpose of tracking clearly. Participant 2 (male, age 23 y) said, “I never know what they use the information for... They want to check whether we stay at home. It’s still not right because it’s an invasion of privacy.” Participant 4 (female, age 49 y) also raised concerns that TraceTogether would gather information beyond what has been told: “[if] I go to the shopping mall, and then they start to want to know how much you spend and say how much you spend in that shopping mall or what exact activities are being conducted.”

In addition, several respondents cited distrust in the government as a factor that increased privacy concerns, specifically with regard to the secondary use of data. Regarding the government’s announcement that the police could use TraceTogether data for criminal investigations, participant 3 (female, age 23 y) expressed her concerns, saying, “I thought it was a bit annoying because there was a lack of transparency about whatever they were going to use the app. If they wanted to do it for this stuff, they should have said it earlier and not let it be like, ‘Oops, I said it as an accident.’” The government’s transparency was revealed as an important factor in determining users’ privacy concerns about the secondary use of data. Transparency on how contact tracing apps work can not only affect user confidence,

but also determine ethical considerations. Participant 2 (male, age 23 y) shared his point, stating, "If they ask for your consent and you decide to give it (tracked information), then sure. If they do it on their own, then that's not okay." Participant 1 (male, age 24 y) shared a similar point, explaining: "It's just that I'm perfectly fine with them in using this app for in terms of national security or intelligence or what, but what I want them to do is be upfront and open."

Discussion

Theoretical Implications

Using a mixed method approach involving a 2-wave survey and in-depth interview data, we expanded our understanding of privacy decisions and calculus in the context of digital contact tracing. Our study has several notable findings. First, we found that privacy concerns had a marginal negative association with use intention, whereas perceived benefits had a strong positive association, consistent with previous research [57,58]. The opposite influences of privacy concerns and perceived benefit on use intention suggest that the privacy calculus in TraceTogether might be viewed as a rational process of weighing privacy risks and use benefits to make an uptake decision. Second, although our findings on the relationships between trust in government and sense of community and privacy calculus are largely consistent with existing research [59], our study demonstrated that their existing perceptions toward the provider and the government in the contact tracing context, as well as the perception of the community triggered by TraceTogether use, may bias user appraisals of privacy risks and benefits of contact tracing. Finally, our research extends the existing knowledge of privacy calculus by delineating how the sense of community moderated the relationship between perceived benefit and trust in government, such that individuals' sense of community elevated perceived benefit, even for those with low trust in government. The study results provides several important theoretical implications: First, the study illuminated how people's trust in the system provider plays a role in privacy calculus in digital contact tracing systems. The digital contact tracing system, including TraceTogether, is a special form of a web-based system built and managed by government organizations during an unprecedented pandemic. Digital contact tracing entails delegating the right to track and process location, contact, and health-related information to the government's discretion. Therefore, we posit that trust in government is a powerful factor in determining social exchange decisions.

As expected, trust in the government significantly influenced privacy calculus at the later stage when the use of TraceTogether became mandatory for entering most venues and workplaces. The results support prior research, which suggests the importance of trust in the government for the successful implementation of the contact tracing program for infectious disease prevention (eg, [32-36]). Trust in the government becomes pivotal in government-citizen relationships, especially during the implementation of new policies. This is largely because trust can reduce the transaction costs in relationships [60]. Our interview responses offer deeper insights into how trust in the government lowers transaction costs, specifically addressing privacy risks in the context of participating in the contact tracing program. We found that one's privacy calculus can be biased according to the level of trust displayed by individuals, and an interviewee showing distrust in the government tends to exaggerate the privacy risk of TraceTogether while doubting its effectiveness without specific evidence. Conversely, another interviewee, who started to use TraceTogether without knowing its purpose of tracking one's location, shared that she downloaded the app simply because she trusted the government, and thus trusted that the app was good for them.

Our results also revealed that the sense of community elevated by TraceTogether use positively influenced users' benefit appraisal, even though it did not reduce privacy concerns. This finding is in line with research [61], which found that in largely collectivistic societies (eg, China), there is a greater acceptance of contact tracing apps compared with more individualistic societies (eg, the United States, Germany), and people are generally willing to accept these technologies, especially if they are considered effective. In our study, the results might be because Singaporeans accept the spirit of the "greater good" underlying the contact tracing measure in the pandemic situation in the community, supporting the extant literature. A prior study compared Singapore and Switzerland and attributed the former's higher rates of acceptance and adoption to its norms that prioritize the "interests of the community" [46]. Interestingly, privacy concerns regarding the use of TraceTogether persisted even when a sense of community was fostered. The follow-up interviews revealed these findings. For instance, our interviews indicated that considering fellow community members while participating in the contact tracing program motivated individuals to endure the discomfort of sacrificing privacy for the greater good rather than directly alleviating the concerns themselves. This aligns with prior studies on the role of sense of community in coping behaviors; they showed that a stronger sense of community motivates individuals to focus on problem-solving coping behaviors [62,63]. By extending these findings to our study, it can be inferred that strengthening the sense of community compels individuals to concentrate on addressing the larger community issue while accepting potential risks associated with participating in the program to tackle this issue.

Our postinterview responses provided an in-depth understanding of privacy calculus in TraceTogether use by dissecting different aspects of privacy concerns [16] that TraceTogether users exhibited. The interviewees responded that they felt they were being surveyed through TraceTogether, which often required excessive personal information. However, interviewees were generally willing to bear surveillance and intrusion for the greater good of the community and their own safety. However, the results indicated that having a sense of control over information is an important factor in the privacy calculus in TraceTogether. Most interviewees also called for greater transparency in data collection and secondary use of data. They actively sought strategies to better control their personal information. For example, some participants indicated that they prefer to use the token rather than the app so that they can take the token only when TraceTogether checking-in is required.

Hence, our study results support the notion that privacy management is a dynamic process involving "*selective control* of access to the self or to one's group" [64].

Another notable finding of our study was how the sense of community could elevate the benefits of contact tracing despite low trust in the government. This is important considering that norms-based approaches [65] are effective in modifying health behaviors in diverse contexts. Existing research has identified several moderating factors that influence users' intention to use contact tracing apps. For instance, demographic factors, such as gender, racial and ethnic identity, and education level, are significant moderators of contact tracing app design on people's intention to install apps [66]. Separately, another study found that self-efficacy was a significant moderator of trust and intention to use contact tracing apps [67]. Although these findings are important for technology developers, they view technology use and acceptance through a largely technocentric and individualistic approach, even though public health scholars [68] have argued for the need to consider societal factors as driving factors of adoption, as evidenced by research [69] on how norms could drive app use, even among marginalized communities.

Practical Implications

Our study offers valuable insights into the policy and design considerations concerning digital contact tracing programs. The interview results revealed that, although Singaporeans are willing to accept a certain level of surveillance for preventive measures via contact tracing, issues arise when data use lacks transparency, potentially causing individuals to reconsider their positive intentions to participate in the greater good. Moreover, because digital contact tracing was made mandatory, they also felt that they had no control over their information, which may overturn their privacy calculus, and thus opted out from participating in the program if it became optional. The results suggest that for the successful implementation of the contact tracing program, it is crucial to implement policy measures to ensure clear and transparent communication regarding the use of data collected from contact tracing practices. In addition, providing as many control options as possible would encourage users to maintain active participation in the contact tracing program.

The moderating effect of a sense of community prompted by contact tracing has valuable practical implications. The interaction result indicated that the negative impact of distrust in government on contact tracing program participation can be overcome by promoting the "social good" nature of the contact tracing program via campaign or application design. According to our study results, the campaign for TraceTogether that framed contact tracing as a community effort and responsibility, with the campaign slogan being "Protect your community," might have enhanced community participation, especially among those with lower trust in the government. If, unfortunately, another pandemic emerges in the future, and a similar program is needed, the contact tracing program can actively incorporate social- and community-related features. For example, in the early stage of implementation, the application can be promoted through social networks, allowing users to invite and encourage their family and friends to opt for the program.

Additionally, the contact tracing app interface can be designed to cue a sense of community when using it. Illustrations of the family and community for the application interface design, as TraceTogether has done, would be an effective strategy to enhance participation in the program. TraceTogether also displays the number of Bluetooth signals shared by others. However, such information can be framed as emphasizing collective efforts for the greater good of the community. For example, information can be shown through a visual illustration of people forming networks.

Limitation and Future Research Direction

This study had some limitations. Although the longitudinal survey design allowed us to establish the temporal sequencing of the variables of interest, the dependent variable (ie, behavioral intention) was assessed in the follow-up survey without obtaining the baseline measurement. Hence, we cannot fully leverage the longitudinal nature of the data to establish the direction of the association or causal relationships between the variables. Future studies may use longitudinal data with repeated measures of the variables (two or more time points) to address them. Additionally, the data provide limited potential for generalizability. Survey participants with a higher socioeconomic status (eg, education) were overrepresented. In addition, the use of self-reported data in surveys may pose the risk of social desirability and recall biases. Finally, we acknowledge that the mandatory use of TraceTogether between waves 1 and 2 of our survey might have an impact on the use intention of participants, as existing research [70] on a Singapore sample showed high adoption due to the mandatory use of the app for entering public venues. To circumvent this, we modified our items such that they captured participants' volitional use in contexts when TraceTogether became voluntary, rather than capturing actual use behavior as the dependent variable due to social desirability bias. Despite the above limitations, we are confident that this study has presented valid evidence of the relationships among trust, privacy concerns, perceived benefits, and TraceTogether use intentions.

Conflicts of Interest

None declared.

Abstract

Background: Hospital apps are increasingly being adopted in many countries, especially since the start of the COVID-19 pandemic. Web-based hospitals can provide valuable medical services and enhanced accessibility. However, increasing concerns about personal information (PI) and strict legal compliance requirements necessitate privacy assessments for these platforms. Guided by the theory of contextual integrity, this study investigates the regulatory compliance of privacy policies for internet hospital apps in the mainland of China.

Objective: In this paper, we aim to evaluate the regulatory compliance of privacy policies of internet hospital apps in the mainland of China and offer recommendations for improvement.

Methods: We obtained 59 internet hospital apps on November 7, 2023, and reviewed 52 privacy policies available between November 8 and 23, 2023. We developed a 3-level indicator scale based on the information processing activities, as stipulated in relevant regulations. The scale comprised 7 level-1 indicators, 26 level-2 indicators, and 70 level-3 indicators.

Results: The mean compliance score of the 52 assessed apps was 73/100 (SD 22.4%), revealing a varied spectrum of compliance. Sensitive PI protection compliance (mean 73.9%, SD 24.2%) lagged behind general PI protection (mean 90.4%, SD 14.7%), with only 12 apps requiring separate consent for processing sensitive PI (mean 73.9%, SD 24.2%). Although most apps (n=41, 79%) committed to supervising subcontractors, only a quarter (n=13, 25%) required users' explicit consent for subcontracting activities. Concerning PI storage security (mean 71.2%, SD 29.3%) and incident management (mean 71.8%, SD 36.6%), half of the assessed apps (n=27, 52%) committed to bear corresponding legal responsibility, whereas fewer than half (n=24, 46%) specified the security level obtained. Most privacy policies stated the PI retention period (n=40, 77%) and instances of PI deletion or anonymization (n=41, 79%), but fewer (n=20, 38.5%) committed to prompt third-party PI deletion. Most apps delineated various individual rights, but only a fraction addressed the rights to obtain copies (n=22, 42%) or to refuse advertisement based on automated decision-making (n=13, 25%). Significant deficiencies remained in regular compliance audits (mean 11.5%, SD 37.8%), impact assessments (mean 13.5%, SD 15.2%), and PI officer disclosure (mean 48.1%, SD 49.3%).

Conclusions: Our analysis revealed both strengths and significant shortcomings in the compliance of internet hospital apps' privacy policies with relevant regulations. As China continues to implement internet hospital apps, it should ensure the informed consent of users for PI processing activities, enhance compliance levels of relevant privacy policies, and fortify PI protection enforcement across the information processing stages.

Introduction

Background

The emergence and rapid expansion of hospital apps represents a significant milestone in the evolution of global health care services [1,2], especially during the COVID-19 pandemic [3-7]. These digital platforms provide a range of medical services, from digital consultations [8,9] to telemedicine [10] and digital care management [6,11]. Their growing use reflects a trend toward digital health solutions as enhanced, accessible, and cost-efficient health care services [12].

However, the rise of hospital apps has been accompanied by substantial concerns regarding patient privacy and data security [13-15], as with other mobile health (mHealth) applications [16,17]. The apps' extensive collection of personal health and medical information, as well as the sensitive nature of that data, suggest a need for comprehensive, rigorously enforced regulations to prevent unauthorized access, misuse, and disclosure. In regions like the United States [18,19] and the European Union, similar digital health initiatives have been developed that focus on interoperability, patient-centricity, and adherence to strict data protection regulations, such as the HIPAA (Health Insurance Portability and Accountability Act) in the United States [20,21] and the General Data Protection Regulation in the EU [22,23]. Striking a balance between leveraging the benefits of digital health services and ensuring the confidentiality and integrity of patient information remains an ongoing challenge in the industry.

In China, the response to the evolution of digital health care has been swift, aided by the prevalence of mobile internet [24] and the development of mHealth services [25-27], as evidenced by the 2014 launch of the country's first officially approved internet hospital in Guangdong province [28,29]. This milestone, coupled with the enactment of several "internet plus healthcare" policies [30], has led to a surge in digital hospital apps, bringing the terms "internet diagnosis" and "internet hospitals" into the national health care context [31-33]. "Internet diagnosis" encompasses medical services provided in digital form by registered doctors, including consultations for certain common and chronic diseases and "internet plus" family doctor services [34]. Hospital apps are divided into two categories: (1) digital extensions of traditional hospitals and (2) stand-alone entities operated by internet enterprises [34]. The former involves local doctors and patients, whereas the latter combines the resources of various medical institutions to expand service to patients across different locations.

Internet hospital apps offer digital consultation, appointment scheduling, diagnosis and treatment of common and chronic diseases, and medical guidance, as well as prescription and delivery of medications and other treatments [32,35]. These apps have significantly enhanced health care by addressing the disparities in resource distribution and access across the mainland of China's large population [26,31,36] and improved overall patient experiences by enhancing communication, transparency, and efficiency [37]. The COVID-19 pandemic further underscored the efficacy of digital health care providers, which facilitated crucial health care services for prevention and control in the pandemic's early stages [38-42].

However, the existing application of these apps presents significant challenges to patient information protection [43,44]. First, sensitive personal information (PI) generated during medical visits, such as biometric and health data, is vulnerable to unauthorized sharing and cyberattacks, which can lead to privacy breaches [45,46]. Second, the complexity of integrating and applying health data weakens individuals' control over their health information once it transforms into big health care data [47-49]. Finally, the difficulty of implementing and upholding informed consent is compounded by the lack of unified industry standards and the realities of "algorithmic black boxes," which often leave individual patients in a relatively disadvantaged position [50,51].

To manage these issues, China has established a regulatory framework to protect PI. Since 2017, the Information Security Technology-Personal Information Specification (PI Specification) has been adopted as a voluntary standard for PI protection practice by all kinds of enterprises in information processing activities [52-54]. In addition, the Personal Information Protection Law (PIPL), guided by the Chinese Civil Code [55] and effective starting November 11, 2021, serves as the nation's first comprehensive national PI legislation. The PIPL specifies the rights of individuals and the obligations of PI processors [56,57]. The Chinese government has also made a specific commitment to protect personal health information and prohibits illegal processing, trade, or disclosure of personal health information in article 92 of the Law on the Promotion of Basic Medical Care, Hygiene, and Health, enacted on June 1, 2020.

Internet hospital apps represent a critical intersection of PI and digital technology, which underscores the urgent need for scrutiny of these providers' privacy policies within a framework that balances self-regulation and governmental oversight [58,59]. Privacy policies delineate how PI processors collect, use, disclose, and manage a customer or client's data [60]. They are also the primary grounds for the transparent data processing requirements mandated by privacy-related regulations [61]. Drawing inspiration from contextual integrity (CI) theory, we also investigated how the privacy policies articulated and adhered to the norms of information flow [62]. In keeping with Nissenbaum's [63] assertion that privacy "is preserved when informational norms are respected and violated when informational norms are breached," we set the basis of evaluation with a focus on the norms and values that govern appropriate flows of PI.

Previous research on privacy compliance of mHealth apps in different countries has identified gaps between rules for privacy protection and the apps' implementations in various aspects, such as lack of complete privacy policies, lack of informed consent, and insufficient protection of sensitive data [64-73]. Such investigations have also raised concerns about internet hospital apps' uneven design quality and the challenges in minimizing users' cognitive load while ensuring information security [74,75]. However, these studies have not thoroughly

examined web-based hospitals' compliance with China's comprehensive legal framework for PI protection.

This study uses a legal framework to assess the compliance of internet hospital apps' privacy policies with China's PI-related regulations. The Methods section elaborates on the collection and selection of sample apps, describes the development of an evaluation scale based on relevant policy documents, and outlines the procedures for app assessment and scoring. In the Results section, we present the compliance scores of sample apps. The Discussion section contextualizes these results within the broader landscape of mHealth app privacy compliance, underscoring the importance of legal compliance in the evolving digital health landscape.

Objective

In this study, we aimed to (1) collect the privacy policies of internet hospital apps developed for users in the mainland of China, (2) develop a scale based on the provisions stipulated in the PIPL, PI Specification, and rules of the hospitals, (3) assess the compliance of the privacy policies within the regulatory framework of PI protection, and (4) offer recommendations for improving the legal compliance of internet hospital apps' privacy policies to enhance PI protection in the evolving landscape of mHealth innovation. This study contributes to the global discussion on balanced policies for PI protection in digital health initiatives in the postpandemic era and provides insights for policymakers, hospital app providers, and users across different countries while highlighting the importance of improving legal compliance and strengthening enforcement.

Methods

Study Design

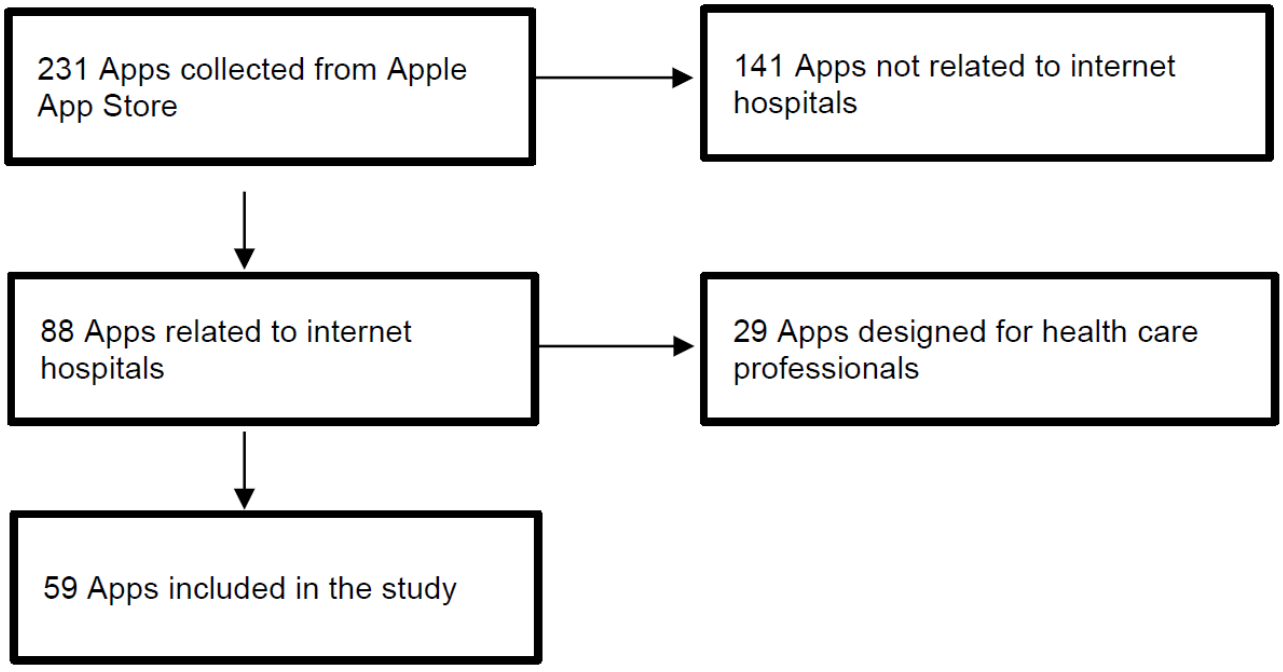
We conducted a content analysis of the privacy policies of internet hospital apps available in the Apple App Store in the mainland of China and evaluated their compliance with the PIPL, PI Specification, and hospital app rules. Drawing from CI theory, we considered the adherence of internet hospital apps' privacy policies to PI norms as essential to PI protection.

App Selection and Inclusion Criteria

In this study, we focused on the privacy policies of internet hospital apps available in the Apple App Store and tailored for the market of Chinese mainland. To identify relevant apps, we used the keyword "internet hospital" (*hu lian wang yi yuan* in Chinese) to search on Diandian (*Dian Shu Ju* in Chinese), a prominent mobile data analytics platform in China. We conducted the search on November 7, 2023.

The apps included in the sample fell under the following definitions: (1) apps or platforms specifically developed to provide a range of hospital app services, and (2) apps intended for use by the general population rather than health care professionals. Excluded apps fit the following: (1) apps designed for health care professionals managing internal hospital operations, and (2) apps with scope or functionality unrelated to hospital app services, such as those dedicated to health insurance, maintaining a healthy lifestyle, or health education and popular science. The initial search resulted in a total of 231 apps, out of which 59 met the inclusion criteria and were included in the final analysis upon review (Figure 1). We obtained and reviewed the full text of corresponding privacy policies as text files or screenshots from the sample apps between November 8 and 23, 2023.

Figure 1. Filtering procedure for the selection and inclusion of hospital apps.



Development of the Compliance Evaluation Scale

Overview

We systematically developed a compliance evaluation scale to assess the privacy policies of internet hospital apps against the PIPL, PI Specification (GB/*t* 35273-2020), and the Rules for Regulation of Internet Diagnosis and Treatment Management (for Trial Implementation). This process entailed the following sections.

Comprehensive Review

First, we obtained and meticulously reviewed the full text of the PIPL, PI Specification, and the aforementioned rules to understand the comprehensive regulatory framework governing PI protection in hospital apps.

Indicator Development

Based on the information processing activities delineated in these policy documents, we identified level-1 evaluation indicators encompassing critical processing stages such as PI collection and usage; PI storage and protection; PI sharing, transfer, disclosure, and transmission; PI deletion; individual rights; and PI processor duties. In addition, we introduced "general attributes" as an additional level-1 indicator to evaluate the overall transparency and ongoing maintenance efforts.

Indicator Elaboration

We then translated the specific chapters and clauses of these policy documents into a more granular set of 26 level-2 indicators and 70 level-3 indicators, which provided a detailed framework for our evaluation. Each level-2 indicator represented a crucial component within the respective PI processing stage—our level-1 indicators. For example, in the stage of PI collection and usage, we followed different rules for general and sensitive PI as stipulated in the PIPL, and further developed 2 level-2 indicators to evaluate the collection and usage of general PI and sensitive PI. Moreover, we established level-3 indicators to assess the specific compliance requirements as detailed under each level-2 indicator. For example, concerning the collection and usage of sensitive PI, we identified 7 level-3 indicators according to the PIPL, which included: highlighting sensitive PI, stating the specific purpose, clarifying the sufficient necessity, implementing stringent protective measures, communicating the implications of processing sensitive PI, obtaining separate explicit consent for processing sensitive PI, and requiring explicit consent for processing PI of minors.

Operational Definitions and Examples

To ensure clarity and consistency in our assessment and support the application of our evaluation criteria, we have included brief explanations, example sentences, and references to the relevant provisions of the policy documents for all the level-3 indicators in Multimedia Appendix 1.

Scoring and Evaluation Procedure

We adopted a binary scoring system for level-3 indicators, awarding a score of 1 for privacy policies that adequately addressed a given indicator and 0 for those that did not. This allowed us to calculate the compliance rate for each level-3 indicator based on the proportion of policies scoring "1" from our app sample. We then calculated the scoring rate for each level-2 indicator as the arithmetic mean of the scoring rates for its associated level-3 indicators. Similarly, we determined the compliance rate for the level-1 indicators as the mean of the scoring rates of the corresponding level-2 indicators, which reflects the overall compliance of each app in specific stages of the information processing activities. The overall compliance of each app's privacy policy was quantified by aggregating the scores of all level-3 indicators and converting this total into a percentage to denote the app's compliance level.

To ensure the reliability of our evaluation, 2 independent raters (JJ and ZZ) were engaged to assess the privacy policies of all 59 internet hospital apps between November 8 and 24, 2023. To gauge interrater reliability, both raters independently evaluated a randomly selected subset of 20 apps (34% of the total), achieving an intraclass correlation coefficient of 0.986 (P<.001), indicating nearly perfect agreement. Following this assessment, the raters convened to discuss score discrepancies in their initial evaluations. After this, the raters divided the remainder of the apps equally and applied the unified standards to ensure scoring consistency.

Results

Sample Collection

We accessed 59 internet hospital apps available in the Apple App Store for Chinese mainland users by registering as users with our own identity documents and mobile phone numbers. We obtained the full text of 52 privacy policies. A small but significant percentage of apps (7/59, 12%) altogether lacked a separate privacy policy, a fundamental requirement for safeguarding PI. This absence is a critical oversight and represents direct noncompliance with established PI protection laws, suggesting an urgent need for these apps to develop and implement comprehensive privacy policies.

Compliance Evaluation

The overall compliance landscape among the 52 assessed privacy policies was mixed. The mean compliance score of all policies was 73 of a possible 100 (SD 22.4%). Moreover, 36 apps (69%) surpassed the mean score, whereas 16 apps (31%) fell below.

The evaluation results for level-1 and level-2 indicators are listed in Figure 2 and Table 1. Level-1 indicators were ranked by score from highest to lowest, as follows: general attributes (mean 92.1%, SD 16.5%); PI collection and usage (mean 81.5%, SD 17.9%); PI sharing, transfer, disclosure, and transmission (mean 75%, SD 25.2%); PI storage and protection (mean 71.5%, SD 30.7%); individual rights (mean 68.4%, SD 31.5%); PI deletion (mean 64.7%, SD 34.8%); and PI processor duties (mean 59.4%, SD 28.4%). The names and evaluation results for each app are listed in Multimedia Appendix 2.

The privacy policies' general attributes (mean 92.1%, SD 16.5%) scored high, indicating effective efforts in transparency and maintenance. For level-2 indicators, PI processors and services recorded an impressive compliance rate of 95.2% (SD 20.2%), indicating a majority of the privacy policies effectively identified the parties responsible for processing PI and providing

services. Policy transparency was a standout area, with a perfect score of 100% (SD 0%) reflecting the apps' commitment to clear and open communication with users. Policy maintenance also emerged as a strong suit, scoring 84.6% (SD 30.3%). This suggests a significant proportion of apps were proactive in updating their privacy policies, a vital aspect of best practices following the implementation of the PIPL. Specifically, 25 apps updated their privacy policies after the PIPL came into force. However, a concerning 12 apps failed to mention either the effective or updated date of their policies, whereas 15 updated their privacy policies before the PIPL came into effect.

Regulations for a description of the collection and usage of general PI had an average compliance rate of 90.4% (SD 14.7%). This indicates the majority of internet hospital apps were conscientious in describing how general PI is collected and used within their service functions. Our evaluation found all the reviewed privacy policies specified the purpose and methods of collecting and using PI, demonstrating a high level of transparency. Additionally, a substantial 90% (n=47) of apps provided a list of the types of PI collected, while 83% (n=43) of the policies clarified the consequences of not providing PI. In terms of differentiating between essential and nonessential PI for services, compliance stood at 69% (n=36). Although significant clarity was currently provided, an opportunity still remained for apps to enhance user understanding of the purpose and optional nature of PI collection.

Meanwhile, the scoring rate of collection and usage of sensitive PI was lower (mean 73.9%, SD 24.2%). We observed strong compliance rates for describing specific purposes (n=48, 92%), protective measures (n=46, 88.5%), implications (n=43, 83%), and necessity (n=41, 79%) of processing sensitive PI. Most assessed apps required explicit consent for processing minors' PI (n=43, 83%). However, the requirement to obtain separate explicit consent for processing sensitive PI revealed a significant gap, with only 23% (n=12) of apps complying.

In the PI storage and protection stage (mean 71.5%, SD 30.7), the scoring of level-2 indicators varied slightly. The compliance rate of storage security was 71.2% (SD 29.3%). Most apps explained potential security risks (n=46, 88.5%) and organizational management measures. Fewer than half (n=24, 46%) outlined the compulsory level of technical security measures. As for security incidents (mean 71.8%, SD 36.6%), although a significant portion of apps committed to notifying users (n=43, 83%) and reporting security incidents (n=42, 81%), just over half of PI processors (n=27, 52%) committed to assuming legal responsibility in the event of such an incident.

In the stage of PI sharing, transfer, disclosure, and transmission (mean 75%, SD 25.2%), the scoring rate of level-2 indicators varied substantially. For public disclosure (mean 93.3%, SD 24.1%), we observed high compliance in specifying conditions for potential public PI disclosure (n=49, 94%) and requiring separate consent for such practices (n=48, 92%). These rates indicated a high degree of transparency and respect for user consent for public disclosure. As for the compliance rate of PI sharing and transfer (mean 77.5%, SD 30%), most privacy policies introduced information about PI recipients (n=37, 71%), the types of PI transferred (n=38, 73%), and the safety precautions adopted in advance (n=37, 71%). In addition, most apps explained the purposes (n=44, 85%) and methods (n=44, 85%) of PI transfer, described the rules governing PI transfer during specific events (n=37, 71%), and required separate consent for sharing or transferring PI (n=44, 85%). Regarding cross-border transmission (mean 71.2%, SD 43.1%), most apps specified PI storage locations (n=39, 75%), whereas fewer mentioned compliance with relevant cross-border transmission laws (n=35, 67%). However, the compliance rate of subcontracting PI processing was low (mean 51.9%, SD 27.7%). Although most apps committed to supervising the subcontracted PI processing activities (n=41, 79%), only a quarter (n=13, 25%) required separate consent for these activities.

Figure 2. Compliance evaluation scores of internet hospital apps for level-1 indicators. PI: personal information.

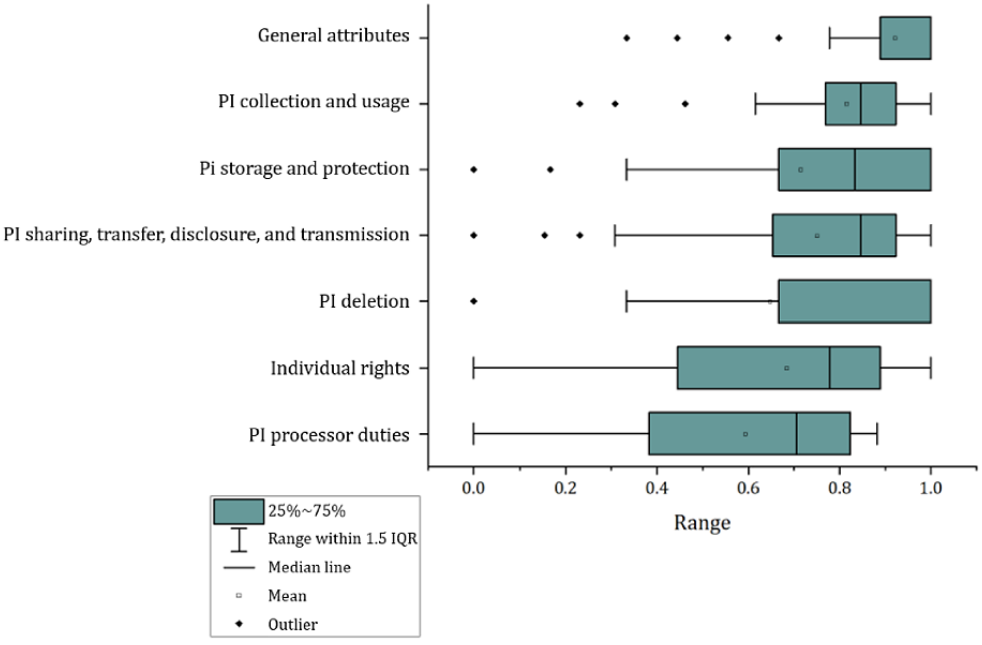


Table 1. Compliance evaluation scores of internet hospital apps for level-2 indicators.

Evaluation results on level-2 indicators	Compliance rate (%), mean (SD)
PI[a] processors and service	95.2 (20)
Policy transparency	100 (0)
Policy maintenance	84.6 (30)
Collection and use of general PI in service functions	90.4 (15)
Collection and use of sensitive PI in service functions	73.9 (24)
Storage security	71.2 (29)
Security incidents	71.8 (37)
Subcontracting of PI processing	51.9 (28)
PI sharing and transfer	77.5 (30)
Public disclosure	93.3 (24)
Cross-border transmission	71.2 (43)
Retention period	76.9 (42)
Deletion and cessation	58.7 (38)
Inquiry of PI	80.8 (39)
Obtain copies of PI	42.3 (49)
Correction of PI	80.8 (39)
Deletion of PI	80.8 (39)
Explanation regarding PI processing	82.7 (38)
Consent withdrawal	51.9 (34)
Deregistration	76.9 (42)
Consent exception scenarios	67.3 (46)
PI protection officer disclosure	48.1 (49)
Compliance audits	11.5 (38)
Impact assessment procedures	13.5 (15)
Request management	72.9 (36)
Complaint management	64.7 (40)

[a]PI: personal information.

In the stage of PI deletion (mean 64.7%, SD 34.8%), most privacy policies stated the PI retention period (mean 76.9%, SD 42.1%). In contrast, the scoring rate for deletion and cessation was lower (mean 58.7%, SD 37.6%). Although most apps committed to PI deletion or anonymization after a retention period (n=41, 79%), only 20 apps (38.5%) required third parties to delete PI or cease processing after the same period.

Concerning individual rights (mean 68.4%, SD 31.5%), most apps explained individuals' various rights effectively, including the rights to inquire about (n=42, 81%), correct (n=42, 81%), and delete PI (n=42, 81%); cancel the account (n=40, 77%); withdraw or modify consent (n=41, 79%); and request an explanation of the privacy policy (n=43, 83%). However, only 22 apps recognized the right of users to obtain copies of their PI (n=22, 42%) and only 13 explained the right to refuse business marketing using automated decision-making. A majority of apps (n=35, 67%) listed exceptions for obtaining consent as provided by applicable laws or administrative regulations.

Concerning PI processor duties, we found a compliance rate of 59.3% (SD 28.4%). Fewer than half of the apps appointed a PI officer and disclosed their information in their privacy policies (n=25, 48%). A quarter of the apps (n=13, 25%) presented impact assessment procedures, whereas 11.5% of apps (n=6) engaged in compliance audits. Many apps provided methods for individuals to inquire about (n=41, 79%), correct (n=41, 79%), and delete PI (n=41, 79%); clarify PI processing rules (n=43, 83%); cancel their account (n=41, 79%); withdraw or modify consent (n=40, 79%); and understand limits on the use of automated decision-making (n=29, 56%). However, fewer than half of all the studied apps provided methods to obtain copies of PI (n=21, 40%). Although many apps provided a means for lodging complaints by disclosing contact information (n=37, 71%), fewer committed to addressing these complaints within the stated time limits or explained the methods of dispute resolution (n=32, 61.5%).

Discussion

Principal Findings

We developed the evaluation scale to align with the characteristics of internet hospital apps, drawing from the essential CI parameters of context, attributes, actors, and transmission principles. We set the context in the realms of internet diagnosis and hospitals and categorized the attributes of PI, emphasizing the distinction between sensitive and general PI processing activities. Actors encompassed both app users and PI processors, including third-party entities outlined in the privacy policies. We translated the transmission principles of lawfulness, legitimacy, necessity, good faith, minimal impact, openness, and transparency into indicators that aligned with PI-related regulations.

Our review of 52 privacy policies from internet hospital apps in the mainland of China reveals a varied spectrum of compliance. The compliance score of the apps' privacy policies varied (mean 73%, SD 22.4%), with some apps demonstrating robust compliance, whereas others fell short. This suggests a need for enhanced regulatory oversight and standardized practices. We also identified variations in legal compliance across different stages of the information processing activities, as shown in Figure 2 and Table 1. This underscores the varying application of PI-related regulations in digital hospital apps, raising concerns about users' potential exposure to privacy risks.

First, our analysis indicates a notable gap between compliance rates for sensitive PI protection (mean 73.9%, SD 24.2%) and general PI protection (mean 90.4%, SD 14.7%), raising significant concerns regarding the provision of stringent safeguards for sensitive PI [76,77]. This gap is especially concerning given the PIPL (specifically section 2, chapter II) mandates special protection for sensitive PI. The inadequate compliance in this area also potentially diminishes users' awareness and understanding of the risks associated with the processing of their sensitive PI. Article 28 of the PIPL stipulates that PI processors may only process sensitive PI with a specified purpose, sufficient necessity, and stringent protective measures. Alarmingly, the practice of seeking explicit consent for processing sensitive PI—a fundamental requirement for lawful processing and respecting user rights—is not as widespread as it should be, implying a pervasive reliance on blanket consent strategies among digital hospital apps. These findings also suggest privacy policies often fail to provide the necessary clarity for users to understand the distinctions between various types of PI and the specific reasons for their processing. Enhancing privacy policies to offer more detailed explanations would not only align with the PIPL's mandate but also elevate the standard of user empowerment, enabling individuals to make informed decisions about their PI.

Second, the fact that many apps did not fully elucidate the role of third-party subcontractors or the conditions of PI sharing, transferring, or deletion in privacy policies may hinder users' understanding of the destinations and protections of their PI, which could consequently affect their trust and the integrity of their informed consent [78]. The lack of detailed disclosure about PI processors (including involved third parties) and protocols for PI sharing and transfer, particularly in critical scenarios like mergers or acquisitions, underscores a disconnect between regulatory intentions and the operational realities of data governance within these digital platforms. In addition, the apps' handling of PI deletion remains challenging and becomes more complex when third-party subcontracting activities are involved [79,80]. It is particularly problematic when privacy policies do not clearly communicate how these third parties are managed or if they are held to the same rigorous standards of PI protection as the primary PI processors.

Third, we found users' rights to inquire about, correct, and delete personal data, along with other user-centric controls, were generally recognized within the apps' privacy policies. The rights of individuals to manage their PI are paramount in the domain of digital health [81,82]. However, a deeper look into the specifics of these policies uncovers a gap in the acknowledgment of users' right to obtain copies of their own PI, a provision stipulated in article 45 of the PIPL. More concerning is the fact that only a quarter of the apps addressed the right to refuse business marketing through automated decision-making, even though article 24 of the PIPL calls for transparency, fairness, and the right to receive an explanation and be able to opt out of such marketing. A lack of explanation of these crucial rights might inadvertently hinder app users from fully realizing their entitlements under PI protection norms.

Finally, our findings reveal inadequacies in how internet hospital apps execute PI-related responsibilities, even though the roles and responsibilities of PI processors are central to the protection of PI [83]. The absence of clear methods for users to obtain copies of their PI or comprehensive explanations of automated decision-making processes stands in stark contrast to the protective intent of the PIPL. Moreover, the relatively low scores of PI protection officer disclosure, compliance audits, and impact assessment procedures suggest a concerning lapse in institutional oversight. Such critical mechanisms are essential for the proactive identification of vulnerabilities and agile adaptation to emergent technological threats.

Recommendations

Since the creation of China's first internet hospital, the nation's government has shown commendable support for the industry in its policy making [25,32,84,85]. China's "internet plus" policy paves the way for a promising future for internet hospital apps beyond their role in the prevention and control of the COVID-19 pandemic [41,86]. Constructing health and medical big data requires the aggregation and integration of personal health care information, so it is essential to address PI risks posed by big data technology. The public-interest nature of health and medical information in areas like infectious disease control, medical research, and public safety further underscores the importance of the reasonable use and sufficient protection of PI [87,88]. However, the rapidly growing sector of internet diagnosis and hospitals still grapples with gaps in patient information protection [43,89], necessitating a balanced approach that judiciously considers both the advantages of processing PI and the inherent challenges associated with PI protection [90].

There is a pressing need to standardize obtaining informed consent in internet hospital services. The prevalent absence of

explicit consent, particularly in subcontracting processes, raises significant privacy concerns, ranging from unauthorized data collection to inadequate user disclosure and excessive data harvesting [91-94]. Individuals often find their control over their own health information reduced, especially as it becomes integrated into big data [48,95]. Drawing on CI's focus on the principles of actors and transmission, it is essential to adopt a dynamic consent model to reinforce granular control over PI. Implementing robust privacy impact assessments and creating transparent platforms for sharing privacy policies can further enhance public trust [50].

Improving the compliance of privacy policies and their enforcement mechanisms requires adherence to CI principles across the information processing stages. This includes ensuring clarity in the collection and use of PI, enhancing protection for PI storage, and promoting transparency in the sharing, transfer, and deletion of PI. Emphasizing the internet diagnosis and hospitals' context and the attributes of PI can help in distinguishing between sensitive and general PI, ensuring PI processing activities are aligned with users' needs and rights. Expanding acknowledgment of individual rights concerning users' PI, a core aspect of CI, involves not only recognizing users' rights to access, correct, and delete their PI, but also ensuring they are adequately informed about the purposes and methods of PI processing. This can be achieved through regular audits, impact assessments, and the appointment of PI protection officers, which ensure internet hospital apps not only comply with legal standards but also respect ethical digital health practices.

Limitations

This study, while comprehensive in scope, encountered several limitations common in privacy policy analyses. First, our methodology primarily relied on content analysis of privacy policies, which may not fully capture the actual practices and implementation effectiveness of these policies. There is often a gap between what is stated in policy documents and how those policies are executed. Thus, the findings may not accurately reflect the on-the-ground application of apps' privacy standards. Second, this study was confined to the examination of publicly available privacy policies, without delving into the apps' technical backend and data-handling processes. This limitation means we could not assess the real-world effectiveness of the stated privacy measures or the security of the apps' data management systems. Future researchers could benefit from incorporating technical audits, user-experience studies, and automated analysis, which could provide a more holistic and dynamic view of privacy protection in internet hospital apps.

Conclusions

Our comprehensive evaluation of privacy policies from 52 internet hospital apps in the mainland of China highlights a landscape marked by varied compliance with relevant regulations. Despite some apps demonstrating adherence to legal standards, notable gaps persist, especially in protecting sensitive PI, obtaining informed consent, and clearly delineating individual rights. Inspired by CI theory, in this study, we underscore the urgent need for enhanced regulatory oversight, standardized privacy practices, and a commitment to user empowerment through transparent, comprehensive privacy policies. Addressing these challenges is critical, not only for protecting PI but also for fostering trust and facilitating the sustainable growth of digital health care services in China and other countries.

Abstract

Background: Mobile apps represent accessible and cost-effective tools to improve nutrition and prevent chronic diseases. However, most of these apps have been characterized as having limited functionality, raising concerns about their effectiveness, acceptability, and efficacy.

Objective: The aims of the study were to assess the quality of popular nutrition-related app platforms in Spain and to describe their characteristics and functionalities.

Methods: We screened apps providing information on dietary advice, food advice, and nutritional content in the Apple App Store and Google Play Store in Spain from March 2 to March 16, 2024. Apps with a star rating of ≥4 (of 5 stars), those available in Spanish, those that were free of charge, those last updated after January 2022, those with >500 reviews, and those with >500,000 downloads were included. The quality of apps was assessed using the user version of the Mobile App Rating Scale (uMARS). General characteristics and nutritional, health, and market-related functionalities of the nutrition-related apps were described. Correlations among total and uMARS sections, star ratings, and number of reviews and downloads were evaluated.

Results: Among the 1460 apps identified in the search, 42 apps met the criteria. The majority of these (n=20, 48%) aimed at recording and analyzing food intake, followed by those providing nutritional plans or diets (n=9, 21%), advising on healthy habits (n=7, 17%), and offering recipes (n=6, 14%). The most prevalent nutritional functionalities offered were recording and monitoring body measurements (n=30, 71%), food tracking (n=26, 62%), and dietary analysis (n=25, 60%), whereas nutrition education was less common (n=16, 38%). Among market-related functionalities, advertisements were the most common among the study apps (n=30, 71%), followed by the option of sharing on social media (n=29, 69%) and customizable reminders (n=26, 62%). Sharing the recorded information in the app with health professionals was infrequent (n=1, 2%). The mean (SD) total uMARS score (maximum 5 points) was 3.78 (0.35), while the mean (SD) uMARS scores for functionality, aesthetics, engagement, and information were 4.21 (0.38), 3.94 (0.54), 3.51 (0.46), and 3.48 (0.44), respectively. Lower mean scores were observed for the subjective quality (mean 2.65, SD 0.56) and perceived impact (mean 3.06, SD 0.67). Moderate to strong positive significant correlations were mostly observed between total uMARS and section-specific uMARS scores, while the correlations between the uMARS section scores were mostly moderate positive. Total uMARS scores were very weakly correlated with user rating, number of reviews, and number of downloads.

Conclusions: The quality of popular nutrition-related app platforms in Spain was acceptable, with observed remarkable differences between sections. The majority of the apps were appealing due to their user-friendly interfaces. Only a few apps, however, provided dietary structure analysis or nutritional education. Further research is needed to assess the long-term impact of these apps on users.

Introduction

Noncommunicable diseases—commonly known as chronic diseases—are responsible for more than 60% of the global disease burden, representing a public health concern [1]. Their high prevalence and mortality rates constitute a threat to individuals, families, health care systems, and governments due to their health and economic impacts [2,3]. Mounting and robust scientific evidence suggests that nutrition, a potentially modifiable lifestyle factor, is linked to chronic diseases, opening up new opportunities for their prevention [4,5]. For instance, a recent umbrella review of meta-analyses, which included 116 primary prospective cohort studies, revealed inverse associations between healthy dietary patterns and risk of chronic diseases, including type 2 diabetes, certain types of cancer, and cardiovascular disease, among others. Conversely, positive associations were found between unhealthy dietary patterns and the risk of chronic diseases [6]. Additionally, extensive research on the Mediterranean diet, one of the most studied and well-known dietary patterns globally, has consistently demonstrated its positive impact on cardiovascular health. This includes a decreased risk in developing lifestyle diseases, such as obesity, hypertension, metabolic syndrome, and dyslipidemia, as well as being linked to lower rates of diabetes, glycemic control, and an age-related cognitive decline [7,8].

In the search for accessible and cost-effective interventions to improve nutrition and prevent chronic diseases, mobile health (mHealth) apps have emerged as an extension of traditional approaches [9]. mHealth apps may provide continuous monitoring, health care provider communication and support, reminders, patient education, and patient involvement strategies that facilitate chronic disease management [10,11]. Moreover, mHealth apps have proven to be effective in achieving healthier lifestyles through behavioral change by helping to increase physical activity levels and improve dietary patterns [12-14]. These relatively new digital health methods stand out for their low cost, innovative functionalities, and high usability [15]. Moreover, the use of these apps has remarkably increased in recent years [16-18]. Currently, 6.9 billion users—86.1% of the world population—own a smartphone [19] with access to more than 350,000 apps in top app stores in 2021 (with approximately 90,000 new mHealth apps added in 2020) [15]. Among these apps, approximately 11% were categorized as diet and nutrition-related apps.

The thousands of mHealth apps available in top stores enable smartphone users to choose the app that best meets their needs. However, over 50% of mHealth apps have limited functionality [20], and there are several concerns about their effectiveness, acceptability, and efficacy [21,22], indicating room for improvement [23]. Moreover, reports suggest that most users stop using mHealth apps after installation or a few interactions [24,25] due to a lack of desired features or the apps not being easy to use [26].

Spain is among the European countries with the highest smartphone penetration rates, with over 47 million people (97% of the population) owning a smartphone. The use of mHealth apps is also continuously increasing, particularly the nutrition-related apps that account for 34% of the mHealth apps market [27,28]. No studies, however, have been conducted to evaluate the quality and functionality of nutrition apps in the Spanish app stores. Therefore, the aims of this study were to evaluate the quality of popular nutrition-related app platforms in Spain and describe the different characteristics and functionalities of these apps.

Methods

Search Strategy

The iOS (Spanish Apple App Store) and Android (Spanish Google Play Store) platforms were used to search for nutrition-related apps from March 2 to March 16, 2024. The search on the Android platform was conducted via laptop, using the Google Chrome browser in an incognito window while logged out of the Google account to prevent any influence of user preferences. The search on the iOS platform was conducted on a mobile device, an iPhone 11 Pro. Of note, the displayed apps may differ from those in other countries due to the search having been carried out in Spanish app stores. The following Spanish search terms were used: “Nutrición” (nutrition), “Dieta” (diet), and “Dieta saludable” (healthy diet). All results for each keyword on both platforms were reviewed.

Screening and Selection Criteria

The selection process of the apps was conducted following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [29]. All apps were initially independently screened and analyzed by 2 study researchers (GS and MIM-V) based on the description and screenshots on their download page, and disagreements between them were resolved by a third reviewer (CIF-L). We based the selection of apps on the following criteria: (1) a minimum rating of 4 of 5 stars; (2) available in the Spanish language; (3) freemium (free of charge); (4) last update after January 2022; (5) more than 500 reviews; (6) more than 500,000 downloads; and (7) dietary advice (eg, diet plan or meal planning), food advice (eg, cooking process or characteristics of food), or nutritional information of food or drinks (eg, nutrient content or recommended intake). The following exclusion criteria were applied: (1) apps initially free of charge but with a monthly subscription later on, (2) apps used as a food diary without dietary analysis, (3) apps requiring external equipment (scales and smartwatches) for use, (4) apps designed for use by health care professionals, (5) restaurant apps for making reservations or displaying menus, (6) apps for taking photos or videos of food, (7) educational food-related apps for children, (8) apps that allow offline payments for health services, (9) apps that exclusively monitor weight and physical activity or display recipes (without including nutritional

information), and (10) apps targeted at specific populations such as pregnant women or individuals diagnosed with diabetes.

After identifying the nutrition-related apps that met all the inclusion criteria and none of the exclusion criteria, duplicates within and between the platforms were removed before each researcher downloaded and explored the remaining apps. Following a more in-depth analysis, apps were examined by the same study researchers and selected for further analysis based on the abovementioned criteria.

Data Extraction

The following general characteristics were extracted from the nutrition-related apps that met these criteria: number of downloads, number of reviews, number of stars, date of last update, and a brief description of the main goal of the apps. Since the Apple App Store does not provide the number of downloads, this information and the rest of the characteristics related to the apps were extracted from the Google Play Store when the apps were available on both platforms. In addition, the nutritional, health, and market-related functionalities of these apps were extracted by the study researchers after a literature review and discussions with experts and were recorded in a Microsoft Excel spreadsheet (Microsoft Corp).

Quality Assessment Using the User Version of the Mobile App Rating Scale

The user version of the Mobile App Rating Scale (uMARS) was used to evaluate the quality of the apps [30]. The uMARS is an adaptation of the Mobile App Rating Scale (MARS) developed for end users, while the MARS is used by professionals who require training and expertise in mHealth in order to perform the assessment [31]. The uMARS is composed of 4 objective sections, each containing multiple items: engagement, functionality, aesthetics, and information. The engagement section (5 items) assesses how entertaining, interesting, customizable, and interactive the app is and whether it fits the target group. The functionality section (4 items) tests the app's performance, ease of use, navigation, and gestural design. The aesthetics section (3 items) evaluates the layout, graphic design, and overall visual appeal. Finally, the information section (4 items) focuses on the quality and quantity of the information, the visual information, and the credibility of the sources. All items are assessed on a 5-point scale (1=inadequate, 2=poor, 3=acceptable, 4=good, and 5=excellent). In addition, the uMARS includes the sections subjective quality (4 items) and perceived impact (6 items), which evaluate whether the app may increase awareness, change attitudes, and promote changes toward healthier behaviors. The same 2 study researchers (GS and MIM-V) independently assessed the quality of the nutrition-related apps using the uMARS. The researchers evaluated the apps from the perspective of users rather than experts.

Statistical Analysis

Descriptive statistics, including frequency and proportions, were used to summarize the general characteristics and the nutritional, health, and market-related functionalities of the selected apps. The overall and section-specific uMARS scores, along with the uMARS scores by the main aim of the apps, were described by their maxima, minima, means, medians, and IQRs and were graphically represented by boxplots. Pearson and Spearman correlation coefficients for normally and nonnormally distributed data, respectively, were determined between app characteristics and total and section-specific uMARS scores. The distribution of the data was checked with the Shapiro-Wilk test. All analyses were performed with Stata (version 16.0; StataCorp LLC), with a 2-tailed level of statistical significance set at $P \leq .05$.

Ethical Considerations

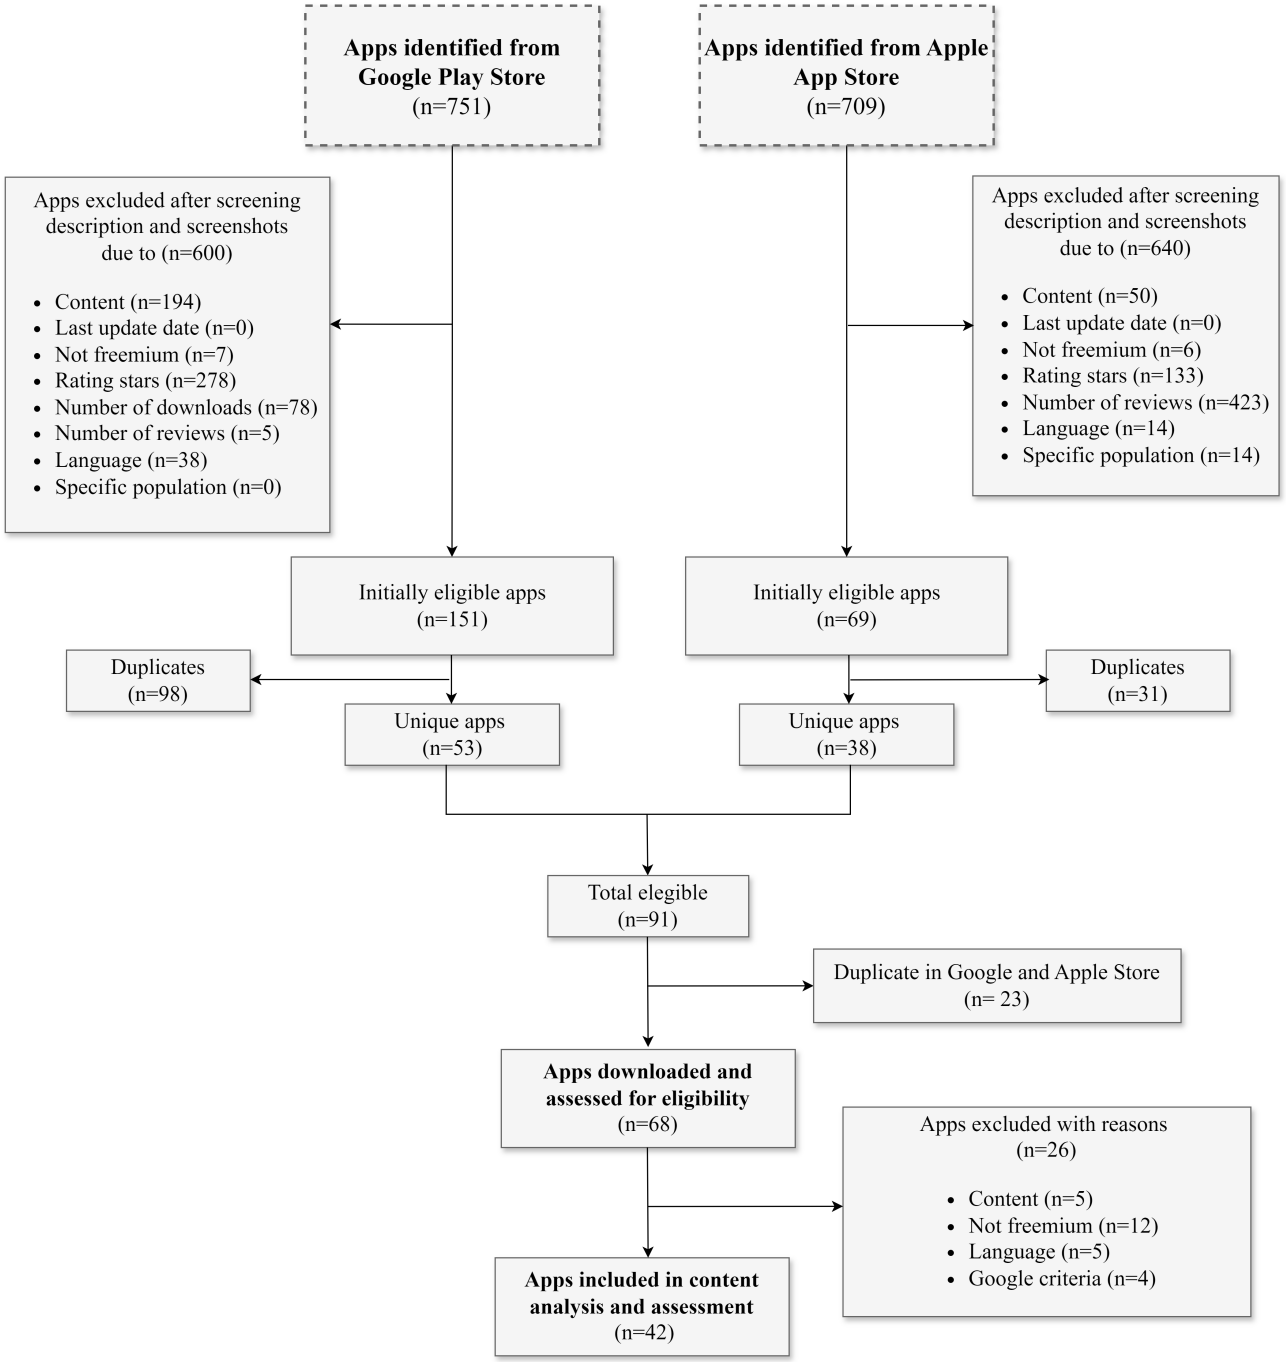
The research conducted in this study did not require the participation of human participants, and no personal data were referenced or collected. The data used in the study were obtained solely from publicly available sources on app stores, and as a result, ethics approval was not needed. This rationale aligns with the institutional policies of the research location [32].

Results

Search Results

Our search yielded a total of 1460 (n=751 from Google Play Store and n=709 from Apple App Store) apps (Figure 1). Of these, 1240 were excluded for not meeting the inclusion criteria (Google Play Store [n=600]: content: n=194, not freemium: n=7, rating stars: n=278, number of downloads: n=78, number of reviews: n=5, and language: n=38; and Apple App Store [n=640]: content: n=50, not freemium: n=6, rating stars: n=133, number of reviews: n=423, language: n=14, and targeted specific population, n=14). After removing duplicates on the same platform (Google Play Store: n=98 and Apple App Store: n=31) and between the Google Play Store and Apple App Store (n=23), the remaining 68 apps were downloaded and further assessed for eligibility. Of these, 26 apps were then excluded (content: n=5, not freemium: n=12, language: n=5, and Google criteria: n=4), resulting in a total of 42 nutrition-related apps that were included in the study for an in-depth analysis.

Figure 1. Flowchart of the selection of nutrition-related apps for the in-depth analysis and quality assessment.



General Characteristics of the Nutrition-Related Apps

The general characteristics of the 42 apps included in the study are displayed in Table 1. A large proportion of the apps (n=21, 50%) were exclusively available on the Android platform, and only a small proportion was exclusively available on the iOS platform (n=5, 12%). The remaining apps (n=16, 38%) were available on both platforms. A great proportion of the selected apps had a rating of 4.6 to 4.8 stars (n=18, 43%), at least 50,000 reviews (n=17, 41%), 1.0 to 4.9 million downloads (n=18, 43%), and offered a premium version with additional paid features (n=38, 91%). Furthermore, the primary aim of many apps was to record and analyze food intake (n=20, 48%), followed by providing nutritional plans or diets (n=9, 21%), advising on healthy habits (n=7, 17%), and offering recipes (n=6, 14%).

Table . General characteristics of the nutrition-related apps included in the study (N=42).

Characteristics	Values, n (%)
Platform	
Android	21 (50)
iOS	5 (12)
Android and iOS	16 (38)
User star rating	
4.0 - 4.2	6 (14)
4.3 - 4.5	16 (38)
4.6 - 4.8	18 (43)
4.9 - 5.0	2 (5)
Number of reviews (in thousands)	
<5.0	9 (21)
5.0 - 14.9	10 (24)
15.0 - 49.9	6 (14)
≥50.0	17 (41)
Number of downloads (in millions)	
Missing	5 (12)
<1.0	4 (10)
1.0 - 4.9	18 (43)
5.0 - 9.9	5 (12)
10.0 - 49.9	7 (17)
≥50.0	3 (7)
Premium version	
Yes	38 (91)
No	4 (9)
Main aim	
Nutritional plan or diet	9 (21)
Recipes	6 (14)
Recording and analyzing food intake	20 (48)
Advice on healthy habits	7 (17)

Nutritional and Health Functionalities

The nutritional and health functionalities of the apps included in the study are described in Table 2. More than half of the apps offered a search function for food and nutritional information (n=23, 55%), specifically on energy content (n=23, 55%) and macronutrients (n=21, 50%). A lower proportion of apps informed about fiber (n=9, 21%), micronutrients (n=6, 14%), and food additives (n=2, 5%). Around two-thirds of the apps included a function to record food intake (n=26, 62%), of which quantification by weight (n=21, 50%) and portion size (n=19, 45%) were the most common. Recipes and dietary plans were provided by 48% (n=20) of the apps, and around one-third of these were customizable to the user's preferences, intolerances, or lifestyle (n=14, 33%). The majority of the apps also offered the recording and monitoring of body measurements (n=30, 71%), such as weight (n=30, 71%) and BMI (n=14, 33%). In addition to nutritional functionalities, a considerable number of apps provided health functionalities related to physical activity (n=25, 60%), with the most common functionalities being type (n=23, 55%) and duration of physical activity (n=22, 52%). Among the apps that offered dietary analysis and suggestions (n=25, 60%), most provided recommendations on water and calorie intake (n=24, 57%) and energy analyses (n=23, 55%), followed by dietary structure analyses (n=20, 48%). The fewest apps provided nutritional education (n=16, 38%).

Table . Nutritional and health functionalities of the nutrition-related apps included in the study (N=42).

Functionalities	Values, n (%)
Searching food and providing nutritional information	23 (55)
Energy	23 (55)
Macronutrients	21 (50)
Micronutrients	6 (14)
Food additives	2 (5)
Fiber	9 (21)
Recording food intake	26 (62)
Quantified by weight	21 (50)
Quantified by portion	19 (45)
Favorite foods	17 (41)
Water consumption	18 (43)
Providing recipes and dietary plans	20 (48)
Customizable according to preferences, intolerances, or lifestyle	14 (33)
With specific amount of food	12 (29)
Shopping list	12 (29)
Recording and monitoring body measurements	30 (71)
Weight	30 (71)
Waist circumference	11 (26)
BMI	14 (33)
Recording physical activity	25 (60)
Type of physical activity	23 (55)
Duration of physical activity	22 (52)
Burned calories	20 (48)
Pedometer	7 (17)
Dietary analysis and suggestions	25 (60)
Energy analysis	23 (55)
Total energy	23 (55)
Energy balance	12 (29)
Energy ratio of meals	5 (12)
Dietary structure analysis	20 (48)
Food groups	1 (2)
Distribution of macronutrients	19 (45)
Monitoring of micronutrient intake and advising on required minimum	1 (2)
Target weight and BMI	11 (26)
Water and calorie intake recommendations	24 (57)
Nutritional education	16 (38)
Independent education module	14 (33)
Minimum micronutrient requirements, their function, and sources	3 (7)

Market-Related Functionalities

The market-related functionalities of the included apps are described in Table 3. Advertisements were the most common market-related functionality among the selected apps (n=30, 71%), followed by the option of sharing on social media (n=29, 69%) and customizable reminders (n=26, 62%). A total of 43% (n=18) of the apps provided challenges and incentives such as

points, badges, or rankings to enhance users' motivation. A more novel function, sharing the information recorded in the app with health professionals, was only provided by 1 (2%) app, while communication with other users was available in 13 (31%) apps. A total of 21 (50%) apps included in the study offered a method to recognize foods through intelligent recognition technology; specifically, 17 (41%) apps offered barcode or QR code recognition, and 14 (33%) offered photo recognition.

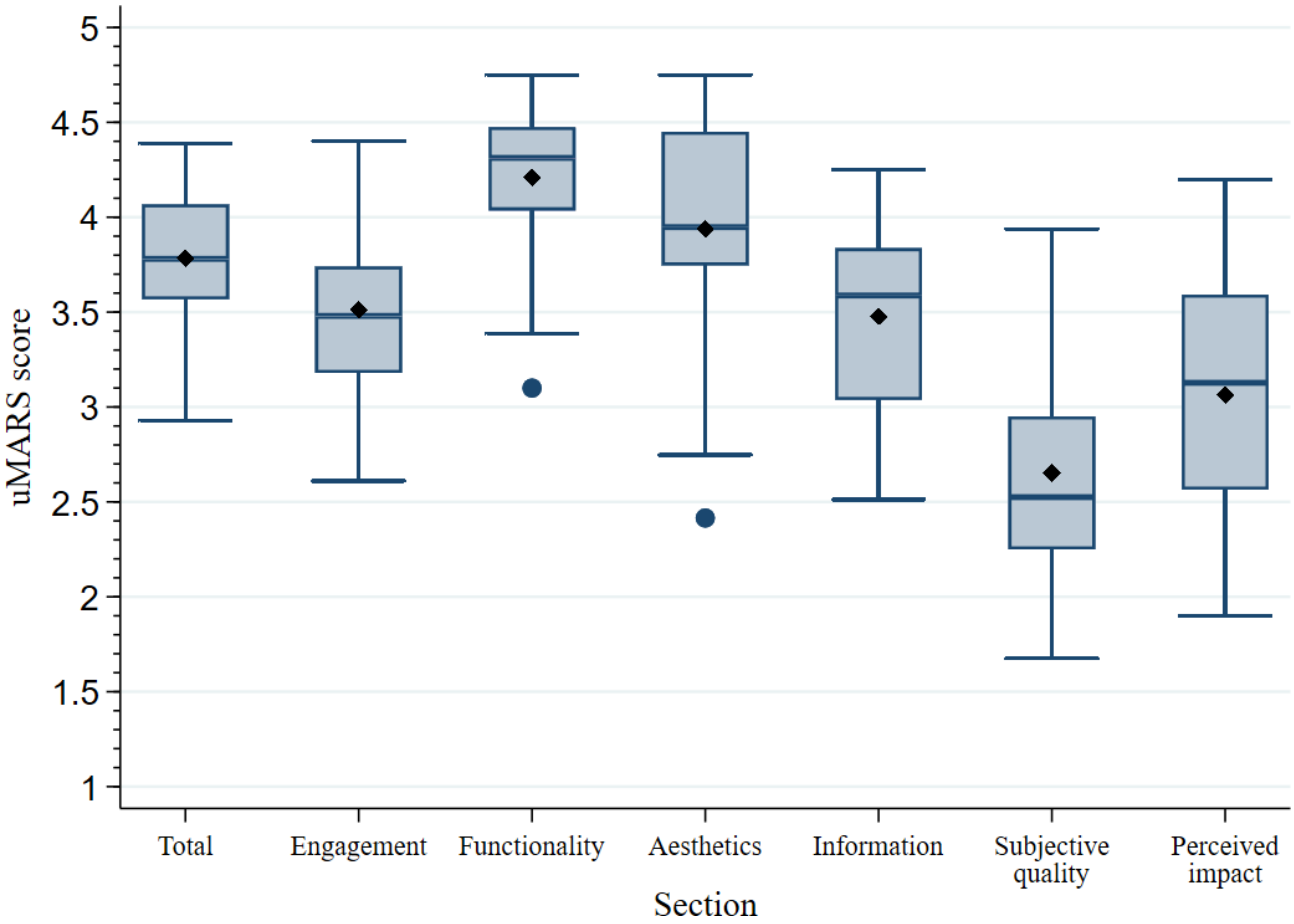
Table . Market-related functionalities of the nutrition-related apps included in the study (N=42).

Functionalities		Values, n (%)
Communicating with other users		13 (31)
Sharing on social media		29 (69)
Receiving invitations to challenges and incentives		18 (43)
Receiving reminders (push notifications)		26 (62)
Receiving advertisement		30 (71)
Buying products		3 (7)
Sharing with health professionals		1 (2)
Intelligent recognition technology		21 (50)
	Barcode or QR code	17 (41)
	Photo	14 (33)

Assessment of the Quality Content

The quality content of the selected nutrition-related apps was assessed using the uMARS scale. The results of the assessment are displayed in Figure 2. A total of 12 (29%) nutrition-related apps scored a mean higher than 4 of 5 points on the uMARS scale. The app with the highest mean total score was 4.39 (SD 0.32), and the lowest mean total score was 2.93 (SD 0.86). The mean total score for all the apps was 3.78 (SD 0.35), and the total median score was 3.78 (IQR 3.57-4.07). Regarding uMARS section-specific scores, functionality was the section with the highest scores, with a mean of 4.21 (SD 0.38), followed by aesthetics (mean 3.94, SD 0.54), engagement (mean 3.51, SD 0.46), and information (mean 3.48, SD 0.44). There was some variability in the scores for each section of the uMARS, with functionality scores ranging from 3.10 to 4.75, aesthetics scores from 2.42 to 4.75, engagement scores from 2.61 to 4.40, and information scores from 2.51 to 4.25.

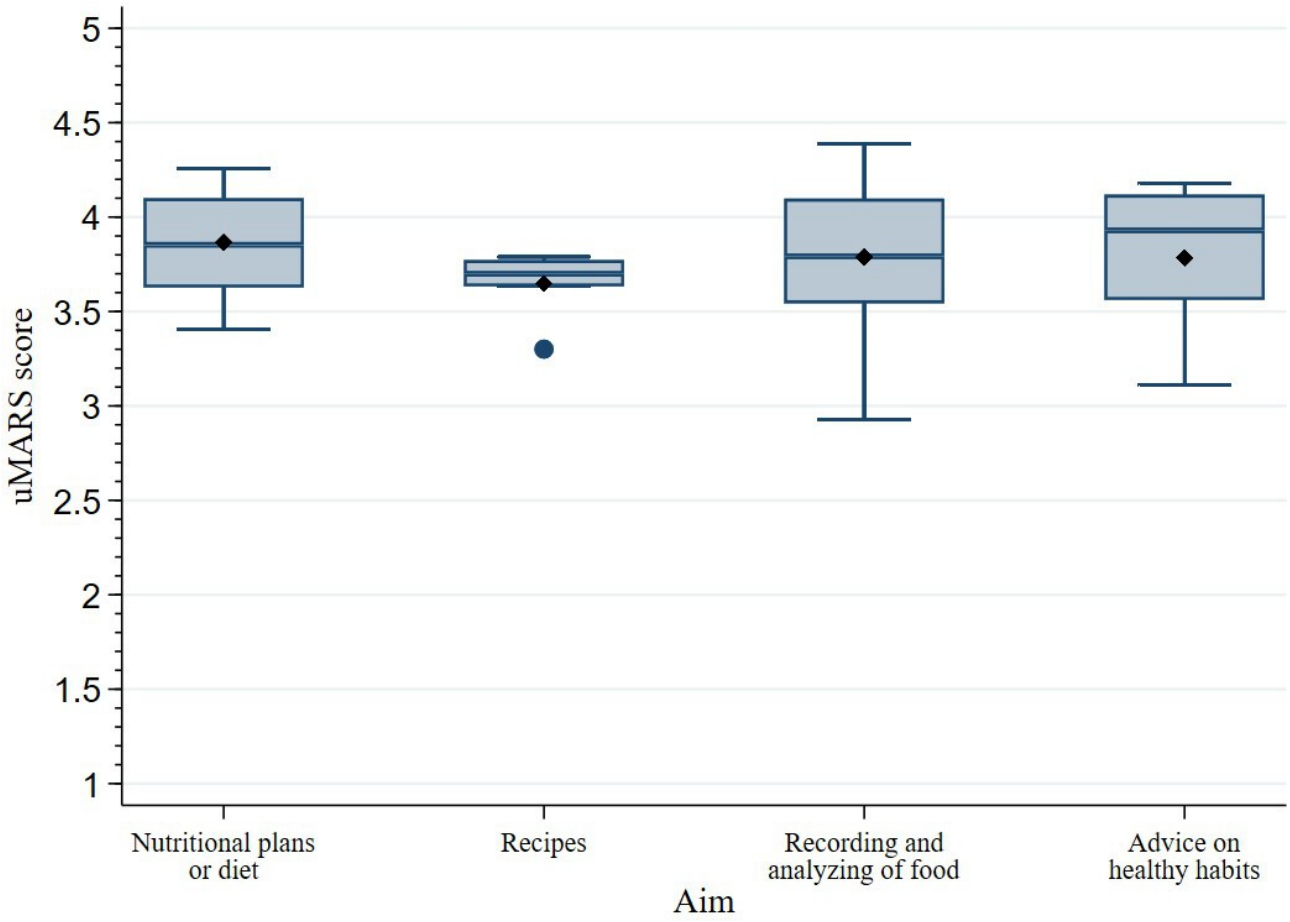
Figure 2. Quality assessment of the nutrition-related apps of the study (N=42). The box plots represent the mean total and section-specific scores of the user version of the Mobile App Rating Scale (uMARS) assessment scores. The line within the boxes represents the median score, the diamond within the boxes represents the mean score, the dot outside the boxes represents an outlier score, and the whiskers represent the maximum and minimum values (except in the presence of outliers).



The sections subjective quality and perceived impact of the uMARS were additionally assessed. The mean scores for the subjective quality and perceived impact sections were lower at 2.65 (SD 0.56) and 3.06 (SD 0.67), respectively, than those of the previously described app quality sections (engagement, functionality, aesthetics, and information). With the exception of aesthetics, a wider range of scores was observed for the perceived impact (1.90 to 4.20) and subjective quality (1.67 to 3.94). Details of the quality content assessment can be found in Multimedia Appendix 1.

The results of the quality content assessment, according to the main aim of the selected nutrition-related apps, are displayed in Figure 3. The apps whose main aim was to provide nutritional plans or diets were the best rated, with a total mean score of 3.87 (SD 0.33). They were followed by the apps that recorded and analyzed food intake (mean 3.79, SD 0.39), the apps that mainly provided advice on healthy habits (mean 3.78, SD 0.37), and those that primarily offered recipes (mean 3.65, SD 0.18). App-specific scores can be found in Multimedia Appendix 2.

Figure 3. Quality assessment according to the aim of the nutrition-related apps of the study (N=42). The box plots represent the mean total score of the user version of the Mobile App Rating Scale (uMARS) assessment by the aim of the apps. The line within the boxes represents the median score, the diamond within the boxes represents the mean score, the dot outside the boxes represents an outlier score, and the whiskers represent the maximum and minimum values (except in the presence of outliers).



Relationship Between App Characteristics, Total uMARS Scores, and Section-Specific uMARS Scores

Pearson and Spearman correlation coefficients between app characteristics and total and section-specific uMARS scores are shown in Table 4. Overall, strong positive significant correlations were observed between total uMARS and section-specific uMARS scores, while the correlations between the uMARS section scores were mostly moderate positive. Notably, total uMARS scores were weakly correlated with user rating, number of reviews, and number of downloads.

Table . Correlations between app characteristics and total and section-specific user version of the Mobile App Rating Scale (uMARS) scores of the nutrition-related apps included in the study (N=42).

Characteristics	uMARS total	User star rating	Number of reviews	Number of downloads[a]	uMARS section-specific

Discussion

Principal Results

To the authors' knowledge, this is the first study conducted with apps from the Spanish app stores (on the iOS and Android platforms) aimed at evaluating the quality of the most popular and freemium nutrition-related apps and at describing their characteristics and functionalities. The study search identified 42 apps that met the inclusion criteria, most of which were aimed at recording and analyzing food intake. The overall quality of the apps included in the study was acceptable; however, remarkable differences between the section-specific quality scores of the uMARS were revealed, with functionality having received the highest rating of the 4 uMARS sections.

The most common functions that the apps provided were recording of body measurements and food intake, searching for food and nutritional information, and conducting dietary analysis. Monitoring and search functions were also found to

be the most common strategies in nutrition-related apps to elicit behavioral change, as indicated elsewhere [33,34]. Only a few apps included in this study offered nutritional education or recipes and dietary plan functionalities, for which a higher development burden could be the reason. The elaboration of these functions is costly and time-consuming, as it requires close collaboration with health care professionals [33].

Comparison With Prior Work

The mean total uMARS score in our study (3.78, SD 0.35) was slightly higher compared to similar nutrition-related app studies conducted in China (3.5) [33] and Korea (2.9) [34]. Unlike our study, the Chinese study [33] included apps regardless of ratings and downloads, while the Korean study [34] used the MARS (opposed to the uMARS used in our study), which requires an assessment by experts rather than by users. Experts may be more inclined to evaluate the quality of the apps more rigorously. Thus, these methodological differences may explain the assessment disparities between the previous studies [33,34] and our study.

In our study, the information section of the uMARS scored the lowest among the 4 main sections, consistent with the study by Martinon et al [35], in which only one-third of the apps offered scientific evidence. This raises concerns about the validity of the information. The information conveyed through apps should be based on empirical evidence, and its accuracy should be rigorously verified, as misinformation can negatively affect users' well-being and health goals. A specialized grading scale designed to evaluate nutritional content could be beneficial in assessing the accuracy of information more effectively [33]. Previous studies have reported overestimations [36] or underestimations [37] of energy intake, while others have found close alignment with validated reference methods [38,39]. The variability in energy intake and nutrient measurements across apps may be explained by the lack of alternative serving sizes offered by the apps [40] and the use of different databases based on distinct nutritional reference guides [36,38,39]. Moreover, self-reported methods of nutritional assessment are subject to a degree of measurement bias, such as underestimation and overestimation of dietary intake, which poses an additional challenge for accuracy calculations [41]. An image-based assessment of the food type and portion could counteract this bias [42]. Along with water and calorie intake recommendations and dietary structure analysis, energy analysis has emerged as one of the most common functionalities offered by dietary analysis apps in our study. In another study [43], energy analysis and calorie intake recommendations were even more prevalent among the apps examined. A possible explanation for this dominance could be the ease of implementing energy calculations within an app [33] and users' interest in tracking energy intake to pursue weight loss goals, as self-monitoring is a crucial element of behavioral weight loss [44,45]. However, the assessment of food group composition or dietary patterns may provide a more comprehensive approach to disease prevention or treatment [46]. In our study and similar research, only a few of the included apps that provided dietary structure analysis actually assessed food group composition [33,39].

Despite the majority of the apps including reminders to inform users about unachieved objectives, and nearly half of the apps offering challenges and incentives, the engagement section scored the second lowest of the 4 main sections, similar to elsewhere [33]. Ongoing motivation is fundamental to continuously engage individuals in successfully achieving app goals and sustaining healthy habits in the long term [47,48]. The inclusion of customizable reminders [49], and in particular gamification, such as receiving digital rewards once a challenge has been successfully completed, may increase the user's motivation through positive, playful experiences [40]. In addition, users seek social support through preferably close-knit communities and continuous guidance by health care professionals. Due to time constraints [47] and a lack of nutritional training [50], physicians often struggle to provide support to their patients regarding nutritional changes. Nutrition-related and other mHealth apps may facilitate the establishment of multidisciplinary health care teams that include dietitians, who can provide nutritional counseling and long-term motivational support to patients. The importance of involving dietitians in promoting dietary lifestyle changes has been studied elsewhere [51,52]. The app environment simplifies the collaboration of different professional groups within the health care system, which would not be feasible otherwise due to location and time constraints.

The functionality and aesthetics sections scored the highest and second highest, respectively. Previous studies have reported functionality as the top uMARS section [33,35,53,54]. When designing apps, it is fundamental to ensure that they work seamlessly and intuitively, as apps that are easy to navigate have been found to reduce usability barriers and motivate people who are less familiar with technology [55]. Regarding aesthetics, the inclusion of visual elements, such as pictures, food icons, or charts, has been previously described as enhancing the user experience [33,34]. For instance, Li et al [33] found that apps with higher aesthetic ratings performed better in overall uMARS scores than those with lower ratings.

The other 2 additional sections of the uMARS, namely, "subjective quality" and "perceived impact," were rated the lowest, which is consistent with findings from other studies [34,35,54]. The low subjective score in relation to the overall uMARS score implies that despite good ratings for engagement, functionality, aesthetics, and information quality, the raters would not recommend the app [35].

Limitations

The results of the study should be interpreted in light of the following limitations. First, this study only included nutrition-related apps in the Spanish language from the app stores in Spain, excluding poorly rated apps (<4 stars), those not free of charge, those with fewer than 500 reviews, and those with fewer than 500,000 downloads. Therefore, this may limit the generalizability of the findings to freemium and the most popular nutrition-related apps in the Spanish app store. Second, since the apps were evaluated from the perspective of users, the assessments could vary from those made by nutrition experts or a joint evaluation by both groups. Third, despite the uMARS [30] having been used in other nutrition-related assessment

studies [33] and being considered a reliable measure of app quality with similar psychometric characteristics and results to the standard version [30,31], the use of questionnaires specifically designed for the assessment of nutrition-related apps such as the App Quality Evaluation may provide more accurate results [56].

Conclusions

This study provides a comprehensive overview of the most demanded nutrition-related apps in the Spanish app market. We found that the majority of the apps were appealing due to their user-friendly interfaces, potentially attracting a larger user base and enhancing adherence. However, few apps provided dietary structure analysis or nutritional education, hindering users' ability to follow a well-balanced diet. Additionally, much of the information provided within the apps raises concerns about its validity. To ensure evidence-based content, collaboration between app developers and nutrition experts is crucial during the app's design phase. Multidisciplinary health care teams, including dietitians, should support patients through mHealth apps to enhance patients' long-term dietary lifestyle changes. Moreover, the findings of this study can help users choose suitable apps and support app developers in the development or refinement of nutrition-related apps. Further research is needed to assess the long-term impact of these apps on users.

Acknowledgments

The authors express their gratitude to Carmen Garcia Mulas for her exemplary dedication as a research assistant. Furthermore, special thanks are extended to the Ministry of Science and Innovation, the Government of Spain, and the European Union for their generous funding of this project. Open Access funding was provided by the Ministry of Science and Innovation, the Government of Spain, and the European Union (project PID2022-141358OBI00).

Authors' Contributions

CIF-L, GS, and DF-L contributed to the conception and design of the study. GS and MIM-V conducted the search and performed the quality assessment. CIF-L and AFM conducted the statistical analysis, interpreted the results, and drafted the first version of the manuscript. GS, MIM-V, and DF-L contributed to writing and editing the manuscript. CIF-L had primary responsibility for the final content of the manuscript. CIF-L resolved disagreements between the 2 reviewers (GS and MIM-V). All authors read and approved the final manuscript.

Conflicts of Interest

Abstract

Background: Pulmonary hypertension (PH) is a chronic and complex condition, requiring consistent management and education. The widespread use of smartphones has opened possibilities for mobile health apps to support both patients and health care professionals in monitoring and managing PH more effectively.

Objective: This study aimed to identify and assess the quality of free smartphone apps for PH targeted at either patients or health care professionals.

Methods: A systematic search was conducted on freely available apps for patients with PH and health care professionals, accessed from a Spanish IP address, on Android (Google Play) and iOS (App Store) platforms. Searches were performed in October 2022 and 2023. Apps were independently analyzed by two reviewers, focusing on general characteristics. Quality assessment was based on the Mobile Application Rating Scale (MARS) framework, and Mann-Whitney *U* tests compared mean MARS scores against specific variables.

Results: In the overall study, 21 apps were identified. In the 2022 search, 19 apps were listed (9 iOS, 7 Android, 3 available on both platforms). In the subsequent 2023 search, 16 apps were identified (6 Android, 7 iOS, 3 available on both platforms). Of those identified in 2022, 14 remained available in 2023, with only 7 updated since 2022. In addition, 12 apps targeted patients or the general population, while 9 targeted health care professionals; none involved patients in the development or design. Conversely, 13 apps involving health care professionals were identified. There were 10 apps that received pharmaceutical industry funding. The primary goal for 81% (17/21) of the apps was to disseminate general information about PH. The overall mean MARS quality was acceptable in 2022 and 2023, with mean ratings of 3.1 (SD 0.6) and 3.3 (SD 0.5), respectively. The functionality category achieved the highest scores in both years, indicating ease of use and intuitive navigation. In contrast, the subjective quality domain consistently received the lowest ratings in the MARS assessment across both years. None of the apps underwent clinical testing themselves; however, 2 incorporated tools or algorithms derived from trials. The overall quality of iOS apps statistically outperformed that of Android apps in both years (P<.05). Furthermore, the involvement of health care professionals in app development was associated with enhanced quality, a trend observed in both years (P=.003 for both years).

Conclusions: This review of mobile health apps for PH reveals their emergent development stage, with generally acceptable quality but lacking refinement. It highlights the critical role of health care professionals in app development, as they contribute significantly to quality and reliability. Despite this, a notable stagnation in app quality and functionality improvement over 2 years points to a need for continuous innovation and clinical validation for effective clinical integration. This research advocates for future app developers to actively engage with health care professionals, integrate patient insights, and mandate rigorous clinical validation for PH management.

Introduction

Pulmonary hypertension (PH) is a pathophysiological disorder encompassing various clinical conditions, often associated with cardiovascular and respiratory diseases [1]. Effective management of PH requires a comprehensive, multidisciplinary approach within specialized centers, ensuring enhanced patient care through collaborative diagnosis, treatment, and continuous quality monitoring [1,2]. Regular communication between patients, their informal caregivers, and the health care professionals involved, including those external to the primary treatment team, is vital for effective disease management [3,4]. This communication enhances patient adherence to the prescribed therapy and ensures meticulous monitoring [5,6]. In this context, mobile health (mHealth) technologies, particularly smartphone apps, present a novel opportunity to enhance disease management. These apps have become pivotal resources for either health care professionals or patients in managing and monitoring diseases such as PH [7,8].

Although the integration of mHealth technologies could expand patient care in PH, it raises significant questions regarding the willingness of patients and health care professionals to invest financially in these digital health tools. Research exploring the willingness to pay for health management apps among these groups is limited [9-12]. Findings suggest a general reluctance among patients to spend money on such apps [9,11,13], likely influenced by the widespread availability of free alternatives that offer similar functionalities. This reluctance underscores the importance of focusing on these no-cost options, reflecting the economic realities and preferences of most patients and health care providers.

Assessing the quality of these free health apps is crucial in order to identify deficiencies and opportunities for improvement and address concerns regarding the accuracy of medical information, user privacy, and accessibility—particularly for populations with limited technology access [14,15]. This analysis can guide the development of future apps and provide valuable insights to health care professionals and patients, aiding them in the selection of more effective and safer apps for health management. However, it is important to acknowledge that the specific application of these technologies in PH may still need to be explored [16].

Currently, our knowledge about the number and quality of free apps for caregivers and patients with PH, as well as the variation in their availability and quality across years, is limited. Therefore, this cross-sectional study aims to conduct a thorough evaluation of commercially available free PH apps, targeted at either patients or health care professionals, for 2 consecutive years. This analysis will focus on the characteristics and overall quality of these apps, addressing the identified gaps in evidence and providing insights into their development and evolution.

Methods

Study Design

This study was designed to evaluate the quality and availability of free smartphone apps for PH targeted at either patients or health care professionals over 2 consecutive years, 2022 and 2023. The decision to conduct the study across these 2 years was based on the dynamic nature of mHealth technologies, where rapid advancements and frequent updates are common. By analyzing the apps over this period, we aimed to capture changes, improvements, and trends that might occur within a relatively short time frame, providing a comprehensive view of the current state and evolution of PH-related mHealth apps.

Search Strategy

A systematic search of mHealth apps specifically relating to PH was conducted using a Spanish IP address on the iOS (App Store) and Android (Google Play) platforms. The initial search was performed on October 5, 2022, with a follow-up search on October 10, 2023, to compare the evolution of apps over 1 year. The search terms used were “pulmonary hypertension,” “pulmonary,” “lung,” “SEPAR” (Sociedad Española de Patología Respiratoria), “European Respiratory Society,” “ERS,” “European Society of Cardiology,” “ESC,” and, when applicable, their equivalents in the Spanish language.

The following inclusion criteria were used for the selection of apps:

- Apps targeted at patients with PH
- Apps targeted at health care professionals providing care for patients with PH
- Apps that included general information about PH

The following exclusion criteria were used:

- Apps that were not freely available
- Apps that were not available in English and/or Spanish
- Apps providing information exclusively about human anatomy
- Apps providing exclusively quizzes or trivia about a disease
- Apps that included inappropriate content (eg, horoscopes, astrology)
- Apps aimed exclusively at fundraising
- Apps with nonfunctional links

The apps had to comply with at least 1 inclusion criteria and none of the exclusion criteria to be included in the data extraction phase.

The search was executed on mobile devices, reflecting a real user’s approach to finding and downloading apps. This method ensures the selection of apps that are directly accessible and functional for end users, aligning with the typical user experience on smartphones and tablets.

The names and descriptions of the apps from the search in the Google Play Store and the Apple App Store were screened against predefined selection criteria. The apps that met the inclusion criteria were downloaded for further screening using a smartphone (Android version 13) for Google Play Store apps. For the apps downloaded from the App Store, an iPad Pro 2020 (Apple Inc) running iOs iPadOS 15.1 was used. For apps available on both platforms, the iOS version was selected for evaluation due to the relatively smaller number of apps on this platform, a method consistent with established methodologies in previous studies [17-19]. This approach not only streamlined the analysis within the confines of our resource constraints but

also was supported by literature indicating minimal variability between the platforms in terms of usability and overall quality scores [20-23].

Data Extraction

Data were obtained from the online app descriptions (including app characteristics and the narrative text) found on the App Store and Google Play Store by 2 independent researchers. Data were extracted and entered into a structured Microsoft Excel 2021 database (Microsoft Corp).

Variables collected for each app were the following: name, developer/owner name, type of developer/owner (eg, commercial, scientific societies, patient associations), platform (Android or iOS), language (English and/or Spanish), app store category (ie, education, health and fitness, medicine), date of publication (year), date of the last update (year), participation of health care professionals in the design and/or development of the apps (yes/no), and participation of patients in the design/development of the apps.

For the purposes of this study, an update was defined as any new version of an app released by its developers, which may include improvements in functionality, user interface changes, additional features, bug fixes, or any other modifications aimed at enhancing the app.

The involvement of health care professionals was acknowledged if specified in the app's description or if health organizations, such as scientific societies and hospitals, developed the app. Patient participation was noted when explicitly mentioned in the app's description.

Technical aspects of the apps were also documented, including features such as social media sharing capabilities (eg, Facebook, Twitter), the requirement of a login, and the necessity of web access for functionality. Additionally, information was collected on whether the apps had received funding or sponsorship from the pharmaceutical industry, and on their potential commercial interests, including the presence of advertisements or options for purchasing services.

The purposes of the apps were classified into the following categories: assessment (ie, apps providing clinical scales, classifying adverse event severity, interpretation for laboratory findings), general information (ie, apps providing information about PH, medication, adverse events), and monitoring of clinical parameters (ie, apps providing a register of laboratory parameters, symptoms). Apps aimed at patients or caregivers were also classified into the following categories: register of patient activities (ie, apps providing calendars for patients to add appointments and treatment administration) and contact with health care professionals.

A descriptive analysis was developed, with continuous and discrete variables presented as mean (SD) and n (%), respectively. The means of continuous variables were compared using the Mann-Whitney *U* test. Results with a *P* value <.05 were considered statistically significant. The data generated were analyzed using IBM SPSS Statistics (version 26.0; IBM Corp).

App Quality Evaluation

To evaluate app quality, the Mobile Application Rating Scale (MARS) was used [24]. The MARS is a validated system to assess health apps, which has been described as the most comprehensive for evaluating technical information and capabilities of apps [24-26]. This tool has been widely used to evaluate health apps designed for many diseases [17,27-29].

The MARS comprises 23 items across 5 subscales:

- Engagement: evaluates the entertainment, interest, customization, interactivity, and adequacy of the target group.
- Functionality: assesses the performance, ease of use, navigation, and gestural design of the app.
- Aesthetics: examines the layout, graphics, and visual appeal of the app.
- Information: assesses the accuracy of the description, establishment of goals, quality and quantity of information, visual information, credibility of the source, and evidence-based development of the app.
- Subjective quality: determines willingness to recommend the app, times the apps will be used, willingness to pay, and overall rating of the app.

Each criterion was evaluated from 1 to 5 (1=inadequate; 2=poor; 3=acceptable; 4=good; 5=excellent). A mean score of the 5 subscales was calculated to describe overall quality.

Mean scores of the engagement, functionality, aesthetics, and information quality objective subscales were calculated, and an overall mean app quality total score was determined. Mean scores were used instead of total scores to accommodate items rated as "Not applicable" and align with familiar star rating formats. The subjective quality items were scored separately or averaged into a mean subjective quality score. This separation ensured that the inherently subjective nature of these measures, based solely on the evaluators' personal opinions and without any predefined criteria, did not unduly influence the overall objective quality assessment. This approach provides a clearer distinction between subjective perceptions and objective functionality and content quality [24].

Before the app search was carried out, reviewers read and became acquainted with the MARS tool. All authors then discussed each rating criterion to achieve a consensus on how to apply it. The first app included was evaluated concurrently by all reviewers to ensure a common understanding and application of the MARS tool. Subsequently, each app included in the study was independently evaluated by 2 reviewers. The scores of each item from these independent evaluations were then compared. In cases where the initial assessments aligned, the average of these scores was calculated to establish the overall mean app quality total score. In instances of significant discrepancy between the 2 primary reviewers' scores—defined as a difference greater than 1 point—where a consensus could not be reached through discussion, a third reviewer was consulted. This third reviewer provided an independent assessment, and the overall mean app quality score was determined by averaging the 2 closest scores among the 3 reviewers.

The MARS was utilized to assess the quality of the apps identified in searches conducted in October 2022 and 2023. For apps identified in both searches, a separate evaluation was conducted after each search if there had been an update to the app. This approach was adopted to examine the changes implemented and to determine whether there was a variation in the app's quality.

Ethical Considerations

This study did not involve human participants or personal data collection. According to local policies, ethics approval was not required for this research.

Results

Description

In the scope of this study, searches conducted in October 2022 and October 2023 resulted in the cumulative identification of 21 apps. The initial search in 2022 identified 19 apps, from a total of 835 apps screened (Figure 1). Of these 19 apps, only 7 received version updates during 2022.

The subsequent search in 2023 identified 16 apps, of which 14 had been initially identified in the 2022 search and remained available. Only 7 of these apps had received version updates in 2023, as compared to their status after the first search in 2022. Moreover, the 2023 search revealed the introduction of 2 new apps unavailable in the preceding year. Table 1 provides detailed general characteristics of the apps included in this analysis.

Almost half of the assessed apps received funding from the pharmaceutical industry (10/21, 48%), and 4 (19%) were developed by the pharmaceutical industry. This influence was observed mostly in the iOS platform apps.

The primary objective of most of the evaluated apps (17/21; 81%) was to provide general information about PH, as well as other pulmonary pathologies in some instances (n=8; 38%). Of the apps targeted at health care professionals, 10 allowed patient assessments through the use of calculators, facilitating the evaluation/classification of patients. There were 2 apps (6 min. test and Pulmonary hypertension) that provided information and tools to assess pediatric patients with PH. None of the apps facilitated the recording of clinical parameters for patient monitoring. Regarding the apps intended for patient use, none permitted users to register activities or contact health care professionals.

For the apps found in the 2022 search, health care professionals contributed to the development or design of 13 of 19 apps (68%). By the 2023 search, health care professionals were involved in 11 of 16 apps (69%). Regarding patient engagement in the development or design process of these apps, such details were not explicitly stated in the descriptions of any evaluated apps. However, the apps "phaware" and "phaware: Aware That I'm Rare," developed by Phaware Global Association (a collective of patients, caregivers, and medical professionals), suggest a potential for patient involvement in designing these apps. Table 2 describes the main characteristics of the assessed apps.

Assessment of App Quality

The overall MARS app quality was considered acceptable in both 2022 and 2023, with mean scores of 3.1 (SD 0.6) and 3.3 (SD 0.5), respectively. Table 3 presents the collected MARS overall quality scores for reference.

The quality assessment of the apps, as detailed in Multimedia Appendices 1 and 2, presents the mean and standard deviations for each MARS item score for the 2022 and 2023 searches, respectively. The engagement scores exhibited significant variation across the apps. Notably, 58% (11/19) of the apps in 2022 and 56% (9/16) in 2023 scored below 3, with the lowest ratings observed in customization and interactivity for both years. In contrast, the functionality category received the highest ratings, achieving a consistent score of 3.8 in both 2022 and 2023. A notable 53% (n=10) of apps in 2022 and 69% (n=11) in 2023 were evaluated with scores of 4 or higher, reflecting commendable performance characterized by ease of use and intuitive navigation. Aesthetically, all evaluated apps received favorable ratings, attributed to their well-designed layouts, graphical design, and visual appeal.

In terms of informational content, most of the apps offered clear descriptions of their features in the app store. However, a significant portion lacked specific objectives, with 47% (n=9) in 2022 and 75% (n=12) in 2023 falling into this category. Evaluations generally favored the quality of the information provided over the quantity, indicating a preference for well-articulated and purposeful content rather than a larger volume of less specific information.

In terms of subjective quality, this domain was the lowest rated in the MARS assessment for both years, with a score of 1.9. Approximately 63% (n=12) of the apps in 2022 and 50% (n=8) in 2023 received a score of 2 or lower, indicating that they were not highly recommendable. Furthermore, 42% (n=8) of the apps in 2022 and 44% (n=7) in 2023 achieved a 3-point score for frequency of use. Notably, when responding to the MARS subjective quality item “Would you pay for this app?” none of the evaluators found the apps worthy of purchase.

[a]The app remained available in both years; however, a reevaluation was not conducted due to the absence of any updates since the initial assessment.
[b]Echoright Pro is the new version (2023) of the Echoright app (2022).

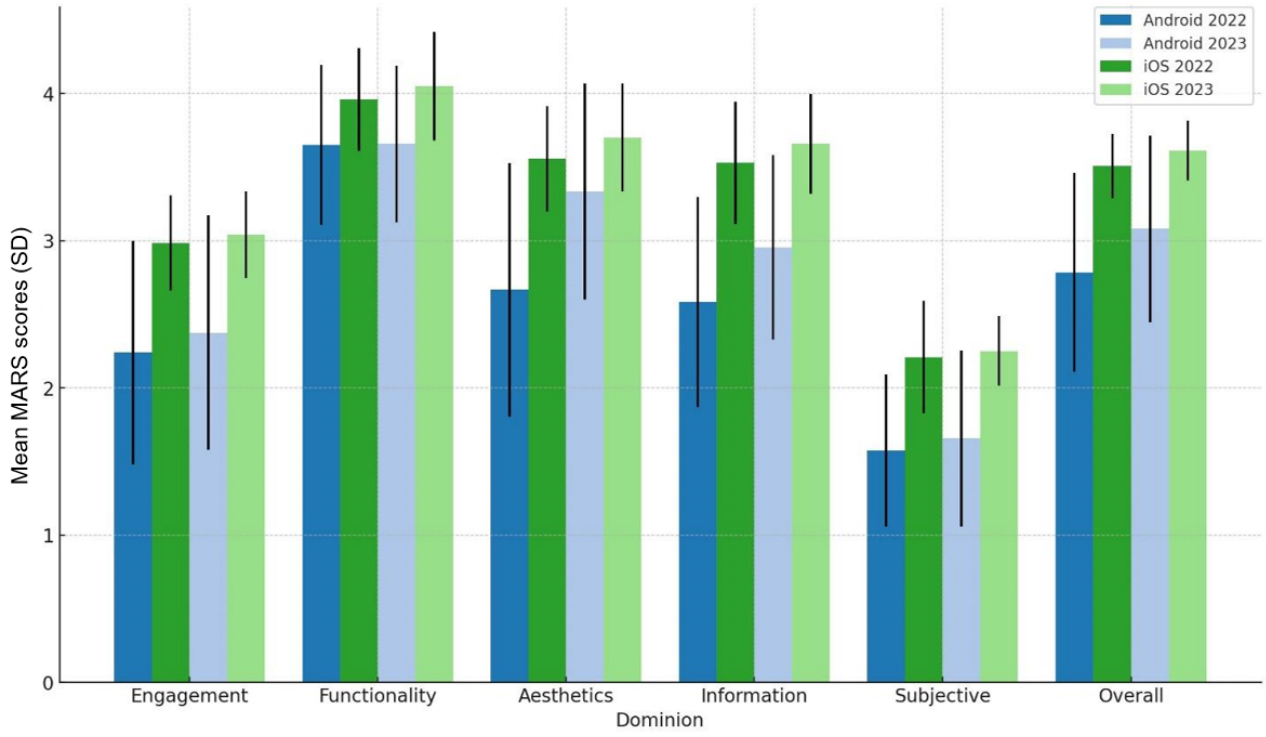
Evolution of Apps Across Two Years

The mean overall MARS score exhibited a slight improvement from 2022 to 2023 (+0.2). However, this variation could be considered not statistically significant, suggesting overall quality remained stable across the evaluated years.

Multimedia Appendix 2 details the differences in scores based on the evaluated platform. Specifically, iOS apps consistently received higher ratings compared to Android apps in terms of the overall mean MARS score for both years, with a difference of +0.7 (*P*=.008) in 2022 and +0.5 (*P*=.03) in 2023. The 2022 search revealed statistically significant differences in the domains of engagement (+0.8, *P*=.02), aesthetics (+0.9, *P*=.01), information (+0.9, *P*=.005), and subjective quality (+0.6, *P*=.008). In contrast, the 2023 search found significant differences only in the information (+0.8, *P*=.01) and subjective quality (+0.6, *P*=.03) domains. Figure 2 illustrates these variations in each MARS domain across the 2 years (2022 - 2023).

Regarding the involvement of health care professionals, apps that incorporated their input in design or development showed higher overall MARS ratings in both the 2022 (+1.1, *P*<.001) and 2023 (+0.9, *P*=.002) searches. Enhanced ratings were observed across all 5 domains in both searches, as detailed in Multimedia Appendix 3.

Figure 2. Quality differences between platforms across the 2-year evaluations.



Discussion

Main Results

Health apps have the potential to become a standard component of care for individuals with chronic conditions. These apps have a demonstrated beneficial impact on patients' health, including enhanced adherence to prescribed medications, improved quality of life, and reduced reliance on health care services [16,30-32]. To our knowledge, this is the first study that systematically evaluated and compared the quality of free mHealth apps aimed at patients with PH and health care professionals over 2 years using a cross-sectional approach, with the aim of examining the progression in the quality and features of PH apps.

In this systematic evaluation, 21 unique PH apps were identified, including 19 in 2022 and 16 in 2023. The overall mean app quality score improved from 3.1 (SD 0.6) in 2022 to 3.3 (SD 0.5) in 2023. According to the MARS 5-point scale, a score above 3, which denotes "acceptable" quality, generally indicates that an app is functional and offers a satisfactory user experience but may still lack certain advanced features or innovative design elements that could elevate its rating to "excellent." However, it is important to note that the MARS framework does not provide explicit guidelines on interpreting the overall mean app quality total score, leaving some ambiguity in assessing app quality [24,25]. Therefore, we acknowledge that for health care apps, especially for complex conditions like PH, more stringent quality standards for "acceptable" quality could be necessary, such as a cutoff score of 3.5 (indicating above-average quality), as defined by Terhorst et al, which may better reflect the standards needed for effective health care management apps [33].

Throughout the 2-year study, from the 19 apps initially identified in 2022, only 14 remained available in 2023. Notably, these persisting apps scored above the median on the MARS, suggesting that higher quality may have contributed to their continued availability in the market. The decrease in availability of the remaining apps calls for further investigation. Potential reasons for this decline could include low overall quality, poor user engagement, lack of economic viability, regulatory challenges, obsolescence in content or technology, organizational changes, or negative performance and reviews [34-36]. In contrast, most apps that remained available over the 2-year period showed durability, although with a relatively low frequency of updates. The minimal changes observed, even after updates, indicate a lack of significant advancement over the year. This might indicate a continuing interest in the digital management of PH but also points to a potential lack of advancement, a significant issue in the fast-evolving mHealth sector [37]. The limited updates could result from funding constraints or inadequate user feedback, both critical for driving innovation in this area.

Simultaneously, the involvement of health care professionals in creating mHealth apps emerged as a crucial factor influencing both the quality and the accuracy of the information provided [17,28,38]. A systematic analysis focusing on the contribution of experts and their compliance with medical evidence in mHealth apps revealed a notable trend: many health apps lack health care professional input and are not consistently grounded in evidence-based information [38]. This is noteworthy considering that the involvement of health care experts in the app development process does not automatically guarantee the inclusion of evidence-based content [38,39]. However, in the context of PH, our review found that more than two-thirds of PH-related apps were developed with the active involvement of health care professionals, correlating with higher app quality scores (2022: 13/19, 68%; 2023: 11/16, 69%). These findings suggest that health care professionals are a key part in developing high-quality PH-related apps.

Moreover, specific app functionalities exhibit significant potential for health care professionals managing PH. Key features such as pulmonary arterial pressure monitoring for patients with implanted devices and easy access to up-to-date PH-specific treatment guidelines are distinctly advantageous [40,41]. Within the scope of this review, 2 apps provided access to PH-specific treatment guidelines ("ESC pocket guidelines" and "ATS journals APP"), and 10 apps included risk assessment tools. However, a critical issue is the infrequent updates; only half of the apps from the year 2022 were updated that year, and just 43% of those available in 2023 had received recent updates, underscoring a significant gap in maintaining current information.

Mobile apps targeted at patients with PH could profoundly impact health outcomes by enhancing self-management, monitoring, and communication [16,30,42]. Such apps could aid patients with PH through various functionalities like symptom tracking, ensuring medication adherence, enabling remote monitoring, offering patient education, creating support networks, facilitating telemedicine, and providing mental health support [43-45]. However, our findings reveal that the majority of apps lack direct patient engagement in their design, resulting in the omission of key features like direct contact with health care professionals and patient activity registration. Notably, only 2 apps, "Pulmonary Hypertension Support" and "phaware," provided community access, with the latter doing so through external links. This gap highlights the need for greater patient involvement in app development to ensure the tools meet the actual needs of end users, potentially through user-centered design approaches [46,47]. The apparent mismatch between app functionalities and patient needs suggests an area ripe for research, aimed at aligning app development more closely with patient priorities [48-50].

A significant finding from our systematic evaluation is the absence of proven clinical efficacy among PH apps, highlighted by the fact that none underwent formal testing in clinical trials for their efficacy in PH management—a stark contrast to chronic conditions like heart failure or chronic obstructive pulmonary disease, where mHealth interventions have demonstrated clinical benefits [51-54]. Notably, apps like "Detect PAH" by Janssen EMEA, which includes a clinically validated diagnostic algorithm [55-57], and the "6 min.test" app by PH Austria, featuring a pediatric-adapted 6-minute walking distance test [58-60], showed promise but lacked validation in broader clinical settings. This lack of broader clinical validation is consistent with findings from other studies assessing health apps [17,28,61]. Further research is crucial to comprehensively

evaluate these apps prior to their integration into standard PH management, considering the potential for eHealth to add to the treatment burden, especially for vulnerable patients [62,63].

Additional Considerations

Beyond the limitations identified in this systematic evaluation, free applications for patients with PH and caregivers should also focus on enhancing interoperability and ensuring robust data privacy.

Enhancing interoperability with existing health care systems is essential to maximize the utility of free health apps. Interoperability ensures seamless communication with other health information systems, which is crucial for real-time updates and integration of the latest treatment guidelines and diagnostic tools. This connectivity keeps apps relevant and effective for both patients and health care providers [64]. By adhering to established health data standards such as Health Level 7 [65] and Fast Healthcare Interoperability Resources [66], these free apps can improve their adaptability and usefulness, facilitating better clinical decision-making and improving patient outcomes [51-54].

However, free apps often pose significant privacy and security risks. According to a report by Timeero [67], free apps tend to share more user data compared to paid apps, increasing the risk of data breaches and unauthorized access. The report indicates that free apps share, on average, 7 times more data points than their paid counterparts, often monetizing user data by selling it to third parties. This practice raises substantial concerns, especially given the sensitive nature of health data. App developers need to implement robust data protection measures to safeguard patient information. This involves encryption of data both at rest and in transit, secure user authentication mechanisms, and regular security audits to prevent unauthorized access and data breaches [68]. Additionally, compliance with regulatory requirements such as the General Data Protection Regulation [69] in Europe or the Health Insurance Portability and Accountability Act [70] in the United States is critical. For free apps, which may lack the financial backing of paid apps, ensuring these privacy and security measures can be challenging but is necessary to gain user trust and ensure safe use in a health care setting.

Limitations

This systematic evaluation is subject to limitations. The evaluation process utilizes the MARS framework [24,26], which introduces a degree of subjectivity in app categorization. However, the dual-reviewer methodology applied in this study likely reduces the impact of this subjectivity. In addition, the MARS framework, while being a widely recognized tool for app quality assessment [17,27,28,71], does not account for crucial factors such as privacy, security, and update frequency, which are critical for comprehensive health software quality assessment [72,73].

In addition, our perspective as health care professionals may influence our interpretation of patient-oriented apps' relevance and utility for patients, potentially overlooking user-specific needs and preferences [49,50]. Furthermore, our analysis was primarily based on app store descriptions and publicly available information, which limits our ability to verify the extent or nature of health care professional or patient involvement in the development of these apps. Additionally, the methodology involved systematic searches conducted via mobile devices in order to simulate the experience of app users. This approach potentially introduces bias based on app store search algorithms and the variable availability of apps. Finally, the review was confined to apps available on Google Play and the App Store. Although these are the major platforms covering most market-available apps [74], other platforms such as Windows Phone and Blackberry Market were not included due to the unavailability of devices for the reviewers, which may have led to the omission of certain PH-related apps.

Conclusions

This systematic evaluation of PH-related mHealth apps targeted at patients and health care professionals has provided critical insights into the current state and potential of these tools. Our analysis identified a relatively small cohort of apps, with an average quality score deemed acceptable, yet revealing a considerable gap in the development and refinement of these digital resources. Furthermore, the involvement of health care professionals in the design and development of mHealth apps was found to be a significant factor in enhancing the quality and reliability of the information these tools provide. Despite this positive impact, our study observed a stagnation in the evolution of app quality and features over 2 years, highlighting a critical need for continuous innovation and improvement. Additionally, our findings emphasize the lack of clinical validation for most of these apps, which is a pivotal step that should not be overlooked if these tools are to be integrated into standard patient care.

In conclusion, while the landscape of mHealth apps for PH shows promise, it remains underdeveloped. Future efforts should focus on leveraging the expertise of health care professionals, integrating patient perspectives, and ensuring that apps undergo rigorous clinical validation. Such measures would significantly enhance the utility, relevance, and effectiveness of mHealth tools, potentially transforming them into indispensable components of PH management. This evolution requires a concerted effort from stakeholders to realize the full potential of mHealth in supporting the complex needs of patients with PH.

Abstract

Background: The success of mobile apps in improving the lifestyle of patients with noncommunicable diseases through self-management interventions is contingent upon the emerging growth in this field. While users of mobile health (mHealth) apps continue to grow in number, little is known about the quality of available apps that provide self-management for common noncommunicable diseases such as diabetes, hypertension, and obesity.

Objective: We aimed to investigate the availability, characteristics, and quality of mHealth apps for common noncommunicable disease health management that included dietary aspects (based on the developer's description), as well as their features for promoting health outcomes and self-monitoring.

Methods: A systematic search of English-language apps on the Google Play Store (Google LLC) and Apple App Store (Apple Inc) was conducted between August 7, 2022, and September 13, 2022. The search terms used included *weight management*, *obesity*, *diabetes*, *hypertension*, *cardiovascular diseases*, *stroke*, and *diet*. The selected mHealth apps' titles and content were screened based on the description that was provided. Apps that were not designed with self-management features were excluded. We analyzed the mHealth apps by category and whether they involved health care professionals, were based on scientific testing, and had self-monitoring features. A validated and multidimensional tool, the Mobile App Rating Scale (MARS), was used to evaluate each mHealth app's quality based on a 5-point Likert scale from 1 (inadequate) to 5 (excellent).

Results: Overall, 42 apps were identified. Diabetes-specific mHealth apps accounted for 7% (n=3) of the market, hypertension apps for 12% (n=5), and general noncommunicable disease management apps for 21% (n=9). About 38% (n=16) of the apps were for managing chronic diseases, while 74% (n=31) were for weight management. Self-management features such as weight tracking, BMI calculators, diet tracking, and fluid intake tracking were seen in 86% (n=36) of the apps. Most mHealth apps (n=37, 88%) did not indicate whether there was involvement of health professionals in app development. Additionally, none of the apps reported scientific evidence demonstrating their efficacy in managing health. The overall mean MARS score was 3.2 of 5, with a range of 2.0 to 4.1. Functionality was the best-rated category (mean score 3.9, SD 0.5), followed by aesthetics (mean score 3.2, SD 0.9), information (mean score 3.1, SD 0.7), and engagement (mean score 2.9, SD 0.6).

Conclusions: The quality of mHealth apps for managing chronic diseases was heterogeneous, with roughly half of them falling short of acceptable standards for both quality and content. The majority of apps contained scant information about scientific evidence and the developer's history. To increase user confidence and accomplish desired health outcomes, mHealth apps should be optimized with the help of health care professionals. Future studies on mHealth content analysis should focus on other diseases as well.

Introduction

Globally, noncommunicable diseases (NCDs) account for 74% of all deaths yearly (41 million people), which highlights the global health burden [1]. In Malaysia, the latest National Health and Morbidity Survey reported that two-thirds of the Malaysian population have at least 1 of 3 common NCDs, namely diabetes, hypertension, or hypercholesterolemia, and about half of the population (50.1%) are overweight or obese [2]. There are barriers to care access, delivery, and self-management for the management of NCDs, such as being unable to visit a clinic in a timely manner and long consultation waiting times [3], prompting policy makers to improve the health care system. The introduction of mobile health (mHealth) technology presents an opportunity for patient self-monitoring, helping health care providers personalize the management of patients [4] and increase cost-effectiveness throughout health management [5].

According to a definition by the World Health Organization, mHealth is the use of mobile and wireless devices such as mobile phones, tablets, and personal digital assistants to support health care management [6]. In the rapidly growing mHealth app market, the presence of these apps could facilitate the health care management system. A recent review of the literature revealed that researchers have recognized that mHealth could be an effective tool in chronic disease management [4] and improve patients' self-management behavior [7]. A growing body of research demonstrates the health benefits of mHealth interventions for patients with NCDs in terms of enhancing patient self-monitoring and health outcomes in NCDs such as type 2 diabetes [8], obesity [9], and cardiovascular diseases [10].

Self-management is crucial in the daily management of chronic diseases to improve quality of life and reduce management costs [11]. However, poor self-management among patients with chronic disease has been observed [12]. Technologies such as mHealth have the potential capacity to empower patients requiring support in their self-management efforts. A review by Cruz-Ramos et al [10] demonstrated that many mHealth apps for cardiovascular diseases support self-management features such as medical advice, reminders, and self-monitoring notifications [10]. Moreover, research has also found that self-monitoring of weight and dietary intake is associated with positive outcomes for weight loss [13]. As the key to person-centered care, mHealth apps enhance self-management for chronic conditions by providing personalized goal setting, active reminders, social interaction, and support [14]. Hence, mHealth apps could help build decision-support systems that bridge the gap between self-management and conventional health care management.

As of 2022, there were nearly 2.67 million mobile apps available on the Google Play Store. Of these, more than 130, 000 apps were health care or health and fitness apps [15]. The number of mHealth apps available on the Google Play Store and Apple App Store continues to grow [16-18]. Globally, it was estimated that 6.6 billion individuals own a smartphone, and the number is expected to grow to 7.7 billion by the year 2027 [19], which allows mHealth technology to be more accessible to individuals. However, caution must be taken regarding this growth, as the evidence related to its efficacy and benefits for chronic health disease management is not well identified.

Previous research on the perception and usability of mHealth apps for NCD management has demonstrated a growing interest in user-centric health-tracking mobile apps among the population with chronic illness [20,21]. An empirical study conducted to predict patients' intentions to continue using mHealth services as part of self-managing their chronic conditions revealed that the participants had high intentions to continue the use of mHealth services [22]. The use of mHealth apps is highly encouraged, as it has been linked to higher rates of health-promoting behavior among people with chronic medical conditions [23]. Self-management using mHealth apps could be a part of health management, as people living with NCDs have the autonomy to take responsibility for their health. Relevant content analysis studies have been carried out in different geographical areas [24-26], but limited studies have been conducted among Southeast Asian countries. As such, there is an emerging need to bridge this research gap by initiating more content analysis studies in Malaysia to contribute to more holistic development of mHealth apps.

This paper provides a review of the current landscape of mHealth apps, with an emphasis on common chronic disease management. Understanding trends in mHealth apps and their relevant features will benefit users in developing informed decisions, as well as help health care providers improve the quality of mHealth. To make better-informed decisions, the reliability of currently existing mHealth apps should be explored. This study aims to describe mHealth apps available in conventional app stores for common NCDs, determine their health categories, explore the features they focus on, identify neglected areas, and evaluate their quality using the Mobile App Rating Scale (MARS) assessment tool.

Methods

This review involved a systematic search of apps available in mobile phone app stores. The protocol adhered to the 5-step framework outlined by Arksey and O'Malley [27], which includes (1) identifying the research question; (2) identifying relevant apps; (3) selecting apps; (4) charting the data; and (5) collating, summarizing, and reporting the results.

Identifying the Research Question

This review aimed to answer the following questions: "What are the available mHealth apps in the Malaysian market for common NCDs?" "What are the app features available in the mHealth apps for NCDs in Malaysia?" and "What is the quality of the mHealth apps for NCDs in Malaysia?"

Identifying Relevant Apps

The search was conducted from July 7, 2022, to August 14, 2022, on the Apple App Store (Apple Inc) and Google Play Store (Google LLC) using the search terms *weight loss*, *obesity*, *diabetes*, *hypertension and cardiovascular diseases*, *stroke*, *weight management*, and *diet*. The search terms were identified using appropriate Medical Subject Headings terms as well as the free text of keywords. The selected NCDs were chosen

because they are among the most prevalent chronic diseases in Malaysia and around the world.

Selecting Apps

To be eligible for inclusion in this review, the title and content of the identified mHealth apps were screened and filtered based on the descriptions provided by the app developer. An app met the inclusion criteria if it (1) was developed in English; (2) had self-monitoring feature(s); and (3) was developed for chronic disease management, namely obesity, type 2 diabetes, hypertension, and cardiovascular disease. An app was excluded based on the following criteria: it was a heart rate tracker, exercise tracker, or game; or it was a medicine-delivery, appointment-based, recipe-sharing, or research study app.

Charting the Data

The data were extracted based on feature categories, which included (1) type of health management, (2) number of downloads, (3) country of the developers, and (4) app features. A data extraction table with the mHealth apps' basic information, such as country of origin, name of app developer, and number of downloads, is shown in Table 1. The details of the mHealth apps' features and characteristics are outlined in Multimedia Appendix 1.

Table . Overview of selected mHealth apps.

Name of app	Number of downloads	Availability of in-app purchase	Cost of in-app purchase (US $)	Country of app developer	App developer	Operating system
MyFitness Pal: Calorie Counter	100,000,000	Yes	0.76-0.70	US	MyFitnessPal, Inc	Android
Health & fitness tracker with calorie counter	5,000,000	Yes	0.65-2.90	India	DROID INFINITY	Android
Lifesum: Healthy eating & diet	10,000,000	Yes	3.95-50.30	Sweden	Lifesum	Android

[a]Not available (information was not found in app stores).

Collating, Summarizing, and Reporting the Results

After obtaining the screening results, we performed a descriptive analysis, comparison, and functionality assessment based on the information provided by the app developers. In addition, we analyzed the mHealth apps' category, as well as whether health care experts were involved, whether they were based on scientific testing, and whether they had self-monitoring, based on the description provided by the app providers. Additional information, such as star ratings and the presence of a privacy policy, was also tabulated. A star rating offers a quick overview of an app's overall user satisfaction, making it a valuable component of quality assessment. The presence of a privacy policy reveals how an app manages user data, ensuring the protection of users' private health information, which is crucial for informed decision-making.

Quality Assessment of mHealth Apps

The quality of the mHealth apps was assessed using the validated MARS evaluation tool, which has demonstrated excellent internal consistency (α=.90) [28]. The MARS has 4 sections for objective evaluation: engagement (eg, the level of entertainment provided, interactivity, and appropriateness of app content), functionality (eg, app performance, ease of use, and navigation), aesthetics (eg, layout, graphics quality, and overall visual appeal), and information (eg, accuracy of the app description, source of information, and quality of information). The subjective quality evaluation section of the MARS subscale has 4 items. However, we excluded this section in this study as the aim was to assess the apps' quality objectively. Each item was evaluated using a Likert scale with a score range from 1 (inadequate) to 5 (excellent). The overall quality score was calculated based on the mean scores for each of the 4 sections. A mean score of 3 was considered the minimum acceptable score, whereas a score greater than 4 of 5 was preferable. Before

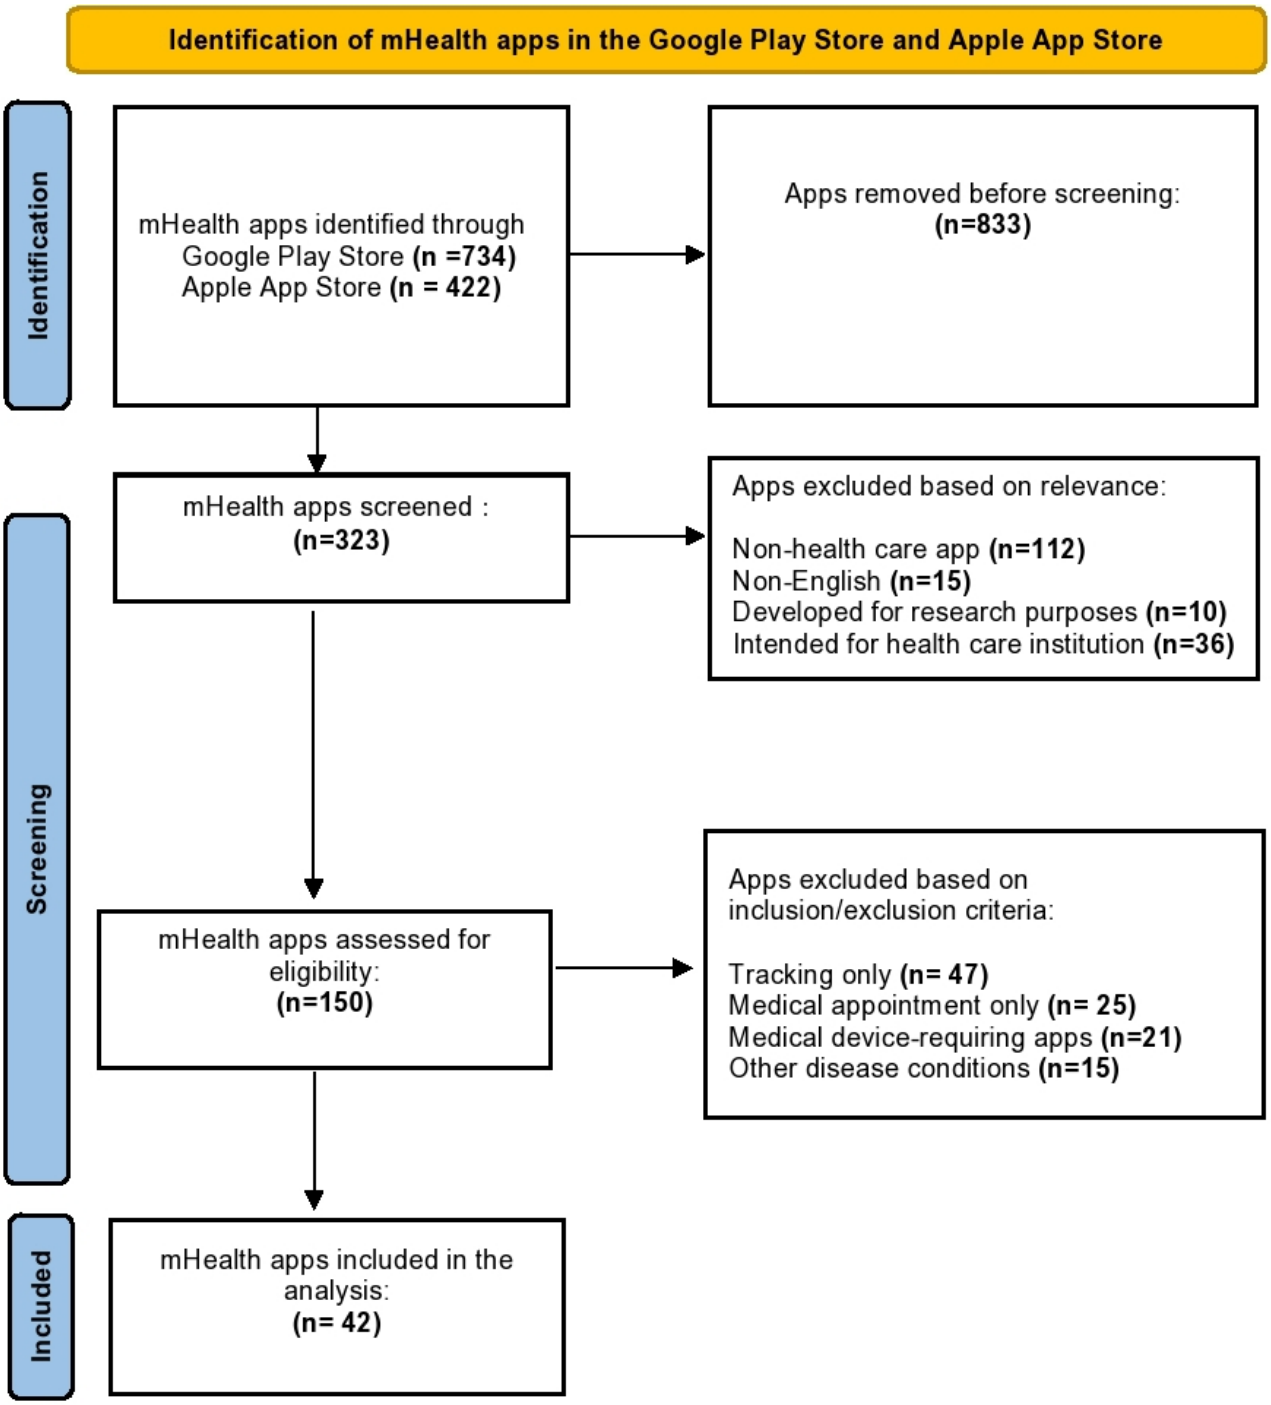
the evaluation, 2 authors independently used each of the apps and conducted the quality assessment in agreement with each other; disagreements were resolved through discussion with a third author.

Results

Search Results

Our search found a total of 1156 apps through keyword retrieval from the Apple App Store and Google Play Store (Figure 1). After removing duplicates, 323 apps were screened; 150 apps met the inclusion criteria as apps focusing on selected chronic disease management (iOS: n=103; Android: n=47) and were included for eligibility assessment. Among them, 42 were included in this study for analysis.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the systematic search and selection of mobile health (mHealth) apps.



Sample Distribution and App Characteristics

A total of 42 apps (n=28 Android and n=14 iOS apps) were included in this review. Among these, 31 (74%) were for weight management while 11 (21%) were dedicated to chronic disease health management. The chronic diseases commonly targeted by the apps included cardiovascular disease (n=1, 2%), type 2 diabetes (n=3, 7%) and hypertension (n=5, 12%). However, there were 9 apps (21%) that did not specify which chronic diseases they targeted. Most of the apps received recent updates, in the year 2022. The general characteristics of the mHealth apps are described in Table 2. The download count is exclusive to Android apps, as this information was not obtainable for iOS apps.

Table . Sample distribution of chronic disease management apps (n=42).

Category		Apps, n (%)
Weight management		31 (74)
Type 2 diabetes mellitus		3 (7)
Hypertension		5 (12)
Cardiovascular disease		1 (2)
General NCDs[a]		9 (21)
Year updated		
	2020	1 (2)
	2021	5 (12)
	2022	36 (86)
Downloads (Android only), n		
	10,000-99,999	3 (7)
	100,000-999,999	12 (29)
	≥1,000,000	13 (31)
Cost to download		
	Free	42 (100)

[a]NCD: noncommunicable disease (this included hypertension, type 2 diabetes mellitus, and cardiovascular diseases).

As shown in Table 1, about 81% (n=34) of the apps provided in-app purchases for live-chat subscriptions, ad removal, and premium feature subscriptions ranging from weekly to yearly, among others. The price for each purchase was between US $0.66 to US $203.26. All the apps included in this review can be freely downloaded by users. Most of the apps (n=15, 36%) were developed in the United States, followed by India (n=7, 17%), Malaysia (n=3, 7%) and Singapore (n=2, 5%).

Star Ratings and Privacy Policies of the Included mHealth Apps

Two apps on the Google Play Store and 6 apps on the Apple App Store received no reviews. The number of users (more than 1 million) who provided ratings for Android apps was significantly greater than the number for iOS apps. Most apps received a user rating of more than 4 stars of a total of 5. In this study, all the apps had a privacy policy. Table 3 shows the star ratings and privacy policies of the included apps.

Table . Star ratings and privacy policies of the included mobile health apps.

	Android[a]	iOS[b]
Star rating (1-5 stars), mean (SD)	4.3 (0.3)	4.6 (0.3)
Privacy policy, n (%)	28 (100)	14 (100)

[a]Apps without ratings: n=2.

[b]Apps without ratings: n=6.

App Feature Assessment

The most common feature that was available on the mHealth apps was self-monitoring (n=35, 83%), which allows users to track their body weight, food intake, fluid intake, and other health indicators. Approximately 16 of 42 apps provided online consultation or personalized feedback via the app as well as goal-setting features (n=35, 83%). Meanwhile, there were no evidence-based apps that used scientific testing or multidisciplinary team involvement in app development, based on the descriptions provided by the developers. About 62% of apps (n=26) introduced at least 1 health care professional (eg, health coach, nutritionist, or dietitian) in the health management of the app. The overview of the functionality characteristics of the apps is presented in Table 4.

Table . Overview of functionality assessment of selected mobile health apps (n=42).

Components		Apps, n (%)	
		Yes	No
Multidisciplinary team involvement in app development		0 (0)	42 (100)
Health care professional involvement in app health management		26 (62)	16 (38)
Self-monitoring features			
	Overall	35 (83)	7 (17)
	Weight tracker (eg, BMI)	35 (83)	7 (17)
	Diet tracker	29 (69)	13 (31)
	Water intake tracker	16 (38)	26 (62)
	Step count tracker	10 (24)	32 (76)
	Exercise tracker	13 (31)	29 (69)
	Personalised feedback (eg, chat with doctor, nutritionist, health coach)	16 (38)	26 (62)
Goal setting			
	Overall	35 (83)	7 (17)
	Weight	35 (83)	7 (17)
	Nutrient intake	16 (38)	26 (62)
	Steps activity	9 (21)	33 (79)
	Exercise	5 (12)	37 (88)
Medical condition monitoring			
	Overall	13 (31)	29 (69)
	Blood pressure	9 (21)	33 (79)
	Glucose	8 (19)	34 (81)
	Heart rate	7 (17)	35 (83)
Social support		15 (36)	27 (64)
Evidence-based testing		0 (0)	42 (100)

App Quality Assessment

The average MARS score among the 42 apps was 3.2 of 5, with a range between 2.0 and 4.1. Of the 4 MARS domains, functionality scored the highest (3.9/5), followed by aesthetics (3.2/5), information (3.1/5), and engagement (2.9/5). There was a large gap in the scores of each subdomain, with the engagement score ranging from 1.6 to 4.0, functionality score ranging from 3.0 to 5.0, aesthetics score ranging from 1.0 to 5.0, and information score ranging from 1.7 to 5.0. The MARS functionality score had the smallest range, and the information score had the largest range. Table 5 shows the MARS subdomain ratings and the total mean score.

Table . App quality rating scores using the Mobile App Rating Scale (n=42).

Objective quality rating	Mean score (SD)	Minimum to maximum score
Engagement	2.9 (0.6)	1.6-4.0
Functionality	3.9 (0.5)	3.0-5.0

Discussion

Principal Findings

Most NCD management apps in Malaysia lack scientific evidence of efficacy, do not involve multidisciplinary teams, and require significant feature improvements. This study provides a snapshot of current mHealth apps for common NCDs in 2022 that were primarily commercially based. It revealed that the mHealth apps varied in terms of features, functionality, and disease management. The most common category that the mHealth apps currently focus on is self-management of weight, followed by hypertension and type 2 diabetes. Some apps need to be purchased to access extended features, health management information, and medical advice.

Self-monitoring or self-management are crucial components of long-term chronic disease management. Self-management of chronic diseases has been reported to be related to positive health outcomes among patients [29]. Most of the mHealth apps (n=35, 83%) from this study incorporated self-monitoring features that allow the user to monitor their weight, blood pressure, blood glucose level, dietary intake, and fluid intake. The most common self-monitoring features found in the apps were weight trackers, food intake trackers, and step trackers. As technology has advanced, self-management through mHealth apps has been the subject of investigation. Systematic reviews in Korea [14] and the United States [12] examined their impact, shedding light on their potential role in achieving desirable health outcomes through self-management. This suggests that self-monitoring features in mHealth apps may be instrumental in achieving desirable health outcomes.

Some of the apps (n=15, 36%) incorporated social support features to allow users to engage with other users as well as health professionals. These social features could be key for users to continue engaging with the mHealth apps to improve their health. Social support has been shown to improve patients' health and well-being, and this also applies to online social support networks [30]. Only 38% (n=16) of the apps offered communication with health care professionals via instant messaging or robotic automated message chat functions. These features are beneficial in the self-management of NCDs, as they allow the user to communicate with a health care professional and receive immediate feedback. There is evidence that 2-way communication between patients and health care professionals can improve health outcomes [31]; therefore, app developers should prioritize the inclusion of communication features and health care professionals in app management.

This study reveals a lack of evidence supporting the use of mHealth apps, with none of the apps reporting scientific evidence to indicate the effectiveness of their health management. Based on the star ratings, we cannot deny that mHealth apps could potentially help users improve their health outcomes. Given the fact that most apps on the Apple App Store (iOS) and Google Play Store (Android) did not provide evidence-based testing to prove their effectiveness [32], the app developers were able to make false or misleading claims about their apps. Moreover, health care providers are less likely to feel skeptical of the role of mHealth apps in health care management if the app is supported by research as clinical evidence [33].

The multidisciplinary team approach is a treatment domain that optimizes the health of patients with chronic diseases [34]. Promoting a multidisciplinary team approach is crucial for coordinating the health care system and aiding patients in self-management [35]. However, our research revealed that the majority of mHealth apps did not incorporate a multidisciplinary team to support health management. In this study, only 16% (n=7) of the apps indicated the participation of medical doctors, specialists, nurses, or dietitians. Our findings emphasize the need for multidisciplinary team involvement in health management by using reliable and high-quality mHealth apps. mHealth apps have the potential to function as proactive disease self-management tools [36], meeting diverse needs through collaborative efforts with multidisciplinary teams within the realm of mHealth technology.

The apps in the app stores generally had high star ratings, ranging from 4.3 to 4.6 of 5 stars, which may suggest good user satisfaction. However, it is important to note that user ratings may not always accurately reflect app quality. Therefore, the MARS was used in this study. The overall MARS score of the included apps was 3.2 of 5, which is considered acceptable. Considering the maximum and minimum MARS scores, substantial variability was observed across domains, including aesthetics, which had a range from 1.0 to 5.0. This variance may indicate a significant diversity in app quality, with some evidence suggesting the presence of low-quality apps currently available in the market. However, lower MARS scores could potentially be attributed to reviews of freely available app features.

The review and analysis of mobile app quality for common chronic diseases is crucial for future mHealth app development, as poor app quality can limit their effectiveness in health management [37]. Research on the quality of mHealth apps in Southeast Asia is limited, and the existing studies have primarily focused on COVID-19–related apps rather than those related to chronic disease management [38,39]. Therefore, the authors compared the MARS results with health care app studies from other countries. Our findings align with an assessment of nutrition-related mHealth apps in Korea, where the majority received an average rating, with a mean score of 3.28 of 5 [40]. In contrast, health apps designed for behavioral change in Denmark achieved a slightly higher average quality score, with an average MARS score of 3.48 of 5 [26]. Consistent with previous studies, our study revealed that functionality was best rated (3.9/5), whereas engagement consistently received the lowest score, with the mean score being 2.9 of 5 [41,42]. This indicates that the app developers focused on the functionality of the apps as an essential element in delivering outstanding experiences to the users. On the other hand, some studies discovered that information scored the lowest or fell into the low-to-moderate category [43-45]. This discrepancy highlights that the mHealth apps in the market need special attention to provide more advanced and effective features and capabilities for health management. Importantly, our results indicate that the key areas for improvement in mHealth apps are engagement and information. App developers should prioritize these

domains, focusing on customization, interactive information delivery, and the integration of prompts such as feedback and reminders. Additionally, enhancing sharing functionality and offering more evidence-based content, engaging visuals, and data-driven information for users would improve the overall mHealth app quality.

From a health management perspective, mHealth interventions offer a significant opportunity to facilitate the monitoring of chronic conditions and improve self-management skills [14,24,26]. Evaluating the quality of mHealth apps can help us identify their positive impact on health and behavior outcomes among people with chronic diseases. According to Ryan and Sawin [46], who described an individual and family self-management theory, successful self-management should involve three key components: (1) individual competence, (2) individual motivation, and (3) social factors. mHealth apps have the potential to bridge these factors together to facilitate health management. Additionally, mobile technology promises to enable real-time remote monitoring systems and prompt feedback systems to improve health management [12]. App developers and users should be alert, as our findings show that most apps available in the market are lacking such components.

Strengths and Limitations

The strengths of this study included that the findings were derived and evaluated from the clinical point of view, the study used a validated tool to determine the quality of mHealth apps, and the results can publicly provide review data to users as well as further direction for mHealth app development. This study has several identified limitations. First, we conducted a comprehensive review solely of the apps' free features, excluding premium features due to budget constraints. Second, at the time the study was completed, it is possible that new mHealth apps or updated features had been released, which we were unable to consider. Third, the review was limited to specific common NCDs, and we could not provide an overview of other diseases. Fourth, our focus was on English-language apps available for download in commonly used mobile app stores, which might limit the generalizability of our findings. According to the world's largest ranking of countries and regions by English skills, Malaysia ranks among the top 3 in the English Proficiency Index among Asian countries [47]. Nevertheless, we acknowledge that the focus on English-language apps could result in some percentage of Malaysians being left out. Importantly, app developers and researchers are increasingly recognizing the need to cater to diverse linguistic needs within mHealth apps to address the cultural and language diversity of countries like Malaysia [48,49].

Future Direction for mHealth App Development

The findings of this study reveal that the current mHealth app market for managing NCDs in Malaysia is still in its nascent stages and is marked by a shortage of high-quality mHealth apps. In contrast to a previous study conducted in Malaysia in 2017, which predominantly featured informational apps [50], the market is currently undergoing a shift. It is now pivoting toward health management apps. This changing trend underscores the potential for mHealth technology to serve as a cornerstone in the management of chronic diseases in the future. For instance, the results of a prior study that specifically examined hypertension indicated that health care apps could serve as valuable additions to conventional treatment methods [51]. To effectively address NCDs, mHealth apps should incorporate self-monitoring capabilities, such as health tracking, goal setting, and personalized feedback. Additionally, app developers should emphasize elevating the overall quality of their apps by incorporating a variety of perspectives, including input from relevant health professionals and the integration of scientific evidence. It is essential to include this information in the app description to establish trust among users.

Conclusion

A search for mHealth apps for common NCDs available in the Google Play Store and the Apple App Store revealed that most apps focused on weight management, followed by hypertension and type 2 diabetes mellitus. Self-monitoring features such as weight trackers, diet trackers, and step trackers are the core functions of current mHealth apps. This review also highlights the current market's lack of evidence-based mHealth apps designed specifically for the self-management of chronic diseases. The lack of multidisciplinary teams in app development and health management was observed in the app stores. Evidently, the quality of mHealth apps currently available in the market should undergo ongoing assessment and enhancement to optimize their benefits for users in the realm of health management. Reviews of these apps can offer valuable insights to researchers, health care providers, and app developers, aiding them in delivering high-quality apps for effective health management. App developers and public health authorities should prioritize the development of evidence-based mHealth apps to enhance the mHealth ecosystem for users. Future studies on mHealth content analysis and app evaluation should encompass a broader spectrum of diseases, aiming for a more comprehensive approach that benefits diverse populations.

Authors' Contributions

KJC and ZAM contributed to conceptualization, methodology, and formal analysis; KJC contributed to writing (original draft preparation); KJC, ZAM, AFML, NHR, SHMA, and NMM contributed to writing (review and editing); ZAM, AFML, and NHR supervised the project. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: An increasing number of people are using vapes (e-cigarettes), and with growing evidence of associated harms, there is a need for acceptable cessation support and interventions. Smartphone apps for health and well-being have increased in popularity and use. Limited published literature assesses the potential of apps to support vaping cessation.

Objective: A systematic search of vaping cessation apps currently available in Australia for iOS and Android platforms was conducted. Apps were assessed against established health app assessment tools for quality and behavior change potential.

Methods: A systematic search through the Australian Apple iTunes and Google Play stores was conducted using the search terms “vape”; “vaping”; “e-cigarette”; and “cessation,” “quit,” or “quitting” in May 2023. Only apps that encouraged the cessation of vaping were included. App descriptions were reviewed to determine if they were relevant for inclusion in this study, and relevant apps were downloaded onto the appropriate mobile device for review. The Mobile App Rating Scale (MARS) was used to rate the quality (engagement, functionality, aesthetics, and information) of the apps using an overall score out of 5. The App Behavior Change Scale (ABACUS) was used to assess the behavior change potential of each app using a score out of 21.

Results: An initial search of the app stores yielded 220 Android apps and 124 iOS apps. Screening against the inclusion criteria left 20 iOS apps and 10 Android apps for review. Six apps were available on both operating systems, and these were downloaded, reviewed, and reported separately for each operating system. The average MARS score for all apps assessed in this review was 3.1 (SD 0.41) out of 5. The reviewed apps overall performed well for the MARS elements relating to functionality, such as ease of use and navigation, but had the lowest scores for information-related elements, such as credibility. The number of ABACUS behavior change features per app ranged from 0 to 19 out of 21, with a mean of 8.9 (SD 4.51). The apps commonly included information-related features, such as requesting baseline information. The least common behavior change features were those relating to goal-setting, such as asking about the user’s willingness for behavior change and providing feedback on current actions in comparison to future goals.

Conclusions: The identified vaping cessation apps had moderate levels of quality and some behavior change components. Future vaping cessation apps could benefit from including more features that are known to support behavior change, such as goal-setting, to improve the potential benefit of these apps to support people to stop vaping. As guidelines for vaping cessation continue to be established, future apps need to reference these in their development.

Introduction

The use of e-cigarettes, also known as vaping, is a growing health issue, particularly among young people [1,2]. There is increasing concern regarding potential links between vaping and lung, heart, and brain damage as e-cigarettes often contain cancer-causing agents, toxins, heavy metals, and very fine particles that can cause adverse health effects [3-5]. There is also concern that vaping is increasing the prevalence of nicotine addiction, and people who vape are three times as likely as those who do not take up tobacco smoking [3]. Young adults and teenagers disproportionally comprise the vaping population [6].

In Australia, 19.8% of people aged 18-24 years used e-cigarettes, compared with 8.9% in the general adult population [7].

Due to the increasing awareness of the adverse effects of vaping, there is a substantial number of people interested in quitting vaping [8]. In this context, the Australian Federal Government has recently legislated significant reforms to limit the accessibility of e-cigarettes [9]. The addictive nature of nicotine in e-cigarettes means that it can be difficult for people to cease vaping, highlighting the need for developing high-quality, easily accessible, and evidence-based cessation supports. There is currently limited evidence on vaping cessation interventions [10]. Research on tobacco smoking cessation has found that mobile phone–based interventions are effective and acceptable smoking cessation support among young adults [10,11]. As nearly all (99%) people aged 18-24 years in Australia have a smartphone [12], this is a potential medium with which to explore vaping cessation support. Preliminary research demonstrates that smartphone apps would be acceptable or preferred as a vaping cessation tool for people aged 14-25 years [13], and a survey among US high school students found that of those seeking vaping cessation support, 18% had used a mobile app or SMS text messaging support [14].

The use of mobile phones to assist with behavior change (also known as mobile health) has become increasingly common, and apps have been developed for a range of health issues, including smoking cessation [15,16], alcohol reduction or cessation [17,18], and increasing physical activity [19]. There has been some research into the effectiveness of health behavior change apps, and several reviews have identified the need for these apps to have greater integration of behavior change theories and techniques [20-22].

Given the recency of vaping as a health issue, there has been scarce research on the use of apps for vaping cessation. A review in 2020 found that most vaping-related apps available on Google Play promoted vaping (they provided instructions on creating e-liquids, finding stores that sell vaping products, etc), and only 3% supported vaping cessation [23]. A subsequent Canadian review identified only 8 apps that were available on both Android and iOS platforms that had been created for vaping cessation [24]. The review assessed the apps for quality and content, and concluded that there were a limited number of apps available for vaping cessation and highlighted a need for more evidence-based practice in the development of future apps.

While the use of apps for self-management of health issues is increasing, assessment of their ability to support people in changing their health behavior is in its nascent stages, and the rapid pace of change in the app market presents a challenge to thoroughly evaluate their effectiveness in changing health behaviors. Assessment tools that appraise apps based on the inclusion of evidence-based behavior change techniques, such as goal-setting and self-monitoring, are a practical way of rapidly assessing the potential of apps to promote health behavior change [25].

As practitioners are increasingly seeking ways to support people to quit vaping, there is a need for information on both the quality and behavior change potential of vaping cessation support apps. This study aims to assess vaping cessation apps available in Australia by conducting a systematic search and using established health app assessment tools to gauge app quality and behavior change potential.

Methods

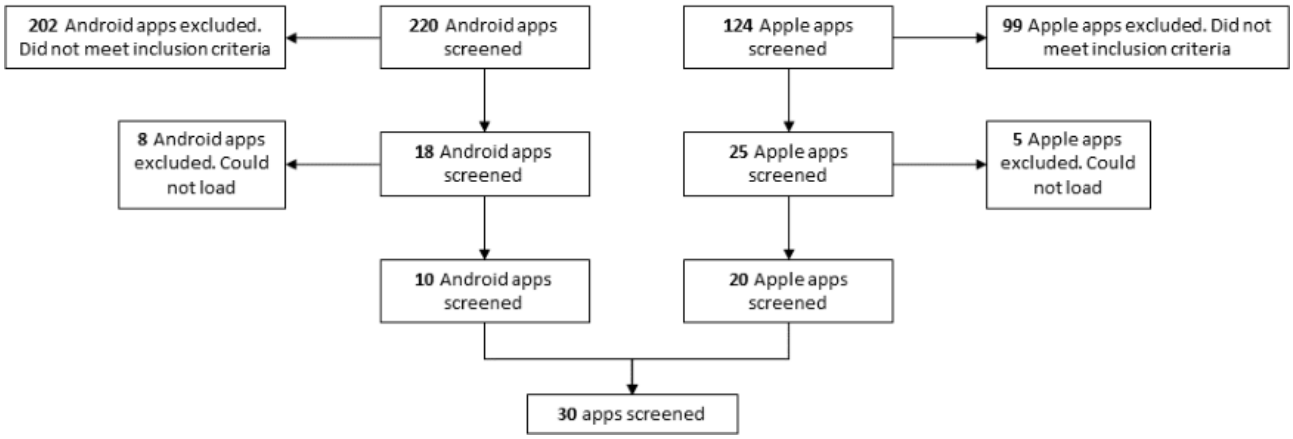
Ethical Considerations

Ethical approval was not required as all data were available in the public domain, and no human participants were involved with this study [26].

Sample Selection and Inclusion Criteria

The Australian Apple iTunes and Google Play stores were searched in May 2023 to identify vaping cessation or quitting apps. The Australian app store was searched as the research is based in Australia, and the research team was interested in the apps available in the Australian context. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guideline [27] was modified and adapted to guide this review (Figure 1). All apps that were designed to encourage or promote vaping cessation that were available in Australia were included for analysis. Apps that were designed for smoking cessation but contained some vaping cessation components were also included. Apps that sought to promote behavior change but were not specifically related to vaping or e-cigarette cessation were excluded. Search terms were developed to include any vaping apps: “vape”; “vaping”; “e-cigarette”; and “cessation,” “quit,” or “quitting.”

Figure 1. App screening process.



All apps available for download in Australian app stores containing any of the above keywords in either the title or description were downloaded for analysis. App titles and descriptions were read to determine inclusion in the review. The inclusion criteria included apps that were created for vaping cessation and those in the English language. Any apps promoting vaping or e-cigarettes were excluded. While previous studies of apps have inclusion criteria such as an average user rating or recent update [21], given the small number of apps and the recency of vaping cessation as an issue, broad inclusion criteria were used to include all available apps.

All apps were downloaded for use on an iPhone or Samsung Galaxy Android phone. Where an app was available on both Google Play (Android) and Apple iTunes (iOS), the app was downloaded on each device and rated separately on each operating system because features and functionality may vary across the same app when developed for different operating systems.

The title and description of downloaded apps were recorded in an Excel (Microsoft Corporation) spreadsheet and rated. This study used two scales to rate the apps. The first was the Mobile App Rating Scale (MARS) [28] for quality, and the second was the App Behavior Change Scale (ABACUS) [25] to determine the potential for behavior change. The MARS and the ABACUS show good internal consistency and interrater reliability (MARS: α=.90, intraclass correlation coefficient 0.79 [28]; ABACUS: α=.93, intraclass correlation coefficient 0.91 [25]).

Quality Review and Rating (MARS)

The quality of each app was rated using the MARS [28]. This rating scale examines 19 app elements across four domains: engagement, functionality, aesthetics, and information. Each element was scored using questions on a 5-point ordinal scale. A detailed description of each element and its scoring criteria are provided in the MARS tool [27]. Based on the scores of each element, an aggregated score is calculated for each domain, and an overall app quality mean score (out of 5) is calculated. All apps were reviewed and scored by two authors (FM and MD) who have experience in evaluating health-promoting apps, including those that address addiction and behavior change. Where quality scores differed, the reviewers considered the app together, sought consensus, and determined a final score. The subjective quality rating of the MARS was not included in the analysis due to the subjective nature of this score, in line with commentary from Stoyanov et al [28]. The MARS assessment tool also includes identification of the strategies used by the app (eg, monitoring/tracking, goal-setting, information/education, meditation/mindfulness, and cognitive behavioral therapy) and affiliations of the app (eg, commercial, government, nongovernment organization, or university). These two sections do not contribute to the overall MARS score but are useful to understand the nature and context of the app.

Each app was downloaded and, consistent with other studies [28-30], used for approximately 10 minutes to allow the reviewers to familiarize themselves with the functionality of the app and user experience. Reviewers attempted to use all parts of each app. During the testing, the reviewers noted if the app crashed or if its functions were not accessible. Apps that were not able to be opened or that crashed were removed from the analysis.

Behavior Change Potential Review and Rating (ABACUS)

The ABACUS [25] comprises 21 items and was used to examine the apps' potential to support behavior change concerning goal-setting, action-planning, barrier identification, self-monitoring, and feedback. Each app was reviewed and scored by two authors (FM and MD). Each app was first explored by the reviewer to gain familiarity with the app and the interface. Reviewers used all app functions including images, cartoons, videos, record-keeping, calendars, and reminders. A total score out of 21 was calculated by summing the item scores. Where behavior change scores differed, reviewers considered the app together, sought consensus, and determined a final score.

Results

Overview of Search

The initial search of the app stores using the specified search terms yielded 220 Android apps and 124 iOS apps (Figure 1). These apps were screened through a review of the title and description; 18 Android apps and 25 iOS apps met the inclusion criteria and were included for assessment and downloaded onto the appropriate device. Eight Android apps and 5 iOS apps could not be downloaded or were no longer available and were

excluded from the sample, leaving 10 Android apps and 20 iOS apps included in this review.

Overview of Included Apps

Most apps that met the inclusion criteria were designed for Apple iOS (n=20), with a smaller number available for the Android operating system (n=10); a minority were available for both operating systems (n=6; see Multimedia Appendix 1 for names of apps). Six apps were created by a commercial organization, 2 by a university, and the remainder (n=22) had an unknown affiliation or developer. Most apps were available for free (n=27); however, of those available for free, most (n=21) had some form of in-app purchase to "enhance" the app experience.

Of the included apps, most used the strategies of allowing the user to monitor/track information (n=25), providing the user with information/education (n=15), providing strategies or tips (n=12), or allowing goal-setting (n=13). A smaller number of apps provided features related to meditation (n=9), cognitive behavioral therapy (n=4), or relaxation (n=2) strategies.

MARS Assessment for Quality

The average overall MARS score of all reviewed apps was 3.1 (SD 0.41). Individual MARS element mean scores ranged from 4 for the elements "ease of use" and "navigation" to 0 for the element "evidence base," as no app included any information about scientific trialing or testing of the app. iOS apps and Android apps were of similar quality, both with an overall mean MARS score of 3.1. Across all apps, the functionality domain score was the highest, while the information domain score was the lowest (Table 1).

Table . Mean app quality calculated using the Mobile Application Rating Scale.

Domain		iOS apps, mean (SD)	Android apps, mean (SD)	Total, mean (SD)
Engagement score		2.7 (0.7)	2.6 (0.8)	2.6 (0.7)
	Entertainment	2.4 (0.8)	2.5 (0.9)	2.4 (0.8)
	Interest	2.4 (0.9)	2.7 (1.0)	2.5 (0.9)
	Customization	2.6 (0.8)	2.4 (0.9)	2.6 (0.8)
	Interactivity	2.8 (0.7)	2.2 (1.0)	2.6 (0.9)
	Target group	3.2 (0.6)	3.1 (0.7)	3.1 (0.6)
Functionality score		3.9 (0.2)	3.9 (0.5)	3.9 (0.4)
	Performance	3.7 (0.5)	3.7 (0.9)	3.7 (0.6)
	Ease of use	3.9 (0.2)	4.0 (0.5)	4.0 (0.6)
	Navigation	4.0 (0.2)	4.1 (0.4)	4.0 (0.3)
	Gestural design	3.9 (0.2)	4.0 (0.6)	3.9 (0.4)
Aesthetics score		3.4 (0.5)	3.6 (0.5)	3.4 (0.5)
	Layout	3.8 (0.3)	3.8 (0.7)	3.8 (0.5)
	Graphics	3.5 (0.5)	3.8 (0.8)	3.6 (0.6)
	Visual appeal	2.8(0.9)	3.3 (0.5)	3.0 (0.8)
Information score		2.7 (0.5)	2.5 (0.7)	2.6 (0.5)
	Accuracy of app description	3.1 (0.6)	2.9 (0.6)	3.1 (0.7)
	Goals	2.8 (0.5)	2.3 (1.0)	2.6 (0.7)
	Quality of information	3.1 (0.7)	3.0 (1.1)	3.1 (0.8)
	Quantity of information	3.1 (0.8)	3.0 (1.2)	3.1 (0.9)
	Visual information	2.4 (0.7)	3.1 (1.0)	2.6 (0.9)
	Credibility	1.6 (0.7)	1.6 (0.6)	1.6 (0.7)
	Evidence base	0 (0.0)	0 (0.0)	0 (0.0)
Total objective score		3.1 (0.5)	3.1 (0.4)	3.1 (0.5)

When considering specific MARS elements across all apps, low mean scores were reported for evidence bases (0, as no apps had this element), credibility (1.6, SD 0.67), and entertainment (2.4, SD 0.84). The highest mean scores were obtained for ease of use (4.0, SD 0.33), navigation (4.0, SD 0.29), and gestural design (3.9, SD 0.41). Over half (n=17, 57%) of all apps were rated with an overall MARS score >3.0.

ABACUS Assessment for Potential to Support Behavior Change

In assessing the apps for behavior change potential, the number of ABACUS behavior change features per app ranged from 0 to 19 out of 21, with a mean of 8.9 (SD 4.51). On average, iOS apps had more behavior change features (9.5, SD 4.6) than Android apps (7.8, SD 4.4). The most common behavior change feature of the 30 apps was the request for baseline information (n=23, 77%), followed by the ability to self-monitor behavior (n=22, 73%) and the ability to personalize or customize the app (n=20, 67%). The least common features were the ability to understand the difference between current action and future goals (n=6, 20%), asking about willingness for behavior change (n=4, 13%), and the ability to export data from the app (n=3, 10%). Table 2 shows the frequencies of the 21 behavior change features evaluated in the apps.

Table . Behavioral change features identified.

Behavior change feature		iOS apps (n=20), n (%)	Android apps (n=10), n (%)	Total apps (N=30), n (%)
Knowledge and information				
	Ability to customize and personalize features	14 (70)	6 (60)	20 (67)
	Consistency with national guidelines or created with expertise	10 (50)	3 (30)	13 (43)
	Request for baseline information	16 (80)	7 (70)	23 (77)
	Instruction on how to perform the behavior	8 (40)	6 (60)	14 (47)
	Information about the consequences of continuing or discontinuing behavior	11 (55)	6 (60)	17 (57)
Goals and planning				
	Request for willingness for behavior change	3 (15)	1 (10)	4 (13)
	Setting of goals	8 (40)	4 (40)	12 (40)
	Ability to review goals, update, and change when necessary	6 (30)	3 (30)	9 (30)
Feedback and monitoring				
	Ability to quickly and easily understand the difference between current action and future goals	5 (25)	1 (10)	6 (20)
	Ability to allow the user to easily self-monitor behavior	16 (80)	6 (60)	22 (73)
	Ability to share behaviors with others or allow for social comparison	10 (50)	3 (30)	13 (43)
	Ability to give the user feedback—either from a person or automatically	8 (40)	3 (30)	11 (37)
	Ability to export data from app	1 (5)	2 (20)	3 (10)
	Material or social reward or incentive	8 (40)	3 (30)	11 (37)
	General encouragement	11 (55)	5 (50)	16 (53)
	Reminders or prompts or cues for activity	13 (65)	4 (40)	17 (57)
	App encourages positive habit formation	8 (40)	2 (20)	10 (33)
	App allows or encourages practice or rehearsal in addition to daily activities	10 (50)	5 (50)	15 (50)
	Opportunity to plan for barriers	8 (40)	2 (20)	10 (33)
	Assistance with or suggest restructuring the physical or social environment	8 (40)	2 (20)	10 (33)

Behavior change feature		iOS apps (n=20), n (%)	Android apps (n=10), n (%)	Total apps (N=30), n (%)
	Assistance with distraction or avoidance	7 (35)	4 (40)	11 (37)

Overall Assessment of Individual Apps

The top 5 apps according to their ABACUS and MARS scores are shown in Table 3. While the app with the highest ABACUS score did not have the highest MARS score, the top 5 apps for each operating system were the same, albeit in a different order (see Multimedia Appendix 1 for the ABACUS and MARS scores of all 30 apps included in this review).

Table . Top apps by App Behavior Change Scale (ABACUS) and Mobile App Rating Scale (MARS) scores.

App name	Operating system	Developer, affiliation	MARS score (out of 5)	ABACUS score (out of 21)	Subjective quality	Costs (up front, in-app purchases)[a]
Quit smoking. Stop vaping app	iOS	Elena Minina, unknown	3.4	19	4	Free up front, no in-app purchases
Quit vaping for good	iOS	Quit Vaping LLC, unknown	3.6	18	4	Free up front, no in-app purchases
Quit Tracker: Stop Smoking	Android	despDev, unknown	3.7	15	2.5	Free up front, Aus $4.99 per feature
QuitSure Quit Smoking Smartly	iOS	Instaquit.org, commercial	3.4	15	3	Free up front, varies Aus $9.99-$39.99
QuitSure Quit Smoking Smartly	Android	QuitSure, commercial	3.8	14	3	Free up front, varies Aus $0.49-$99.99
Kwit Quit smoking for good	iOS	KWIT, unknown	3.8	14	4	Free up front, varies Aus $6.49-$119.99

[a]A currency exchange rate of Aus $1=US $0.66 is applicable.

Discussion

Principal Findings

This review identified 30 vaping cessation apps available in app stores and assessed their quality and potential to support behavior change. The 30 apps were created for either iOS (n=20) or Android (n=10), with 6 being available on both operating systems. On average, the vaping cessation apps performed best in functionality features such as navigation and ease of use, and commonly had behavior change features such as allowing users to self-monitor their behaviors. Areas of deficiency were related to specific behavior change strategies such as comprehensive goal-setting, a lack of evidence of trials or testing, and a lack of transparency in the source of the app and its information.

Behavior Change Potential

This review goes beyond the existing research [24] by including an assessment of behavior change potential through the use of the ABACUS tool. The mean ABACUS score identified in this review of vaping cessation apps of 8.9 out of 21 is comparable to the mean ABACUS score of apps focused on other health behaviors, such as 7.6 for physical activity apps, 8.0 for apps to reduce alcohol consumption, and 8.7 for apps to improve mental well-being [21]. Notably, the mean ABACUS score for tobacco cessation apps has been reported as 10.2 [21]. As vaping cessation has some similarities with tobacco smoking cessation [31], app developers could look toward smoking cessation apps to identify strategies and features that could be adapted for vaping cessation apps.

The findings of this assessment indicate that there is potential for developers to create vaping cessation apps that include more features known to support behavior change. Goal-setting is an important feature of behavior change interventions [32], but only 12 of the 30 apps included a goal-setting feature. App developers could consider including more comprehensive goal-setting features, such as adding elements that ask the user about their willingness or readiness for behavior change and providing the user with feedback on how their current actions compare to their future goal, such as in the form of a visual graphic. Future apps could also consider the inclusion of additional features that draw on behavior change strategies, such as meditation, cognitive behavioral therapy, and relaxation, particularly as evidence shows that a significant proportion of young people vape to relieve stress or anxiety [33].

Quality of Apps

The overall quality of vaping cessation apps as assessed by the MARS was moderate, scoring 3.1 out of 5. A review of apps related to other health behaviors identified mean scores ranging from 2.71 for healthy eating apps to 3.26 for apps that aimed to improve mental well-being [21]. One of the areas where vaping cessation apps scored poorly was in credibility, with a mean score of 1.6 compared with a mean of 2.11 that has been identified for health behavior apps overall [21]. It would be

valuable for future vaping apps to provide more transparency about their information, development, and funding source. One major challenge is that information and guidelines on vaping cessation are in their infancy and may vary across different countries or jurisdictions. As health organizations begin to publish clinical guidelines for vaping cessation [34,35], it would be beneficial for app developers to consider these in the app development process.

The other key area where apps could be strengthened to provide more potential for behavior change is in the establishment of an evidence base. No reviewed app included evidence of being trialed or tested by the developer or an external party. This is a challenge for health apps broadly as the app landscape changes rapidly, and because app development generally outpaces research and knowledge translation, there is often little time for rigorous research. In practice, developing an evidence base for vaping cessation apps may need to occur in parallel to the promotion and general uptake of these apps, as the need for these apps is already present among people who want to stop vaping, particularly among young people for whom digital cessation support is acceptable [14]. Trialing and evaluation of existing and new vaping cessation apps will allow for continual development and improvement over time, and future apps could benefit from partnerships between app developers, researchers, and health behavior change experts.

Considerations for Clinicians and Practitioners

Individuals may seek out assistance and advice from their health care providers when considering vaping cessation. While the treatment approaches for tobacco cessation are long established, there is little guidance relating to vaping cessation [36] nor are there evidence-based clinical guidelines on cessation of dual use (the use of both vapes and tobacco cigarettes) [37]. The Canadian Paediatric Society recently provided preliminary clinical guidance on e-cigarette cessation for young people [38]. These guidelines suggest that behavioral therapy, either in combination with or without pharmacotherapy, should be considered when supporting young people in ceasing vaping or e-cigarette use [38]. This is consistent with Australian guidelines [35] and guidelines from the American Heart Association and American College of Cardiology [39] that suggest that practitioners engage in a range of strategies when advising young people on vaping cessation. A recent randomized controlled trial suggested that tailored mobile interventions could be considered an effective tool to support vaping cessation [40]. As such, in their discussions about vaping cessation, practitioners could encourage people interested in vaping cessation to engage in behavior strategies, such as those apps included in this review.

Considerations for App Developers

Future vaping cessation apps must be developed with an understanding of their target audience and in collaboration with users and clinicians. Users from different age groups may require different features to support their vaping cessation efforts, particularly as they may have different patterns and motivations for vaping [35]. The names and descriptions of some apps included in this review suggest that they were initially developed for tobacco smoking cessation and subsequently adapted for vaping cessation. In Australia, 10.7% of those aged 14 to 17 years are dual users [7], and there are similarities in barriers to and motivations for quitting for both behaviors [31]. Therefore, apps that provide dual support for both health behaviors could be beneficial for some audiences. However, it is important for app developers to create apps with this dual purpose in mind, rather than simply adding vaping cessation to existing smoking cessation app titles.

Finally, it is important to consider the barriers to the uptake of vaping cessation apps. While most of the apps identified in this review were free, many had in-app purchases to access additional features. If a user is unwilling or cannot afford to pay for the additional features, the effectiveness of the app may be compromised. The cost must not be a barrier for people to access health apps [41] and to ensure that people who may not have the ability to pay can access the full level of support for vaping cessation.

Limitations

While there are important findings presented here, this study presents an analysis of apps available at a point in time (May 2023) and only those available in the Australian app stores—app stores in other countries may have different apps. Although this research provides a reference point for further research into the quality of vaping cessation apps, given the fast-moving nature of this field, app developers may modify and update the features of these apps. While the development of the ABACUS assessment tool included reference to tobacco cessation evidence, the tool has only been studied for validity and reliability for physical activity apps [25]. There are perhaps differences in behavior change techniques relevant to vaping cessation in comparison to physical activity. It is also important to note the potential limitation of reviewing apps that were available on both iOS and Android platforms separately. While this may potentially duplicate the identification of certain features in the pool of available apps, this approach has been designed with careful consideration that recognizes that app features and functionality may vary when developed for different operating systems. Unlike other reviews [21], we did not include the app store star rating in our analysis. Many of the apps identified in the app stores were relatively new and as a result had a small number of reviews, making this an unreliable indicator of quality or usability.

Finally, it is important to note that with these data, we are unable to draw firm conclusions relating to long-term behavior change or provide clinical recommendations. It is also known that apps are sometimes used only for a short duration [42]. This is an area that needs more research attention as we strive to create apps that will be able to assist in improving population health at a low cost.

Conclusion

This review of vaping cessation apps found that while apps that are currently available performed reasonably in terms of quality, this review suggests that there is room for improvement, particularly in including features that support behavior change. There is a growing interest and need for effective apps to support people to stop vaping, and future vaping cessation apps could

be improved by including specific features known to support behavior change, such as goal-setting, meditation, and relaxation activities, and observing the growing body of clinical guidelines for vaping cessation.

Abstract

Background: The prevalence of chronic wounds is predicted to increase within the aging populations in industrialized countries. Patients experience significant distress due to pain, wound secretions, and the resulting immobilization. As the number of wounds continues to rise, their adequate care becomes increasingly costly in terms of health care resources worldwide. eHealth support systems are being increasingly integrated into patient care. However, to date, no systematic analysis of such apps for chronic wounds has been published.

Objective: The aims of this study were to systematically identify and subjectively assess publicly available German- or English-language mobile apps for patients with chronic wounds, with quality assessments performed by both patients and physicians.

Methods: Two reviewers independently conducted a systematic search and assessment of German- or English-language mobile apps for patients with chronic wounds that were available in the Google Play Store and Apple App Store from April 2022 to May 2022. In total, 3 apps met the inclusion and exclusion criteria and were reviewed independently by 10 physicians using the German Mobile App Rating Scale (MARS) and the System Usability Scale (SUS). The app with the highest mean MARS score was subsequently reviewed by 11 patients with chronic wounds using the German user version of the MARS (uMARS) and the SUS. Additionally, Affinity for Technology Interaction (ATI) scale scores were collected from both patients and physicians.

Results: This study assessed mobile apps for patients with chronic wounds that were selected from a pool of 118 identified apps. Of the 73 apps available in both app stores, 10 were patient oriented. After excluding apps with advertisements or costs, 3 apps were evaluated by 10 physicians. Mean MARS scores ranged from 2.64 (SD 0.65) to 3.88 (SD 0.65) out of 5, and mean SUS scores ranged from 50.75 (SD 27) to 80.5 (SD 17.7) out of 100. *WUND APP* received the highest mean MARS score (mean 3.88, SD 0.65 out of 5) among physicians. Hence, it was subsequently assessed by 11 patients and achieved a similar rating (uMARS score: mean 3.89, SD 0.4 out of 5). Technical affinity, as measured with the ATI scale, was slightly lower in patients (score: mean 3.62, SD 1.35 out of 6) compared to physicians (score: mean 3.88, SD 1.03 out 6).

Conclusions: The quality ratings from physicians and patients were comparable and indicated mediocre app quality. Technical affinity, as assessed by using the ATI scale, was slightly lower for patients. Adequate apps for patients with chronic wounds remain limited, emphasizing the need for improved app development to meet patient needs. The ATI scale proved valuable for assessing technical affinity among different user groups.

(JMIR Mhealth Uhealth 2024;12:e51592) doi:10.2196/51592

Introduction

Background

Aging societies in industrialized nations are experiencing an increasing prevalence of chronic wounds, resulting in growing challenges in patient care. The high costs of therapy and personnel often limit proper treatment. Chronic wounds significantly impact patients' quality of life, requiring intensive therapy multiple times per week, along with regular medical checkups. Moreover, they have substantial economic implications, including hospitalizations, personnel costs (eg, wound care nurses, home health care services, physicians, wound managers, day clinics, etc), material costs, and management (eg, medical transportation). Purwins et al [1] identified hospitalizations, nursing staff, and material costs as the main contributors to the overall expenses.

Mobile health (mHealth) apps hold promise for bridging gaps in health care. However, a lack of evidence exists for the effectiveness of available mHealth apps [2], and high-quality trials are needed to examine their effects [3]. So far, only reviews of the use of mHealth apps without systematic searches and evaluations have been performed [4]. To address this gap in evidence for patients with chronic wounds, a systematic analysis is necessary to gather reliable data in this area.

A study by Svendsen et al [5] demonstrated that patient-centered smartphone apps can significantly improve treatment adherence in cohorts of patients with psoriasis and patients with rheumatic diseases. Participants expressed favorable views toward medical apps, indicating a willingness to use such apps if available.

To subjectively assess app quality, the Mobile App Rating Scale (MARS) [6] was developed, which evaluates engagement, functionality, aesthetics, and information. Additionally, the System Usability Scale (SUS) is a 10-item questionnaire for assessing the usability of a system. It has been effectively applied to evaluate mobile apps related to dementia, depression, pediatric obesity, and smoking cessation [7]. Moreover, the Affinity for Technology Interaction (ATI) scale [8] provides an easy and reliable means to quantify an individual's technology affinity. An aim of this study was to conduct a focused analysis on the core functionalities and core features of the included apps; therefore, we excluded apps with advertisements in order to prevent disruptions in users' experiences and advertisements' effects on usability [9]. Advertisements can be confounding variables and make it difficult to compare apps' performance or users' experiences. Advertisements can frustrate or annoy users and reduce the clarity and intuitiveness of an app's interface [10]. We also excluded paid apps to prevent bias toward users with financial means, maintain analysis inclusivity, and ensure that preferences align with intrinsic app quality rather than financial considerations, thereby enhancing the analysis' fairness and validity.

Aim of This Study

The primary objectives of this study were to identify and evaluate publicly available smartphone apps designed for patients with chronic wounds. The assessment aimed to provide subjective quality ratings for these apps, while also collecting data on the technical affinity of this specific patient group. To date, a systematic review and assessment of smartphone apps tailored for patients with chronic wounds has not been conducted.

Methods

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki, and ethical approval was waived by the local ethics committee of the University of Würzburg.

App Selection

A systematic search of the German Google Play Store and the Apple App Store was performed from April 2022 to May 2022. The search terms used were "wound," "pressure ulcer," "ulcus," "Wunde," "Wunddokumentation," and "wound documentation." Two independent reviewers searched each app store. The inclusion criteria were that apps had to (1) be available in both app stores, (2) be available in English or German, and (3) be specifically designed for patients. Apps that were not available free of charge and apps that contained advertisements were excluded.

The following information, when available in the app stores and on the associated app websites, was collected: app name, target group (eg, patients and medical personnel), cost, platform, advertisements, features, and search term used to identify the app.

Evaluation of App Quality

The MARS [11] was developed for professional raters to evaluate mobile apps, and it is a validated and reliable scale. The user version of the MARS (uMARS) [12] was designed for users to evaluate the quality of mHealth apps. Both scales are based on a 5-point Likert scale for the following four sections: "Engagement," "Aesthetics," "Functionality," and "Information." Additionally, there is a "Subjective" section. Studies using the MARS have already been performed for several chronic diseases and apps related to breast cancer. The uMARS [12] has been broadly applied to evaluate apps for rheumatic diseases, weight loss, nutrition tracking, and menstrual tracking. The SUS is a simple, 10-item attitude Likert scale that gives an overall view of subjective assessments of usability [13].

Prior to the evaluation, suitable apps were selected based on the inclusion and exclusion criteria, resulting in a total of 3 apps. The quality of these three apps was then evaluated by 10 physicians using the MARS and SUS. Before the assessment, the physicians first watched a short training video that explained the MARS and were then asked to use the apps for more than 10 minutes.

Finally, the best app—the one with the highest mean MARS score among the physicians—was evaluated by 11 patients with chronic wounds using the uMARS and SUS.

Evaluation of Technical Affinity

Many studies that evaluate the quality of mobile apps lack information on cohorts' technical affinity, which is necessary

to assess and interpret the results. Therefore, the ATI scale [8] was used to gather information on physicians' and patients' technical affinity. The ATI scale was designed to quantify a tendency to actively engage in intensive technology interaction or a tendency to avoid technology interaction. In both the patient group and the physician group, ATI scale scores were collected. A Pearson correlation was used to correlate the ages of patients and ATI scale scores.

Comparative Analysis of Patients' and Physicians' Data

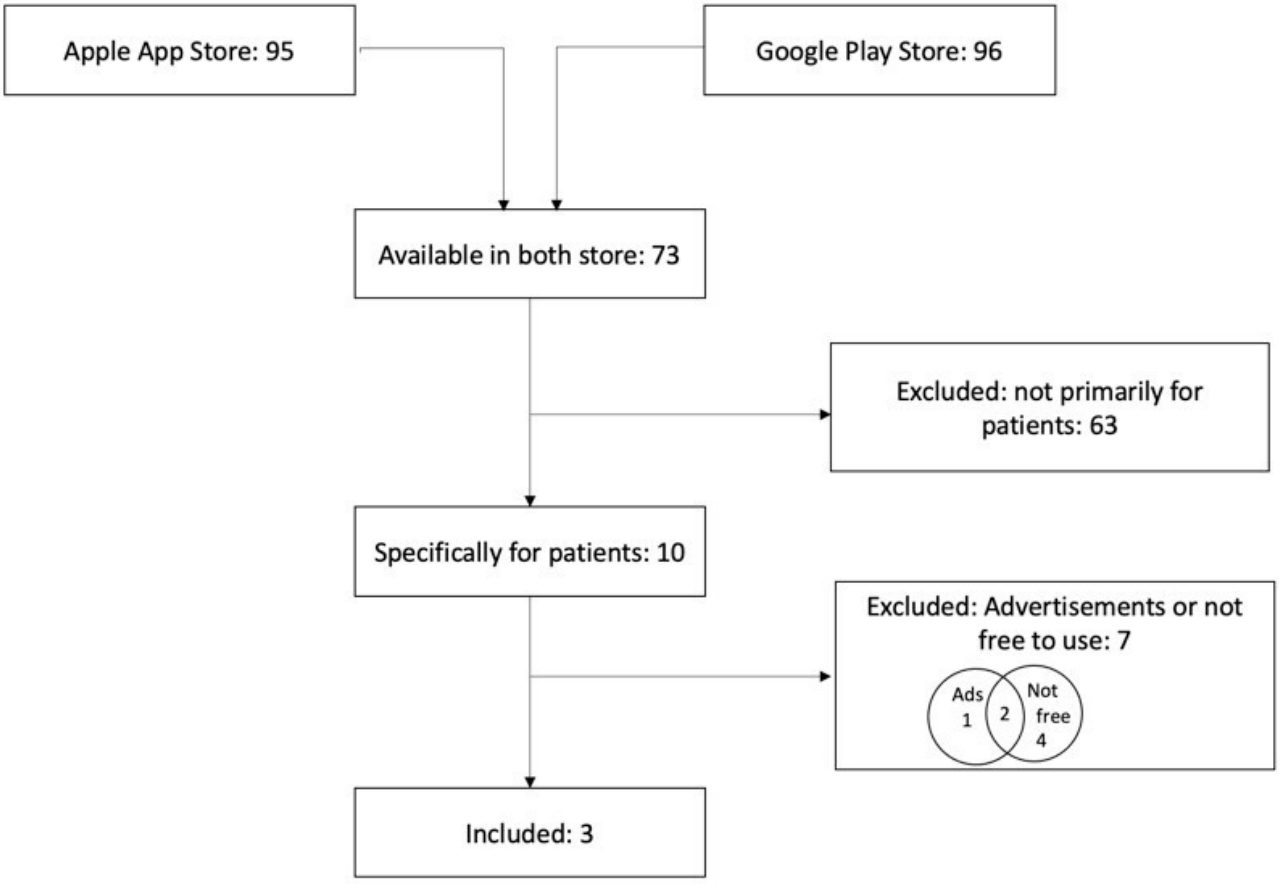
The MARS results represented the physicians' evaluations, as stated in the *Evaluation of App Quality* section, whereas uMARS results corresponded to the patients' evaluations. As a next step, after normalization, the Mann-Whitney *U* test was used to analyze whether there was a significant difference between MARS and uMARS scores and between patients' and physicians' SUS and ATI scale median scores. A comparison of the five subcategories within the MARS was performed. *P* values of <.05 were considered significant. The data analysis was performed with SPSS 23 (IBM Corp).

Results

App Selection

A total of 118 apps were identified—95 in the Apple App Store and 96 in the Google Play Store—of which 73 were available in both app stores (Figure 1). Of these 73 apps, 10 were specifically designed for patients. Of these 10 apps, 1 contained advertising, 4 were not free of charge, and 3 met both exclusion criteria, resulting in a total of 7 apps that were excluded from further analysis.

Figure 1. Flowchart illustrating the screening process for identifying suitable mobile apps.



Evaluation of App Quality

A total of 3 apps—*WoundEducation*, *APD Skin Monitoring*, and *WUND APP*—met all inclusion and exclusion criteria and were evaluated by 10 physicians. *WoundEducation* provides an overview of different wound types and treatment options. *APD Skin Monitoring* includes an automated area calculation function to quantify wound area. *WUND APP* offers advice and information on chronic wounds and contains a diary function to track patient-related outcomes, such as pain or the level of wound secretion.

The mean MARS scores (and SDs) of the physicians, including subcategory scores and SUS scores, are provided in Table 1.

Table . Evaluation of *WUND APP*, *APD Skin Monitoring*, and *WoundEducation* by 10 physicians using the Mobile App Rating Scale (MARS) and System Usability Scale (SUS).

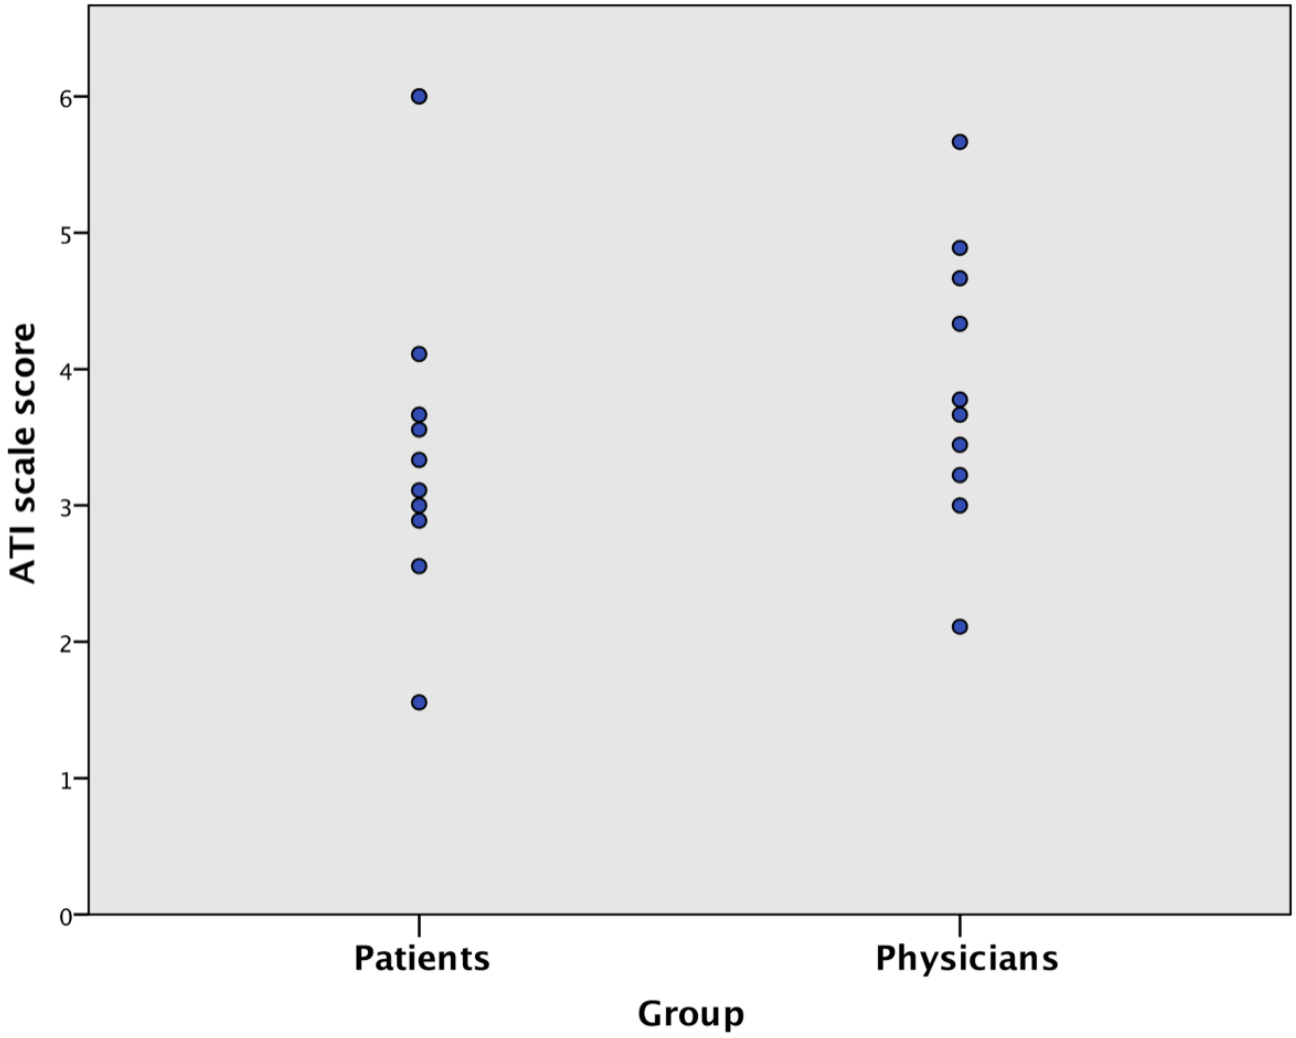
Mobile app name	MARS score, mean (SD)	Engagement score, mean (SD)	Functionality score, mean (SD)	Aesthetics score, mean (SD)	Information score, mean (SD)	Psychotherapy score, mean (SD)	SUS score (%), mean (SD)
WUND APP	3.88 (0.65)	3.36 (0.89)	4.38 (0.66)	4.13 (0.76)	3.67 (0.56)	2.98 (0.36)	80.5 (17.7)
WoundEducation	3.01 (0.5)	2.14 (0.44)	3.93 (0.99)	2.73 (0.75)	3.25 (0.58)	2.57 (0.46)	72.75 (18.5)
APD Skin Monitoring	2.64 (0.65)	2.36 (0.56)	2.65 (0.83)	2.77 (0.69)	2.79 (0.82)	2.47 (0.63)	50.75 (27)

WUND APP had the highest mean MARS score (mean 3.88, SD 0.65 out of 5) and was subsequently analyzed by 11 patients with chronic wounds. *WUND APP* had a similar mean uMARS score (mean 3.89, SD 0.4 out of 5) when analyzed by the patients.

Evaluation of Technical Affinity

The ATI scale scores ranged from 1.56 to 6 out of 6 for patients and from 2.11 to 5.67 out of 6 for physicians (Figure 2). An ATI scale score of >3 indicates average technology affinity, and a score of >4 indicates high technology affinity [8]. Mean ATI scale scores were slightly lower for patients (mean 3.62, SD 1.35 out of 6) than those for physicians (mean 3.88, SD 1.03 out of 6), but the difference was not statistically significant (P=.43). Patients ranged in age from 28 to 70 years; 7 were male, and 4 were female. Physicians ranged in age from 26 to 43 years; 4 were male, and 6 were female. The Pearson correlation coefficient between ATI scale scores and the ages of patients was –0.706 (P=.02), indicating a strong negative correlation.

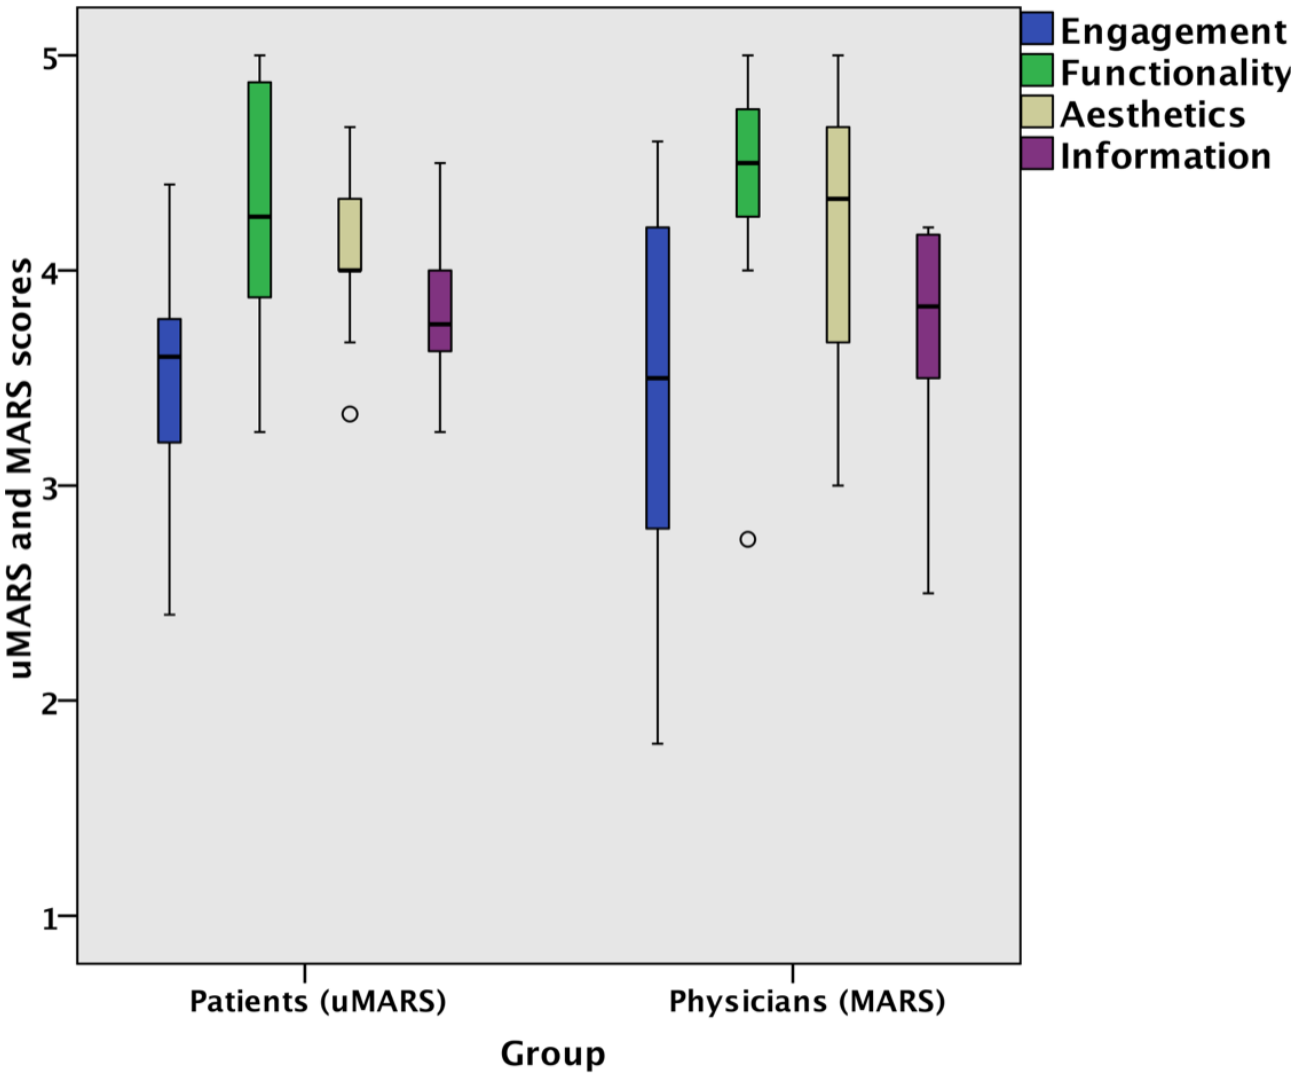
Figure 2. Scatter plot depicting ATI scale scores in patients and physicians. ATI: Affinity for Technology Interaction.



Comparative Analysis of Patients' and Physicians' Data

MARS and uMARS scores were almost identical. The subcategory "Information" was rated worse by physicians, while the subcategory "Functionality" was rated worse by patients (Figure 3). For the subcategories "Aesthetics" and "Engagement," no differences between physicians and patients were found. No statistically significant difference (Mann-Whitney *U* test) was found between MARS and uMARS scores (P=.76) or between patients' and physicians' SUS scores (P=.39; Multimedia Appendix 1).

Figure 3. Comparison of MARS and uMARS subscale scores ("Engagement," "Functionality," "Aesthetics," and "Information" scores). Physicians (professional raters) used the MARS, and patients used the uMARS. MARS: Mobile App Rating Scale; uMARS: user version of the Mobile App Rating Scale.



Discussion

Principal Findings

This study represents the first systematic examination that aimed to identify and assess smartphone apps specifically designed for patients with chronic wounds. The quality of these apps was evaluated by independent professional reviewers (physicians) and patients using well-validated scoring systems—the MARS, uMARS, and SUS. Using subjective measures in the assessment of eHealth is relevant and essential, and it is crucial to recognize this fact. Agreement among the assessors, even for subjective measures, is a good sign of the reliability of the assessment [14].

The overall findings indicate that the apps received moderate ratings. Among all apps evaluated, *WUND APP* achieved the highest mean MARS score (mean 3.88, SD 0.65) when assessed by physicians. Similarly, it received a mean uMARS score of 3.89 (SD 0.4) when evaluated by patients. Given that the preselection was exclusively conducted by physicians, patients' assessments might have differed.

WUND APP includes a diary function for documenting wound photos and patient-related outcomes, such as pain or wound secretion. Furthermore, it has a reminder function for necessities such as physician appointments and dressing changes. Its user interface is clear, and the app is user-friendly. Consequently, physicians assigned high scores for the subcategories "Engagement" (mean 3.36, SD 0.89), "Functionality" (mean 4.38, SD 0.66), and "Aesthetics" (mean 4.13, SD 0.76). Additionally, the app provides information on the causes, diagnostics, and treatments of the different wound types,

resulting in a mean MARS score of 3.67 (SD 0.56) for the subcategory "Information."

WoundEducation presents information in a straightforward structure that resembles an article with embedded links, delivers medical information, and illustrates various wound types through examples. The app received high ratings for overall functionality (mean 3.93, SD 0.99) and information provision (mean 3.25, SD 0.58). However, it demonstrated limited interactivity, as reflected by having the lowest score for the "Engagement" subcategory (mean 2.14, SD 0.44). Additionally, its aesthetics (mean 2.73, SD 0.75) were rated the lowest among the three apps.

APD Skin Monitoring [15] uses a coin as a reference for calculating the area of a wound, proving particularly useful in assessing wound progression and healing status regardless of whether the wounds are irregularly shaped. In addition, the coloration of wounds can be analyzed and tracked over time. However, the app received the lowest ratings for the subcategories "Functionality" (mean 2.65, SD 0.83) and "Engagement" (mean 2.36, SD 0.56).

Our findings revealed that a limited number of wound apps were specifically tailored for patients, accounting for only 14% (10/73) of all wound apps that were available in both app stores. Overall, both physicians and patients rated *WUND APP* similarly; however, although not statistically significant, it is noteworthy that differences emerged in 2 subcategories ("Information": P=.97; "Functionality": P=.56). Physicians rated the information content lower, which could be attributed to their expert medical knowledge. As professionals, they may have had higher expectations regarding the app's information content and may have found certain aspects less informative. In a recent study, it was shown that patients trusted recommendations and reviews from medical organizations and health care professionals when selecting apps [16]; their motivation to continue using apps was driven by features that supported goal setting and tracking, data sharing, decision-making, and empowerment.

On the other hand, patients rated the functionality of *WUND APP* lower, which was possibly due to their limited involvement in the app's development process. A systemic review reported that health care professionals were engaged in the development process for only 35% of the 7 analyzed apps that were specifically designed for patients with rheumatoid arthritis [17]. Another systematic review revealed that patients were only engaged in the development process for 15% of the 32 analyzed apps that were designed for individuals with rheumatic and musculoskeletal diseases [18]. The inclusion of patients in the development process of future wound apps could help to ensure that the apps meet their specific needs and preferences. Our study highlights the scarcity of wound apps designed explicitly for patients and the importance of involving patients in the app development process. Tailoring apps to meet patients' specific requirements and involving them in the design process would likely result in improved app functionality and overall user satisfaction.

To the best of our knowledge, this study represents the first systematic study to collect data on the technical affinity of patients with wounds. Surprisingly, no statistically significant difference in technical affinity was observed between wound care patients and physicians, even with the inclusion of patients aged up to 70 years (P=.43). Nevertheless, future studies and app development projects should aim to include older patients and comprehensively assess and address their specific needs. The low adoption and use of mHealth apps among older patients are frequently attributed to inadequate designs [19].

In 2019, Germany introduced a digital health app (DiGA) directory that includes scientifically validated apps. Physicians can prescribe DiGAs in a manner similar to how they prescribe medications [20]. However, to date, no DiGAs specifically tailored for patients with chronic wounds are available in the directory. It is worth noting that physicians with a higher technical affinity and those who are female hold significantly more positive attitudes toward DiGAs [21].

The absence of wound care apps highlights the unmet potential for innovative digital solutions to address the needs of patients with chronic wounds. The inclusion of validated and effective wound care apps in the DiGA directory could significantly improve patient outcomes and health care management in this specific area. It is imperative for future app development initiatives to focus on developing and validating apps that cater to the unique requirements of patients with chronic wounds, to provide them with accessible and effective digital health care resources.

Multiple attempts have been made to integrate mHealth apps into wound care [22], including apps for wound care measurements [23], wound care dressing decision support systems [24], and home-based self-management systems [25]. An Australian study assessed an artificial intelligence app for wound assessment, involving 166 patients in the standard group and 124 in the intervention group. The intervention group demonstrated significantly improved wound documentation, along with positive outcomes such as enhanced patient adherence, efficient digital care provision, and substantial reductions in wound size [26].

A cultural shift toward greater technology affinity has been accelerated by the COVID-19 pandemic [27]. Patients are increasingly using mobile apps when they perceive clear benefits to their use, such as reducing social contact during the COVID-19 pandemic. For patients with chronic wounds, these benefits may include using an app as a diary, while for others, apps may offer the advantage of saving time and transportation costs through telemedicine services. Telemedical approaches could significantly alter and improve the current wound care landscape, bearing the potential to improve the efficiency, accuracy, and accessibility of both diagnoses and treatments. Telemedicine in chronic wound management was shown to be noninferior to conventional standard care in a systematic review and meta-analysis [28]. The earlier diagnosis of complications, such as wound infections, can reduce the use of antibiotics and lower health care costs by preventing hospital stays.

Limitations

Due to the limited number of apps that met our strict inclusion and exclusion criteria, only a small subset could be analyzed in

this study. The selection of apps was conducted within a relatively short time frame, which might have further restricted the available options for evaluation.

The nonsignificant differences between physicians' and patients' ratings in this study may be attributed to the small sample of only 11 patients and 10 physicians, which resulted in limited statistical power. Therefore, we emphasize the importance of cautious interpretation and the consideration of larger sample sizes for future research.

Another factor that influenced this study's results was the inclusion of patients who agreed to evaluate *WUND APP*. This approach potentially introduced selection bias, as our patient sample may not represent the true technical affinity of all patients with chronic wounds. The overall technical affinity of a larger and more diverse patient population might be lower than what was observed in this study. Future studies with larger patient cohorts might provide a more comprehensive understanding of the technical affinity and usability experience of patients with chronic wounds who use mHealth apps. Further, the assessment relied on a qualitative survey—a method that may be susceptible to various biases. However, to truly ascertain the effectiveness of *WUND APP*, a randomized controlled trial is needed.

Conclusions

Patient involvement is crucial in app development. By involving all stakeholders, including physicians, wound care experts, and patients, throughout the development process, apps can be tailored to meet the specific needs and preferences of the end users, resulting in increased user satisfaction and improved health outcomes.

The validated ATI scale proved to be a valuable tool for evaluating an individual's technical affinity. In future studies and app evaluations, technical affinity should be determined to generalize outcomes to specific patient and consumer cohorts.

Abstract

Background: Controlling saturated fat and cholesterol intake is important for the prevention of cardiovascular diseases. Although the use of mobile diet-tracking apps has been increasing, the reliability of nutrition apps in tracking saturated fats and cholesterol across different nations remains underexplored.

Objective: This study aimed to examine the reliability and consistency of nutrition apps focusing on saturated fat and cholesterol intake across different national contexts. The study focused on 3 key concerns: data omission, inconsistency (variability) of saturated fat and cholesterol values within an app, and the reliability of commercial apps across different national contexts.

Methods: Nutrient data from 4 consumer-grade apps (COFIT, MyFitnessPal-Chinese, MyFitnessPal-English, and LoseIt!) and an academic app (Formosa FoodApp) were compared against 2 national reference databases (US Department of Agriculture [USDA]–Food and Nutrient Database for Dietary Studies [FNDDS] and Taiwan Food Composition Database [FCD]). Percentages of missing nutrients were recorded, and coefficients of variation were used to compute data inconsistencies. One-way ANOVAs were used to examine differences among apps, and paired 2-tailed *t* tests were used to compare the apps to national reference data. The reliability across different national contexts was investigated by comparing the Chinese and English versions of MyFitnessPal with the USDA-FNDDS and Taiwan FCD.

Results: Across the 5 apps, 836 food codes from 42 items were analyzed. Four apps, including COFIT, MyFitnessPal-Chinese, MyFitnessPal-English, and LoseIt!, significantly underestimated saturated fats, with errors ranging from −13.8% to −40.3% (all $P<.05$). All apps underestimated cholesterol, with errors ranging from −26.3% to −60.3% (all $P<.05$). COFIT omitted 47% of saturated fat data, and MyFitnessPal-Chinese missed 62% of cholesterol data. The coefficients of variation of beef, chicken, and seafood ranged from 78% to 145%, from 74% to 112%, and from 97% to 124% across MyFitnessPal-Chinese, MyFitnessPal-English, and LoseIt!, respectively, indicating a high variability in saturated fats across different food groups. Similarly, cholesterol variability was consistently high in dairy (71%-118%) and prepackaged foods (84%-118%) across all selected apps. When examining the reliability of MyFitnessPal across different national contexts, errors in MyFitnessPal were consistent across different national FCDs (USDA-FNDSS and Taiwan FCD). Regardless of the FCDs used as a reference, these errors persisted to be statistically significant, indicating that the app's core database is the source of the problems rather than just mismatches or variances in external FCDs.

Conclusions: The findings reveal substantial inaccuracies and inconsistencies in diet-tracking apps' reporting of saturated fats and cholesterol. These issues raise concerns for the effectiveness of using consumer-grade nutrition apps in cardiovascular disease prevention across different national contexts and within the apps themselves.

Introduction

Cardiovascular diseases (CVDs) are leading causes of global mortality and major contributors to disability [1]. Excessive intake of saturated fats and cholesterol was significantly associated with increased risks of CVDs and all-cause mortality [2-4]. The American Heart Association has emphasized that reducing saturated fat intake in favor of unsaturated fats can significantly diminish CVD risks [5]. Managing these nutrients is crucial for early prevention efforts [6,7]. In this context, the advent of mobile diet-tracking apps may offer a modern solution for monitoring dietary saturated fats and cholesterol, with benefits such as accessibility, cost-effectiveness, and efficiency over traditional dietary assessment methods [8-10].

Khazen et al [11] has categorized diet-tracking apps into 2 main types: academic and commercial. Academic apps are developed with research-based validation but are often limited by their geographical scope and reliance on local food composition databases (FCDs). Some examples of academic apps are Australia's Electronic Dietary Intake Assessment [12], Canada's Keenoa [13], and Taiwan's Formosa FoodApp [14]. On the other hand, commercial apps (such as MyFitnessPal, FatSecret, and Lose It!) are known for their extensive, international FCDs and are designed to cater to multilingual users [11,15,16]. They include a function that allows users to add new food products not available in the existing FCD, characterizing them as consumer-grade apps with a consumer-oriented approach. Language availability is another factor differentiating academic and consumer-grade apps [11]. Academic apps typically support only 1 or 2 languages and are tailored for specific research within certain populations, thus limiting their use in global studies [11,17]. In contrast, commercial apps, with their support for multiple languages [18], are aimed at a global audience, positioning them as versatile or "universal" tools accessible to users across the world.

The primary concerns with consumer-grade apps are the quality and reliability of their FCDs to estimate energy and nutrient intake [11,19]. Regarding the reliability, academic apps have been in agreement with conventional self-report dietary assessment methods such as 24-hour dietary recall [14,20,21]. In contrast, the accuracy of consumer-grade apps varies, generally showing a trend of underestimating nutritional values, with variability in accuracy across different commercial apps [19,22]. This is likely due to the varying quality of FCDs among commercial apps, which tend to suffer from missing or redundant data [19,22]. Although many studies have emphasized the disparities in dietary intake of total energy and macronutrients between data from commercial apps and national food databases [10,22,23], very few have delved into the variability in saturated fat and cholesterol values. While many commercial apps derive data from nutrition labels with mandated disclosures for saturated fats and cholesterol, these aspects in commercial nutrition apps remain insufficiently evaluated.

Currently, the reliability of the consumer-grade apps in tracking nutrients across different national standards remains underexplored. This study aimed to examine the reliability of mobile nutrition apps by focusing on saturated fat and cholesterol intake and the consistency of commercial apps across different national contexts. This critical evaluation focused on 3 key concerns: omission of saturated fat and cholesterol data, data consistency within an app, and the reliability of commercial apps across different national contexts.

Methods

App Selection

We selected widely used apps from 2 distinct regions, Taiwan and the United States, to represent linguistic and cultural differences. Specifically, we chose the academic app Formosa FoodApp [14] and the commercial app COFIT [24] given their widespread clinical and educational acceptance in Taiwan. In addition, we also explored 2 commercial US-based apps—MyFitnessPal and Lose It!—based on their broad acknowledgment, dominant presence in both clinical settings and among consumers, and citations in earlier literature [10,15,19]. The primary sources for nutrient data included the Taiwan FCD, US Department of Agriculture (USDA)–Food and Nutrient Database for Dietary Studies (FNDDS), and US food manufacturers and restaurants. Notably, MyFitnessPal and LoseIt! make user-generated food entries available to all users (Table 1).

Table . Description of the mobile app food composition databases (FCDs) in the study.

Characteristics	Formosa FoodApp	COFIT	MyFitnessPal-Chinese	MyFitnessPal-English	LoseIt!
Type of FCD	Academic	Commercial	Commercial	Commercial	Commercial
Manufacturer and country	Professor Susan Chang's Lab (Taipei Medical University), Taiwan	Cofit Healthcare, Taiwan	Francisco Partners, United States	Francisco Partners, United States	FitNow, United States
FCD language	Chinese	Chinese	Chinese (added by users)	English	English
FCD sources	Taiwan FCD, USDA[a]-FNDSS[b], Vietnam FCD, Indonesia FCD, food manufacturers, and restaurants	Taiwan FCD, food manufacturers, and restaurants	Taiwan FCD and users	USDA-FNDSS, food manufacturers, restaurants, and users	USDA-FNDSS, food manufacturers, restaurants, and users
User-added function	No	No	Yes	Yes	Yes

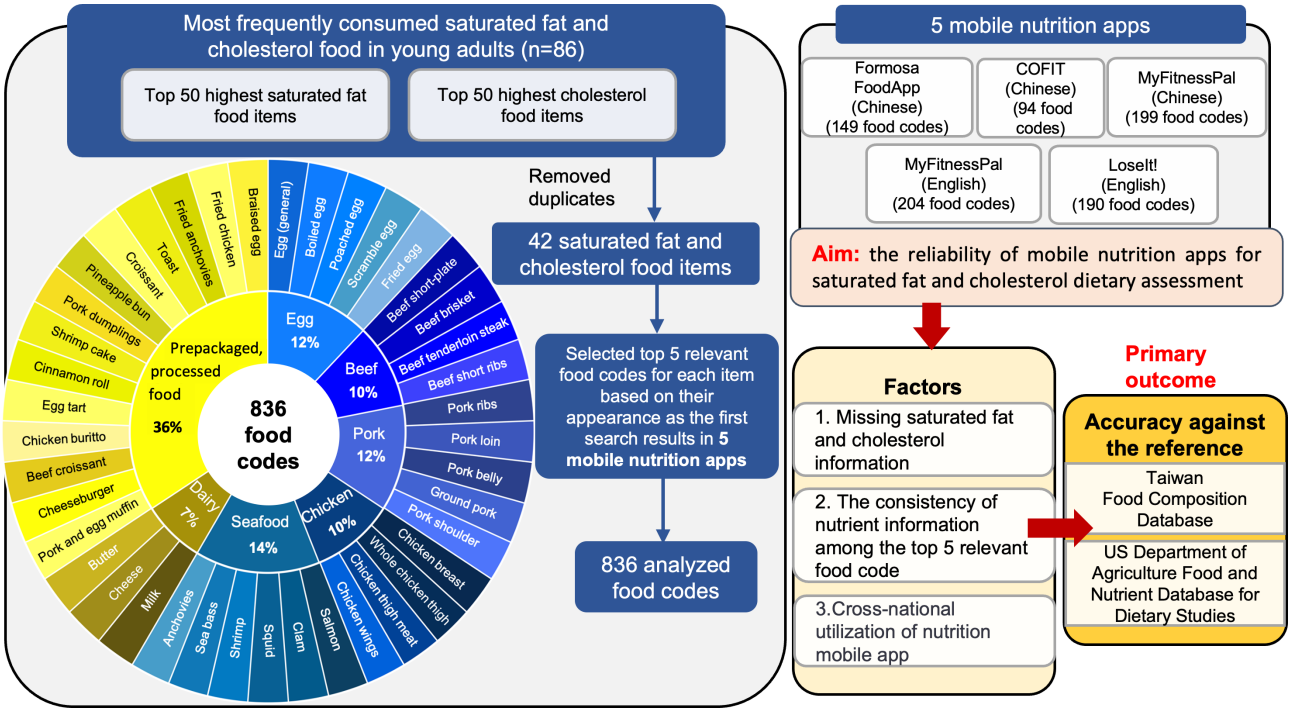
[b]FNDSS: Food and Nutrient Database for Dietary Studies.

Food Items and Code Selection

Figure 1 shows the flowchart of the food item and food code selection process. Briefly, data from our Formosa FoodApp validation study were used for the analyses [14], which involved 86 healthy adults aged 19-26 years who tracked their daily diet using the Formosa FoodApp. To identify food items that contributed to high cholesterol and saturated fat intake, a nutrition-trained investigator ranked frequently consumed, saturated fat– and cholesterol-containing items from our prior study. The initial assessment generated 2 lists of 50 food items each. After eliminating duplicates and similar entries, we finalized a list comprising 42 unique food items.

Figure 1. Flowchart of the selection process for food items and food codes. Food items included are those that contribute the most to cholesterol and saturated fat intake levels, ranked based on findings from our previous Formosa FoodApp validation study [14].



To mitigate potential biases from initially using data from the Formosa FoodApp, which may predominantly reflect Taiwanese dietary preferences, we verified the availability of these 42 food items across all apps selected for this study. The comprehensive list of these food items is provided in Multimedia Appendix 1 for reference. We further grouped these 42 food items into broader categories—such as eggs, beef, pork, chicken, dairy, seafood, and prepackaged and processed foods—to enhance the representativeness of our analysis across diverse national diets.

Food items were entered using the search feature for the free versions of Formosa FoodApp, COFIT, MyFitnessPal, and Lose It!. Searches were performed across Formosa FoodApp and COFIT in Chinese and LoseIt! in English. To explore MyFitnessPal's reliability across different national contexts,

searches were conducted in both Chinese and English, and we compared the errors in nutrient data from its English and Chinese versions. To ensure a clear distinction between MyFitnessPal in Chinese and English, we refer to them as MyFitnessPal-Chinese and MyFitnessPal-English, respectively, throughout the manuscript. Given the vast array of food codes that appeared in the search results and to make the analysis more manageable and representative, we selected the top 5 relevant food codes that appeared first in the search results for each item as representative subsets. Energy contents and nutrients including total carbohydrate, protein, total fat, saturated fat, and cholesterol values were extracted from the apps (Figure 1). The selection process underwent a review and confirmation by a second investigator. Portion sizes for the selected food codes were standardized at 100 g across all databases. Data from all selected apps and reference databases were documented for each food code and entered into a Microsoft Excel dataset.

Data and Statistical Analysis

We calculated the mean percentage error for energy, total carbohydrate, protein, total fat, saturated fat, and cholesterol values as the difference between the nutrient intake values from the apps and the corresponding values from the reference databases, expressed as a percentage error. This error, calculated for each food code in each app, is given by the following:

$$\text{Percentage error (\%)} = \frac{\text{App nutrient value} - \text{Reference nutrient value}}{\text{Reference nutrient value}} \times 100$$

We focused on 2 key components of variability for saturated fats and cholesterol: missing nutrient data and inconsistencies of nutrient data for the same food item across 5 codes. Missing nutrient information for each food item was determined as the ratio of missing nutrient information to the total selected food codes for that item, presented as a percentage:

$$\text{Percentage of missing data (\%)} = \frac{\text{Number of missing nutrient information in the selected food codes}}{\text{Total number of selected food codes}} \times 100$$

We calculated coefficients of variation (CVs) to address nutrient data inconsistencies across 5 food codes for the same item within an app. CVs were obtained by taking the square root of the average reporting variance within a food item, divided by the mean of the items (app values over food codes). A CV was calculated for each food item, and then mean CVs were determined based on the food group and app. Our analysis involved paired 2-tailed *t* tests for app-to-reference comparisons (paired within food codes) and a 1-way ANOVA for app-to-app variations. A linear regression analysis was used to assess the factor associated with the percentage of underestimated error of nutrients compared to reference databases. To assess the reliability of a commercial app universally used in different national contexts, we conducted a cross-national analysis, comparing errors in both MyFitnessPal-Chinese and MyFitnessPal-English against the USDA-FNDDS and Taiwan FCD reference databases. All analyses were performed in SPSS (version 23; IBM Corp) and GraphPad Prism 8 (GraphPad Software), with *P* values of <.05 considered statistically significant.

Ethical Considerations

This study conducted a secondary analysis of data previously collected in an earlier study [14], which received approval from the Taipei Medical University Institutional Review Board (N202101046). Written informed consent was obtained from all participants. The data used in this analysis were deidentified.

Results

Characteristics of Mobile Nutrition Apps

Among the selected nutrition apps, Formosa FoodApp is an academic mobile nutrition app, while COFIT, MyFitnessPal-Chinese, MyFitnessPal-English, and LoseIt! are all commercial apps (Table 1). Figure 1 details the distribution of 42 food items across 7 main food categories. The dominant food groups were prepackaged processed foods (15 items), seafood (6 items), and pork and egg (5 items each).

Reliability of Mobile Nutrition Apps Across Different National Standards

Figure 2A presents the mean percentage errors of app nutrient data against national reference databases. Most apps showed no differences in energy or macronutrients compared to their respective national references, with the exception of LoseIt!, which underestimated protein by −1.3% and fats by −22.4% compared to the USDA-FDNSS. COFIT, MyFitnessPal (in both languages), and LoseIt! underestimated saturated fats with errors ranging from −16.3% to −40.3% (all $P<.05$). All apps underestimated cholesterol, with errors ranging from −26.3% to −60.3% (all $P<.05$).

Figure 2B displays the mean percentage errors in MyFitnessPal-Chinese and MyFitnessPal-English using the USDA-FNDSS and Taiwan FCD. The Chinese version underestimated saturated fats by around −40% (−43.2% for the Taiwan FCD and −39.4% for the USDA-FNDSS) and cholesterol by −60% (−58.2% for the USDA-FNDSS and −60.3% for the Taiwan FCD). In contrast, the English version showed −10% errors for saturated fat (−16.8% for the USDA-FNDSS and −4.3% for the Taiwan FCD) and −40% for cholesterol (−40.4% for the USDA-FNDSS and −38.8% for the Taiwan FCD). Notably, these discrepancies, significant at $P<.01$ for both nutrients, remained unchanged regardless of the reference database used.

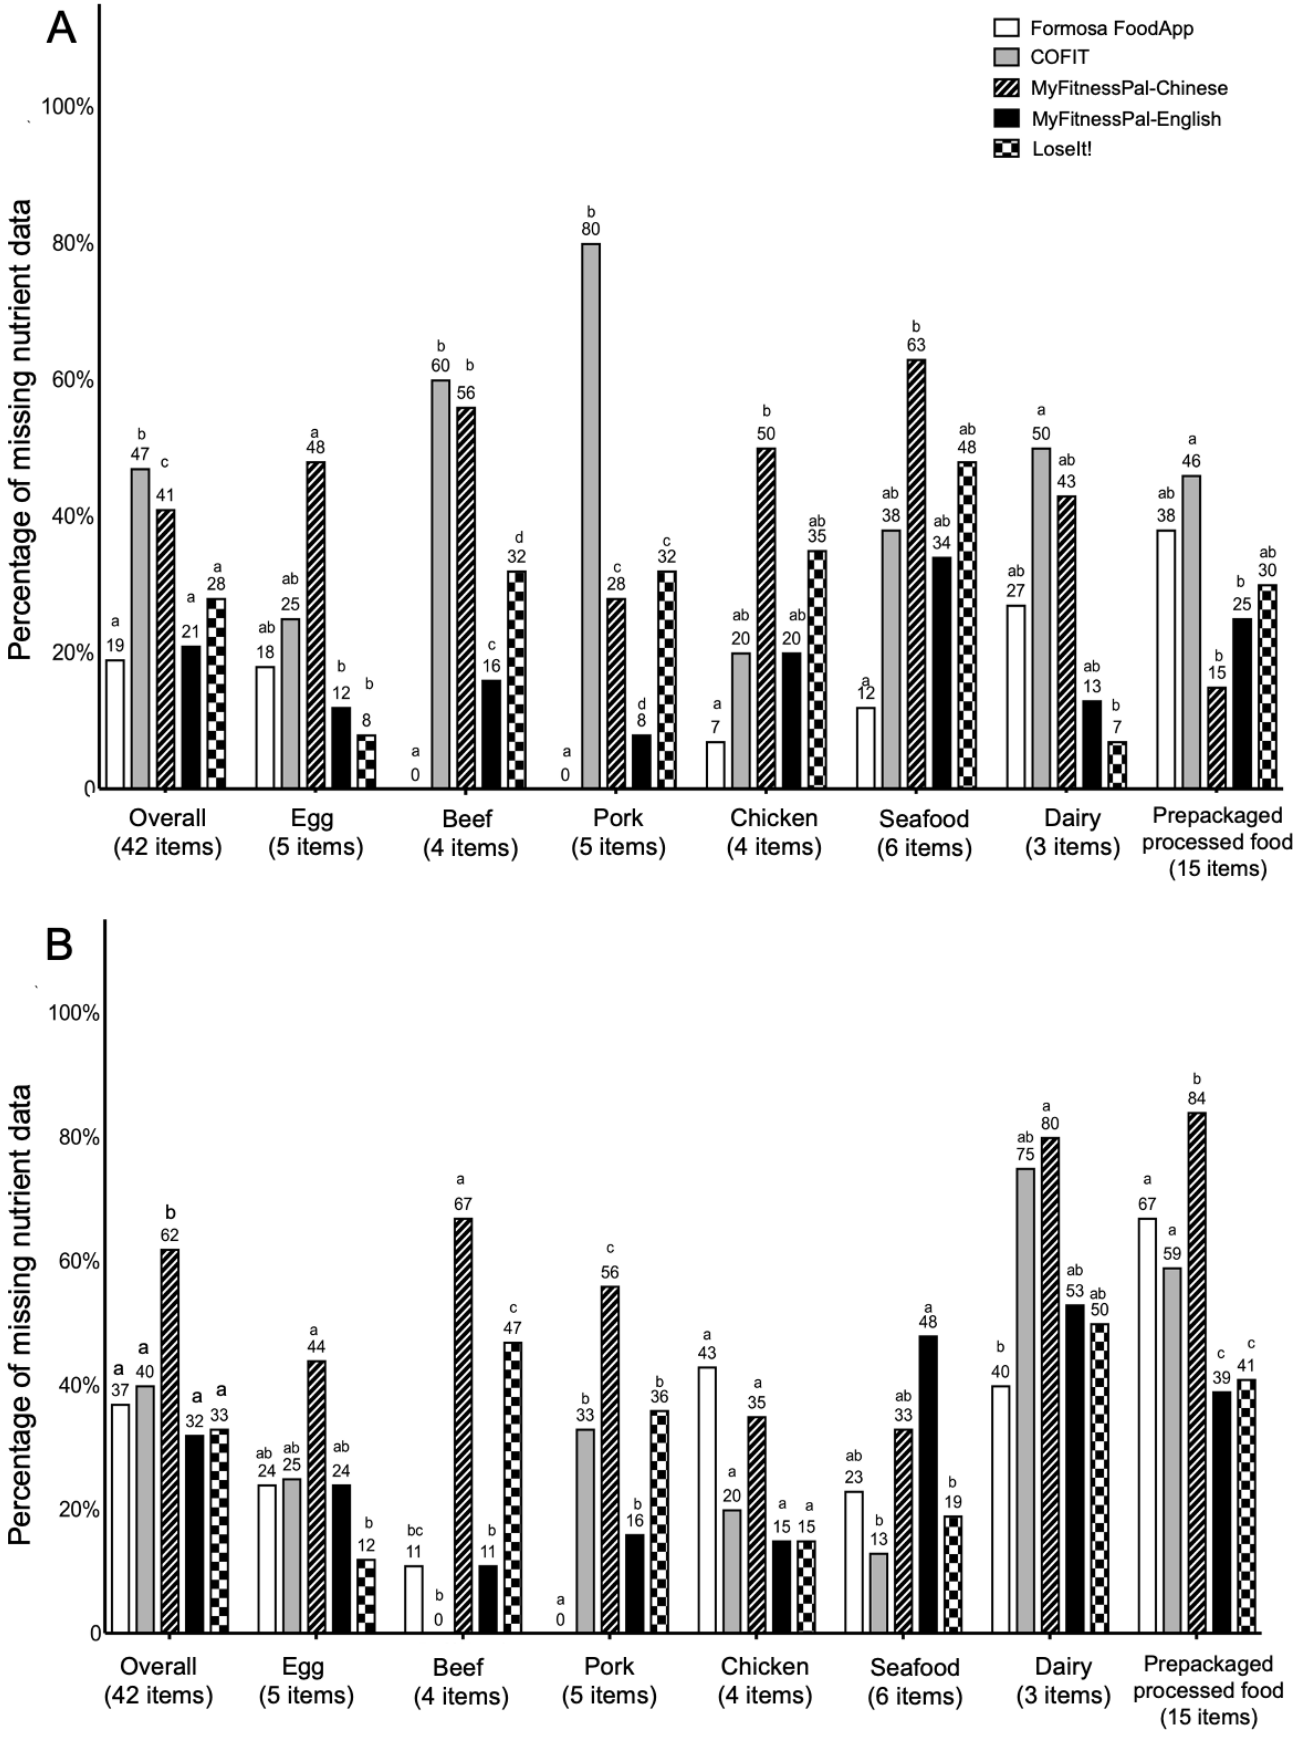
Figure 2. (A) Heat map of mean percentage errors of nutrients across mobile apps compared to reference databases. Different letters (a, b, ab, c, bc, and abc) indicate statistically significant differences in mean percentage errors among groups based on 1-way ANOVA ($P<.05$). a: statistically different from b, bc, and c; b: statistically different from a, ab, and c; ab: not significantly different from a or b; c: statistically different from a, ab, and b; bc: not significantly different from b or c, but different from a; abc: not significantly different from a, b, or c. Asterisks (*) denote the level of statistical significance in paired 2-tailed *t* tests between the app and the reference database: *$P<.05$, **$P<.01$, ***$P<.001$, and ****$P<.0001$. (B) Cross-national comparison of percentage errors in saturated fats and cholesterol between the English and Chinese platforms of MyFitnessPal. **$P<.01$ by a 1-way ANOVA indicating differences in percentage errors among groups. FCD: Food Composition Database; FNDDS: Food and Nutrient Database for Dietary Studies; USDA: US Department of Agriculture.

Omissions of Saturated Fats and Cholesterol

Omission rates for different nutrients considerably varied. Total fats exhibited the lowest omission range, spanning from 0% to 21%. In comparison, saturated fats and cholesterol showed higher rates of omission, ranging from 19% to 47% and from 21% to 62%, respectively (data not shown). COFIT showed the highest missing information for saturated fats at 47% (Figure 3A), while MyFitnessPal-Chinese recorded the highest omission at 62% for cholesterol (Figure 3B).

For saturated fats, both COFIT and MyFitnessPal-Chinese showed substantial omissions, especially for beef (60% and 56%, respectively), pork (80% and 28%, respectively), and dairy (50% and 43%, respectively). For cholesterol, there were significant differences in omission rates between MyFitnessPal-Chinese and MyFitnessPal-English (62% vs 32%; $P<.05$), notably for beef (67% vs 11%), pork (56% vs 16%), dairy (80% vs 53%), and prepackaged processed foods (84% vs 39%).

Figure 3. Omission rates (percentage of missing nutrient information) for (A) saturated fats and (B) cholesterol across the mobile nutrition apps. Different letters (a, b, c, d, ab, and bc) indicate a significant *P* value ($P<.05$) for Fisher test comparing differences in omission rates between the apps among the mobile app food databases. a: statistically different from b, bc, c, and d; b: statistically different from a, ab, c, and d; ab: not significantly different from a or b; c: statistically different from a, ab, b, and d; d: statistically different from a, b, and c; bc: not significantly different from b or c, but different from a and d.

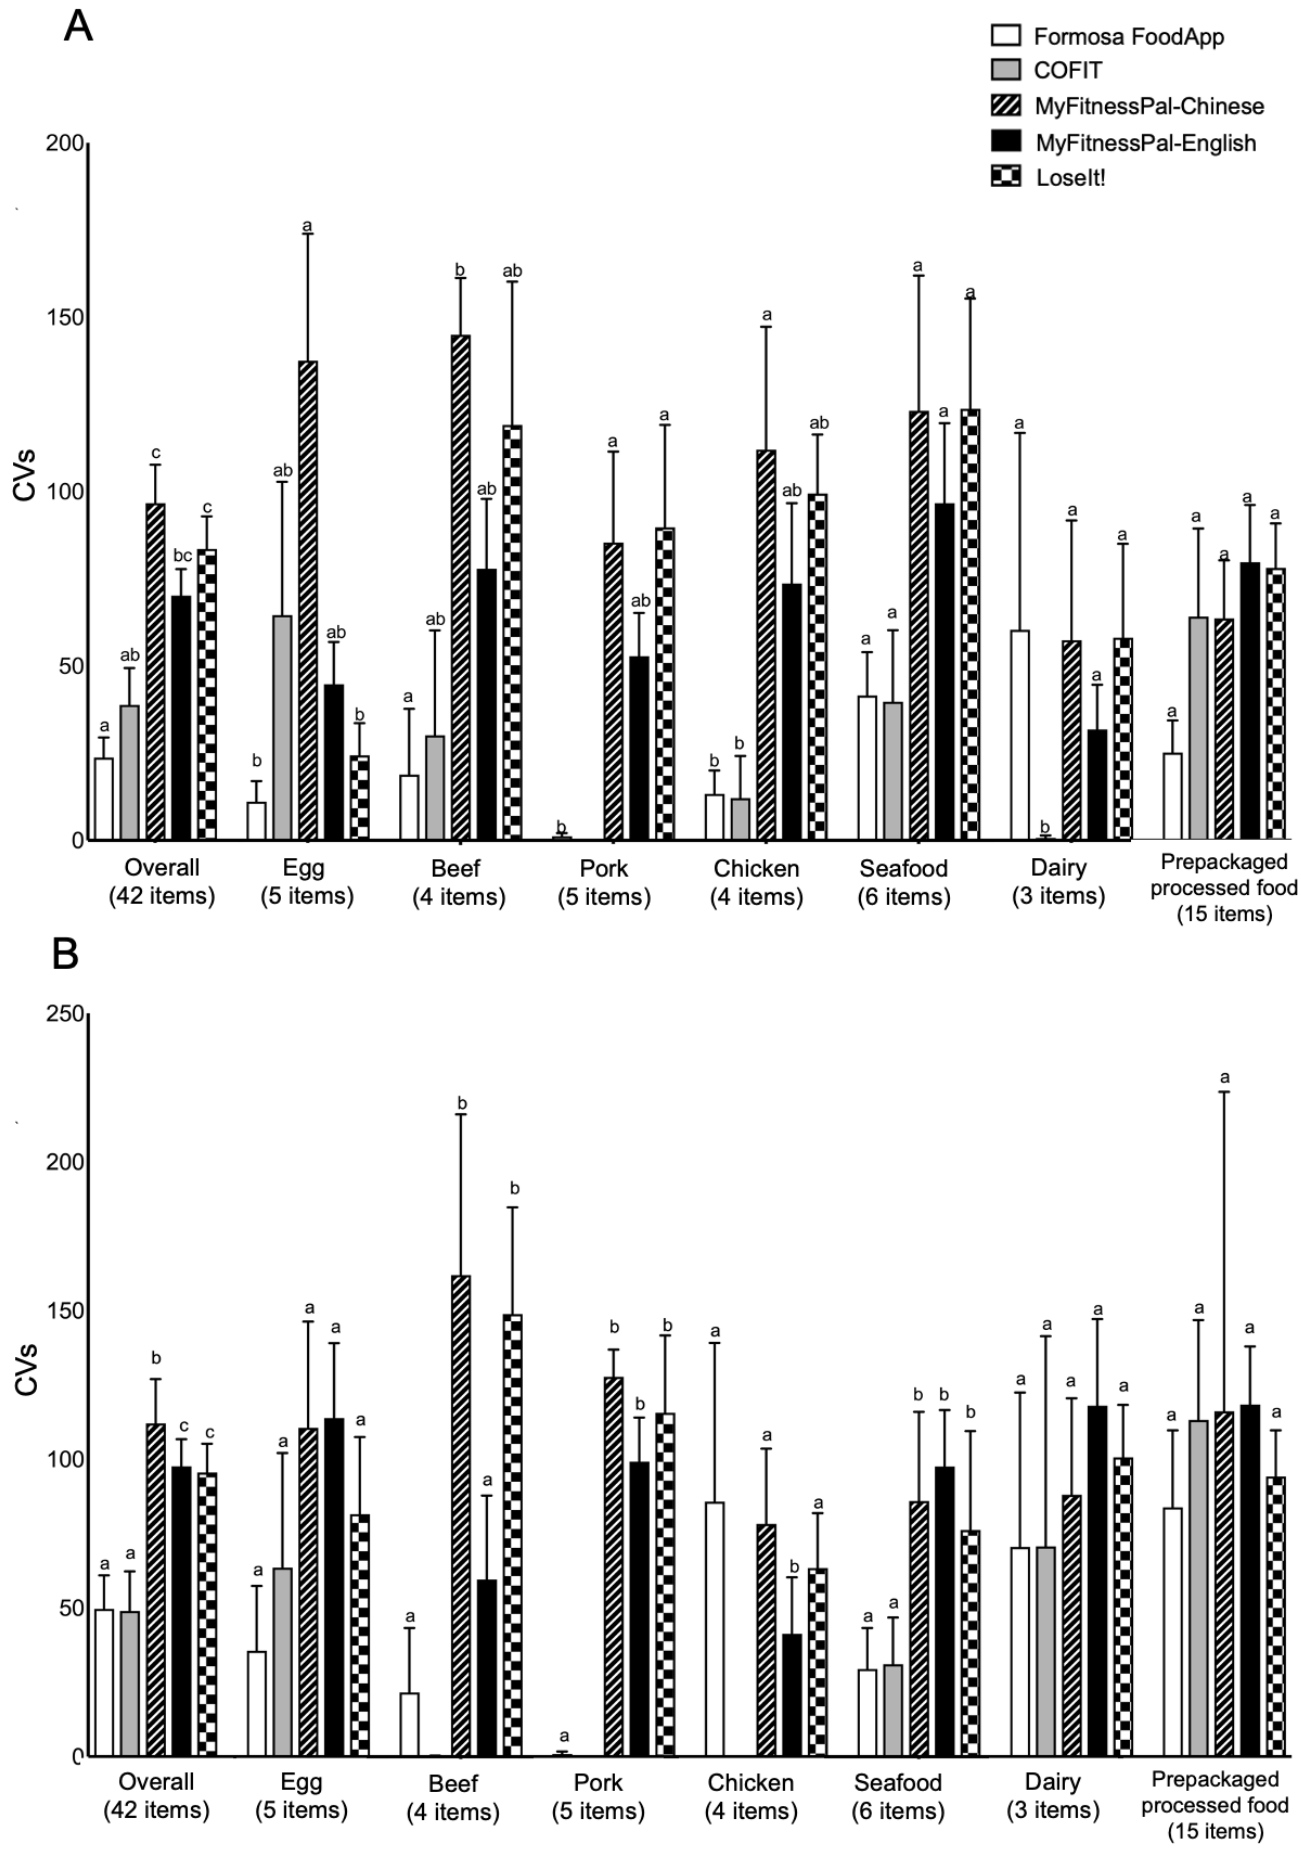


Variability Extents of Saturated Fat and Cholesterol

We calculated CVs to address saturated fat and cholesterol data consistencies, by assessing 5 food codes for identical items within a given app (Figure 4). For saturated fats, the lowest mean CVs were observed in Formosa FoodApp (23.8%) and COFIT (38.9%). The highest mean CVs were observed in MyFitnessPal-Chinese (96.7%) and LoseIt! (83.6%). A similar trend was also observed for cholesterol.

Saturated fat variability was high for beef (78%-145%), chicken (74%-112%), and seafood (97%-124%) among MyFitnessPal-Chinese, MyFitnessPal-English, and LoseIt!, respectively. Cholesterol variability was high for dairy (71%-118%) and prepackaged foods across all apps (84%-118%; Figure 4).

Figure 4. Mean coefficient of variations (CVs) for (A) saturated fats and (B) cholesterol, calculated as the percentage ratio of the SD to the mean, for 42 food items grouped by food groups across the apps. Different letters (a, b, ab, and c) indicate a significant *P* value (*P*<.05) for 1-way ANOVA comparing differences in the CVs among the apps within food groups. a: statistically different from b and c; b: statistically different from a, ab, and c; ab: not significantly different from a or b; c: statistically different from a, ab, and b.



Discussion

Principal Findings

To the best of our knowledge, this is the first study to critically examine the reliability of mobile nutrition apps' reported data on saturated fats and cholesterol against 2 different national FCDs. We found significant errors up to −40.3% for saturated fats and −60.3% for cholesterol, suggesting that these apps may provide unreliable data when assessing diets, particularly in the context of CVD prevention. These findings align with the findings by Shinozaki and Murakami [25] on MyFitnessPal's nutrient underestimation of saturated fats and cholesterol (85.1% and 97.6%, respectively). Similarly, Siniarski et al [16] also reported errors up to 57.3% in mobile app predictions for saturated fats compared to Polish reference data. Furthermore, our results demonstrate that errors in MyFitnessPal's nutrient reporting are consistent across different national FCDs (USDA-FNDDS and Taiwan FCD). Such errors remained statistically significant, regardless of the FCDs used as a reference. This problem suggests that the errors are not merely due to mismatches or variations in external FCDs but are rooted in the app's core database.

Data inconsistencies within consumer-grade apps, evidenced by significant omissions and variability, compromise their reliability. For instance, saturated fat variability was notably high across different food groups, with beef ranging from 78% to 145%, chicken from 74% to 112%, and seafood from 97% to 124% among MyFitnessPal-Chinese, MyFitnessPal-English, and LoseIt!, respectively. Similarly, cholesterol variability was consistently high in dairy (71%-118%) and prepackaged foods (84%-118%) across all apps. COFIT lacked almost 50% of its saturated fat data, and MyFitnessPal-Chinese was missing over 60% of its cholesterol information. This is concerning as food labeling regulations require clear disclosure of these nutrients [6], yet many entries incorrectly list these values as zero, deviating from standard guidelines [26]. This issue is even more pressing in the context of prepackaged foods. Previous research from our team emphasized this challenge, revealing that data omissions related to prepackaged foods significantly impact the reliability of mobile dietary assessments [14]. This emphasizes the urgency for databases to stay updated with new market introductions.

The lack of transparency in food sourcing within consumer-grade apps, particularly when combined with the extensive volume of FCDs [11,27], can significantly confuse users during food logging [28,29]. As consumer-grade apps allow for a vast array of food items to be listed—often without clear sourcing information, users face the daunting task of navigating through numerous results to find the most accurate match for their consumed foods. The entries frequently do not specify their nutritional data sources. Our data showed that only a fraction of the analyzed food codes transparently disclosed their sources. Specifically, just 51.5% (n=105) of MyFitnessPal-English's 204 food codes and 43.7% (n=87) of its Chinese counterpart's 199 food codes provided clear sourcing information. Meanwhile, LoseIt! transparently sourced only 37.4% (n=71) of its 190 codes. Formosa FoodApp led with 78.2% (n=115) for its 147 codes, while COFIT lagged at 61% (n=57) for its 94 codes. This lack of clarity can lead to confusion and inaccuracies, underscoring the need for improved transparency in food sourcing to facilitate more precise dietary tracking.

Our analysis also delved into the complexities of maintaining accuracy within multilingual universal apps, using MyFitnessPal as a case study. Although errors in MyFitnessPal's nutrient reporting are consistent across different national FCDs (USDA-FNDDS and Taiwan FCD), it is important to note that the larger errors observed in MyFitnessPal-Chinese, as opposed to the English version, highlight another challenge for universal apps: ensuring uniform accuracy across different languages and, by extension, cultural contexts. Several factors may contribute to the discrepancies observed in MyFitnessPal. First, the integration of multiple FCDs combined with user-generated content without stringent quality control can introduce variability in nutrient data [27]. Second, nutritional composition can also vary by region due to differences in food production, processing, and preparation practices, further complicating accurate nutrient estimation [30]. Lastly, user-generated content can exacerbate inaccuracies, as this content may not undergo rigorous verification processes, leading to inconsistencies in nutrient reporting [27]. Together, these factors highlight the complexities of providing accurate, universal dietary tracking tools and the critical need for app developers to address these challenges to enhance the reliability and global applicability of their platforms.

This study has highlighted significant errors and inconsistencies in various consumer-grade apps. Academic apps such as Formosa FoodApp, which show fewer reporting errors and greater transparency in nutrient sourcing, are crucial for health professionals who require precise and validated data to make evidence-based dietary recommendations, particularly for CVD prevention. However, these apps encounter financial and regional limitations that restrict their usability. As academic apps are usually funded by research grants or academic institutions for specific purposes, their development and maintenance are often constrained, limiting updates and expansion. Moreover, many academic apps are tailored for specific regional diets, such as the Taiwanese focus of Formosa FoodApp, which narrows their international relevance. Additionally, these apps often lack engaging user interfaces and features that are essential for widespread user adoption [14]. Innovative funding models supporting extensive food databases and multilingual capabilities are needed to make these tools globally accessible and competitive with commercial apps. Khazen et al [11] suggested that an ideal dietary tracking tool would combine the features of commercial apps with the accuracy of academic apps, increasing their utility in global research and public health initiatives.

Our study contributed to the current literature by critically examining how accurately mobile apps can estimate the intake of saturated fats and cholesterol in different national contexts. Additionally, by investigating the consistency of data within and across the apps, we have highlighted several challenges these apps face in providing reliable nutritional information in the context of CVD prevention. Nonetheless, our methodology has inherent limitations. The data from a young demographic

may introduce bias, potentially limiting the applicability of findings across all age groups. By focusing on only the top 5 food codes per item, we might not have captured the full extent of the data variability within each app. This strategy, although deliberate, possibly overlooked broader inaccuracies or consistencies in less frequently selected food items. Our cross-national examination predominantly relied on MyFitnessPal's performance, potentially narrowing the applicability of our findings to other multilingual apps. Furthermore, the discrepancy in the number of selected food codes across apps—with MyFitnessPal at 204 and COFIT at 94, for instance—introduces bias when comparing results across platforms. Additionally, we did not factor in user behaviors such as app update frequencies, which can intermittently influence data accuracy. The evolving nature of these apps, with ongoing food item additions and updates by developers and users alike, suggests that database accuracy might shift over time. As the landscape of mobile health apps is dynamic, future studies would benefit from broader sampling and recognizing of these continual database evolutions, ensuring a more encompassing perspective on app reliability.

Conclusions

Our study reveals substantial inaccuracies and inconsistencies in mobile nutrition apps' reporting of saturated fats and cholesterol, highlighting challenges in ensuring data reliability across different national contexts and within the apps themselves. As digital tools are increasingly incorporated in CVD prevention and care, rigorous assessments and continuous refinements are crucial to ensure that they serve as dependable resources for both professionals and the public.

Acknowledgments

The authors would like to thank Trung Vinh Ly and Chi Cuong Hoang for developing the Formosa FoodApp. Finally, we thank all students and research staff at the School of Nutrition and Health Sciences, Taipei Medical University, for supporting our undertaking of this work. All persons named in the *Acknowledgments* section gave permission to be named. JSC was supported by grants from the National Science and Technology Council, Taiwan (MOST 111-2410-H-038-019-MY2 and MOST 111-2320-B-038-030-MY3).

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

DKNH and JSC designed the study. JWK, HTT, CYL, PHH, YRF, KHC, TYS, CHY, and CYY contributed to development of the Formosa FoodApp. WCC, HYS, PHW, JSC, and DKNH acquired or interpreted the data. DKNH conducted the statistical analysis. JSC and DKNH drafted the manuscript. JSC supervised the study and obtained funding. All authors read and agreed to the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: As the Chinese society ages and the concern for health and quality of life grows, the demand for care services in China is increasing. The widespread use of internet technology has greatly improved the convenience and efficiency of web-based services. As a result, the Chinese government has been implementing “Internet+Nursing Services” since 2019, with mobile apps being the primary tools for users to access these services. The quality of these apps is closely related to user experience and the smooth use of services.

Objective: This study aims to evaluate the functionality, services, and quality of “Internet+Nursing Service” apps; identify weaknesses; and provide suggestions for improving service programs and the research, development, improvement, and maintenance of similar apps.

Methods: In December 2022, two researchers searched for “Internet+Nursing Service” apps by applying the search criteria on the Kuchuan mobile app monitoring platform. After identifying the apps to be included based on ranking criteria, they collected information such as the app developer, app size, version number, number of downloads, user ratings, and number and names of services. Afterward, 5 trained researchers independently evaluated the quality of the apps by using the Chinese version of the user version of the Mobile App Rating Scale (uMARS-C). The total uMARS-C score was based on the average of the five evaluators’ ratings.

Results: A total of 17 “Internet+Nursing Service” apps were included. Among these, 12 (71%) had been downloaded more than 10,000 times, 11 (65%) had user ratings of 4 or higher, the median app size was 62.67 (range 22.71 - 103; IQR 37.51-73.47) MB, 16 (94%) apps provided surgical wound dressing change services, 4 (24%) covered first-tier cities, and only 1 (6%) covered fourth-tier cities. The median total uMARS-C score was 3.88 (range 1.92-4.92; IQR 3.71-4.05), which did not correlate with app store user ratings (r=0.003; P=.99). The quality of most apps (11/17, 65%) was average. Most apps (12/17, 71%) were rated as “good” or above (≥4 points) in terms of information quality, layout, graphics, performance, and ease of use; however, the vast majority of apps were rated as “fair” or even “poor” (<4 points) in terms of credibility (14/17, 82%) and demand (16/17, 94%).

Conclusions: “Internet+Nursing Service” apps need to broaden their service coverage, increase service variety, and further optimize their service structure. The overall quality of these apps is generally poor. App developers should collaborate with medical professionals and communicate with target users before launching their products to ensure accurate content, complete functionality, and good operation that meets user needs.

KEYWORDS

mobile phone; mobile applications; home care services; telemedicine; nursing services; China; apps

Introduction

As IT continues to develop, the number of internet users worldwide has reached 4.95 billion in 2022, including 1.067 billion internet users in China, with an internet penetration rate of 75.6%. The proportion of mobile phone users accessing the internet has reached 99.6% [1]. Mobile apps continue to grow steadily, with people using them for communication, shopping, office work, and socializing. The field of internet health care is becoming increasingly standardized, and it was the fastest-growing field in terms of user scale in 2022. As of December 2022, the number of internet health care users in

China reached 363 million—an increase of 64.66 million when compared to December 2021—accounting for 34% of all internet users [1]. Mobile health (mHealth) apps are the main media for mHealth and the primary channels for users to obtain medical support and health information. In 2019, 65.9% of internet users chose medical and health apps for medical consultations when feeling unwell [2].

People are increasingly inclined to use health care apps to manage their health due to these apps' cost-effectiveness, convenience, and speed in accessing health information [3-5] and ability to provide evidence-based health information for better health guidance [6]. There are several popular health care apps in China. According to a report on Statista, as of December 2022, the most popular medical app in China was Ping An Good Doctor—a health care platform owned by the Ping An Insurance Group—with almost 23 million monthly active users [7]. The mobile portal provides real-time medical consultations, web-based appointment booking services, and a health-related discussion forum.

As people become more health conscious, the demand for health care services is increasing. To alleviate the pressure on offline medical institutions and meet the needs of the public, China launched "Internet+Nursing Services" [8]. These services are provided by registered nurses from fixed medical institutions and operate on a web-based app and offline service model. They are designed to serve discharged patients or special populations with medical conditions and limited mobility [9]. Since 2019, "Internet+Nursing Service" organizations in China's provinces and regions have been actively providing services to countless older adults living at home, pregnant women, infants, and young children who have difficulty with leaving their homes. These services have received unanimous positive reviews [10,11]. The "Internet+Nursing Service" model integrates nursing services with internet technology, using internet IT to break the spatial limitations of traditional medical treatment. It can meet the multilevel nursing care needs of service users, allow for personalized and continuous care, alleviate social problems that result in difficulties with visiting a physician, improve the quality of life of service users, and broaden the channels of communication between nurses and patients [12].

Patients place orders through an app, and managers dispatch orders based on various factors, such as web-based nurses' qualifications, professionalism, and distance. Platform nurses receive orders within a specified period of time and travel to patients' homes to provide services, including routine nursing operations (eg, intramuscular injections, intravenous injections, urinary catheterization, gastric tube insertion, and blood sample collection), as well as specialty care (eg, peripherally inserted central venous catheter medication exchange, wound stoma care, and neonatal examinations). By downloading high-quality "Internet+Nursing Service" mobile apps, users can quickly access the care services they need without leaving their homes. However, low-quality apps may not only affect the user experience but also make it impossible for users to obtain the care services they need.

As people become increasingly dependent on smartphones and apps, they are also becoming more concerned about the quality of apps. Users not only expect apps to function properly but also have high expectations for their aesthetics, security, and personalization settings [13]. App quality issues can affect the user experience, determine whether users continue to use the app, and even lead to economic and property losses for both the users and the app development departments. mHealth apps are a special type of app, and studies have shown that factors such as usability, navigability, accuracy of information, and security all affect the user's experience with and evaluation of an mHealth app. If an mHealth app is of low quality, users may doubt its usefulness and effectiveness, which can even lead to users obtaining low-quality health services and generating erroneous health management concepts that affect their health beliefs and behaviors [6,14,15].

In recent years, various software development organizations have been paying more attention to improving app quality, but there are still deficiencies [16]. The quality of an app is mainly judged by checking user ratings and reviews on app stores. However, the actual quality of an app can be unclear, and it is impossible to know whether an app's functions are comprehensive or whether its content is scientific based on the data displayed on app store pages. Therefore, it is necessary to objectively evaluate the quality of medical and health apps to identify shortcomings in their development; promote their continuous improvement; improve their applicability, usage experience, and compliance (eg, compliance with data protection laws); and allow users to use apps that are of high quality, are reasonably designed, and are safe to use. There are various methods for evaluating the quality of medical apps, which are also known as *mHealth apps*. According to a study by Stoyanov et al [17], the quality of mHealth apps is evaluated based on different categories, including engagement, functionality, aesthetics, information quality, and subjective quality [18]. There are various methods for evaluating mHealth services, such as the use of questionnaires, the conduction of interviews, and observation [18]. A systematic review by Nouri et al [19] identified the following seven main classes of assessment criteria for mHealth apps: design, information and content, usability, functionality, ethical issues, security and privacy, and user-perceived value. These criteria can be used to assess the quality of a medical app.

Most studies on "Internet+Nursing Services" focus on service effects [20-22], the establishment of service quality index systems [23], risk management strategies [24,25], and the demand for services from various groups [26-28]. However, there is little attention paid to the quality of "Internet+Nursing Service" apps and a lack of studies that use evaluation tools to objectively evaluate these apps' quality and functions. The aim of this study was to review the "Internet+Nursing Service" mobile apps that are available on China's app stores and evaluate their quality.

Methods

Selection of the "Internet+Nursing Service" Apps

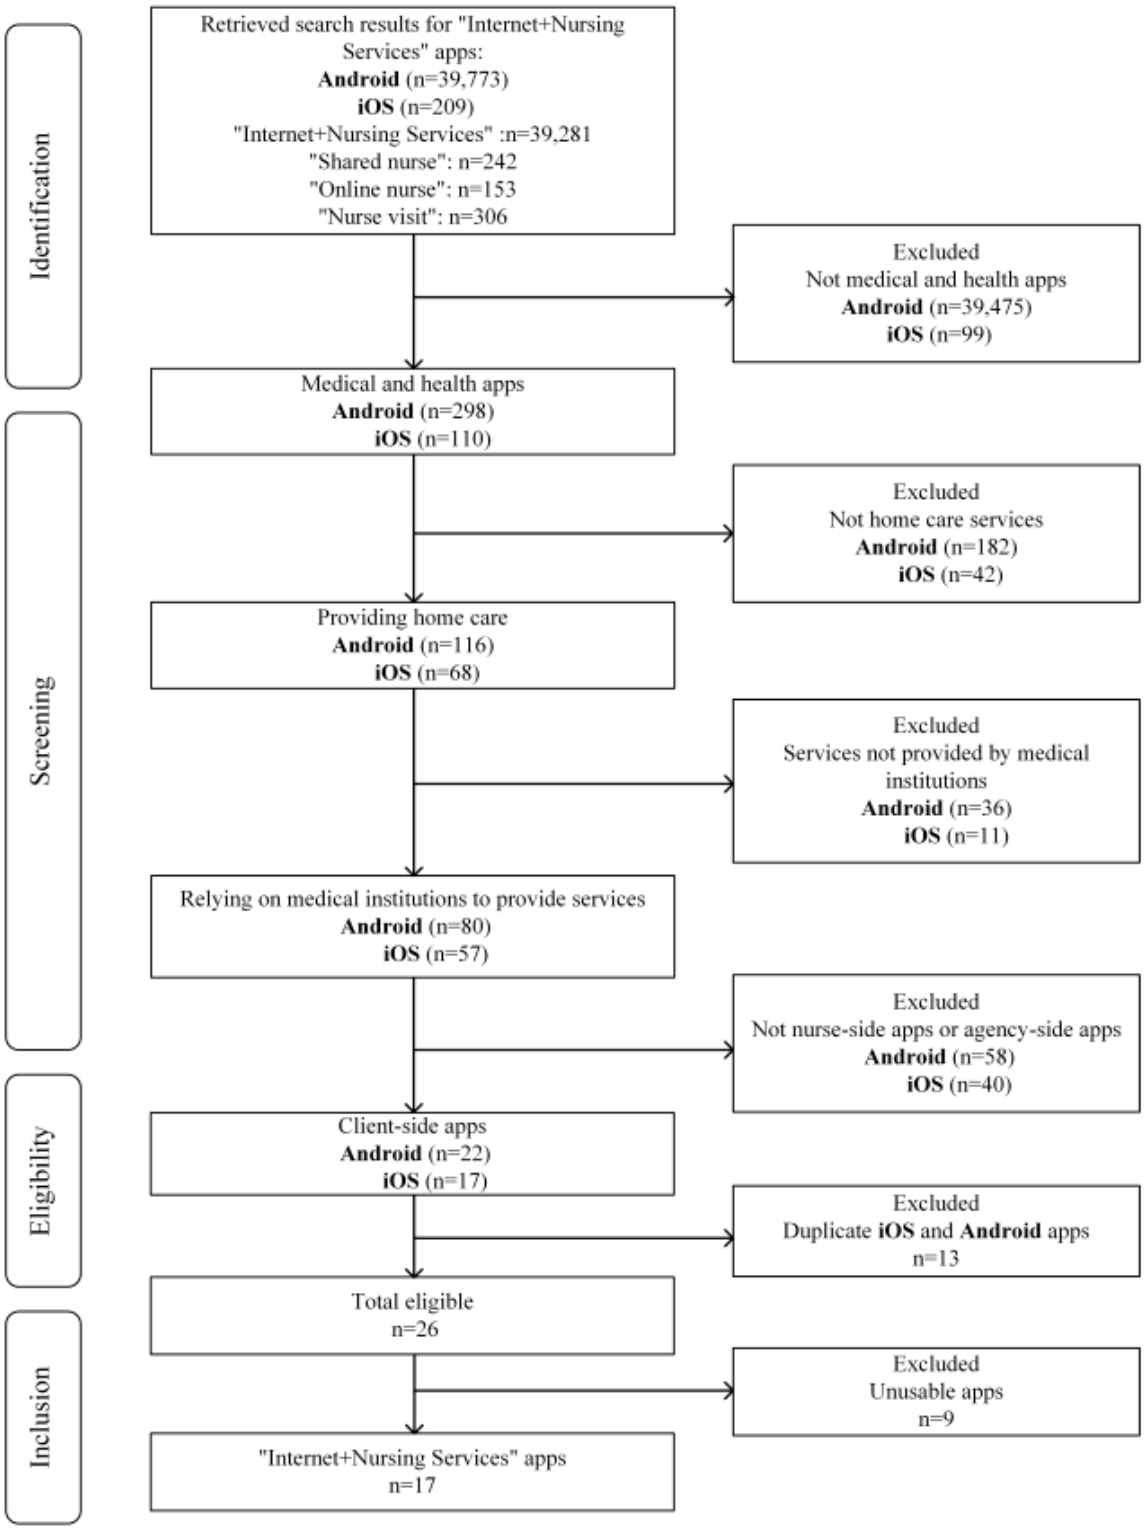
We used the Kuchuan mobile app monitoring platform (Beijing Kuchuan Technology Co.) to monitor data from the iOS and Android app stores. This platform provides real-time information

about mobile app developers, the latest versions of apps, and the number of app downloads. Two researchers searched for apps that were available as of December 1, 2022, using the keywords "Internet+Nursing Service," "Home Nursing," "Nurses at Home," "online nurse," and "shared nurse."

The inclusion criteria for the apps were (1) apps with content that includes home nursing services, (2) apps categorized as health care apps, (3) apps in Chinese, (4) free apps, and (5) functional apps. The exclusion criteria were (1) non–user-side apps, (2) old versions of the same app, (3) apps with different names but the same content, and (4) duplicate apps.

Two researchers independently screened the apps based on their names, profiles, and display images. They then discussed their findings to finalize the list of evaluated apps (Figure 1).

Figure 1. Flowchart of the selection of apps.



Selection of a Standardized Rating Scale for Mobile Apps

We used the Chinese version of the user version of the Mobile App Rating Scale (uMARS-C), and we obtained authorization from the authors of the uMARS-C [29]. Adapted from the Mobile App Rating Scale (MARS), the user version of the MARS (uMARS) has been used for assessing a wide variety of apps, including apps for mental health [30], rheumatology patient management [31], cancer risk assessment [32], and hospital registration [33]. The uMARS-C includes 14 objective items that are rated on a 5-point Likert scale and divided into the following three dimensions: engagement, functionality, and information. Dimension scores are calculated by dividing the total entry score by the number of entries, and the uMARS-C total score is calculated by dividing the total dimension score by the number of dimensions. According to the rating scale, a uMARS-C total score of 1 indicates poor quality, a score of 2 indicates inadequate quality, a score of 3 indicates fair quality, a score of 4 indicates good quality, and a score of 5 indicates excellent quality.

The uMARS-C has good reliability and validity, with a Cronbach α coefficient of 0.890 and dimension Cronbach α coefficients ranging from 0.853 to 0.895. The test-retest reliability value is 0.967, the item content validity index ranges from 0.78 to 1.00, and the scale content validity index/average is 0.969.

Process of Evaluating "Internet+Nursing Service" Apps

A total of 5 researchers—2 nurses with more than 5 years of experience in their roles, 2 graduate nursing students, and 1 professional internet engineer with more than 7 years of experience in their role—assessed the quality of the apps. Before the evaluation, we made sure that each researcher properly understood and was familiar with the uMARS-C. To ensure their understanding of the scale, they downloaded and assessed 2 mHealth apps that were not included in this study. When there was a difference of more than 2 points in dimension scores or total scores, they discussed until reaching a consensus. The researchers then downloaded the apps that were included in the final analysis onto iOS and Android smartphones. After downloading the apps, they used each app for at least 10 minutes and independently evaluated the ease of use, performance, security, and settings of each app, using the uMARS-C. Basic app information was collected from the app store download page, including the app developer, app size (in MB), version number, number of downloads, user ratings (ranging from 0 to 5), and number and names of services, among others. Some app download data were missing because the iOS app store did not provide these data. The researchers also graded the service coverage cities based on the categorized statistical service items in the *Beijing Internet Home Care Service Item Catalog* (2022 edition) [34] and the city class divisions in the *2022 China's City Business Attractiveness Ranking* [35].

Statistical Analysis

We used EpiData 3.1 (EpiData Association) for data entry and SPSS 24.0 (IBM Corp) for statistical analysis. Nonnormally distributed measurement data were expressed as medians and quartiles, while count data were expressed as numbers and percentages. The uMARS-C dimension scores for each app were averaged across the five raters, and the final scores were calculated by using the scale's formula.

Ethical Considerations

This study did not involve human subjects, clinical trials, and vulnerable groups and was therefore exempt from ethical approval.

Results

Characteristics of Selected Apps

Our search found a total of 39,982 apps (iOS: n=209; Android: n=39,773). After initial screening based on the inclusion and exclusion criteria, we downloaded 26 apps. After using them, we excluded 8 apps that were not working properly, leaving a total of 17 apps, which were included in this study (Table 1 and Multimedia Appendix 1). Of these 17 apps, 4 (24%) were released by medical institutions and 13 (76%) were released by corporations (Table 1). Further, 12 (71%) apps had been downloaded more than 10,000 times, with Champion Nurse having the highest number of downloads (n=37,321,776). The median app size was 62.67 (range 22.71-103; IQR 37.51-73.47) MB. App store user ratings ranged from 2.8 to 5.0, with 14 (82%) apps being rated 3.0 or higher and 11 (65%) apps being rated 4.0 or higher. In terms of service coverage, 4 (24%) of the "Internet+Nursing Service" apps covered first-tier cities, including Beijing; 8 (47%) covered new first-tier cities; 4 (24%) covered second-tier cities; and 1 (6%) covered fourth-tier cities.

Table . Characteristics of the "Internet+Nursing Service" apps.

Characteristic		Apps (N=17), n (%)
Download count [a]		
	0-9999	2 (12)
	10,000-99,999	7 (41)
	100,000-999,999	3 (18)
	1,000,000-9,999,999	1 (6)
	≥10,000,000	1 (6)
Platform		
	iOS and Android	13 (76)
	iOS	3 (18)
	Android	1 (6)
User rating (number of stars)		
	0-2.9	3 (18)
	3.0-3.9	3 (18)
	4.0-4.9	5 (29)
	5.0	6 (35)
Developer		
	Individual developer	8 (47)
	Corporation	9 (53)

	New first-tier cities	8 (47)
	Second-tier cities	4 (24)
	Fourth-tier cities	1 (6)

[a]Download count for Android apps only.

Categories of Nursing Services Provided by Apps

The 17 apps provided at-home nursing services, including intravenous injection, intramuscular injection, and nebulized inhalation services, among others. These services were classified as *Health Assessment and Guidance*, *Clinical Nursing*, *Maternal and Infant Nursing*, *TCM* (traditional Chinese medicine) *Nursing*, *Specialty Nursing*, *Hospice*, and *Rehabilitation Nursing* services per the categories in the *Beijing Internet Home Care Service Item Catalog* [34]. Any services that were not in the catalog were classified as *uncategorized items*.

Of the 17 apps, 16 (94%) provided surgical wound dressing change services (*Clinical Nursing* category), 15 (88%) provided services for the maintenance of peripherally inserted central catheters (*Specialty Nursing* category), 14 (82%) provided maternal and infant nursing services (*Maternal and Infant Nursing* category), and 10 (59%) provided TCM nursing services (*TCM Nursing* category) and disease rehabilitation guidance (*Rehabilitation Nursing* category). Further, 4 (24%) apps provided hospice care services (*Hospice* category), 3 (18%) provided health assessments and guidance (*Health Assessment and Guidance* category), and only 1 (6%) app provided gastrointestinal decompression, previsit physical examination, conjunctival capsule irrigation, T-tube drainage care, and family room services (uncategorized items).

Quality of the "Internet+Nursing Service" Apps

In our study, the Cronbach α coefficient of the uMARS-C was 0.871, and the dimension Cronbach α coefficients ranged from 0.761 to 0.811. Based on the uMARS-C scores, of the 17 apps, 1 (6%) was rated as "poor," 11 (65%) were rated as "fair," 5 (29%) were rated as "good," and none were rated as "insufficient" or "excellent." The median total score for the "Internet+Nursing Service" apps was 3.88 (range 1.92-4.92; IQR 3.71-4.05; Figure 2), with Champion Nurse having the

highest score (4.92) and Health WuHan having the lowest score (1.92). There was no significant correlation between app store user ratings and total uMARS-C scores (r=0.003; P=.99). The median information dimension score was 3.97 (range 1.86-5.00; IQR 3.57-4.29), the median functionality dimension score was 3.95 (range 1.25-5.00; IQR 3.25-4.50), and the median engagement dimension score was 3.80 (range 1.00-5.00; IQR 3.33-4.33; Figure 3). A heat map comparing the scores of each entry in the uMARS-C for the 17 "Internet+Nursing Service" apps showed that Health WuHan scored below 3 points in most entries (11/14, 79%; Multimedia Appendix 2). Further, 14 (82%) apps scored below 4.0 points in the *Credibility* entry, indicating an average or poor level; 16 (94%) scored below 4.0 points in the *Demand* entry; 14 (82%) scored at a good or above level in the *Quality of Information* entry; and 12 (71%) scored at a good or above level in the *Layout*, *Graphics*, *Performance*, and *Ease of Use* entries.

Figure 2. uMARS-C overall scores of the "Internet+Nursing Service" apps (N=17). The bottom and top edges of the boxes represent the first and third quartiles, respectively; the lines within the boxes represent the medians; the ends of the bottom and top whiskers represent the minimum and maximum values, respectively; and the circles represent outliers. uMARS-C: Chinese version of the user version of the Mobile App Rating Scale.

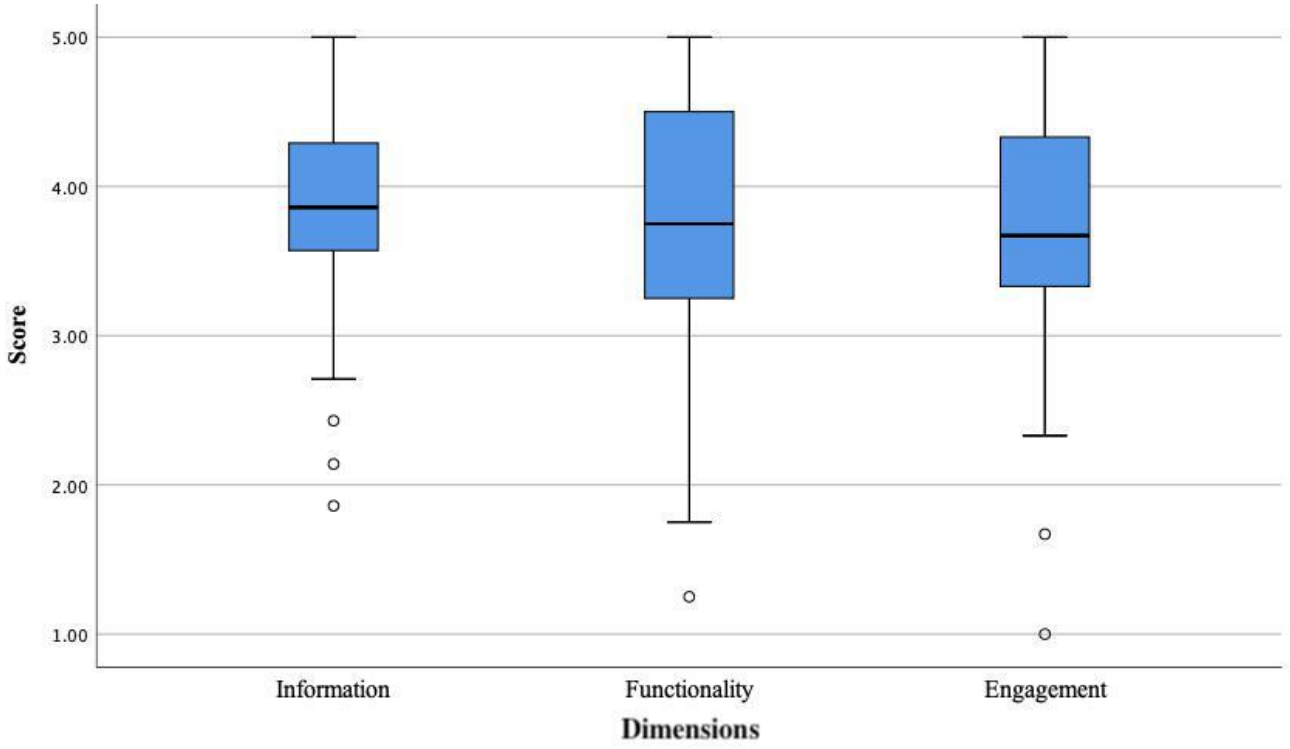

Figure 3. uMARS-C dimension scores of "Internet+Nursing Service" apps (N=17). The bottom and top edges of the boxes represent the first and third quartiles, respectively; the lines within the boxes represent the medians; the ends of the bottom and top whiskers represent the minimum and maximum values, respectively; the circles represent outliers; and the asterisk represents an extreme outlier. uMARS-C: Chinese version of the user version of the Mobile App Rating Scale.

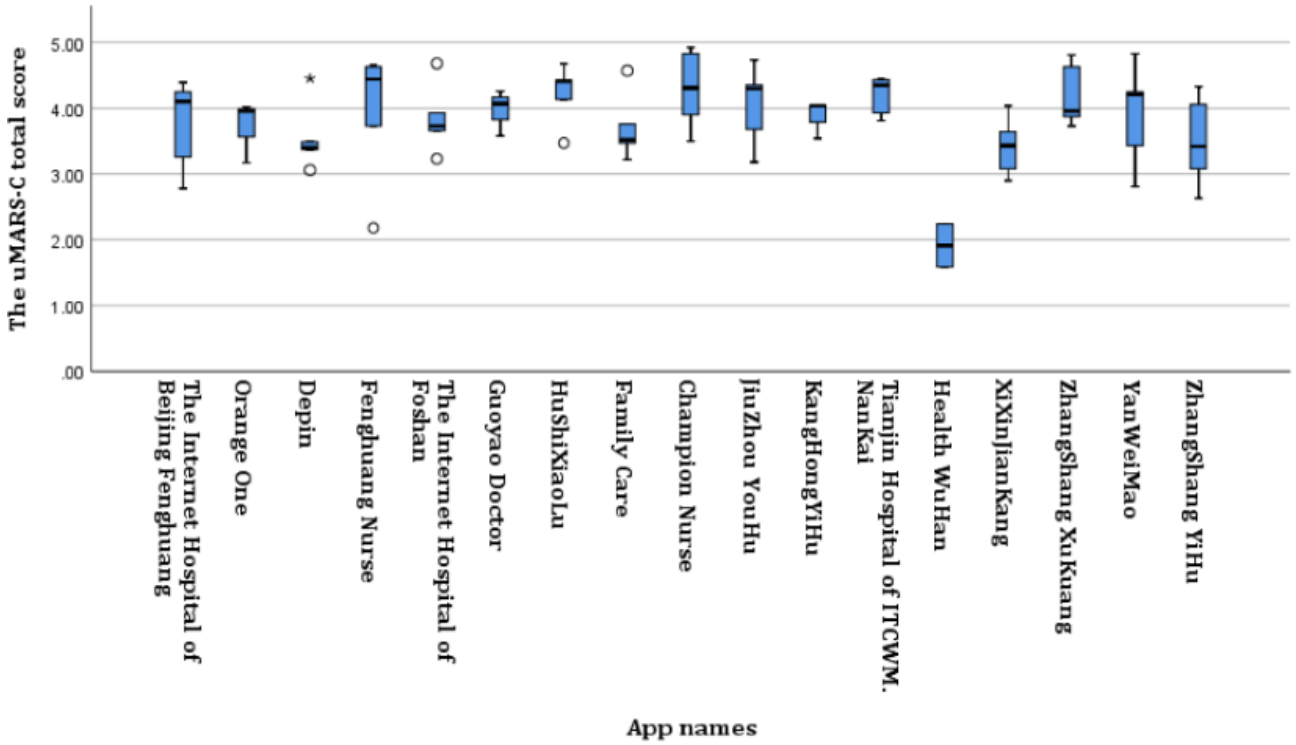

Discussion

Principal Results

As internet technology continues to develop, all industries are integrating the "Internet+" model to promote innovation and development [1]. However, unlike services in other industries, "Internet+Nursing Services," as web-based health care services, are characterized by the high risks and high professionalism of the medical industry, as well as the special risks associated with mHealth [25].

There are several risks associated with "Internet+Nursing Service" apps. One of the risks is that technology barriers can prevent some patients from accessing telehealth services. These barriers can include a lack of access to the internet, a lack of access to the necessary devices, or difficulty with using the technology. Another risk is that there may be issues with insurance coverage for telehealth services, as well as regulatory obstacles that can limit the use of telehealth [36]. Therefore, it is necessary to strengthen the supervision of "Internet+Nursing Service" apps and strictly control all aspects. "Internet+Nursing Services" are human-centered services and aim to improve health. Therefore, "Internet+Nursing Service" app design should fully consider user characteristics and needs. In this study, we downloaded and used "Internet+Nursing Service" apps, evaluated them from a user perspective, and rated them objectively based on our usage experience.

Most apps (16/17, 94%) provided services in first-tier cities, new first-tier cities, or second-tier cities, with only 1 app providing "Internet+Nursing Services" in a fourth-tier city. The "Internet+Nursing Service" scope does not yet cover remote areas and townships. Data from China's seventh national census show that the rural population consists of about 509.79 million people, accounting for 36.11% of the total population [37]. However, 80% of medical resources are concentrated in medium- and large-sized medical institutions in medium- and large-sized cities, leading to an imbalance between the demand for care and the supply of care resources for the grassroots population [38].

Providing high-quality nursing resources and services is key to improving the health and quality of life of people at the grassroots level. Medical institutions at all levels should actively promote the distribution of medical resources to enhance access to basic medical and public health services. Therefore, "Internet+Nursing Service" apps should integrate medical resources and promote a 3-tier "hospital-community-family" linkage to bring professional nursing services into the homes of grassroots people. This would encourage more medical institutions to provide home care, expand the scope of services, make full use of medical resources, and address the imbalance between the supply of and demand for medical resources.

Our study found that "Internet+Nursing Service" apps provide a limited number of service programs—mostly routine care programs—with few special care programs, such as psychological care, hospice care, and child care programs. Only 4 of the 17 apps provided hospice care services, and none provided psychological care services, despite the high demand for these programs. In one study, it was found that 92.3% of the older adult population in urban and rural areas needed psychological comfort [39], and in another study, 10.32% of housebound older adults believed that hospice care should be carried out [40]. Further, as the concept of childbearing changes,

people are pursuing more scientific and specialized childcare, and child health care and nursing have become more emphasized. Research has shown that providing nutritional guidance, growth and development guidance, and child psychological care to families of preterm infants through "Internet+Nursing Service" platforms could promote the growth and intellectual development of preterm infants [41]. Medical institutions in each region should have an in-depth understanding of the needs of service users and the characteristics of different groups of people. They should gradually expand the list of "Internet+Nursing Services" by taking into account the actual situations of medical institutions and the local medical resources to optimize the structure of service items and meet the needs of service users.

The total quality scores of the 17 apps ranged from 1.92 to 4.92, with 1 (6%) app rated as "poor" and 11 (65%) rated as "fair," indicating that the overall quality of "Internet+Nursing Service" apps was not good. This may be related to the fact that app development engineers do not fully understand the medical industry. Most "Internet+Nursing Service" apps (9/17, 53%) were developed by corporations, and the developers may not have taken into account the specificity of medical software before development. They also may not have communicated well with medical staff during app development or understood the content and characteristics of "Internet+Nursing Service" apps.

The process of target user evaluation not only strengthens the interactions between users and the software but also identifies weak points (ie, from user feedback) that developers may have missed [42]. Our researchers found that some apps had problems, such as crashes and the inability to log in during use, which affected the user experience. Therefore, research and development organizations need to conduct premarket research and postmaintenance work to ensure the smooth operation of platforms.

From the heat map (Multimedia Appendix 2), it can be seen that most apps (12/17, 71%) scored at a good or above level in terms of the *Layout*, *Graphics*, *Performance*, and *Ease of Use* entries. This indicates that most app development teams pay more attention to the visual effects, ease of use, and smoothness of their apps. However, of the 17 apps, 14 (82%) had average scores of less than 4.0 in the *Credibility* entry, and 16 (94%) had average scores of less than 4.0 in the *Demand* entry, indicating average or even poor performance in these areas. During the evaluation, our researchers found that some app development teams did not clearly label the source or publisher information when publishing health science articles or videos. This may cause users to doubt the authenticity, authority, and reliability of the articles when reading them, affecting their ability to build health knowledge and manage their own health [43]. It is important to publish health science articles with scientific evidence and to clarify the sources, authors, time of publication, and applicable populations of standardized content to increase the credibility of information. In terms of meeting user needs, we found that most apps provided information from health science literature in text form, with content mostly focused on introducing services, medical institutions, and health care experts. We also noted that after content was published on an app, the content was not updated for a long time. Some apps also only had 2 to 3 articles and could not meet user needs. Therefore, in addition to not meeting user needs in terms of service programs, there are also deficiencies in providing up-to-date and relevant health information.

App developers can improve the credibility of health science articles and videos by taking several steps. First, they should ensure that the information provided is based on scientific evidence and comes from reputable sources. This can be done by clearly labeling the sources, authors, time of publication, and applicable populations of the content. Second, they should regularly update the content to ensure that it is current and relevant. Third, they should provide references or links to the original sources of information, so that users can verify the accuracy of the information. By taking these steps, app developers can increase the credibility of their health science articles and videos and help users build their health knowledge and manage their own health.

Health science popularization should aim to provide basic concepts and knowledge in the field of health, with a focus on healthy lifestyles and behaviors. Health science content should be regularly updated to keep up with social hot spots, seasonal changes, and the occurrence of epidemics to provide users with the most up-to-date and relevant information. To achieve this, app development teams should conduct market research to understand the needs and characteristics of their users, including users' cultural levels and reading habits. They should also keep track of social hot spots, seasonal changes, and other factors to provide relevant health policies, basic medical knowledge, diet and exercise guidance, psychological guidance, and knowledge regarding disease prevention or first aid in daily life. In addition to providing information in graphic form, app developers can also use video and audio formats to present health science information from multiple angles, dimensions, and levels to meet the needs of users at different levels. By providing accurate and scientific health information in a timely manner, app developers can help users improve their health knowledge and quality of life.

Our study found no correlation between uMARS-C ratings and app store ratings, suggesting that app store ratings do not reflect the quality of apps. This may have been due to the small number of app store ratings, differences in app store rating mechanisms, developer marketing strategies, or users' preferences (eg, app favoritism among users). If the quality of apps is judged solely based on app store ratings, users may download low-quality apps, thereby affecting their usage experience and even causing them to distrust care services. Additionally, health care professionals may be unable to accurately recommend high-quality apps to patients or their families. This further demonstrates the necessity of evaluating the quality of "Internet+Nursing Service" apps by using objective rating scales.

Limitations

This study has several limitations. First, we only searched for "Internet+Nursing Service" apps that were updated until December 1, 2022, and did not consistently track the uploads and downloads of related apps. Second, we only used iPhone,

Huawei, and Xiaomi phones to download and evaluate apps and did not use other systems, such as Meizu, Samsung, and Windows phones. During app development, the development team may modify app functions for different systems due to differences in system algorithms, resulting in differences in app functions. Therefore, future research should take system differences into account and conduct more comprehensive quality evaluations of apps for different systems. Third, there were only 5 researchers in this study; all were under the age of 30 years and had a high level of e-literacy, which may have introduced bias in entries, such as the *Ease of Use* entry, during the evaluation process. However, older people, who are the main target of "Internet+Nursing Services," have varying levels of e-literacy and may have different understandings and judgments of an app's ease of use. Therefore, future studies may consider including evaluators with different backgrounds and health literacy levels.

Conclusions

In this study, we used the uMARS-C to evaluate the quality of "Internet+Nursing Service" apps. We found that the service coverage of these apps was concentrated in first-tier cities (eg, Beijing and Shanghai), new first-tier cities, and some second-tier cities, with a limited number of service items and a need to optimize the structure of service items. The quality evaluation results showed that the quality of apps was not good, especially in terms of information credibility and meeting users' needs. Further, the scale scores did not correlate with app store scores. Therefore, "Internet+Nursing Service" app development teams need to pay attention to improving the quality of their apps. Before releasing an "Internet+Nursing Service" app, they should fully understand the needs of their target users, as well as the characteristics of this type of app, and communicate with relevant professionals in the field. They should also orient the release of health knowledge in the app toward user needs and improve the credibility and readability of content. After releasing an app, it is necessary to maintain and update it to ensure its normal operation and the timely updating of health education content.

Acknowledgments

We would like to thank three other researchers (Guanghan Zhang, Ying Liu, and Liping Fan) for their participation. This work was supported by the Key Project of Natural Science Research in Colleges and Universities of Anhui Province (grant KJ2021A0255).

Abstract

Background: Asthma is a chronic respiratory disorder requiring long-term pharmacotherapy and judicious patient self-management. Few studies have systematically evaluated asthma mobile health (mHealth) apps for quality and functionality; however, none have systematically assessed these apps for their content alignment with international best practice guidelines.

Objective: This review aims to conduct a systematic search and evaluation of current mHealth apps in the Australian marketplace for their functionality, quality, and consistency with best practice guidelines.

Methods: The most recent Global Initiative for Asthma (GINA) guidelines were reviewed to identify key recommendations that could be feasibly incorporated into an mHealth app. We developed a checklist based on these recommendations and a modified version of a previously developed framework. App stores were reviewed to identify potential mHealth apps based on predefined criteria. Evaluation of suitable apps included the assessment of technical information, an app quality assessment using the validated Mobile App Rating Scale (MARS) framework, and an app functionality assessment using the Intercontinental Medical Statistics Institute for Health Informatics (IMS) Functionality Scoring System. Finally, the mHealth apps were assessed for their content alignment with the GINA guidelines using the checklist we developed.

Results: Of the 422 apps initially identified, 53 were suitable for further analysis based on inclusion and exclusion criteria. The mean number of behavioral change techniques for a single app was 3.26 (SD 2.27). The mean MARS score for all the reviewed apps was 3.05 (SD 0.54). Of 53 apps, 27 (51%) achieved a total MARS score of ≥3. On average, the reviewed apps achieved 5.1 (SD 2.79) functionalities on the 11-point IMS functionality scale. The median number of functionalities identified was 5 (IQR 2-7). Overall, 10 (22%) of the 45 apps with reviewer consensus in this domain provided general knowledge regarding asthma. Of 53 apps, skill training in peak flow meters, inhaler devices, recognizing or responding to exacerbations, and nonpharmacological asthma management were identified in 8 (17%), 12 (25%), 11 (28%), and 14 (31%) apps, respectively; 19 (37%) apps could track or record “asthma symptoms,” which was the most commonly recorded metric. The most frequently identified prompt was for taking preventive medications, available in 9 (20%) apps. Five (10%) apps provided an area for patients to store or enter their asthma action plan.

Conclusions: This study used a unique checklist developed based on the GINA guidelines to evaluate the content alignment of asthma apps. Good-quality asthma apps aligned with international best practice asthma guidelines are lacking. Future app

development should target the currently lacking key features identified in this study, including the use of asthma action plans and the deployment of behavioral change techniques to engage and re-engage with users. This study has implications for clinicians navigating the ever-expanding mHealth app market for chronic diseases.

Introduction

Background

Asthma is a chronic respiratory disorder that is clinically defined as a combination of typical episodic respiratory symptoms, such as wheezing, shortness of breath, cough, chest tightness, and significant variable reversible airflow limitation [1]. When the frequency or severity of these symptoms increases compared with the baseline respiratory status, it represents an "asthma exacerbation" or "flare-up" [2]. Judicious self-monitoring and management of regular asthma medications, symptoms, and exacerbations are key to allowing patients with asthma to live with a high quality of life and prevent hospitalizations or death [3]. The Global Initiative for Asthma (GINA) regularly releases updated best practice asthma guidelines based on reviews of scientific literature by an international panel of experts [4]. Many local asthma management guidelines have been derived from these international guidelines. In addition to pharmacotherapy, the guidelines advise that patient education on medication adherence, exacerbation recognition, and management is key to self-management [4].

Asthma is a significant chronic health issue worldwide, affecting 1% to 18% of the global population [4]. Australia is no exception, with asthma affecting millions and accounting for 34% of Australia's respiratory disease burden and 2.5% of the total disease burden [5]. Asthma leads to numerous emergency department visits and urgent health care visits [5]. Furthermore, those living with asthma report a poorer quality of life and are less likely to rate their health status as excellent or very good [5]. When observing the total cost that asthma has on the Australian health system, it is evident that hospital-related costs outweigh non–hospital-related costs (Aus $205 million/year [approximately US $150 million] vs Aus $163 million/year [approximately US $120 million]) [5]. Theoretically, reducing exacerbations would reduce the requirement for hospitalizations; unplanned primary care presentations; and indirect costs, such as work absenteeism, and thus assist in reducing these costs.

With the increasing availability of smartphones, mobile health (mHealth) apps have become accessible to a large percentage of the population and represent a potential medium through which patients can improve their ability to self-manage asthma. Deloitte's recent review of Australia's telecommunication status found that 89% of the Australian population uses smartphones [6]. These apps are already available for download and use; however, it is imperative that a review of their quality, functionality, and alignment with evidence-based best practices is conducted to inform both users and health professionals. These apps represent an opportunity for new ways to empower patients to track asthma symptoms, learn about their condition, and undertake practical self-management strategies. The established Mobile App Rating Scale (MARS) is generally used to assess the usability and overall quality of mHealth apps [7,8]. Although systematic evaluations of asthma mobile apps have been conducted in the past, many of these studies did not assess the apps' functionality or quality using a validated rating scale, such as MARS [9-11]. Furthermore, to our knowledge, none of these prior evaluations assessed all available apps systematically for the presence and quality of information they provide compared with available best practice management guidelines, such as the GINA guidelines [9-11].

This systematic search and evaluation review assessed the functionality and quality of free and paid asthma mHealth apps targeted toward adults with asthma available from the Apple App Store (iOS) and Google Play Store (Android), as well as their consistency with recommendations from the GINA guidelines, making it the first review of its kind.

Objective

The objective of this review was to conduct a systematic search of available English-language mHealth apps targeted toward adults with asthma in Australia, to evaluate their overall quality and functionality and to assess the consistency and quality of the content and information they provide in alignment with current best practice guidelines for asthma management.

Methods

Overview

The GINA guidelines were reviewed by 2 medical professionals to identify and establish a consensus of key recommendations from the guidelines that could feasibly be incorporated into an app for asthma management. The mobile apps in the selected app stores were identified and screened based on the selection criteria. Finally, we assessed the quality, functionality, and alignment of the apps with the guidelines identified in the first step of the screened mHealth apps. An in-depth description of the research protocol was published the previous year [12].

Study Setting

Given the primary residences of the researchers involved in this review, this study was conducted by medical practitioners,

medical students, and digital health researchers using apps available in Australia. The mHealth apps presented in English on Australian mobile app stores were assessed. Some mHealth apps identified in this review may not be available in regions outside Australia. Similarly, apps available in other regions may not be available in Australia. However, given that most of the apps identified in this review are also available in other English-speaking regions such as the United Kingdom and the United States, the results are largely generalizable to these regions. Given that the researchers were adult medical practitioners who did not manage pediatric patients, only those mHealth apps targeted toward adults with asthma were evaluated.

Wherever possible, the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for systematic reviews were followed [13]. Given that this was a review of mobile apps instead of journal articles, some items in the PRISMA checklist were not relevant to this review. The checklist is shown in Multimedia Appendix 1.

Review of the GINA Guidelines and Checklist Creation

To assess the usability and overall quality of the app, we used the established MARS [7,8]. A review of the available literature using the CINAHL, MEDLINE, Embase, and PubMed databases revealed that 1 research group had developed an asthma app assessment framework yet to be derived and validated into an instrument [14]. For the reasons outlined in our published research protocol, we decided to combine aspects of the framework by Guan et al [12] with our own checklist derived from the GINA guidelines. Two reviewers, BR and KS, independently assessed the 2020 GINA guidelines for identifiable recommendations that could be incorporated into an mHealth app. Following this, the reviewers examined each other's identified recommendations to see whether a consensus could be reached on the recommendations from the GINA guidelines that could be incorporated into an mHealth app. The identified recommendations from each author and those where a consensus was reached, which represent the final identified recommendations, are shown in Table 1.

A final checklist modified from the framework by Guan et al [14] (Table 1) was developed to include recommendations we identified from the above process while excluding the information we gathered through the MARS framework. To determine app consistency with the GINA guidelines, participants were assessed for the presence or absence of features identified through this process. This is further discussed in subsequent sections.

Table 1. Recommendations identified from the Global Initiative for Asthma guidelines that could be incorporated into a mobile health app.

Reviewer 1	Reviewer 2	Consensus reached
Assess symptom control (eg, ACQ[a])	Support for assessing symptom control for a 4-week period	Support for assessing symptom control for a 4-week period considering the frequency of asthma symptoms, night waking because of asthma, frequency of SABA[b] use, and any activity limitation because of asthma; uses recognized screening, symptom control or numerical asthma control tools, and tracks peak flow measurement
Ability to self-track symptoms with or without peak flow	—[c]	Encourages patients to track symptoms and peak flow measurements
Risk factors for future exacerbations	Helps users identify the future risk of exacerbations	Helps users identify the risk of future exacerbations
Screens for comorbidities and education regarding managing them	Screens for comorbidities and assists patients with managing them	Screens for relevant comorbidities and educates patients on the management of these comorbidities
Inhaler technique with or without video	Provides education on appropriate inhaler techniques	Provides education on appropriate inhaler techniques with visual aids
Ability to record action plan	Provides an area for patients to keep and refer to their written action plan	Provides an area for patients to keep and refer to their written action plan
Reminder to engage with primary care	Reminds users to see their HCP[d] for management and review of asthma	Provides reminders to users to see their HCP for management and review of asthma
—	Specifically provides suggestion to see an HCP if a patient is using only a SABA.	Specifically provides suggestion to see an HCP if a patient is using a SABA alone
Medication adherence	Prompts users to adhere to controller medications even when symptoms are infrequent	Prompts users to adhere to controller medications even when symptoms are infrequent
General asthma education	Provides knowledge on general asthma information, management of asthma, modifiable risk factors and strategies to address them, and when to see an HCP	Provides knowledge on general asthma information, management of asthma, modifiable risk factors and strategies to address them, when to see an HCP, and identification and management of comorbidities
Help with activating action plan	Provides advice on when to refer to a patient's asthma action plan based on self-monitoring of symptoms or PEF[e]	Provides advice on when to refer to a patient's asthma action plan based on self-monitoring of symptoms or PEF
—	Prompts patient to see the primary HCP if features of asthma exacerbation (symptoms and SABA use) are identified using the app	Prompts patient to see the primary HCP if features of asthma exacerbation (symptoms and SABA use) are identified using the app

[a]ACQ: Asthma Control Questionnaire.

[b]SABA: short-acting β-agonist.

[c]Recommendation identified by one reviewer but not the other.

[d]HCP: health care provider.

[e]PEF: peak expiratory flow.

Identification, Screening, and Selection of Mobile Apps for Review

This review included both free and paid apps from the 2 most popular app stores in Australia across the iOS and Android operating systems: the Apple App Store (Apple) and Google Play Store (Google). Our published protocol outlines the steps taken for quality assurance [12]. Our approach for identifying these apps followed the approach used in similar studies [9-11]. Before commencing the initial search for apps, the reviewers ensured that the operating systems on the chosen smartphones were up to date. Each reviewer used different phones to assess the apps, but all updated the Android operating system (OS) to the Android 11 OS (Google) when reviewing apps from the Google Play Store. In the search bar of each store, we input the term *asthma*. Two reviewers (BR and DZ) independently searched both app stores on August 10, 2021, from Melbourne, Australia. After obtaining the results for this search term, each reviewer stored the information on an Excel (Microsoft Corp) spreadsheet (Multimedia Appendix 2). The reviewers then compared their results to ensure that they captured all the available apps.

For further evaluation of all the apps identified above, BR and DZ individually reviewed the app title, description, and attached photos and determined whether the app met all inclusion criteria and no exclusion criteria. An identified asthma app was included in the evaluation stage if all the following applied: (1) its primary role was related to asthma, (2) it was targeted to those with asthma, (3) it could be run on mobile phones, and (4) it was in English. Apps were excluded if any of the following

applied: (1) they were not primarily related to asthma, (2) they were primarily targeted toward health care professionals (as stated in the product description), (3) they were not in English, and (4) they were targeted toward pediatric patients. This information was entered into an Excel (Microsoft Corp) spreadsheet for record-keeping (Multimedia Appendix 3). For further evaluation, all apps identified as meeting the above criteria were downloaded by a third reviewer (EP) who identified apps that did not install or function properly after downloading, eliminating them from the review. Finally, the last round of screening was conducted by the reviewer EP. In this round, duplications (ie, apps available on both stores), inaccessible apps, and "lite" version apps, where a pro version was available, were removed from the review. This process was comparable with similar reviews that examined the quality of mobile apps for diabetes self-management [15].

App Evaluation and Data Extraction

Reviewer Training

A day-long training session was conducted before the initial data extraction. This training session was similar to the one performed by Gong et al [15] for their diabetes app review [15]. A step-by-step reference guide was created by the primary researchers to inform reviewers regarding how to complete the various frameworks and checklists involved in the study. This is provided in Multimedia Appendix 4 [3,4,16,17].

App Evaluation and Data Extraction Overview

An internet database was established on Qualtrics (Qualtrics International Inc) for data extraction. A total of 3 reviewers were involved in data collection. A web-based random team generator was used for all apps identified for further evaluation during the screening process so that each app was randomly allocated to 2 assessors (BR, DZ, or EP). The 2 assessors assigned to the app independently reviewed the in-store app description, downloaded the app, and used it for a minimum of 20 minutes to become familiar with all its functions [12]. The reviewers subsequently conducted the evaluations and entered the data into the Qualtrics database. Each reviewer performed this process individually without communicating their results to one another. There are 4 key aspects of the app evaluation and data extraction process, as summarized in the checklist provided in Multimedia Appendix 5 and the step-by-step guide to data collection in Multimedia Appendix 4.

Technical Information About the App

The first step in data collection involved gathering basic technical information about the app. The decision of which technical information to include was based on the MARS checklist and previous app review studies [7,9,15]. This was derived from publicly available information in the in-store app descriptions and in-app information sections. If required, the app developer's website was used. The technical information collected included the app name, date of release, date of update, developer, developer affiliations, price, rating, number of ratings, platform or platforms, size of the app, and number of downloads. A checklist for this section is provided in Multimedia Appendix 5.

App Quality Assessment

The app quality assessment was completed using the MARS tool to objectively determine the quality of the apps selected. This scale has 4 separate domains that are assessed to evaluate mobile app quality. These domains are engagement, functionality, esthetics, and information quality [7]. A total of 19 items, each with a 5-point scale regarding quality in the 4 domains mentioned above, make up the MARS score [7]. This framework is presented in Multimedia Appendix 5. Reviewers completed this tool by entering the information into the Qualtrics (Qualtrics International Inc) checklist for each app. Once this was completed, the mean score for that domain and the overall MARS score were calculated for every app. Following the objective MARS section, there are several subjective questions to evaluate user satisfaction and the perceived impact of the app on the user's knowledge, attitude, motivation to change, likelihood of change, and awareness of the importance of changing their asthma self-management [7]. These questions were answered by reviewers based on their experience using the app and their knowledge gained through the training sessions and clinical practice. Once the data were collected, the mean total MARS value and SD were calculated for each app.

The MARS tool assesses the presence or absence of 19 behavioral change techniques (BCTs). Although 93 types of BCTs are known, only the techniques outlined in MARS were assessed. This approach aligns with previous research, with a scope comparable with our review [7,10,15]. These techniques are outlined in Multimedia Appendix 4. To capture the presence of BCTs, an app was considered to have a BCT present, even if only 1 reviewer identified it. The median number of BCTs and the corresponding IQR of the apps was calculated using Stata (StataCorp) statistical software.

App Functionality

App functionality refers to what the app can do for a user and is an important marker of whether an app offers much benefit to users and the overall quality of the app. Although the MARS framework examines the overall quality of a mobile app, it focuses on the performance, ease of use, gestural design navigation, and navigation of the app [7]. Therefore, the Intercontinental Medical Statistics Institute for Health Informatics (IMS) Functionality Scoring System, henceforth known as the IMS functionality score, was used. This score was developed by the above institute and is based on 7 functionality criteria and 4 subcategories in the *record* functionality criterion. The IMS functionality score focuses on the scope of functions, including the ability of the app to inform, instruct, record, display, guide, remind or alert, and communicate information [18]. Each app was assessed for having or not having these functions and then given a total functionality score between 0 and 11 [18]. To capture the presence of all functionalities, an app was considered to have a functionality present even if one reviewer identified it. The mean, median, and IQR were calculated. The reviewers assessed each app for these functions and entered the data into Qualtrics (Qualtrics International Inc) database. This scoring system is presented in Multimedia Appendix 5.

Presence of App Features Consistent With Asthma Guidelines

As discussed above, key recommendations that could feasibly be incorporated into an asthma mHealth app were identified from the GINA guidelines. These recommendations, summarized in Table 1, were used to develop a more extensive checklist provided in Multimedia Appendix 5. The main functions of the app that we were interested in assessing in our checklist included asthma information, self-management skill training (including peak flow use, inhaler technique, and nonpharmacological strategies), monitoring of asthma symptoms, risk evaluation, and prompting (medication reminders, referring to action plan reminders, and suggestions for seeking health advice). Each of the selected apps was assessed using this checklist, and the data were entered into the Qualtrics (Qualtrics International Inc) database. To ensure consistency, an app was only assessed for the presence of the above function if both reviewers reached a consensus that the said feature was present. For single-reviewed those apps, the sole reviewer's analysis was used to determine whether the app did or did not have the examined feature.

Quality Assurance, Data Management, and Data Analysis

Training was provided to all the researchers, and a handbook for reviewers was provided to ensure the quality of this research. Selected apps were allocated to reviewers using a web-based random allocation software, and 2 different major app databases were searched to reduce selection bias. The apps were independently reviewed by 2 reviewers to reduce the likelihood of bias affecting the results. A protocol was published to reduce publication bias and enhance the transparency of this study [12]. During app evaluation, all data were entered into either an Excel (Microsoft Corp) spreadsheet during the screening process or into the web-based Qualtrics (Qualtrics International Inc) database. These were stored on a cloud-based system that only the researcher team could access. Once the evaluation was completed, all data were downloaded for subsequent analysis. This analysis comprised a descriptive analysis and calculation of the mean and SD or median and IQR.

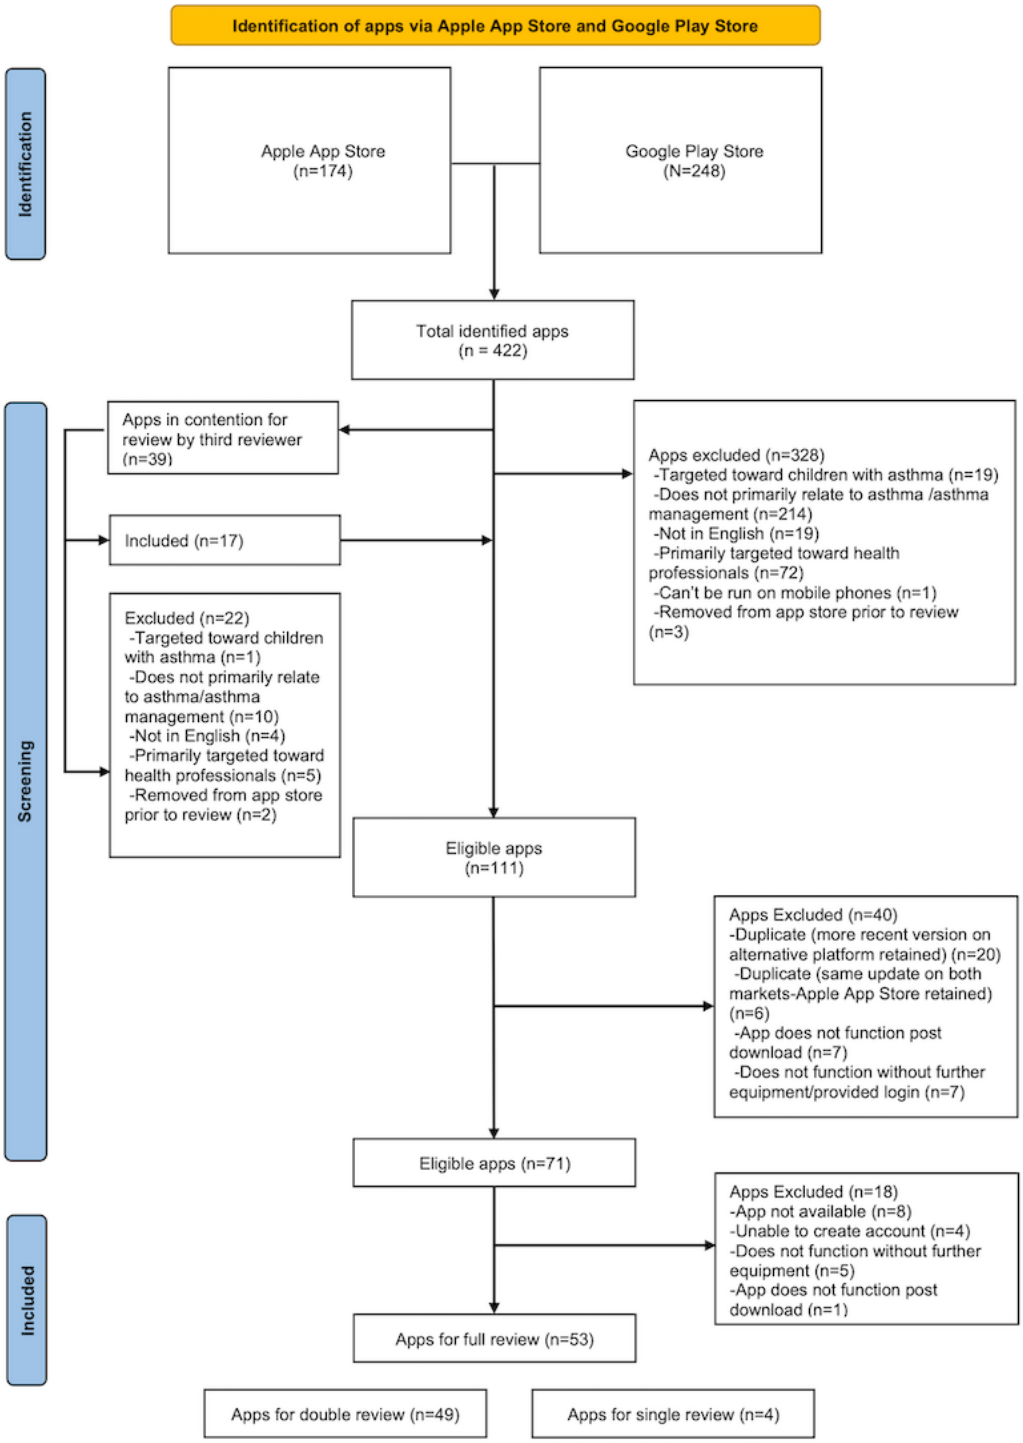
All data analyses were performed using Stata statistical software version 14 (StataCorp). Visual figures were generated using Excel (version 16; Office 365; Microsoft Corp).

Results

Identification, Screening, and Selection of Mobile Apps for Review

The process and results of identifying, screening, and selecting mobile apps are shown in Figure 1. A total of 174 unique apps from the Apple Store and 248 unique apps from the Google Play Store were identified. These 422 apps were assessed by 2 reviewers (BR and DZ). In total, 94 apps met all inclusion criteria and no exclusion criteria, although there was a discrepancy between the reviewers' opinions regarding the eligibility of 39 apps. A third reviewer (EP) identified 17 of these 39 apps as suitable for further review, which resulted in a total of 111 apps suitable for further assessment. A total of 40 apps were removed for reasons outlined in Figure 1. When a more recently updated app was available on 1 platform compared with the other, the older version was excluded from the review. When duplicate apps were available on both platforms and had been updated on the same date, the app from the Apple App Store was retained, whereas the app from the Google Play Store was excluded from the review. This was done to ensure consistency between reviewers and prevent skewing of results by assessing the same app twice. This resulted in 71 apps that were suitable for a complete assessment. Given the delay between the identification of apps and analysis, 18 of the above 71 apps were no longer assessable for the reasons outlined in Figure 1. A total of 4 apps were downloaded by 1 reviewer but not the other before they were removed from the market. This resulted in 49 apps assessed by 2 reviewers and 4 apps assessed by 1 reviewer (53 apps and 102 total reviews).

Figure 1. App screening process and results based on PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.



Technical Information About the App

The technical information for each reviewed app can be found in Multimedia Appendix 2. Of the 53 apps assessed, 29 (55%) were from the Apple App Store, and 24 (45%) were from the Google Play Store. A total of 19 (36%) apps downloaded from the Apple App Store were also available on Google Play Store. As outlined above, apps available on both marketplaces were only downloaded from the Apple App Store and assessed on the iOS platform. The apps' last date of update ranged from February 2016 to April 2022. A total of 26 (49%) apps were updated from January 2020. The mean app size was 46.33 MB, and the median app size was 27 MB (IQR 9.2 MB-47.38 MB). App developers were primarily technical companies (28 apps), health care or pharmaceutical companies (4 apps), or a combination of both (4 apps). Six apps were created by private individuals, 3 were created from research or clinical institutions and the remaining 8 were created from developers from a variety of other backgrounds. The number of app downloads ranged from 10 to >10,000. Of 53 apps, 24 (45%) apps had a published user rating, and the median rating was 4 out of 5 (IQR 2.9-4.9). The number of people who provided a rating ranged from 0 to 523, with a median of 2.5 ratings per app (IQR 1-20). Of 53 apps, 42 (79%) apps were completely free, 5 (9%) apps required

users to pay to download, and 6 (11%) of the above free apps had the in-app ability to upgrade for a cost.

Presence of Behavior Change Techniques

The total number of each BCT identified across the 53 apps assessed is demonstrated in Table 2. The most frequent BCT observed was *self-monitoring or tracking*, which was identified in 38 (72%) of the 53 apps. The next commonly identified BCTs were *information or education*, seen in 33 (62%) apps, and *advice, tips, strategies, or skills training*, seen in 26 (49%) apps. The average number of BCTs in a single app from those reviewed was 3.26 (SD 2.27). The median number of BCTs for the apps reviewed was 3 (IQR 1-4).

Table 2. Assessed behavioral change techniques and the number of apps found to use these techniques (n=53).

Behavioral change technique	Apps with this technique, n (%)
Information or education	33 (62)
Self-monitoring or tracking	38 (72)
Advice or tips or strategies or skills training	26 (49)
Assessment	17 (32)
Feedback	12 (23)
Self-efficacy	9 (17)
Model or demonstrate behavior	3 (6)
Rewards and self-rewards	6 (11)
Goal setting	5 (9)
Provide social support	3 (6)
Perceived risks	1 (2)
Model or demonstrate behavior	3 (6)
Action planning	11 (21)
Motivation	2 (4)
Motivational readiness	2 (4)
Mindfulness or meditation	1 (2)
Perceived benefit	1 (2)

App Quality (MARS)

The mean MARS score for all reviewed apps was 3.05 (SD 0.54)**.** Of the 53 apps, 27 (51%) achieved a total MARS score of ≥3. A score of 3 on the MARS tool correlates to an "acceptable" quality app, <3 is inadequate or poor quality, and >3 represents a good or exceptional app [7]. Functionality was the highest rated MARS category with a mean score of 3.85 (SD 0.52), followed by esthetics with a mean score of 3.21 (SD 0.6). The information category had an average score of 2.78 (SD 0.83), and engagement had a mean score of 2.77 (SD 0.59). Table 3 shows the mean score for each of the 19 items on the MARS tool. Notably, the apps reviewed had higher scores in the gestural design, app description accuracy, and ease of use domains and lower scores in the evidence base, credibility, and entertainment domains. The mean scores for the quality and quantity of information were 3.21 (SD 1.95) and 2.68 (SD 1.63), respectively.

The final component of MARS allows reviewers to complete a subjective assessment of their opinions on the app. For double-reviewed apps, the mean value for the level of agreement for each domain was first calculated. Therefore, the number of apps will not be a whole number. This is summarized in Table 4 and demonstrates that there were few apps that reviewers would recommend to others, use >2 times in a 12-month period, or pay for. Only 8% (n=4) of the apps were rated >3 stars by the reviewers. For >50% of the apps, reviewers either disagreed or strongly disagreed that the app would impact the user's knowledge, attitudes, and intentions to change or change the rate of asthma exacerbations. For <20% of the apps, reviewers either strongly agreed or agreed that the app would improve the user's knowledge, attitudes, awareness, or intention to change behaviors to improve asthma self-management. However, reviewers either strongly agreed or agreed that 29% (n=15) and 27% (n=14) of apps would encourage users to seek further help in asthma management and reduce asthma exacerbations, respectively.

Table 3. Mean score for each category in the Mobile App Rating Scale (MARS) tool for the 53 assessed apps. Each category is assessed on a 5-point scale.

MARS category	Mean score for category
Entertainment	2
Interest	2
Customization	2
Interactivity	2
Target group	3
Performance	3
Ease of use	3
Navigation	3
Gestural design	4
Layout	3
Graphics	3
Visual appeal	2
Accuracy of app description	4
Goals	3
Quality of information	3
Quantity of information	2
Visual information	2
Credibility	1
Evidence base	1

Table 4. Results from the subjective assessment section of the Mobile App Rating Scale framework (n=53).

	Apps, n (%)
Would you recommend this app to people who might benefit from it?	
Not at all, I would not recommend this app to anyone.	12 (23)
There are very few people I would recommend this app to.	18 (35)
Maybe, there are several people whom I would recommend it to.	18 (35)
There are many people I would recommend this app to.	4 (8)
Definitely, I would recommend this app to everyone.	0 (0)
How many times do you think you would use this app in the next 12 months?	
0	4(8)
1-2	28 (52)
3-10	7 (13)
11-50	14 (27)
>50	0 (0)
Would you pay for this app?	
No	34 (64)
Yes	18 (35)
Maybe	1 (2)
What is your overall star rating for the app?	
1 (one of the worst apps I have used)	10 (19)
2	20 (38)
3 (average)	18 (35)
4	3 (6)
5 (one of the best apps I have used)	1 (2)
Strongly disagree or disagree that the app will improve	
Awareness	40 (75)
Knowledge	37 (69)
Attitudes	32 (60)
Intention to change	32 (60)
Help seeking	27 (50)
Behavior change (reduce asthma exacerbations)	29 (54)
Strongly agree or agree that the app will improve	
Awareness	8 (15)
Knowledge	10 (19)
Attitudes	7 (13)
Intention to change	6 (12)
Help seeking	15 (29)
Behavior change (reduce asthma exacerbations)	14 (27)

IMS Functionality Score

Out of a potential 11 functionalities, an average IMS functionality score of 5.1 (SD 2.79) was achieved by the reviewed apps. The median number of functionalities identified was 5 (IQR 2-7). A total of 3 apps had 11 functionalities, although most apps had the ability to capture user-entered data (n=37, 70%), provide information in a variety of formats (n=35, 66%), and provide instructions to the user (n=33, 62%). Out of 53 apps, 7 (13%) apps had the ability to send alerts or propose behavioral interventions based on the collected data. The total number of apps that met these IMS functionality criteria is summarized in Table 5.

Table 5. Total number of apps meeting each of the Intercontinental Medical Statistics Institute for Health Informatics (IMS) functionality criteria (n=53).

IMS functionality	Apps containing this functionality, n (%)
Inform	35 (66)
Instruct	33 (62)
Record	37 (70)
Display	30 (57)
Guide	11 (21)
Remind or alert	27 (51)
Communicate	17 (32)
Collect data	37 (70)
Share data	26 (49)
Evaluate data	12 (23)
Intervene	7 (13)

Presence of App Features Consistent With Asthma Guidelines

Knowledge

Table 6 outlines the results of evaluating the presence of information or knowledge identified as important based on the GINA guidelines. This details the number of apps where reviewer consensus was achieved, the number of apps that provided knowledge or did not provide knowledge in the subcategories, whether knowledge was individualized, and whether knowledge was based on evidence.

Table 6. Number of apps providing knowledge in asthma in the various relevant domains identified as important based on the Global Initiative for Asthma guidelines (n=53).

	Reviewer consensus achieved, n (%)	Apps that provided knowledge in this domain, n (%)	Apps that did not provide knowledge in this domain, n (%)	Apps that provided individualized knowledge, n (%)	Apps that provided evidence-based knowledge, n (%)
General asthma knowledge	45 (85)	10 (22)	35 (78)	0 (0)	7 (16)
Asthma medications	46 (87)	13 (28)	33 (72)	0 (0)	12 (26)
Exacerbation management	44 (83)	14 (32)	30 (68)	0 (0)	12 (27)
Asthma risk factors and triggers	46 (87)	11 (24)	35 (76)	0 (0)	11 (24)

Skill Training

The number of apps that provide skills training in peak flowmeter use, inhaler device use, recognizing and responding to asthma exacerbations, and nonpharmacological management to reduce asthma exacerbations are summarized in Table 7.

Table 7. Number of apps which provide the specific skill training in the areas identified as important in the Global Initiative for Asthma guidelines (n=53).

	Apps with reviewer consensus, n (%)	Apps that provide skill training, n (%)	Apps which provide personalized skill training, n (%)
App provides general skill training in peak flowmeter use	46 (87)	8 (17)	0 (0)
Describes why and when to use peak flowmeter	0 (0)	5 (11)	0 (0)
Describes operational criteria for peak flowmeter	0 (0)	2 (4)	0 (0)
Demonstrates the use of peak flow meter through photos or videos	0 (0)	5 (11)	0 (0)
App provides general skill training in inhaler device use	49 (93)	12 (25)	0 (0)
Describes how to use a spacer	0 (0)	0 (0)	0 (0)
Demonstrates how to use a spacer through videos or photos	0 (0)	0 (0)	0 (0)
Demonstrates how to care for a spacer	0 (0)	0 (0)	0 (0)
Describes how to use common inhaler devices	0 (0)	0 (0)	0 (0)
Demonstrates how to use common inhaler devices through videos or photos	0 (0)	0 (0)	0 (0)
App provides general skill training in recognizing and responding to exacerbations	39 (74)	11 (28)	3 (8)
Encourages patients to monitor for signs of asthma exacerbation	0 (0)	9 (23)	1 (3)
Provide an area for asthma action plan	0 (0)	5 (13)	2 (5)
Specifically guides patients to use their asthma action plan	0 (0)	3 (8)	2 (5)
Provide information on how to use an asthma action plan	0 (0)	7 (18)	1 (3)
Prompts patient to see health care provider when required	0 (0)	7 (18)	0 (0)
App provides general skill training in nonpharmacological management strategies to reduce asthma exacerbations	45 (85)	14 (31)	1 (2)
Helps identify triggers that make symptoms worse	0 (0)	9 (20)	1 (2)
Advises avoidance of environmental smoke exposure	0 (0)	13 (29)	0 (0)
Advises avoidance of medications that can worsen asthma	0 (0)	2 (4)	0 (0)
Advises avoidance of occupation exposures	0 (0)	1 (2)	0 (0)
Advises on the avoidance of allergen exposure	0 (0)	13 (29)	0 (0)
Advises on avoidance of indoor or outdoor pollution	0 (0)	12 (27)	1 (2)
Advises on avoidance of emotional stress	0 (0)	4 (9)	0 (0)
Advises on regular moderate physical activity	0 (0)	6 (13)	1 (2)

App's Ability to Track and Display Health Information

Table 8 demonstrates the results of the assessment of whether apps had the ability to track and display different aspects of a user's key asthma information. All information is only related to apps where reviewer consensus was achieved or those that were reviewed by a single researcher. This demonstrates that most apps did not support tracking of all relevant asthma data, and for those that did, manual data input was the predominant entry method.

Table 8. Number of apps which allowed tracking and displaying of the specified asthma information identified as important from the Global Initiative for Asthma guidelines and by what means this information could be input into the app (n=53).

App's ability to track and display users' asthma information	Apps with reviewer consensus, n (%)	Apps that allow tracking and recording of data, n (%)	Apps with manual data input, n (%)	Apps that allow data entry through external sensors or devices, n (%)	Apps with the ability to create tables or graphs demonstrating trends or analysis of entered data, n (%)
Asthma symptoms	51 (96)	19 (37)	19 (37)	1 (2)	14 (27)
Night waking because of asthma	49 (92)	4 (8)	4 (8)	0 (0)	2 (4)
Activity limitation because of asthma	47 (89)	3 (6)	3 (6)	0 (0)	3 (6)
Peak flow meter values	50 (94)	20 (40)	17 (34)	4 (8)	20 (40)
SABA[a] use	46 (87)	14 (30)	14 (30)	3 (7)	10 (21)
Preventive medication adherence	48 (91)	11 (23)	11 (23)	3 (6)	8 (17)

[a]SABA: short-acting β-agonist.

App's Ability to Provide Prompts or Reminders

Table 9 demonstrates the results of the assessment of whether the apps could provide reminders or prompts on the areas deemed relevant from the review of the GINA guidelines, as outlined in the Methods section. Overall, there were few apps that provided reminders or prompts to users, with only 9 (20%) out of 53 apps providing a reminder to use a person's daily preventive medication. Few apps prompted users to assess the severity and frequency of their asthma symptoms or to seek health advice based on the data they entered.

Table 9. Number of apps that provided reminders and prompts on the specified asthma features chosen based on Global Initiative for Asthma guidelines (n=53).

App provides reminders or prompts on asthma features	Apps with reviewer consensus, n (%)	Apps that provide reminders or prompts, n (%)	Apps where reminders or prompts can be individualized, n (%)
Assessing asthma symptoms for the last month	50 (94)	2 (4)	1 (2)
Appointment with physicians	47 (89)	1 (2)	1 (2)
Performing peak flow test	50 (94)	5 (10)	4 (8)
Preventive medication adherence	45 (85)	9 (20)	8 (18)
Checking the date of expiry and dosage of inhalers	51 (96)	0 (0)	0 (0)
Warning of changing health data (ie, very frequent exacerbations)	53 (100)	0 (0)	0 (0)
Seeking urgent health advice based on the health data the user inputs into the app	52 (98)	2 (4)	2 (4)

Other App Information

Table 10 summarizes the other important features assessed during this review. Only 1 app allowed the user to make an appointment with a physician. Of import, only 5 (10%) of the apps were identified as having an area where users could keep a record of their asthma action plan. Most of these (4 apps) allowed the user to type in their action plan, and 1 app allowed users to upload a photo of their action plan. Only 1 app was identified using recognized asthma screening tools to assess patient's current asthma symptoms and severity.

Table 10. Summary of number of apps containing further features and content identified as important (n=53).

	Reviewer consensus, n (%)	Apps with this feature, n (%)	Apps without this feature, n (%)
Make appointment with physicians	53 (100)	1 (2)	52 (98)
For web-based consultation	0 (0)	0 (0)	53 (100)
For face-to-face consultation	0 (0)	1 (2)	52 (98)
App provides an area for patients to keep record of their asthma action plan	52 (98)	5 (10)	47 (90)
Can type in action plan	0 (0)	4 (8)	48 (92)
Can upload a photo of action plan	0 (0)	1 (2)	51 (98)
The app includes social forums or blogs that promote peer-support and communication among asthma patients	50 (94)	1 (2)	49 (98)
The users could send recorded data to others	44 (83)	11 (25)	33 (75)
To physicians	0 (0)	11 (25)	33 (75)
To each other	0 (0)	9 (21)	33 (75)
The app could help the users to evaluate the risk of having future asthma exacerbations	44 (83)	2 (5)	42 (96)
Using a validated scoring system	0 (0)	0 (0)	44 (100)
Yes, but not using a validated scoring system	0 (0)	2 (5)	42 (96)
The app could guide the users to find out the closest pharmacy, hospital, or clinic	51 (96)	0 (0)	51 (96)
The app uses recognized screening, symptom control and numerical asthma control tools	46 (87)	1 (2)	45 (98)
Yes, all 3	0 (0)	0 (0)	46 (100)
Yes, screening tool	0 (0)	0 (0)	46 (100)
Yes, symptom control tool	0 (0)	0 (0)	46 (100)
Yes, numerical asthma control tools	0 (0)	1 (2)	45 (98)
The app allows users to connect to wearable technology	53 (100)	8 (15)	45 (85)
Smartwatch	0 (0)	0 (0)	53 (100)
Activity sensor (eg, Fitbit)	0 (0)	0 (0)	53 (100)
Smart peak flowmeter	0 (0)	4 (8)	49 (93)
Handheld spirometer	0 (0)	3 (6)	50 (94)
Oximeter	0 (0)	2 (4)	51 (96)
Other	0 (0)	6 (11)	47 (89)

Discussion

Principal Findings

This review aimed to evaluate the quality and functionality of asthma apps and their consistency with international best practice guidelines. We conducted a comprehensive review of 422 asthma apps available on the Australian App Store and Google Play Store, of which we selected 53 apps that met our inclusion and exclusion criteria for detailed analysis. The most common reason for app exclusion was that they were not primarily related to asthma. Most apps were developed by technical companies rather than health care facilities and clinical or research institutes. This lack of involvement of practicing experts in the field of health care is concerning, as these apps are primarily related to the management of chronic health conditions. Apps that involved a clinician during the designing phase demonstrated a greater ability to facilitate behavioral change than those that did not [19]. We believe that in the future, asthma mHealth apps should be developed in consultation with health care professionals and organizations to ensure that they meet an appropriate standard.

Our review revealed that most asthma apps do not use key BCTs that can promote behavioral changes through feedback, goal setting, and rewards. Instead, the most commonly used BCTs were self-monitoring or tracking, education, and advice. This is consistent with other studies and demonstrates a potential area where asthma apps could be improved in the future [19,20]. Functionalities describe what an app can do for its user and are an important marker of whether an app offers much benefit to users. Our review demonstrated that although basic functionalities, such as informing, reading, collecting, instructing, and displaying, were prominent, more complex functionalities were lacking. The ability to evaluate and intervene based on the app information entered is not present

in most apps. Creating apps with this functionality could, for example, guide patients to see their health care provider based on the data they are entering, such as excessive short-acting β-agonist use or asthma symptoms. This feature was demonstrated in the Asthmahub app from NHS Wales, one of the higher-rated apps on assessment.

Our evaluation using the MARS tool showed that the asthma mHealth apps performed poorly in the information and engagement domains compared with the functionality and esthetics categories. These findings are consistent with previous asthma app reviews that showed poorer results in these categories [9]. Only half of the apps achieved an acceptable standard, and even fewer achieved a dual rating average >4, indicating a "good-quality" app. These apps were Kiss myAsthama, Asthmahub, and AioCare Patient. Acceptable or good ratings for subcategories such as app credibility, evidence base, and entertainment were particularly lacking in the apps we assessed. In contrast to this lack of evidence-based content identified through app assessment with the MARS framework, assessment with our checklist found that the knowledge presented in apps was largely based on evidence. "Evidence-based" in the MARS checklist refers to whether an app has undergone a clinical trial. By contrast, in our checklist we refer to "evidence-based" as that the information presented in the app was factual and in alignment with our clinical knowledge of asthma and the GINA guidelines. This explains the contrasting results between the MARS framework and our checklist for "evidence-based" knowledge. Although information was often factual and based on guidelines, the apps had not undergone clinical trials. The subjective star rating provided by reviewers was rarely >3, whereas the mean user rating was 3.56 out of 5, indicating a discrepancy between the perspectives of the reviewers and the user. This discrepancy in user ratings and reviewers' perspectives has been demonstrated in similar app reviews in the past [9]. We propose that this could be because of our health care background bias when assessing the apps, even though we were attempting to assess apps from the perspective of a patient with asthma, or because we were approaching the review with a critical lens following an objective app assessment, a different mindset from the usual user.

Our review demonstrated that asthma mHealth apps do not contain key features consistent with international best practice guidelines for asthma management. Few apps contained important information regarding asthma and asthma management, and even when provided, they were not individualized to the user. Personalization is a key part in the management of asthma, with an individual's triggers, baseline respiratory function, and inhaler device being common things we assess for, educate on, and consider when managing asthma in the community. Furthermore, personalized therapeutic management is a key aspect of asthma management, as outlined in the GINA guidelines [4]. There is also an expectation from previous research that personalized technological interventions may lead to better health outcomes, although this has not yet been specifically demonstrated for asthma mHealth apps [21]. The NHS Wales AsthmaHub app provides one solution to this problem by starting with the creation of a profile in which the user answers questions regarding asthma triggers, control, and medications. This allows the app to provide information targeted toward the user. Skill training in a field can be achieved by apps through written and visual information to teach users how to use peak flow meters, inhalers, and nonpharmacological strategies to manage asthma and asthma exacerbation. These are skills that the GINA guidelines advocate patients to learn and become proficient in, with the support of their health care provider [4]. Training in the use of inhaler devices, spacers, and peak flow meters, all of which in our experience, patients can inadvertently misuse, is lacking in most apps and is something that we feel is key to be included in an asthma mHealth app. Although not essential for all inhaler types, such as dry-powder inhalers, spacers are considered an essential part of using metered-dose inhaler preventer and reliever medications. Therefore, we believe it is reasonable that a high-quality asthma mHealth app should include advice to the users regarding the use of spacers, particularly given the prevalence of salbutamol or albuterol metered-dose inhaler use among those with asthma. No apps could individualize this training to the user, and given the magnitude of devices on the market and the difference in how they work, this represents a deficiency. In total, 40% (n=20) of the apps could record and display peak flow meter values and asthma symptoms. Peak flow is representative of worsening airway obstruction or asthma. If this value is reducing, it can indicate that a person's asthma may be on the precipice of or in the middle of an exacerbation, and as such, it can be a valuable metric for patients and clinicians to monitor. Other key metrics that could be tracked were lacking, such as the amount of short-acting β-agonists and adherence to preventive medications. It is important for these metrics to be recorded, as excessive SABA use can indicate an asthma exacerbation or poorly controlled asthma and should prompt a review by a health care professional. Subtler signs of poor asthma control, such as activity limitation or night waking because of asthma, were rarely recorded and represented missed opportunities. Prompting and reminding users to do something is a basic functionality that is largely underutilized by apps. Chronic asthma management involves remembering to consume daily inhaler medications, assessing symptoms, and regular interactions with a health care provider [4]. All these tasks lend themselves to a reminder from an app to assist with asthma management, and their absence from most apps is a missed opportunity.

Asthma action plans are a key aspect of contemporary patient self-management of asthma [4]. The ability to quickly refer to this plan on a user's digital device should be easy to include; however, most apps lack this feature. We see this as a significant deficiency and missed opportunity. Few apps use validated asthma symptom scoring systems for users to assess their symptoms and risk of exacerbation. Wearable technology and external sensors are a growing medium through which data related to a patient's asthma status can be captured, yet only few apps use this technology. When external sensors are used, they are often smart spirometers (such as in AioCare patient) or peak flow meters, both of which carry extra costs and may not be palatable to all users. No apps were found to be linked to smartwatches or activity sensors, the use of which is becoming more prominent [22]. With the availability of pulse

oximetry in smartwatches, this may be a new method for asthma apps to collect crucial data in the future.

Overall, we determined the quality of apps to be average at best, with many lacking features consistent with international best practice guidelines. Three apps achieved a MARS rating of >4. These were Kissmyasthma, Asthmahub, and AioCare patient. Their alignment of these apps with international best practice guidelines was mixed, with Aiocare patients not having many of the functions deemed important by the guidelines. The Kissmyasthma and Asthmahub apps had great amounts of information related to asthma, consistent with the guidelines. Asthmahub stood alone in having these features and many features to support skill training and track and record information; however, its prompting or reminding functions were minimal. Notably, both these apps that ranked higher in MARS and our checklist were developed by health services or medical research centers (NHS Wales, the University of Sydney, The University of Melbourne, and the Woolcock Institute of Medical Research). All 11 functionalities from the IMS scale were identified in Asthmahub and Aiocare patients, and Kissmyasthma had 6 functionalities, which were above the mean identified. A total of 6 to 8 BCTs were identified in these apps, which, although greater than the median number of BCTs, still did not include several potential BCTs.

Comparison With Previous Work

Prior studies that have conducted these assessments have primarily focused on evaluating the quality and functionality of apps using the MARS framework [9-11]. From a review of the literature for the past 5 years, only 2 prior studies were found to have conducted some sort of assessment of the alignment of apps with asthma self-management principles. Both these studies only looked at free apps, eliminating a number of apps from the review [11,23]. Data collection for both reviews occurred years ago [11,23]. In the rapidly developing marketplace of mobile apps, a number of new apps have been released during this time. Our review examined both free and paid apps, and provided an updated assessment, given that our data collection took place in 2022. Furthermore, Househ et al [23] did not assess apps from the Apple App Store, focusing only on the Google Play Store, and therefore, did not fully assess the breadth of available English-language apps in the marketplace. These authors evaluated whether apps included or did not include information consistent with GINA guidelines as per a checklist created by 1 author [23]. This was limited to asthma information and education and did not include further features, such as the ability of an app to track information, provide asthma skill training, or personalize information. This review also did not examine the overall app quality using the validated MARS framework [23].

Our review benefits from having 2 independent clinicians review the guidelines to establish all GINA self-management recommendations that can be feasibly incorporated into an mHealth app and review app quality using the MARS framework. Furthermore, we examined not only the presence of information, but also the presence or absence of the ability to track asthma symptoms and provide reminders and skill training, as well as all features derived from the GINA guidelines provided in Multimedia Appendix 5. As part of their app review, Tan et al [11] established a framework for assessing the alignment of mHealth apps with the theoretical principles of self-management of allergic rhinitis or asthma [11]. A total of 6 asthma self-management principles were identified based on a literature review and author consensus [11]. Our review has taken this a step further, specifically deriving self-management principles from the international best practice GINA guidelines and creating a more extensive checklist based on these principles. The inclusion of paid apps, the creation of an asthma self-management principle checklist derived from international best practice guidelines, and the up-to-date nature makes our study unique.

Limitations

This study has several limitations. First, we limited it to English-language apps available from 2 app stores in Australia. Although these stores make up a significant portion of the market, other stores do exist, such as the Blackberry store, which were not included in the review. It is also expected that some apps available on the Australian marketplace may not be available on international marketplaces, whereas some apps available internationally may not be available on the Australian marketplace, and thus not included in the review. Although the operating systems for phones used by reviewers were updated on the same day to ensure that the same OS was on each smartphone, the phones themselves were different models. This may have affected the user or reviewer experience to an unknown degree, reducing standardization in this study. A total of 4 apps were reviewed by 1 researcher only as they were removed from the market or were not available to the second reviewer by the time they tried to assess it. This may skew some results, although previous studies have only single-reviewed apps; therefore, the fact that the most apps in this study are double-reviewed is a strength of this research.

Furthermore, we only assessed the presence or absence of those BCTs embedded in the MARS checklist. This limited the number of BCTs that we assessed; however, reviewing the presence or absence of all 93 BCTs was outside the scope of this review and our protocol and requires further research.

This evaluation was researcher-based, and thus does not reflect the real assessment from a patient's perspective. Future research should also include people with asthma to determine their responses to the quality and functionality of these apps.

Conclusions

Currently, there is a lack of high-quality asthma apps aligned with international best practice asthma guidelines. Most apps do not provide patients with important asthma information, skills training in key aspects of asthma management, recording and tracking relevant data, or reminders regarding asthma control. The lack of interaction with smart technology or use of asthma action plans are significant flaws that merit attention in future apps. Few BCTs or in-depth functionalities have been deployed to engage and re-engage with users or generate meaningful behavioral modifications. Again, we see that app designers are typically skilled in providing an esthetically pleasing functional app but lack skills in providing engagement and information, as assessed in the MARS tool. Future app

development should target the key features identified in this study as currently lacking. Furthermore, not only are high-quality asthma mHealth apps lacking, there are minimal robust clinical trials examining the use of these apps and their effect on patient outcomes. Further research in this area will be valuable to determine the true clinical utility of these apps.

A wide spectrum of technological quality, accuracy, and breadth of health information was seen among available apps. Given this spectrum of poor-to high-quality apps in an unregulated market, it is unlikely that future guidelines or health professionals will be able to make generic recommendations to patients regarding asthma mHealth app use and instead will need to make targeted recommendations about specific apps. Guidelines that incorporate reviews such as this review that identify apps known to be of high quality, such as Asthmahub, AioCare patient, and Kissmyasthma, will be an important future resource for general clinicians navigating the ever-expanding mHealth app market for chronic diseases.

Acknowledgments

Funding was received from the Northern Health Respiratory Department (Victoria, Australia) for the costs associated with submitting the protocol and manuscript and purchasing mobile health apps. No funding or sponsorship was received from the mobile app developers or third parties.

Authors' Contributions

BO and KS conceived this study. BR developed the study protocol by adapting a protocol previously created by EG for a diabetes mobile health app review project. KS and BR reviewed the Global Initiative for Asthma guidelines to establish key recommendations that could be feasibly incorporated into a mobile health app. BO and KS provided valuable guidance and advice for this research. BR, DZ, and EP reviewed the apps. BR was the primary author of this manuscript. EG and BR also provided training to all the reviewers of the project. All authors contributed to the refinement of the study protocol and approval of the final manuscript. The Respiratory Research Team at the Northern Hospital assisted in providing general advice to the authors.

Conflicts of Interest

The Northern Health Respiratory Department is providing funding for this study. The head of this department, KS, is a key author of this paper. The department does not have competing or fiduciary interests that could be affected by the results of this study. KS is not responsible for directly reviewing the apps included in the study or for the data analysis.

Abstract

Background: The field of eHealth is growing rapidly and chaotically. Health care professionals need guidance on reviewing and assessing health-related smartphone apps to propose appropriate ones to their patients. However, to date, no framework or evaluation tool fulfills this purpose.

Objective: Before developing a tool to help health care professionals assess and recommend apps to their patients, we aimed to create an overview of published criteria to describe and evaluate health apps.

Methods: We conducted a systematic review to identify existing criteria for eHealth smartphone app evaluation. Relevant databases and trial registers were queried for articles. Articles were included that (1) described tools, guidelines, dimensions, or criteria to evaluate apps, (2) were available in full text, and (3) were written in English, French, German, Italian, Portuguese, or Spanish. We proposed a conceptual framework for app evaluation based on the dimensions reported in the selected articles. This was revised iteratively in discussion rounds with international stakeholders. The conceptual framework was used to synthesize the reported evaluation criteria. The list of criteria was discussed and refined by the research team.

Results: Screening of 1258 articles yielded 128 (10.17%) that met the inclusion criteria. Of these 128 articles, 30 (23.4%) reported the use of self-developed criteria and described their development processes incompletely. Although 43 evaluation instruments were used only once, 6 were used in multiple studies. Most articles (83/128, 64.8%) did not report following theoretical guidelines; those that did noted 37 theoretical frameworks. On the basis of the selected articles, we proposed a conceptual framework to explore 6 app evaluation dimensions: *context*, *stakeholder involvement*, *features and requirements*, *development processes*, *implementation*, and *evaluation*. After standardizing the definitions, we identified 205 distinct criteria. Through consensus, the research team relabeled 12 of these and added 11 more—mainly related to ethical, legal, and social aspects—resulting in 216 evaluation criteria. No criteria had to be moved between dimensions.

Conclusions: This study provides a comprehensive overview of criteria currently used in clinical practice to describe and evaluate apps. This is necessary as no reviewed criteria sets were inclusive, and none included consistent definitions and terminology.

Although the resulting overview is impractical for use in clinical practice in its current form, it confirms the need to craft it into a purpose-built, theory-driven tool. Therefore, in a subsequent step, based on our current criteria set, we plan to construct an app evaluation tool with 2 parts: a short section (including 1-3 questions/dimension) to quickly disqualify clearly unsuitable apps and a longer one to investigate more likely candidates in closer detail. We will use a Delphi consensus-building process and develop a user manual to prepare for this undertaking.

Introduction

Background

eHealth, that is, "the use of information and communication technology for health" [1], can support the delivery of interventions for self-management support and behavior change in patients with acute and chronic illnesses [2,3]. According to the World Health Organization (WHO) [4], self-care health interventions can be classified into individual agency (eg, promoting awareness about self-care), health information seeking (eg, education for informed health decision-making), social and community support (eg, peer mentorship and counseling), personal health tracking (eg, home-based records for health and diagnostic data), self-diagnosis of health conditions (eg, self-testing), self-management of health (eg, self-medication or treatment), individuals' links to their health systems (eg, individuals sharing data with health care professionals [HCPs]), and individuals' financial outlays for health (eg, expenses for prescription medicines). However, a recent evaluation of self-care interventions delivered via eHealth apps noted that only 20% of the 100 included apps used evidence-based information, whereas experienced HCPs considered only 32% to be useful and deemed 52% to be misleading and 11% to be dangerous [5].

Searching for a common characteristic linking the most effective apps, several systematic reviews and meta-analyses have found that those developed on firm theoretical foundations are more likely to be effective [6,7]. However, a systematic review of health-promoting smartphone apps found that only 55.6% of the included 27 studies described a theoretical basis for their smartphone app development [8]. A 2018 review found that only 8 (1.2%) of 681 smartphone apps to support medication adherence had documented evidence of their effectiveness. Such evidence is health care systems' main consideration regarding certification and reimbursement [9]. Furthermore, although a user-centered design (sometimes also called human-centered design) and the involvement of patients and HCPs in the development of smartphone apps is known to provide insights into end users' needs and helps ensure both relevant, reliable content and high quality [9,10], only 84 (12.3%) of the apps in this review had been developed in collaboration with HCPs. None reported patient involvement in their development processes [9].

Owing to the increasing availability of eHealth smartphone apps, it is vitally important and increasingly challenging for HCPs to identify, evaluate, and recommend relevant, trustworthy, and high-quality eHealth smartphone apps [11-14]. One tempting way for HCPs to form a first idea of an eHealth smartphone app's quality is the star ratings and written reviews it receives on an app store [15]. However, this information is often subjective and distorted by individuals, comes from unverified or fraudulent sources, or provides no insights on an eHealth app's quality [15-18]. HCPs also face a lack of reliable guidance on evaluating eHealth smartphone apps' applicability to clinical practice [13,19,20]. Therefore, many are now struggling to describe and evaluate eHealth smartphone apps. A guideline regarding their characteristics and quality using standardized methods that will allow HCPs to propose reliable apps to their patients is needed [21,22].

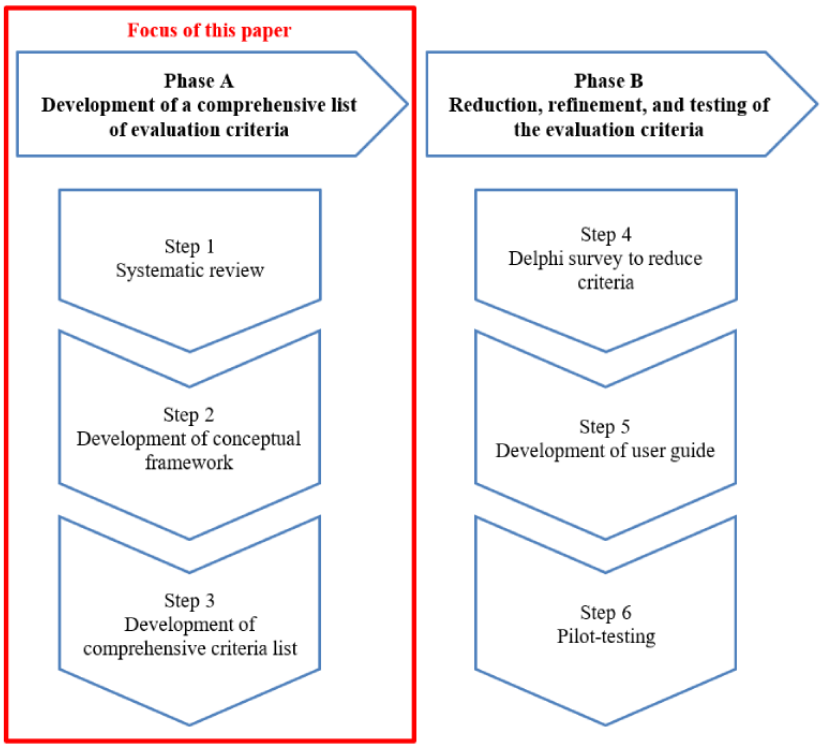
Previous efforts to evaluate apps have generally focused on guidance for researchers [23-25]. Although the criteria were often overly complex or tailored to specific health areas, they also tended to be incomplete. Their underlying theories, scientific rationales, and development processes have rarely been described [20,25-27]. Furthermore, their unsuitable foci, nontransparent development processes, complexity, and often excessive time demands make them a poor fit for clinical practice. Finally, the existing instruments used a variety of criteria that only partially overlapped [20,23-27]. A clear description and evaluation of an app is important as, in rapidly evolving fields, even small changes or improvements to an app can have significant impacts on its use and usefulness [28]. To date, evaluation tools to help clinicians describe and evaluate eHealth apps, allowing them to recommend high-quality apps to their patients and share their thoughts using common terminology, are lacking [29,30].

Objectives

Therefore, the aim of this study was to obtain an overview of the evaluation criteria used in the literature. This process was conducted in three steps: (1) conducting a systematic review to identify existing criteria for evaluating eHealth apps, (2) developing a conceptual framework for the evaluation of eHealth smartphone apps, and (3) developing a comprehensive list of criteria for describing and evaluating eHealth smartphone apps. This was the foundational phase 1 of an overarching project to develop and pilot-test a theory-based tool to help HCPs evaluate the characteristics and quality of eHealth smartphone apps in a practical and standardized way (Figure 1). Phase 2 will involve

narrowing down, refining, and testing the evaluation criteria via 3 further steps: conducting a Delphi survey to narrow down the criteria (step 4), developing a user guide for the processes of description and evaluation (step 5), and pilot-testing the user guide and processes with HCPs (step 6). This paper focuses on reporting on the foundational phase 1 and outlining the proposed steps for phase 2.

Figure 1. Overview of the 2 phases and steps in the development of the eHealth smartphone app evaluation tool (the focus of this paper is framed on the left side).



Methods

Design

We used a 3-step descriptive, iterative, and developmental approach in phase 1. We first conducted a systematic review, then iteratively developed a new conceptual framework, and finished by compiling a comprehensive list of criteria for the evaluation of eHealth apps. The methodology for each of these steps is described in detail in the following sections. As this study did not deal with human participants or identifiable data, no ethics approval was needed.

Step 1: Systematic Review

To identify existing criteria for evaluating eHealth apps, we conducted a systematic review complying with the *Cochrane Handbook for Systematic Reviews of Interventions* [31]. The manuscript was written following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [32].

Protocol and Registration

Our review was registered in PROSPERO (CRD42021227064 [33]). No other protocol has been published.

Eligibility Criteria

Our systematic review included studies on any health condition fulfilling the following inclusion criteria: all had to be primary studies or reviews (1) explicitly describing tools, guidelines, dimensions, instruments, criteria or items, or development processes for tools to evaluate eHealth smartphone apps; (2) clearly describing the evaluation of interventions delivered via eHealth smartphone apps according to predefined (self-developed or existing) criteria; (3) having full-text versions available; and (4) being available in English, French, German, Italian, Portuguese, or Spanish. We incorporated criteria encompassing a broad spectrum of health care areas, including health promotion, prevention, and both physical and mental health. Recognizing the interconnected nature of physical and mental health and the diverse purposes and user groups for which eHealth is used, we integrated a wide array of objectives and stakeholders into our evaluation. Although these areas may exhibit distinct characteristics, it is conceivable that there are fundamental criteria that could be consistently applied in evaluating eHealth apps across different domains. These fundamental criteria may encompass aspects such as user-friendliness, data security, privacy, and usability, forming a shared foundation for evaluation to ensure that essential quality aspects are addressed. In summary, our systematic review encompasses these comprehensive topics to provide a thorough evaluation of eHealth quality criteria, which are applicable to diverse health care needs. Our aim was to encourage consistency and standardization in the evaluation process. Articles were excluded if they (1) described criteria to evaluate interventions delivered via eHealth websites and videos, among other media, but not smartphone apps; and (2) were study protocols, conference abstracts, editorials, or letters to the editor.

Information Sources

We queried the MEDLINE (OvidSP), CENTRAL (via Cochrane), CINAHL (EBSCOhost), and Web of Science databases. Supplementary searches were conducted on trial registries (ClinicalTrials.gov and WHO trial registry) and the reference lists of the included papers. The search was conducted on December 5, 2022. No time restrictions were imposed.

Search Strategy

We developed our MEDLINE search string based on the terms used in articles on (partially) similar topics [34-41] combined with key Medical Subject Heading and free-text terms (see the search strategy in Multimedia Appendix 1). For the other databases, we adapted the search string accordingly. We combined thematic blocks with various keywords related to *eHealth*, *smartphone*, *application*, *evaluation*, and *tool*. No filters were applied.

Selection Process

All identified titles and abstracts were independently screened for relevance by 2 reviewers (JR and TH). The full texts were assessed by the same reviewers using the criteria described previously. The reasons for full-text exclusion were reported. In one case of disagreement, an independent third researcher (SDG) contributed to help reach a consensus.

Data Collection Process and Data Items

In total, 2 reviewers (JR and TH) independently extracted the data and cross-checked their results. We extracted information on the author, year, country, research question or study aim, design, operating system, population or specific condition, main intended intervention purpose, name of the tool, and framework or theoretical guidance. The intended purpose of each eHealth app–delivered intervention was categorized according to the WHO classification for self-care health interventions [4]: individual agency, health information seeking, social and community support, personal health tracking, self-diagnosis of health conditions, self-management of health, individuals' links to their health systems, and individuals' financial outlays for health. Specific eHealth app quality evaluation dimensions or criteria were extracted and tabulated in a separate table.

Study Assessment

The included studies were assessed using the Appraisal of Guidelines for Research and Evaluation–II (AGREE-II) instrument [42], which is widely used to evaluate guideline development processes. As many of the included studies did not a priori intend to develop an evaluation guideline, this instrument might not have been the best option for all studies. However, as we were mainly interested in the justification and development of the dimensions or criteria used in the studies, this instrument provided us with the best support for evaluating these aspects. The AGREE-II instrument consists of 23 items classified into 6 domains (3 items on scope and purpose; 3 on stakeholder involvement; 8 on rigor of development; 3 on clarity of presentation; 4 on applicability; and 2 on editorial independence, ie, whether funding body and competing interests were reported). We concluded our AGREE-II assessment by rating the degree to which each included study described each domain. For this, we used a 4-descriptor scale: *accurately* (all AGREE-II items fulfilled), *partially* (two-thirds of all AGREE-II items fulfilled), *hardly* (one-third of all AGREE-II items fulfilled), and *not at all* (0 AGREE-II items fulfilled).

Step 2: Development of a Conceptual Framework

The original dimensions of the frameworks reported in the selected articles were listed in a table. Similar descriptions of dimensions were merged. The first draft of the proposed conceptual framework and graphical representations was reviewed and discussed with various stakeholders (researchers, clinicians, designers, and software developers with backgrounds in nursing, medicine, ethics, and informatics). During these discussions, the participants recommended that we distinguish between technical dimensions (eg, design, usability, security, safety, and privacy) and those that focused on content (eg, evidence base and scientific evaluation). It was also recommended that the dimensions be presented as a linear, step-by-step process. During these meetings, the first author (JR) took notes and recorded the proposed changes until consensus was reached on the next version.

The second draft of the framework was discussed with 18 international volunteers (patient representatives, researchers, clinicians, and technology developers) from diverse backgrounds in health care (eg, psychology, nursing, and pharmacy) who were participating in a public webinar on quality evaluation of eHealth technology. As it was a public webinar, only limited data on participant demographics were collected (Table S1 in Multimedia Appendix 2). A survey via AhaSlides (AhaSlides Pte Ltd) to rate the importance and clarity of the dimensions and subgroups (1=not important; 5=very important) and open-ended questions to add missing dimensions or subgroups were used to engage with the participants. In addition, the participants were engaged to add comments orally that the first author (JR) put in writing. The quantitative data were analyzed descriptively (eg, frequency and mean), whereas the qualitative data were analyzed using the mind-mapping technique. The participants found the *technology* dimension too large (ie, covering too many subtopics) and partially unclear. Therefore, it was recommended to split this dimension into technological concerns (eg, technical requirements, security, safety, and privacy) and functional requirements (eg, the user-centeredness and usability of the design). In addition, they understood eHealth evaluation as a cyclical process and recommended presenting the conceptual framework as a continuous circuit as opposed to the initially linear process recommended previously.

Their feedback was used to draft a third version of the framework, which was presented and discussed with 34 researchers, clinicians, and technology developers (Table S2 in Multimedia Appendix 2; only 1 person overlaps with the volunteers from the webinar) mainly with a background in pharmacy who participated in the Next Chapter in Patient Care Conference in April 2022 in Pärnu, Estonia. This time, a survey via Mentimeter (Mentimeter AB) was used to rate the importance and clarity of the dimensions and subgroups (1=not important; 5=very important), and open-ended questions were used to add missing dimensions or subgroups. In addition, the participants were engaged to add comments orally while the

first author (JR) took notes. Quantitative data were analyzed descriptively, whereas qualitative data were analyzed using the mind-mapping technique. The Next Chapter in Patient Care participants recommended highlighting the overarching nature of the ethical, legal, and social aspects, which must be considered in all eHealth smartphone app evaluation dimensions. This resulted in a fourth version reflecting the general character of relevant ethical, legal, and social considerations.

Subsequent rounds of discussion and feedback with the research team focused on the scope and relationships between the dimensions. The participants highlighted the legal, ethical, and social aspects to be treated as part of the context. In addition, they agreed that stakeholder involvement should be seen as another overarching aspect that is important in all dimensions of eHealth app evaluation. This discussion resulted in the final version of our new conceptual framework for evaluating eHealth apps: the eHealth Smartphone App Evaluation (eHAPPI) framework.

Step 3: Development of a Comprehensive Criteria List

The eHAPPI framework was then used to synthesize all the eHealth smartphone app evaluation criteria identified in the selected studies. The redundant criteria were combined. The classification of the criteria according to the eHAPPI dimensions and suggestions for changes and regarding additional or irrelevant criteria were discussed and refined by the research team according to consensus.

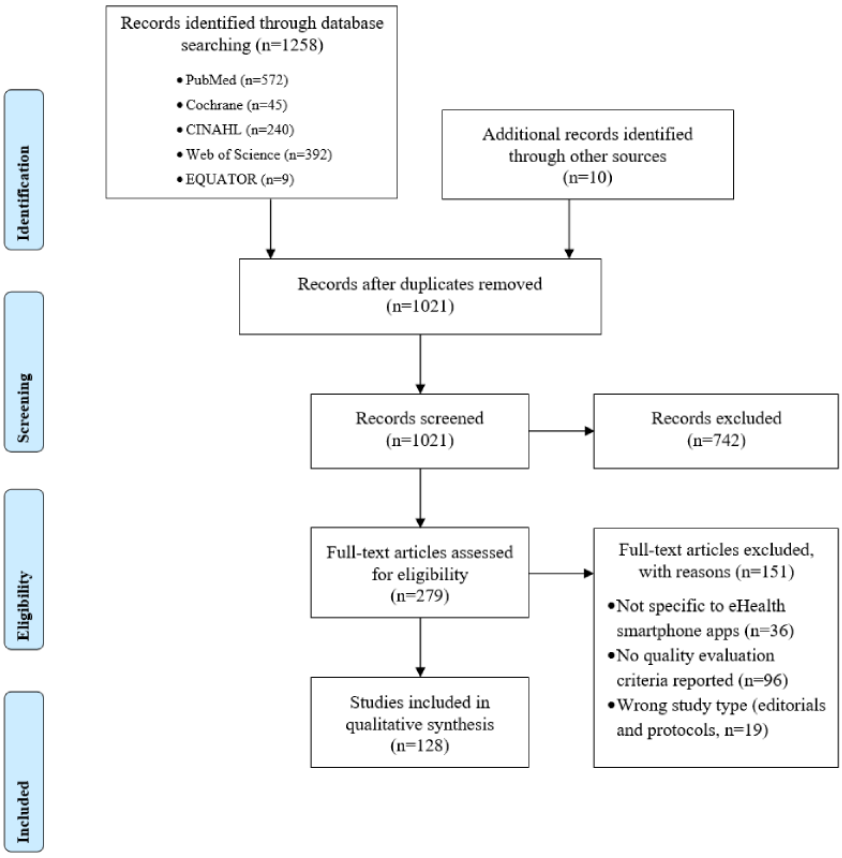
Results

Step 1: Systematic Review

Study Selection

The results of our study selection process are presented in the PRISMA flow diagram (Figure 2). The search strategy described previously yielded 1021 nonduplicate titles. After screening of the titles and abstracts as well as full-text assessment for eligibility, our final analysis included 128 articles that met all the inclusion criteria (Multimedia Appendix 3 [43]).

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Study Characteristics

General Description

A detailed description of the characteristics of the included studies can be found in Multimedia Appendix 4. The years of publication ranged from 2013 to 2022. All but 1.6% (2/128) of the articles were written in English—1 was in French [44] and the other in Spanish [45]. Four-fifths of the studies (101/128, 78.9%) were conducted in Western Europe, North America, or Australia. The studies used a variety of designs, mainly cross-sectional reviews of existing apps (42/128, 32.8%); reports on various app development and evaluation approaches (29/128, 22.7%); quantitative, qualitative cross-sectional, or longitudinal user testing of a single app (27/128, 21.1%); or different forms of reviews (15/128, 11.7%). The 128 included studies involved apps covering 30 topics, such as mental health, health promotion, or support for specific physical conditions (eg, heart disease and diabetes). However, only 50.8% (65/128) of the studies provided enough detail to categorize them according to

the WHO classification for self-care interventions for health and well-being [4].

Evaluation Tools

In total, the included studies used 142 distinct tools to evaluate eHealth apps. Although 76.6% (98/128) of the included studies used a single evaluation tool, 23.4% (30/128) used multiple tools and scales. Almost one-quarter of the studies (30/128, 23.4%) used an evaluation tool with investigator-developed criteria and then provided only scantily described development processes or theoretical backgrounds for those criteria. The most frequently used tool was the Mobile App Rating Scale (33/128, 25.8%) followed by its adapted versions (8/128, 6.3%) and the System Usability Scale (22/128, 17.2%). Less frequently used tools were the Post-Study System Usability Questionnaire (2/128, 1.6%), the Questionnaire for User Interaction Satisfaction (2/128, 1.6%), and the quality of experience survey (2/128, 1.6%). A total of 43 other tools were used in only 0.8% (1/128) of the studies each. In total, 10.2% (13/128) of the studies used qualitative methods (eg, interviews and focus groups) to generate the app evaluation criteria. In some cases (4/128, 3.1%), the origin of the criteria was unclear, or similar names were used for different tools.

Theoretical Frameworks

Most studies (83/128, 64.8%) did not clearly report a theoretical underpinning. The 32% (41/128) that did used 59 different frameworks, including various non–eHealth-specific behavioral, social, or implementation theories (10/59, 17%), the technology acceptance model (7/59, 12%), heuristic evaluation (5/59, 8%), models of the International Organization for Standardization (3/59, 5%), the (extended) Unified Theory of Acceptance and Use of Technology (3/59, 5%), or user-centered design (2/59, 3%). In total, 29 frameworks were used in only 2% (1/59) of the studies each. Of the 59 frameworks used in the included studies, 16 (27%) guided the development and 43 (73%) guided the evaluation of eHealth smartphone apps. In 1.6% (2/128) of the studies, different frameworks were used for development and evaluation.

Study Assessment

On average, the studies described 8.6 (SD 2.4; range 3-15) of the AGREE-II instrument's 23 items [42]. Few studies described the scientific or theoretical basis and development processes of the app evaluation criteria that they applied. The most completely described or justified domains were related to *scope and purpose* (116/128, 90.6% described it accurately; 11/128, 8.6% described it partially; and 1/128, 0.8% hardly described it), *editorial independence* (91/128, 71.1% described it accurately; 30/128, 23.4% described it partially; and 7/128, 5.5% did not describe it at all), and *stakeholder involvement* (13/128, 10.2% described it accurately; 42/128, 32.8% described it partially; 70/128, 54.7% hardly described it; and 3/128, 2.3% did not describe it at all). The least fulfilled domains were *applicability* (1/128, 0.8% described it accurately; 2/128, 1.6% described it partially; 22/128, 17.2% hardly described it; and 103/128, 80.5% did not describe it at all), *rigor of development* (13/128, 10.2% described it partially; 53/128, 41.4% hardly described it; and 62/128, 48.4% did not describe it at all), and *clarity of presentation* (14/128, 10.9% described it accurately; 32/128, 25% described it partially; 52/128, 40.6% hardly described it; and 30/128, 23.4% did not describe it at all).

Step 2: Development of a Conceptual Framework

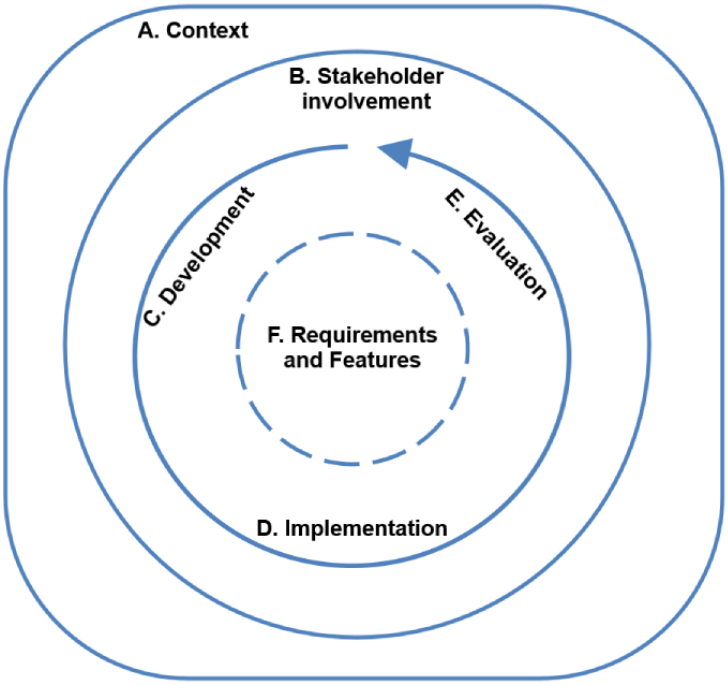
The full list of frameworks and original eHealth evaluation dimensions identified in the selected studies can be found in Multimedia Appendix 5 [43,45-47]. Some dimensions were included in only a few frameworks, and no framework included all possible dimensions.

The condensed dimensions were presented graphically and refined iteratively with the stakeholders until consensus was reached and no further adaptions were needed. The final eHAPPI conceptual framework (Figure 3) consists of six interrelated dimensions: (1) *context*, (2) *stakeholder involvement*, (3) *development processes*, (4) *implementation*, (5) *evaluation*, and (6) *features and requirements*.

A detailed definition of each dimension, including the subgroups, is presented in Textbox 1. *Context* describes a set of unique factors and conditions in which the app will be implemented [48]. This is an overarching dimension that depends on and, in turn, influences the other domains. *Stakeholder involvement* is essential in all aspects of eHealth. It involves the active engagement of relevant partners in all processes of the app life cycle, from conceptualization to sustainable implementation (eg, with end users, HCPs, researchers, and health insurers) [49,50].

Several subgroups were defined to further outline and structure the framework: *basic information* (concerning the app) and *ethical, legal, and social aspects* were seen as relevant subgroups of the *context* dimension. The *featuresandrequirements* dimension was assigned 4 subgroups: *evidence-based content*; *functionality*; *usability*, *privacy*, *and security*; and *performance.* Similarly, the *development process* dimension was divided into *cocreation/user-centered design* and *characteristics of the development team*, and *adoption (integration into daily life)* and *maintenance* were seen as relevant subgroups of the *implementation* dimension. Finally, the *evaluation* dimension included only 1 subgroup: *scientific evaluation*.

Figure 3. The final eHealth Smartphone App Evaluation framework.



Textbox 1. Overview of framework dimensions, subgroups, and definitions.

Context

- *Context* describes the set of unique factors and conditions in which the app is implemented. During the implementation process, the app, implementation, and context interact, influencing, modifying, facilitating, or hindering one another. As an overarching concept, context encompasses a physical location and roles, relationships, and interactions at various levels (ethical, legal, social, geographical, epidemiological, and political) [48,51].
- *Basic information* describes general information concerning the app (eg, name, URL, or available languages).
- *Ethical, legal, and social aspects* describe activities to help evaluators consider ethical, legislative, and social implications of an app's development and implementation. These aspects cannot be completely separated from each other as they overlap somewhat [28].

  Ethics describes activities to understand and explore *the moral life*, wherein *morality* includes beliefs, norms of behaviors, principles, and rules that guide individual and institutional behavior. Morality is a widely shared set of norms that result from a certain social consensus. Ethical aspects include the prevailing moral norms and values during the development and implementation of apps. Although moral values are influenced by cultural, sociopolitical, religious, and economic differences, many ethical reflections are shared by all countries and societies. Regarding apps, important ethical topics include *benefit-harm balance*, *autonomy, respect for persons*, and *justice and equity and legislation* (when using the app, ethical challenges may arise that were not considered in existing legislation and regulations) [28].

  Legal aspects include rules and regulations that must be considered when developing and implementing apps. Rules and regulations are designed to protect the rights and interests of the patients and other members of society (eg, legislation on patients' rights; data protection laws; or the regulations, rights, and obligations of health care professionals [HCPs] in general). Important legal topics are, for example, *autonomy of the patient* (eg, legal requirements), *privacy of the patient* (eg, no use of "unnecessary" patient information), *equality in health care*, *ethical aspects* (eg, impact on achievement of human rights), *authorization and safety* (eg, laws and rules regarding safety), *ownership and liability*, and *regulation of the market* [28].

  Social aspects describe human-centered activities that approach end users and their social networks as reference points in an app's development and implementation. These include groups of patients or individuals who might require special consideration (eg, vulnerable populations, people living in remote communities, people with learning difficulties, older people, ethnic minority individuals, and immigrants). Patients', individuals', and relatives' perspectives should be considered when developing and implementing apps. Some social groups may be important for a particular app (eg, ethnic minority individuals and individuals with disabilities), which should be specified. Important social topics include *patients' perspectives* (eg, expectations and wishes), *social group aspects* (accessibility), and *communication aspects* (eg, explanation of treatment choices) [28]

Stakeholder involvement

- *Stakeholder involvement* describes the active engagement of relevant partners in all processes of the smartphone app life cycle, from conceptualization to sustainable implementation (eg, end users, HCPs, researchers, and health insurers [49,50].

  Note: for end-user involvement in the development process, see the *Cocreation/user-centered design* section under the *Development process* subheading in this textbox).

Development process

- *Development process* describes all activities performed regarding the app's creation, such as activities related to its aim, target population, guiding principles, applied approaches, stakeholder contributions, required changes for subgroups, or continuing uncertainties [52-54].
- Cocreation of technologies or user-centered design: *cocreation* describes a stepwise process in which partners (eg, patients, caregivers, and HCPs) are actively involved in the strategic design and planning of the app's development and implementation at every stage of the process [55].

  User-centered design is a multidisciplinary design approach using cyclic iteration and evaluation. As it actively involves users to improve the developers' understanding of their requirements and wishes, this approach is seen as essential regarding product benefits and usability [56].
- *Characteristics of the development team* describes information about the multidisciplinary group responsible for the creation of the working, validated app. Important characteristics of the development team include the name of the app provider (developer and manufacturer of technology and content), contact details, organization attributes, and funding, as well as any conflicts of interest [57].

Evaluation

- *Evaluation* describes the assessment of the app's efficacy, effectiveness, cost-effectiveness, safety, implementation, and impact [58].
- *Scientific evaluation* is the systematic assessment of the app's efficacy, cost-effectiveness, safety, implementation, and impact through observation, measurement, and experimentation in a scientific study. Such an evaluation is essential to reliably measure an app's effects and outcomes as a basis for decision-making [58-60].

Implementation

- *Implementation* describes the uptake and sustainable integration of evidence-based innovations such as apps into routine use [61].
- *Adoption* (ie, integration into daily life) deals with the app's uptake (ie, activities focused on using the app in everyday life). This includes the user's reaction to the app with respect to desired activities and interactions, such as downloads, clicks, and data entries. User engagement, that is, the user's investment in learning about and participating in the app (eg, time and memory load), is an important prerequisite for the app's long-term integration into daily life [62-64].

- *Maintenance* covers activities that ensure that an app is sustained in an acceptable and safe condition to perform its specified functions. Maintenance also includes repair as a stand-alone action to restore deteriorated or damaged parts. The activities needed to ensure the required performance of the app during its lifetime include updates, performance evaluations, and the planning and execution of necessary repairs [65].

Features and requirements

- *Features and requirements* describe the app and the characteristics or attributes it must provide to meet the users' needs (ie, its *information content*, *functionality*, *usability*, *security*, *privacy*, and *performance*). The indications, performance features, and app options may differ for different generations or versions of an app. Important *features and requirements* topics include app description, claimed benefits, care level of use, reference values, or cutoff points used [28, 66]. A clear description of the app is important as, in rapidly evolving fields, even small changes or improvements to an app can have large impacts on its use and benefits. The description should enable those who are not familiar with the app to understand what it does, how it works, and how it can be used..
- *Evidence-based content* describes information, subject matter, and data content made available by the app based on the best available scientific knowledge and clinical expertise [67].
- *Functionality* describes the properties or functional requirements that affect the app's use (ie, its *features*, *components*, and *usefulness*). In the context of self-monitoring, there are specific requirements related to design issues, particularly those concerning wearable technologies, as well as requirements regarding the behavioral aspects that are part of the design. These requirements need to be considered when evaluating a product or system for self-monitoring. The *functionality* information is intended to summarize the app's overall suitability for use in a particular situation [38,68,69].
- *Usability*, *privacy*, and *security* are nonfunctional requirements (ie, they deal with how the system should operate in terms of usability, security, privacy, design, modularity, modifiability, reliability, availability, portability, and operability).

  Usability describes the extent to which an app can be used by its target users to achieve its intended goals *effectively*, *efficiently*, and *satisfactorily*. Ideally, an app should be *easy to use*, *easy to learn*, and *easy to understand* [70].

  Privacy describes the protection of and control over personal data during the app's processing operations [71].

  Security describes the provision of safeguards that serve the security of the individual or community. For example, this helps prevent or avoid poverty, hardship, theft, or espionage. Security is a major component of a stable, relatively predictable environment in which people can pursue their goals without interference, harm, or the fear of them. This includes protecting the app and associated data from events that could cause loss or severe damage, such as fire, burglary, theft, or vandalism [72,73].
- *Performance* describes whether an app works quickly and without errors and does not cause problems. Important performance topics include reliability and scalability (ie, whether an app still works properly when the number of users increases [74,75]).

Step 3: Development of a Comprehensive Criteria List

In total, 205 criteria for describing and evaluating eHealth smartphone apps were reported in the selected articles. None of the articles included all the possible criteria. The use of terminology differed within the publications or was attributed different meanings. For example, several were named *usability* but referred to different aspects of that criterion, such as *ease of use*, *usefulness*, or *speed*. Others, such as *research-backed*, *scientific references*, *information accuracy*, and *information quality*, were named differently but clearly referred to a single criterion—in this case, *evidence-based information*.

Using the new eHAPPI framework, it is clear that most studies reported criteria that focused on usability, evidence-based content, functionality, or scientific evaluation. However, only 1 reported criterion dealt with context, and only 5 dealt with development processes.

The research team's discussions emphasized that some criteria are objective (eg, *average rating in the app store* and *purpose of the app*). In contrast, others are more subjective (eg, *matching the needs of the target population* and *intention to use*). In addition, several were dependent on the tested app's purpose or content (eg, *whether an app community exists* and *features to support behavior change*).

The research team agreed on how all the criteria were classified into dimensions and how most were formulated. However, to improve understanding or align with known formulations, they suggested revisions to the wording of 12 criteria [28]. On the basis of the research team's recommendations (Multimedia Appendix 6 [25,45-47,76-85]), 11 new criteria were added (Multimedia Appendix 7 [28]). These additions were mainly to the *ethical, legal, and social aspects* section. No criteria were deemed completely irrelevant, so none were removed. Finally, the research team agreed to classify these added criteria into the existing dimensions.

The final list contained 216 criteria for describing and evaluating eHealth smartphone apps (Multimedia Appendix 8). Although this list was comprehensive, our discussions highlighted that it was not practical for use by HCPs in clinical practice. The research team agreed that, in the next phase, a short version with only 1 to 3 items per dimension would be useful to make a quick initial decision (ie, acting as an algorithm to gauge whether an app should be given further consideration). Only if an app passed this pretest would it undergo a more thorough evaluation using detailed criteria and offering nuanced results. In addition, the research team recommended a specific algorithm with thresholds that could be adjusted depending on each tested app's purpose and context.

The research team recommended that the next step for the project's second phase be a Delphi process to condense the list and develop the proposed decision support tool. This process will have two aims: (1) to provide a means to reach a consensus and (2) to develop a useful and feasible (ie, practical for use in

clinical practice) tool to describe and evaluate eHealth smartphone apps.

Moreover, participants expressed concerns that the necessary information to complete the tool may be difficult to find. Therefore, the development of a user guide for HCPs on how to apply the tool and where to typically find the required information was also proposed for the next phase. Finally, the eHealth smartphone app evaluation tool and user guide will need to be pilot-tested with HCPs.

Discussion

Principal Findings

Although the eHealth field is rapidly expanding and evolving, there is no consensus on how the quality of eHealth apps should be defined and evaluated by HCPs [13,19,20,86]. In this paper, we described how we developed a comprehensive list of criteria to evaluate eHealth apps. We used a meticulous methodological approach to derive the list, consisting of a systematic literature review and iterative rounds with stakeholders from various backgrounds to compose a comprehensive framework—the eHAPPI—and use it to synthesize all the criteria identified in the selected studies. We found 6 overarching dimensions (ie, *context*, *stakeholder involvement*, *features and requirements*, *development processes*, *implementation*, and *evaluation*) of eHealth app evaluation and 205 criteria in the literature. A research team discussion resulted in 11 additional criteria, bringing the new total to 216. Using this comprehensive list, HCPs would be able to evaluate eHealth apps designed for diverse health care needs. No original studies included all the dimensions or all the criteria. Most of the selected studies (83/128, 64.8%) did not describe an underlying framework or theoretical guidance or how their criteria were developed. In addition, a general lack of common terminology among the included studies further complicated efforts toward comparison and direct application in clinical practice.

Although the proposed complete list of criteria was comprehensive, applicable to diverse health care needs, and applied consistent terminology, its length and depth limited the feasibility of using it in clinical practice. As a stand-alone reference, this list would be better suited for comprehensive evaluations of a broad range of eHealth apps by a regulatory body. Therefore, we proposed a 2-step approach to developing these criteria for use by HCPs. The first step would be defining a few critical initial decision criteria. A more detailed description and assessment would be useful only for positive evaluations using these first criteria. Using such an algorithm would allow the most obviously inferior apps to be quickly excluded from the process.

However, our progress in this direction was slowed by a lack of consensus regarding which criteria were essential and which would simply be nice to have [23]. As a compromise, we agreed that developing the proposed algorithm would require more expertise than we had and further expert discussion. Therefore, for the second phase of this project, we proposed a Delphi process [87] to guide the further development and fine-tuning of the final evaluation tool.

Although we did not reach a consensus on which criteria qualify as essential, our group discussions provided insights into which qualities to consider in describing and evaluating apps as well as how an optimal tool might be structured. For example, given the dynamic and rapidly evolving use of apps in clinical practice [29,88], flexibility is a significant concern [23,25]. Therefore, the research team recommended an algorithm not only whose cutoff criteria can be modified to fit each evaluated app's purpose and context but also whose overall functionalities can evolve alongside the surrounding technology [89].

Another point of discussion concerned the difficulty we encountered in finding the information to complete this evaluation tool. HCPs who are less familiar with eHealth apps may have difficulty gathering even basic data, such as the name of an app's developer or its latest update [13,21,22]. More technologically savvy individuals may have trouble finding information on that app's scientific basis, how or whether its development processes included stakeholder involvement, or which strategies were used in its implementation. Therefore, we suggest that the proposed tool include a user guide describing why such criteria are important and where to find and how to judge the required information. This echoes a recommendation by the European Network to Advance Best Practices and Technology on Medication Adherence in their Cooperation in Science and Technology Action (CA19132), which facilitates the use of a web-based repository of information on medication adherence technology [90,91]. Although eHealth app developers clearly need to provide relevant details in a clear and easily accessible way, health educators also need to include eHealth evaluation in HCP education and training curricula.

The previous discussion provides the foundation for conducting phase 2 of this study. This phase has three goals: (1) to conduct a Delphi survey to narrow down the number of criteria and develop an algorithm for initial decision-making, (2) to develop a user guide, and (3) to pilot-test the resulting iteration.

Limitations

This study has several limitations. Most notably, at this point in the project, although our list of eHealth app description and evaluation criteria is comprehensive, it remains a preliminary version. That is, despite discussions with various interdisciplinary experts, phase 1 did not produce an in-depth consensus on the essential criteria for a richly detailed but broadly feasible means of evaluating eHealth apps. This drove the decision to design a 2-phase project. In phase 2, which will be a Delphi study [87], we aim to develop a criteria-sorting algorithm. With this in place, the phase will culminate in a version of an eHealth app evaluation tool for pilot-testing.

In addition, all the included studies were assessed using the AGREE-II instrument [42], which was specifically designed to assess clinical practice guideline development reports. Considering the high level of heterogeneity across many of the study characteristics, direct comparability using a single tool was limited. However, although other instruments would have been more suitable in many cases, using various instruments would have yielded equally varied results. As we were primarily interested in the rationales and development processes that

supported the dimensions and criteria, the AGREE-II scales provided a consistent assessment of these aspects.

Finally, the participants in the discussion rounds for the development of the conceptual framework were primarily health care researchers and professionals. There were very few technology developers or industry representatives present, and only 2 patient representatives participated. This may have resulted in a limited consideration of the patient perspective and an increased risk of interventions exacerbating existing health care inequalities [92]. Therefore, we included in the *context* dimension of the eHAPPI framework subgroups focusing on ethical and social aspects. These subgroups aim to underscore the necessity of addressing the risk of intervention-generated inequalities.

Comparison With Prior Work

Although 23 of the existing tools were explicitly intended for HCPs [14,43,46,47,76-86,93-100], none of these were complete; rather, they were too focused on specific conditions, or their theoretical justifications or development processes were not described. Such omissions make it difficult for HCPs in clinical practice to comprehensively but feasibly describe and evaluate eHealth apps in a standardized way to guide the recommendation of relevant, reliable, and high-quality apps to their patients [11,13,14]. Other studies supplemented the dimensions and criteria for describing and evaluating apps. However, it remains unclear which criteria are essential and how detailed they need to be. Recently, there has been much discussion about how to define and evaluate eHealth quality and what criteria are needed for an app to be used in the health care system [23,89,101]. Future findings from the planned phase 2 will likely provide a basis for further discussion on this topic among app developers or providers, HCPs, patients, researchers, and policy makers. Our first comprehensive list of criteria as a result of phase 1 provides an excellent basis for the next steps in phase 2 to develop a new eHealth app evaluation tool.

The need for a tool to describe and evaluate eHealth apps and help HCPs and their patients navigate the digital health ecosystem is pressing [23]. Our path to a proposed resolution has been quite complex as this field is also complex. After listing the criteria identified via a literature review, we developed them through expert discussions, revealing important improvement areas. In particular, compared with recommendations from the Health Technology Assessment Core Model [28], the criteria concerning the ethical, legal, and social aspects of eHealth apps were deemed incomplete. Therefore, in addition to adapting many criteria, we added several.

Contribution of This Study

This study focuses on addressing the rapidly growing and somewhat chaotic field of eHealth, particularly the challenges faced by HCPs when it comes to evaluating and recommending health-related smartphone apps to their patients. This study's contribution lies in its comprehensive methodology for gathering and categorizing existing criteria for evaluating health apps, which is essential as no single framework or evaluation tool effectively serves this purpose. The methodology involved a systematic review of the literature, which resulted in the identification of 216 distinct evaluation criteria organized within a conceptual framework comprising 6 app evaluation dimensions. These dimensions encompass various aspects, including the app's context, stakeholder involvement in its development, features, development processes, implementation, and evaluation. This study highlights the need for a more purpose-built, theory-driven tool to help HCPs assess and recommend apps effectively and outlines plans to create a 2-part app evaluation tool based on the gathered criteria, which will expedite the process of disqualifying unsuitable apps and scrutinizing potential candidates more closely. This study serves as a crucial foundational step toward developing a practical tool that can guide HCPs in evaluating and recommending health-related apps.

Conclusions

Developing a tool comprehensive enough for HCPs to reliably describe and evaluate the full range of eHealth apps yet short enough to be feasible for daily clinical practice is a daunting challenge. After our literature review yielded a list of criteria too bulky for routine use, there was a lack of consensus either on terminology or on relevance to define and evaluate app quality. In this report of phase 1, we provided our initial comprehensive overview of 216 relevant criteria used in the selected studies to describe, evaluate, and recommend eHealth apps. To condense this list to a more manageable size, in phase 2, we will formulate and apply a robust consensus-building process to generate a list of criteria ranked by importance, followed by the creation of an algorithm to produce short- and long-form evaluations to match the characteristics of the apps to be evaluated. In addition, the development of a user guide and pilot-testing of the tool are planned. As a basis for informed guidance and decision-making, such a tool will help HCPs reliably describe and evaluate eHealth apps for their patients.

Acknowledgments

This work was conducted mainly by a PhD student as part of her PhD project funded by the University of Basel. The funders had no role in the study design; collection, analysis, and interpretation of the data; writing of the report; or decision to submit the paper for publication. The authors thank all the participants in the various discussion rounds for their reflections and input for the development of the conceptual framework and criteria. Special thanks also go to the participants of the Research Round Table Meeting seminar for their critical feedback in developing the study methods and manuscript, as well as to Chris Shultis for his language editing.

Authors' Contributions

The study was conceptualized by JR, SDG, and ADD. The literature search strategy was developed by JR, SDG, and FD. Articles were located, identified, and evaluated by JR and TH. Data were extracted and checked by these same authors. The initial dimension and criteria list was composed and discussed by all the authors. The manuscript was drafted and edited by JR with close revision and feedback from SDG as well as review and feedback from all other coauthors.

Abstract

Background: Against the backdrop of globalization, China remains one of the most heavily burdened countries in Asia with regard to AIDS. However, many high-risk groups and patients affected by AIDS may be less likely to actively seek care from medical institutions because of fear of experiencing shame or discrimination. Mobile apps provide a promising avenue for supporting the prevention, diagnosis, and treatment of AIDS. However, a comprehensive systematic evaluation of these mobile apps' functionality and quality has not been conducted yet.

Objective: This study aims to identify the available mobile apps for AIDS in China, assess and discuss the functional features and quality of these Chinese AIDS mobile apps, and offer decision support for patients and clinical practitioners in accessing high-quality AIDS mobile apps. Furthermore, based on the evaluation results, recommendations for improvement will be provided.

Methods: A systematic search was conducted on the Qimai app data platform, the Aladdin WeChat applet data platform, and WeChat to identify mobile apps related to AIDS. A snowball sampling method was used to supplement the potentially overlooked apps. The selected mobile apps underwent a rigorous screening process based on unified criteria. Subsequently, assessments were independently undertaken by 3 separate researchers and 2 patients with HIV, using both the Mobile App Rating Scale (MARS) and the User Mobile App Rating Scale (uMARS). Quantitative interpretations of the data were facilitated by the MedCalc statistical software (version 20.217, MedCalc Software).

Results: A total of 2901 AIDS mobile apps were included in the study, with 2897 identified through information retrieval and an additional 4 added via snowball sampling. After a rigorous selection process, 21 apps were determined to be usable. Among them, the Hong Feng Wan app achieved the highest combined average score, calculated based on the MARS (3.96, SD 0.33) and uMARS (4.47, SD 0.26). Overall, there was no significant correlation between MARS and uMARS ($r_{\text{app quality total score}}$=0.41; P=.07; $r_{\text{subjective quality}}$=0.39; P=.08). A notable issue was the widespread lack of user privacy protection, with only 24% (5/21) of the apps offering this feature.

Conclusions: The number of available Chinese AIDS mobile apps is limited, with WeChat applets dominating the market. Nonetheless, the performance of WeChat mini-apps is generally inferior to that of independent apps, and there may be significant discrepancies between assessments conducted by researchers and those provided by genuine end users, emphasizing the necessity of involving real users in the development and evaluation of HIV mobile apps. In addition, developers of these Chinese HIV mobile apps need to devote attention to improving privacy protection mechanisms, in addition to considering the evaluations of researchers and real users. This will help attract more users and increase user loyalty.

(JMIR Mhealth Uhealth 2024;12:e52573) doi:10.2196/52573

HIV; mobile app; evaluation; mobile phone

Introduction

Background

AIDS is a chronic infectious disease caused by HIV infection, resulting in high mortality rates. Since the first reported case of AIDS, it has rapidly spread worldwide, becoming a major public health concern. China, influenced by globalization, is no exception. According to the 2021 National Notifiable Infectious Diseases Summary released by the Chinese Center for Disease Control and Prevention, AIDS has the highest mortality rate and death toll, with 19,623 reported deaths. Available data indicate that as of 2022, the number of confirmed AIDS cases in China has exceeded 1.05 million and is projected to surpass 1.6 million infections by 2023. AIDS remains a significant infectious disease affecting public health and socioeconomic development in China [1].

For individuals who are at a high risk of HIV infection but have not yet been infected, pre-exposure prophylaxis (PrEP) is a highly effective method of preventing HIV through daily medication. However, the current use of and adherence to PrEP remain low. However, mobile apps have shown effectiveness in promoting PrEP use and adherence among high-risk populations [2]. Muessig et al [3] highlighted the advantages of internet and mobile-based interventions, which facilitate wider dissemination of PrEP at a lower cost compared with conventional methods. The MyChoices app developed by Biello KB demonstrated feasibility and potential in improving HIV PrEP use rates among gay and bisexual men in the United States [4]. The prevalence of HIV infections remains disproportionately high among gay, bisexual, and other men who have sex with men (GBMSM) [5]. With the widespread use and convenience of smartphones, sexual networking apps have replaced traditional dating websites as the primary online social platform for GBMSM. As such, apps have become crucial venues for sexual health research [6]. Targeted video and text-based sexually transmitted infection and HIV information provided through mobile apps has proven effective in reducing new infection rates among GBMSM [5].

For people living with HIV, the highly active antiretroviral therapy developed by scientist David Ho represents the most effective treatment method. Highly active antiretroviral therapy can suppress HIV replication and prevent the emergence of drug-resistant viruses. However, strict adherence is required, necessitating patients to adhere to prescribed medication schedules [7]. Despite simplified treatment regimens, adherence remains challenging for some people living with HIV [8]. Evidence suggests that HIV case management can improve treatment adherence and quality of life and reduce risky sexual behavior [9,10]. However, case managers face significant workloads and limited policy and funding support [11,12]. Mobile health (mHealth) apps have demonstrated potential in assisting people living with HIV with effective self-management and delivering personalized interventions. Schnall et al [13,14] identified ideal features for an HIV app, including reminders, health information delivery, medication logs, communication, settings, and search functions. However, comprehensive apps meeting these criteria are scarce in the current market, and there is a lack of rigorously evaluated mHealth apps specifically designed for people living with HIV [13,14]. Yang et al [15] found that most Chinese GBMSM apps, selected based on relaxed inclusion criteria, primarily focused on dating and lacked HIV prevention and health information.

For both high-risk populations and individuals infected with HIV, HIV testing plays a vital role in combating HIV. Early HIV testing allows individuals to learn about their infection status promptly, facilitating timely access to antiretroviral therapy and significantly reducing mortality rates. However, fear of shame or discrimination may discourage many high-risk populations and patients from actively seeking care at health care facilities [16-19]. With the increasing prevalence of mobile phones, various mHealth interventions have been developed to diversify HIV self-testing (HIVST) approaches, including telephone hotlines, SMS text messaging–based interventions, and internet-based interventions. These interventions have shown potential in improving testing rates, particularly among hard-to-reach populations [20-26]. Although these platforms have achieved varying levels of success, the use of mobile apps has emerged as a highly popular trend because of their flexibility and scalability. For instance, the mLab app serves to enhance users' understanding of their HIV test results while facilitating their access to pertinent HIV information and services [27]. Another noteworthy app is Aspect HIVST, which offers an acceptable means of uploading mobile HIVST results and demographic information to a centralized database [28]. In addition, ApiDé serves as a multilingual electronic tool (app) that assists health care providers in offering and explaining HIV screening to immigrants facing language barriers [29].

In conclusion, the use of mobile apps is becoming increasingly prevalent in HIV/AIDS prevention and control. These apps provide a convenient and accessible means for high-risk individuals and patients to access information, consultations, and support related to HIV/AIDS. They serve as effective adjunct measures in improving antiretroviral therapy adherence and reducing AIDS incidence rates, thereby mitigating the currently imbalanced resource allocation between patients and health care providers involved in antiviral treatment. However, research on Chinese AIDS mobile medical apps is relatively scarce and late, and empirical studies evaluating the effectiveness of HIV mobile medical apps remain sparse. Therefore, the effectiveness of Chinese HIV mobile apps in meeting user needs requires further assessment. To evaluate the efficacy of AIDS mobile apps in China, the Mobile App Rating Scale (MARS) and the User Mobile App Rating Scale (uMARS) scales, which are widely accepted and applied for uses such as assessing chronic disease management [30], COVID-19 tracking [31], psychiatric interventions [32], physical exercise among older people [33], and menstrual monitoring [34], were incorporated into this study as standardized assessment tools for the quality of mobile apps.

Objectives

This study aims to achieve the following objectives:

1. To identify a comprehensive list of available Chinese mobile apps for HIV/AIDS.

2. To evaluate the functional features and quality of Chinese HIV/AIDS mobile apps from 2 distinct standpoints: those of researchers and those of individuals diagnosed with HIV, and to provide decision support for AIDS-related groups and health care professionals in accessing high-quality AIDS mobile apps.
3. To conduct a thorough analysis of the evaluation results and to provide improvement recommendations based on the findings, with the ultimate goal of enhancing the quality of Chinese HIV/AIDS mobile apps.

Methods

Search Strategy

Considering the use status of Chinese AIDS apps, a systematic search was conducted on the Qimai app data platform, Aladdin WeChat applet data platform, and WeChat from February 18 to 19, 2023, adhering to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. The specific search strategies are as follows.

Data Collection of Apps

The Qimai platform, a well-known domestic mobile app data analytics platform, was used to retrieve AIDS-related apps. Qimai provides comprehensive data on iOS and Android app markets (including Huawei, Baidu, Xiaomi, Vivo, etc), along with app store optimization and app store search marketing optimization service tools and SearchAds data reports. It also offers professional data analysis and optimization strategies. The platform features an intelligent keyword expansion and association tool, which proved valuable for obtaining the required data for this study. In this research, the Qimai Keyword Expansion Assistant was used to search for AIDS-related terms. We selected keywords with a relevance score exceeding 50% and a search index surpassing 4605 (typically indicating a higher search frequency) to identify relevant apps that met the criteria. The search was conducted on February 18, 2023.

WeChat Applet Data Collection

WeChat applets, launched in China in 2017, are app programs developed on the WeChat platform. These applets offer users the convenience of accessing and using various functionalities and services directly within the WeChat app without requiring any separate downloads or installations. Known for their lightweight, fast, and user-friendly nature, they have gained popularity. To collect WeChat applet data, searches were performed on both the Aladdin Index and WeChat. The Aladdin Index, developed by Beijing Aladdin Future Technology Co, Ltd, serves as a ranking platform for the WeChat applet, providing a comprehensive reference for applet developers' operations nationwide. For this study, keywords such as *HIV*, *AIDS*, *Human Immunodeficiency Virus*, *Acquired Immunodeficiency Syndrome*, as well as their corresponding Chinese keywords with similar meanings, such as *huo-de-xing-mian-yi-que-xian-zong-he-zheng*,*ai-zi*, *ai-zi-bing*, and *ai-si-bing*, were used to search for the WeChat applet related to AIDS in both the Aladdin applet list and WeChat. The search was conducted on February 19, 2023.

Supplementary Method

In collaboration with the HIV prevention and control team at the local Centers for Disease Control and Prevention (CDC), a snowball sampling method was used to distribute electronic questionnaires to individuals living with AIDS during their follow-up visits conducted by the CDC staff. The questionnaires (without personal information and providing adequate privacy protection) aimed to inquire about the HIV/AIDS apps they had used. Participants were encouraged to provide feedback using the Wenjuanxing platform and to share the electronic questionnaire with other individuals living with AIDS they knew. This supplementary method aimed to identify AIDS-related apps that were widely used within the AIDS community but were not captured by the aforementioned search strategies. The feedback collection period was extended from February 20 to May 19.

The exclusion criteria for apps were as follows: (1) nonsimplified Chinese language, (2) games, (3) apps with excessively limited functionality, (4) mobile apps that did not primarily focus on HIV or AIDS-related content, (5) >50% of the content is inaccessible, (6) apps that had terminated their services, (7) apps restricted to internal use by specific personnel (apps had to be accessible and functional for evaluation purposes), and (8) apps predominantly intended for advertising and product sales.

Evaluation Tool

In this study, we selected the MARS and uMARS scales as the evaluation tools for assessing the quality of the apps. These scales were chosen for 2 main reasons. First, these scales have been extensively validated and have demonstrated good reliability and validity across different contexts. Second, in our study, the included apps were a mix of independent apps and WeChat applets, with the majority being WeChat applets rather than independent apps. However, the MARS and uMARS scales offer broader applicability in this regard.

Developed by Zelmer et al [35], the MARS scale provides a standardized set of criteria for evaluating mobile apps in terms of engagement, functionality, esthetics, and information quality. The MARS scale has been widely used in user research, mobile app evaluations, and related fields. Previous studies have indicated that the MARS scale demonstrates good validity and reliability, making it a reliable measurement tool [30-34]. The uMARS scale, developed by Manning et al [36], serves as an extension of the original MARS scale, specifically designed to prioritize the assessments of average users toward mobile apps.

Evaluation Process

The evaluation was conducted by 3 researchers. Rater 1 (PL) holds a master's degree in medical informatics and has extensive experience in medical information analysis. Rater 2 (Bin Li) holds a master's degree in computer science and has abundant software development experience. Rater 3 (FW), an esteemed scholar in medical informatics in China, possesses a master's degree in computer science and a PhD in social medicine. Being an expert in app quality evaluation, rater 3 boasts rich experience and high authority in research on assessing mobile app quality. Both rater 1 and rater 2 were recruited as real patients with HIV.

The evaluations by the researchers and patients with HIV were conducted separately to avoid any interference. Each group followed a 3-step evaluation process. First, basic information for 21 apps, including their names, developers, platforms, and core functionalities, was collected from the SevenMa platform, Aladdin WeChat platform, and WeChat. Second, 2 WeChat applets and 2 independent apps were randomly selected for pilot evaluation. Before conducting the pilot evaluation, all 3 raters watched training videos on the MARS scale to better understand the purpose and significance of each item on the scale. Third, the 21 collected apps underwent a formal evaluation. To ensure consistent evaluation results, rater 1 and rater 2 independently assessed the same samples, completing the evaluation of the nth subdimension for all samples before moving on to evaluate the n+1th dimension. In cases where rater 1 and rater 2 had conflicting evaluations, we applied the Delphi method, which involved multiple rounds of consultation and feedback with experts, to achieve agreement regarding the discrepancies. Rater 3, an expert with relevant qualifications, reassessed the dimension that exhibited disagreement. The evaluation results from rater 3 were then shared with rater 1 and rater 2, along with appropriate explanations. This gave rater 1 and rater 2 the opportunity to revise their ratings and evaluations. If substantial differences persisted even after re-evaluation, the entire process was repeated until their evaluations converged or reached a satisfactory level of agreement.

Statistical Analysis

All analyses were performed using MedCalc software (version 20.217, MedCalc Software). Descriptive scores were derived from the MARS and uMARS scales. To evaluate the reliability of the raters' assessments, Bland-Altman analysis was used to assess both interrater agreement and the range of variability in their scores. Visual representations were also used to visualize the differences in ratings between the 2 evaluators, providing a more concrete quantification of the discrepancies.

Ethical Considerations

This study focused solely on mobile apps and did not involve the collection of any personal information or data. Therefore, there were no ethical concerns or disputes associated with this research.

Results

Overview

A total of 21 apps that met the criteria were obtained through screening, with 18 being WeChat applets, dominating in terms of quantity, whereas only 3 were independent apps (Figure 1). Representative AIDS mobile apps were also displayed, as detailed in Figure 2. The characteristics of these apps are shown in Tables 1 and 2.

The developers of these apps can be categorized into 3 groups: companies (6/21, 29%), government organizations (7/21, 33%), and nonprofit social organizations (8/21, 38%). In addition, of the 21 included apps, 18 (86%) provided HIV/AIDS knowledge dissemination, 12 (57%) offered appointment booking for testing, 11 (52%) had counseling services, 8 (38%) had features related to PrEP and postexposure prophylaxis (PEP), 2 (10%) had community networking functionalities, and only 1 (5%) had live streaming capabilities. Of the 21 apps included in the study, 16 (76%) were able to update their content within a year, whereas 5 (24%) had not been updated for >1 year. Only 6 apps had privacy protection features, all of which provided privacy policies or agreements, with 2 of the apps offering privacy password functionality.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of the selection process for inclusion of the apps.

Functionality of the App

Most mobile apps (18/21, 86%) provided HIV/AIDS knowledge dissemination, and 71% (15/21) of the apps offered appointment booking for testing. Nearly half of the apps (10/21, 48%) provided counseling services, whereas 38% (8/21) of the apps offered features related to PrEP or PEP. Only 10% (2/21) of the apps had functionalities for live streaming and web-based community.

In addition to these functions related to function evaluation, we also included additional statistics on privacy protection settings. Among the 21 apps included in the study, only 6 (29%) provided privacy protection settings and 2 (10%) designed privacy passwords.

Quality of the App

Overview of App Composite Scores

The composite scores for the app quality total score in MARS and uMARS were obtained by averaging the scores for each app. The overall composite score for the 21 included apps was 3.43 ($mean_{app\ quality\ total\ score\ of\ MARS}$=3.47, SD 0.37; $mean_{app\ quality\ total\ score\ of\ uMARS}$=3.38, SD 0.53). Hong Feng Wan achieved the highest composite score, with a score of 4.22 ($mean_{app\ quality\ total\ score\ of\ MARS}$=3.96; $mean_{app\ quality\ total\ score\ of\ uMARS}$=4.47), followed by Wu Ai Fang Hua with a composite score of 3.9 ($mean_{app\ quality\ total\ score\ of\ MARS}$=4.06; $mean_{app\ quality\ total\ score\ of\ uMARS}$=3.74), and Chabei secured the third rank with a composite score of 3.76 ($mean_{app\ quality\ total\ score\ of\ MARS}$=3.66; $mean_{app\ quality\ total\ score\ of\ uMARS}$=3.86). Suzhou Red Ribbon obtained the lowest composite score, with a score of 2.68 ($mean_{app\ quality\ total\ score\ of\ MARS}$=3.67; $mean_{app\ quality\ total\ score\ of\ uMARS}$=1.68).

Comparative Analysis of MARS Score and uMARS Score

Figure 3 presents a correlation analysis between the scores of MARS and uMARS. No significant relationship was observed between the app total quality scores of MARS and uMARS (0.41; *P*=.07) or between their subjective quality scores (0.39; *P*=.08). The app most reflective of the disparity between MARS and uMARS is Suzhou Red Ribbon, which had the greatest discrepancy between its app total quality scores on MARS (3.67) and uMARS (1.68). Its score on uMARS (1.68) was the lowest in the ranking, with respective dimensional scores of engagement (1.8), functionality (1.5), esthetics (1.67), information (1.75), and subjective quality (1). Conversely, for MARS, it ranked seventh for the app quality total score, with respective dimensional scores of engagement (2.9), functionality (4.38), esthetics (3.5), information (3.92), and subjective quality (2.5). There was considerable variation disclosed in the rankings of the most highly rated apps between MARS and uMARS. The top 5 app total quality scores on MARS were Wu Ai Fang Hua (4.06), Hong Feng Wan (3.96), Ai Yi Jian (3.95), Qing Ai Health Services (3.77), and Ai Zhiku (3.76), whereas the top 5 on uMARS were Hong Feng Wan (4.47), Chabei (3.86), Wu Ai Fang Hua (3.74), Linqu County CDC (3.66), and Zhecheng County AIDS consulting and test (3.62).

Interpreting composite data from Figures 4 and 5 and Table 3 reveal that within the 4 MARS scale dimensions of the evaluated 21 apps, the functionality dimension achieved the highest score (4.28, SD 0.39).

The information (mean 3.82, SD 0.33), aesthetics (mean 3.4, SD 0.49), and engagement (mean 2.4, SD 0.53) dimensions sequentially trailed behind. In contrast, under the uMARS scale's evaluation, the information dimension prevailed with the top score (mean 3.89, SD 0.74), followed by the functionality (mean 3.84, SD 0.59), aesthetics (mean 3.21, SD 0.48), and engagement (mean 2.56, SD 0.63) dimensions.

Comparative Analysis of Quality Between WeChat Mini-Apps and Independent Apps

As shown in Table 4, insignificant disparities are discernible between WeChat mini-apps and stand-alone apps regarding 2 metric domains: app quality (P_{MARS}=.70; P_{uMARS}=.54) and subjective app quality (P_{MARS}=.48; P_{uMARS}=.80).

Table 4. Independent samples *t* test for unequal variances.

MARS[a] quality	MARS, mean (SD)	uMARS[b], mean (SD)	MARS, *t* value (*df*)	uMARS, *t* value (*df*)	MARS, *P* value	uMARS, *P* value
App quality	__[c]	—	−0.448 (2.4)	0.73 (2.3)	.70	.54
WeChat applets	3.45 (0.37)	3.33 (0.50)	—	—	—	—
Independent apps	3.58 (0.47)	3.66 (0.76)	—	—	—	—

[c]Not available.

Internal Consistency and Reliability Testing for MARS and uMARS Scores

Similarly, we formed 4 Bland-Altman plots using the disparities and mean values between the scorings by reviewers on app quality (both MARS and uMARS) and app subjective quality (MARS and uMARS). The relatively limited range of the 95% limits of agreements suggest that the evaluators' judgment outputs contain minor dissimilarities. A significant proportion of dots in all 4 Bland-Altman plots lie within the concordance interval (Figures 6-9), with their arithmetic means impressionably approaching 0 (Table 5).

This provides evidence of the high degree of internal uniformity and dependability in both MARS and uMARS scores.

Figure 6. Bland-Altman plot of the app quality (Mobile App Rating Scale).

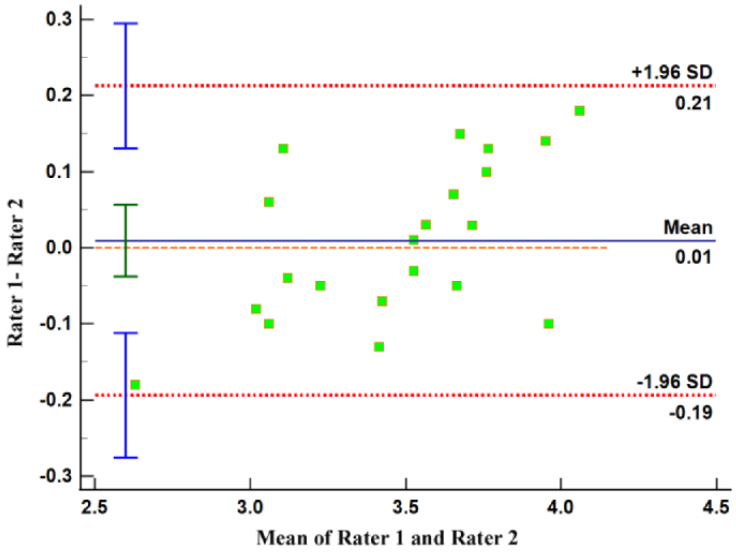

Figure 7. Bland-Altman plot of the app subjective quality (Mobile App Rating Scale).

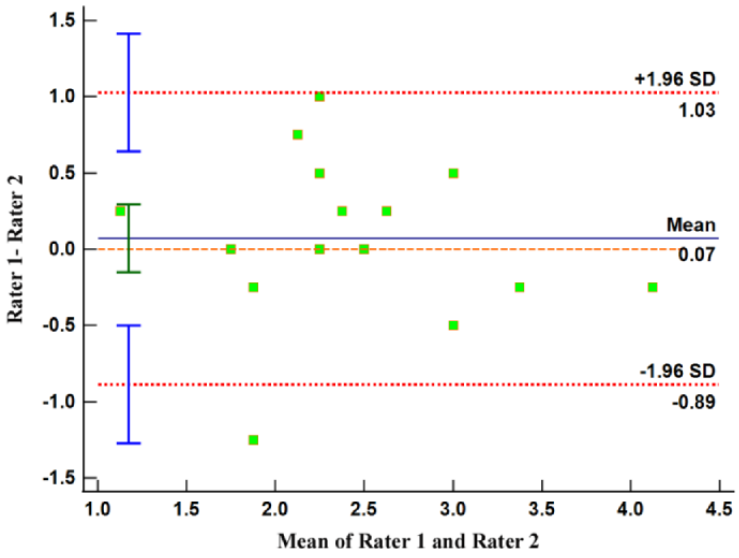

Figure 8. Bland-Altman plot of the app quality (User Mobile App Rating Scale).

[c]uMARS: User Mobile App Rating Scale.

Discussion

Principal Findings

This study provides a comprehensive statistical summary of the functionalities and characteristics of 21 Chinese HIV-related mobile apps, along with their quality assessment using the MARS scale. The primary objectives behind the development of these mobile apps were the dissemination of HIV prevention knowledge (18/21, 86%), appointment booking for testing (15/21, 71%), and counseling services (10/21, 48%). These mobile apps aim to assist users in HIV prevention and treatment while improving the quality of communication and interaction between patients and health care providers.

Overview of App Functions

In recent years, the Chinese government has implemented a series of regulations and policies for HIV/AIDS prevention and has established an effective mechanism for HIV/AIDS control. These efforts have achieved certain progress in HIV/AIDS prevention. However, the burden of AIDS disease continues to increase, and the prevention and control situation remains severe. With the widespread adoption of smartphones and the rapid development of mobile internet, mobile apps have played an increasingly important role in disseminating HIV/AIDS knowledge and raising public awareness of prevention [1,37]. Among the 21 apps included in this study, 18 (86%) had HIV/AIDS knowledge dissemination functionality. This indicates that HIV/AIDS knowledge dissemination is an almost indispensable feature of Chinese HIV/AIDS mobile apps, which have become important tools for promoting HIV/AIDS knowledge in China.

In this study, 17 (81%) of the 21 mobile apps were identified, including 14 (67%) WeChat applets (such as Chabei, Danlan Happy Test, Baiyin HIV test, Suzhou Red Ribbon, Linqu County CDC, E Ai Jian, Ai Yi Jian, Rong Ai Jian, Liaocheng Dongchangfu District Anti-AIDS Service Platform, Zhecheng County AIDS consulting and test, Qing Ai Health Service, Ai Cheng Wang Shi, Beijing AIDS Association, and Dou Ai Jian) and 3 (14%) independent apps (Life4me+, Hong Feng Wan, and Xiao Ai). These apps provided various forms of health services, including appointment booking, counseling, risk assessment, and PrEP or PEP. A total of 2 mobile apps (Wu Ai Fang Hua and Hong Feng Wan) offered web-based community functionalities and scored excellently in terms of app quality and subjective quality, ranking among the top 2 positions. This finding is consistent with that of a previous study by Nour et al [38]. Therefore, we recommend considering the incorporation of web-based community functions when developing and designing mobile apps related to AIDS. This can encourage users to share their experiences, ask questions, provide

suggestions, and offer mutual assistance and support. Organizing regular web-based or offline activities can also promote face-to-face interactions among users, thereby enhancing their sense of belonging and engagement.

Privacy protection is another crucial topic that should be given sufficient attention in AIDS-related mobile apps. As social stigmatization and discrimination are still associated with AIDS, many users are concerned about their personal information being disclosed or misused, posing a threat to their privacy and security [39]. Therefore, unlike general mobile apps, ensuring user privacy protection in AIDS mobile apps is of utmost importance, aligning with previous research findings [40]. However, in this study, of the 21 apps, only 5 (24%) mobile apps, including 2 (10%) WeChat applets (Chabei and Su Zhou Red Ribbon) and 3 (14%) apps (My Life+, Hong Feng Wan, and Xiao Ai), provided privacy policies or agreements. The average subjective quality score (mean 2.85, SD 0.77) was significantly higher than that of the mobile apps without privacy protection features (mean 2.34, SD 0.58). This observed phenomenon may be attributed to the fact that inadequate privacy protection design may lead to user wariness and lower intentions and frequencies of use regarding AIDS mobile apps [41]. Therefore, we strongly suggest that all AIDS-related mobile apps incorporate privacy policies or agreements to alleviate user concerns about privacy protection, enhance user trust, and promote willingness to use these apps. In addition to transparent privacy policies and user agreements, user education is also critical. Developers of AIDS mobile apps should provide users with relevant information and educational resources on privacy protection. This can be achieved through in-app prompts, tutorials, and frequently asked questions. Users should receive clear instructions on configuring their privacy settings, handling their personal data, and the steps to take in reporting privacy concerns or data breaches. These instructions should be easily accessible, comprehensible, and provide specific examples to guide users through each process.

Rating of App Quality

According to the results from MARS scores, among the 4 dimensions of app quality, both researchers and patients with HIV rated 21 mobile apps lowest on engagement ($mean_{MARS}$ 2.4, SD 0.53; $mean_{uMARS}$ 2.56, SD 0.63), especially the WeChat mini-apps, which had the lowest average scores ($mean_{MARS}$ 2.33, SD 0.43; $mean_{uMARS}$ 2.47, SD 0.42). The average engagement scores for the 7 mobile apps developed by the Chinese government were even lower ($mean_{MARS}$ 2.27, SD 0.33; $mean_{uMARS}$ 2.34, SD 0.30). This underlined the concern that the level of engagement would remain low, even for officially developed apps. An analysis of the respective scores for each item within the MARS and uMARS engagement portions revealed a predominant lack of interest and amusement within these mobile apps, thus leading to decreased user engagement. Many AIDS-related mobile apps merely provide basic information and functions without interactive and stimulating designs to attract user participation, lacking a strong appeal to users. In addition, the absence of personalized and customized features limits user engagement. A study has shown a significant correlation between user engagement and an increase in the adoption rate of mobile apps [42]. Therefore, it is recommended that developers not only provide high-quality HIV/AIDS prevention and treatment information but also focus on meeting users' needs in terms of multidimensionality, functionality, and depth. In addition, attention should be paid to design in terms of amusement, entertainment, customization, interactivity, and other participatory aspects. This will help attract more user participation and enhance user stickiness.

This investigation revealed a lack of correlation between the MARS and uMARS scores. Specifically, (1) the app with the lowest overall uMARS scores across all dimensions surprisingly ranked seventh in terms of MARS scores. (2) A notable discrepancy was found in the functionality dimension ratings among patients with HIV and researchers, exposing the highest demographic variance in this attribute. (3) Moreover, the apps predominantly preferred by patients with HIV exhibited robust performance in functionality and information dimensions, with the latter appearing particularly predominant. However, the apps gravitating toward researchers demonstrated high competence in functionality, esthetics, and information, with functionality being the most superior. These data imply possible significant divergences distinct between the evaluations of researchers and genuine users of the apps. To maintain superior app quality and consumer satisfaction, rigorous surveillance of app quality should be sustained from both research and real-user perspectives. This bifocal assessment permits the accurate identification of genuine user requirements and researcher appraisal, providing valuable insights for the pinpoint and scientific enhancement of both app quality and user experience.

In this study, we observed that most Chinese AIDS-related mobile apps are WeChat applets. A reason for this is that the WeChat applet has advantages such as not requiring downloading or installation, having minimal resource consumption, and high user retention rates, which independent apps do not possess [43]. Another reason is that the HIV/AIDS population is relatively niche [44], which means that the market for AIDS mobile apps represents a low-frequency demand niche market. Independent apps often overlook this niche market owing to their high development costs, whereas WeChat applets, with their low development costs and the ability to cater to low-frequency demand niches through segmented scene construction, can effectively meet the needs of this market. Although WeChat mini-apps dominate the landscape of mobile apps for HIV/AIDS in China, their comprehensive performance lags behind that of stand-alone apps. The app quality score ($mean_{MARS}$ 3.45, SD 0.37 vs 3.58, SD 0.47; $mean_{uMARS}$ 3.33, SD 0.50 vs 3.66, SD 0.76) and subjective quality score ($mean_{MARS}$ 2.39, SD 0.57 vs 2.92, SD 1.05; $mean_{uMARS}$ 2.72, SD 0.58 vs 2.88, SD 0.90) for WeChat mini-apps are both lower compared with stand-alone apps. A granular analysis of the scores in different dimensions reveals the greatest discrepancy in the engagement dimension, with WeChat mini-apps scoring markedly lower ($mean_{MARS}$ 2.33, SD 0.43 vs 2.83, SD 0.93; $mean_{uMARS}$ 2.47, SD 0.42 vs 3.13, SD 1.40). This can be attributed to the constraints and limitations imposed by the WeChat platform, which prevent WeChat applets from providing the same user experience as independent apps in terms of

interface design, interaction methods, and customization settings. Improvement in these aspects should be a key focus for the future development of AIDS-related WeChat applets.

Limitations

The mobile apps evaluated in this study represent a snapshot of the current status of Chinese HIV-related mobile apps during the research period. Over time, mobile apps may be removed or updated, so the list of included mobile apps meeting the criteria may change in the future. In addition, some mobile apps intended solely for internal organizational use or no longer available in the market were excluded.

Conclusions

This study presents a systematic introduction to the functionality and quality of the currently available Chinese mobile apps for AIDS, providing valuable decision-making support for AIDS-related groups and health care professionals in accessing high-quality AIDS mobile apps. Through our systematic search and evaluation of existing Chinese mobile apps for AIDS, it has been observed that because of the lower demand frequency of AIDS mobile apps in China, less costly WeChat mini-apps have become the primary mode of app, and the overall quality attains a merely average level. A significant implication of our research is identifying the potentially significant discrepancy between the assessments made by researchers and the authentic users of the apps. Consequently, the inclusion of genuine users during the assessment and refinement stages of HIV apps is crucial. The main purpose of developing these mobile apps is to spread HIV prevention knowledge and facilitate booking appointments for testing and counseling services. However, most of these apps lack privacy protection features. Unlike general mobile apps, privacy protection is especially crucial in AIDS-related mobile apps because it directly affects users' willingness to use them [40]. Therefore, the introduction of legal and ethical frameworks for privacy protection as well as privacy protection technologies is essential. In addition, enhancing user education on privacy protection and ensuring informed consent is of utmost importance. Research related to privacy protection in Chinese AIDS mobile apps may be a vital and urgent topic to address in the future. It is our intent that the findings of our research may function as a road map and reference for the future development of HIV apps in China. Furthermore, we aim to provide crucial decision-making support for individuals living with HIV in their quest for superior HIV apps.

Acknowledgments

The authors sincerely acknowledge the editors and anonymous reviewers for their insights and comments to further improve the quality of the manuscript. The authors thank Wang Xiang, chief of the AIDS Prevention Section of Bengbu Centers for Disease Control and Prevention, for his great help in the investigation. Finally, the first author (PL) would like to personally express his gratitude to his son (Liu Daixin) and his family for their support all through this work. This work was supported by the Anhui Provincial University Philosophy and Social Science Major Project (grant 2023AH040283).

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: With the rapid development of mobile health (mHealth) technology, many health apps have been introduced to the commercial market for people with back pain conditions. However, little is known about their content, quality, approaches to care for low back pain (LBP), and associated risks of use.

Objective: The aims of this research were to (1) identify apps for the self-management of LBP currently on the market and (2) assess their quality, intervention content, theoretical approaches, and risk-related approaches.

Methods: The UK iTunes and Google Play stores were initially searched for apps related to the self-management of LBP in May 2022. A repeat search in June 2023 was conducted to ensure that any relevant new apps developed in the last year were incorporated into the review. A total of 3 keywords recommended by the Cochrane Back and Neck Group were used to search apps “low back pain,” “back pain,” and “lumbago.” The quality of the apps was assessed by using the 5-point Mobile App Rating Scale (MARS).

Results: A total of 69 apps (25 iOS and 44 Android) met the inclusion criteria. These LBP self-management apps mainly provide recommendations on muscle stretching (n=51, 73.9%), muscle strengthening (n=42, 60.9%), core stability exercises (n=32, 46.4%), yoga (n=19, 27.5%), and information about LBP mechanisms (n=17, 24.6%). Most interventions (n=14, 78%) are consistent with the recommendations in the National Institute for Health and Care Excellence (NICE) guidelines. The mean (SD) MARS overall score of included apps was 2.4 (0.44) out of a possible 5 points. The functionality dimension was associated with the highest score (3.0), whereas the engagement and information dimension resulted in the lowest score (2.1). Regarding theoretical and risk-related approaches, 18 (26.1%) of the 69 apps reported the rate of intervention progression, 11 (15.9%) reported safety checks, only 1 (1.4%) reported personalization of care, and none reported the theoretical care model or the age group targeted.

Conclusions: mHealth apps are potentially promising alternatives to help people manage their LBP; however, most of the LBP self-management apps were of poor quality and did not report the theoretical approaches to care and their associated risks. Although nearly all apps reviewed included a component of care listed in the NICE guidelines, the model of care delivery or embracement of care principles such as the application of a biopsychosocial model was unclear.

KEYWORDS

smartphone; mHealth; mobile health; low back pain; self-management; treatment interventions; mobile phone

Introduction

Low back pain (LBP) is a complex multifactorial disorder, often considered a combination of physical, psychological, and social dysfunction [1]. A multidisciplinary self-management intervention based on a biopsychosocial model holds significant potential to manage LBP [2,3] and has been demonstrated to be more effective than unimodal exercise therapy [4]. The

National Institute for Health and Care Excellence (NICE) guidelines recommend using self-management for LBP, which can be described as the patient's proactive adoption of strategies to manage their symptoms and monitor their health and well-being [5]. Despite being a promising approach to managing LBP, it can be challenging for an individual to self-manage any long-term condition [6]. The adherence to self-management strategies is commonly poor, especially without support, feedback, and positive reinforcement [7,8]. A qualitative study also noted poor adherence to advice and exercises as a limiting factor to recovery from LBP [9].

With the increasing popularity of electronic products, digital health solutions such as smartphone apps can be used as an innovative way to support self-management for many conditions, including LBP and may provide a solution to some of the problems outlined above [6,10]. Mobile health (mHealth) apps for pain management may be beneficial to patients [11,12], helping monitor those with acute or chronic pain and providing them with information and support for pain management. However, while many mHealth apps have been introduced into the commercial marketplace to manage pain, most have not been regulated in a uniform or standardized way before being released to the market [12,13]. The involvement of health care professionals in their development and content has been lacking [14]. This has raised concerns about the quality of these mHealth apps and whether their content information is evidence-based [15,16]. It is therefore desirable to assess the quality of current apps in the UK market and whether their content aligns with guideline recommendations. Another concerning issue is the paucity of evidence on specific intervention approaches in developed mHealth apps that have been developed, including underpinning evidence and theory [17] and relative risk management [18]. This potentially impacts on safety and efficacy of health-related smartphone apps [19].

Since there is no unified framework for assessing the theoretical and risk-based approaches associated with LBP self-management applications, we developed a theoretical framework that considers the theoretical care model of the intervention, the personalization of care, and the rate of intervention progression, as well as a risk-related framework that includes the targeted age group and the provision of appropriate safety checks. Interventions based on specific theoretical frameworks are known to be more effective in health care [20]. The Medical Research Council (MRC) guidelines strongly recommend using theoretical approaches in designing complex interventions [21], thus its inclusion in the evaluation. A critical factor in mHealth apps is personalization, where the management or treatment of the disease is tailored to the patient's situation and individual needs, which will make the user feel that it is relevant and meaningful to them [22,23], thus the inclusion of criteria in relation to personalization. Treatment methods such as exercise need to be both adaptable and progressive. This means starting with basic exercises and gradually advancing to more complex levels at a pace that patients with LBP can comfortably handle. Such a progression helps enhance their functional abilities and quality of life, while simultaneously equipping them with strategies to effectively manage their pain. [24]. Since the treatment paths for LBP vary according to different age groups, including children, adults, and the elderly [25], the target user age group must be defined. Finally, patient safety is an essential component of health care provision and is critical to primary care management, which will effectively reduce the clinical risks associated with LBP management [18,26].

Therefore, this app review, aimed to first, identify apps for the self-management of LBP currently on the market and second, to assess their quality (eg, functionality and design), intervention content (compliance with best practice guidelines), underlying theory (eg, theoretical care model), and risk-related approaches (eg, the age group targeted).

Methods

Search Strategy

Apps currently on the market for the self-management of LBP were identified, reviewed, and analyzed using a systematic approach. The UK official app stores for both Apple's iOS and Google's Android OS were used to search for mobile apps. These 2 operating systems currently dominate the marketplace of mobile medical apps [27]. We logged into Apple iTunes and Android Google Play stores in May 2022. A total of 3 keywords recommended by the Cochrane Back and Neck Group [28] were used to search apps "low back pain," "back pain," and "lumbago." A subsequent search in June 2023 was repeated to ensure that any relevant new apps in the last year were incorporated into the review.

Study Selection

Criteria for inclusion in the review were (1) apps were a self-contained product (ie, did not depend on an external device or add-ons), (2) apps offered at least 1 active treatment option for LBP (eg, unsupervised exercise program or patient education), (3) apps only designed for people with LBP, (4) apps created or updated in the last 5 years to ensure software functionality and ongoing technical support, and (5) apps developed in English. Exclusion criteria were (1) apps targeted at managing general chronic pain, (2) apps only focused on risk factors and diagnostic tests for LBP, (3) apps only focused on specific LBP pathologies (eg, lumbar disk herniation), (4) apps designed for clinicians, (5) general back fitness apps with no mention of physiotherapy or physical therapy or musculoskeletal (MSK) conditions, and (6) apps were not downloadable or had restrictions (eg, requiring an activate access password). Apps that incurred a cost were also included; however, when both paid and free versions of an app were available, we reviewed only the paid version to ensure access to the full content. If the same app was available on iOS and Android, the iOS version was kept for inclusion and analysis.

An independent reviewer initially screened the eligible apps based on the apps' names and descriptions and the screenshots provided. After the preliminary screening phase, the same independent reviewer downloaded apps that met the eligibility criteria for a second screening. Concerns regarding inclusion were discussed and resolved within the research group (AM and DS) until a final decision was reached.

Data Extraction

The selected apps were downloaded onto either a Samsung SM-N975F (Android version 7.1.2) or an iPhone 12 (iOS version 16.5) for a complete assessment of eligibility and characteristics. Relevant background information offered in the included apps was extracted, including the name, version, developer, update date, cost, and presence of in-app purchases. We extracted the age or content rating and consumer rating (5-star rating system) when available. In addition, we extracted if the apps contained advertisements and whether these adverts were relevant to their back pain. It was also noted if the apps were asynchronous or synchronous (available with support from a provider), and whether the apps tracked user engagement. The collection of personally identifiable information by apps and whether consent is stated were also checked. The category of management content, specific intervention component, theoretical care model, personalization of care, the rate of intervention progression, the age group targeted, and safety checks were also extracted.

App Content Assessment

Main categories and specific components of LBP app management content were identified and classified. Frequency analysis was performed to determine the number of apps providing these intervention contents. The recently updated 2020 NICE guideline for LBP was used to assess whether the included apps provided evidence-based interventions (categorized as "yes/no") [29]. For this, we mapped app interventions to recommendations listed in the NICE guidelines. This guideline provides the most recent best practice recommendations for assessing and managing LBP and sciatica in people aged 16 years or older [5].

App Quality Assessment

The Mobile App Rating Scale (MARS) was used to assess the quality of included apps in this review. MARS is a brief tool with a 23-item questionnaire to classify and assess the quality of mHealth apps for researchers, professionals, and clinicians [30]. It assesses app quality across 4 domains: engagement, functionality, aesthetics, and information quality. All items are assessed on a 5-point scale (1=inadequate, 2=poor, 3=acceptable, 4=good, and 5=excellent). The MARS has demonstrated excellent internal consistency and interrater reliability for evaluating the quality of mHealth apps [30]. To standardize the quality ratings, the assessor completed a MARS video training recommended by the developers of MARS [30]. A total of 10 apps were randomly selected for training until a consensus on the scores was reached.

App Assessment of the Theoretical and Risk-Related Approaches

A total of 5 aspects considered in our theoretical and risk-related approaches were assessed. These included the underpinning LBP management theory, tailoring of content, the intervention of progression approach, the age group the app targeted, and appropriate safety checks.

Ethical Considerations

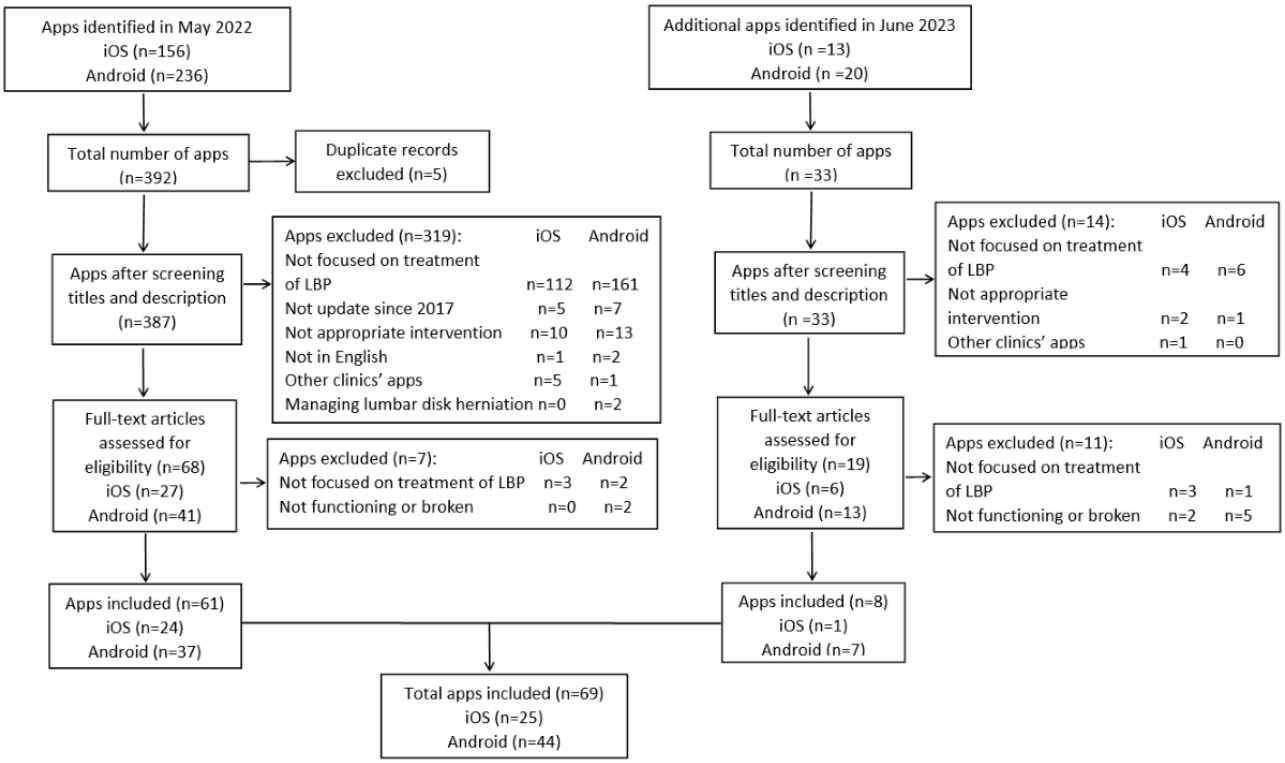
This study does not involve human participants.

Results

App Selection

The searches performed in May 2022 yielded 392 apps from 2 platforms. Of these, 156 apps were identified from iTunes stores, and 236 apps were identified from Google Play stores. A total of 5 duplicates were removed, resulting in 387 apps identified for screening based on the titles and app descriptions. After initial screening, 319 apps were excluded. The eligible 68 apps were downloaded for a full evaluation and further 7 apps were excluded. The subsequent search in June 2023 found a total of 33 newly developed apps based on the initial search, of which 8 apps were newly developed. Finally, 69 apps were included in this review, of which 25 were iOS apps and 44 were Android apps. Figure 1 illustrates the selection procedure of smartphone apps for LBP.

Figure 1. The flowchart of the app selection process. LBP: low back pain.



Characteristics of Included Apps

Of the 69 apps included in this review, 25 (36%) were found on iTunes exclusively, 44 (64%) on Google Play exclusively, and 5 (7%) were found on both app stores. There are 5 (7%) of 69 apps that required payment, ranging in price from US $1.13 to US $22.87 (median US $8.17). The majority (n=64, 93%) of the apps included were free of charge. Of these, 8 offered in-app purchases ranging from US $3.80 to US $12.70. Android apps (n=41, 93%) were more often free to access full functionality than iOS apps (n=15, 60%). Of the 41 apps reviewed by customers on a 5-star rating system, the median customer rating in 19 apps from iTunes (4.3 stars) was higher than in 22 apps from Google Play (4.1 stars). With respect to age or content rating, most of the included iOS apps (n=19, 76%) were downloaded without any age limitation: 4 apps were restricted to those of 12 years or above and 3 apps were restricted to those of at least 17 years old. However, all Android apps were labeled as suitable for all age groups.
